2. What **ordering or invariant** must hold? ("foo before bar", "never more than 2 H in a molecule", "never more than capacity items")
3. Who **waits**, for **what condition**, and who **signals** it?
4. Pick the primitive: turn-taking → semaphores; "wait until predicate" → condition variable; groups → barrier; mutual exclusion → lock; single-variable update → atomic.
5. Check **liveness** (the guarantee that every thread eventually makes progress): can anyone wait forever? Does every thread exit at the end?

13.1 Print FooBar Alternately (LeetCode 1115)

Problem

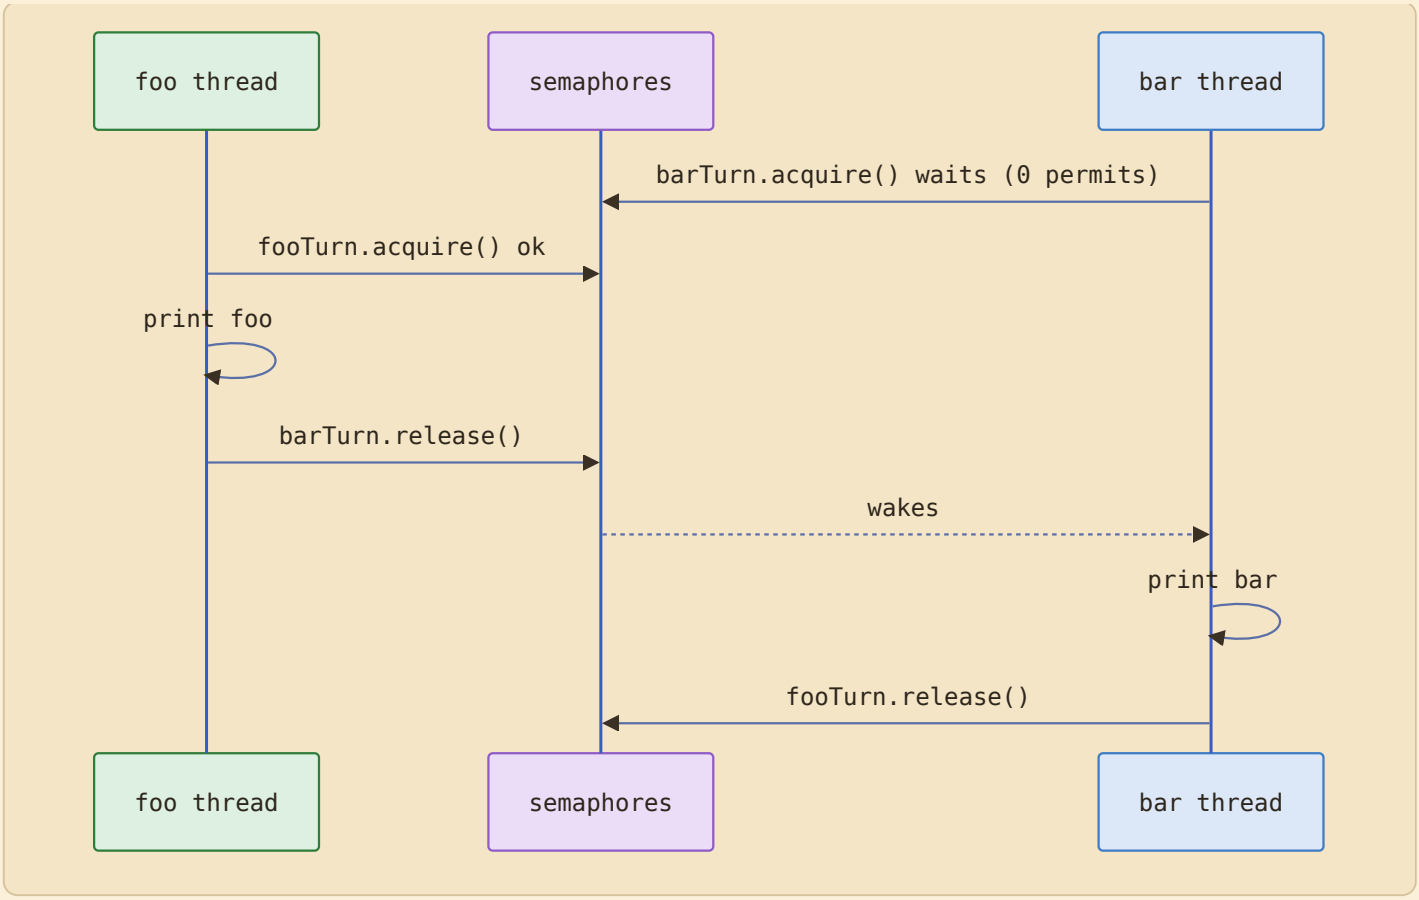
One `FooBar` object is shared by two threads. Thread A calls `foo()`, which prints `"foo"` *n* times; thread B calls `bar()`, which prints `"bar"` *n* times. Make the output exactly `"foobar"` repeated *n* times, whichever thread starts first.

Approach

This is pure **signaling** (12.20): a baton passes back and forth.

- `fooTurn = Semaphore(1)` — foo may go first.
- `barTurn = Semaphore(0)` — bar must wait.
- `foo`: acquire `fooTurn`, print, release `barTurn`. `bar`: acquire `barTurn`, print, release `fooTurn`.

Alternative: one monitor with a boolean `fooTurn`, `while (!fooTurn) wait();` then flip it and `notifyAll()`.



foo thread
semaphores
bar thread
barTurn.acquire() waits (0 permits)
fooTurn.acquire() ok
print foo
barTurn.release()
wakes
print bar
fooTurn.release()
foo thread
semaphores
bar thread

Java solution

```java
// File: code/lld/ch13/foobar/Main.java
package lld.ch13.foobar;

import java.util.concurrent.Semaphore;

/**
 * LeetCode 1115 - Print FooBar Alternately.
 * Thread A calls foo() n times, thread B calls bar() n times; output must be "foobar" repeated n times.
 */
public class Main {

    /** Solution 1: two semaphores used as a baton that is passed back and forth. */
    static class FooBarSemaphore {
        private final int n;
        private final Semaphore fooTurn = new Semaphore(1);   // foo may go first
        private final Semaphore barTurn = new Semaphore(0);   // bar must wait

        FooBarSemaphore(int n) { this.n = n; }

        void foo(Runnable printFoo) throws InterruptedException {
            for (int i = 0; i < n; i++) {
                fooTurn.acquire();       // wait for my turn
                printFoo.run();
                barTurn.release();       // hand the baton to bar
            }
        }
        void bar(Runnable printBar) throws InterruptedException {
            for (int i = 0; i < n; i++) {
                barTurn.acquire();
                printBar.run();
                fooTurn.release();
            }
        }
    }

    /** Solution 2: one monitor + a turn flag (wait/notifyAll). */
    static class FooBarMonitor {
        private final int n;
        private boolean fooTurn = true;                        // guarded by 'this'

        FooBarMonitor(int n) { this.n = n; }

        void foo(Runnable printFoo) throws InterruptedException {
            for (int i = 0; i < n; i++) {
                synchronized (this) {
                    while (!fooTurn) wait();
                    printFoo.run();
                    fooTurn = false;
                    notifyAll();
                }
            }
        }
        void bar(Runnable printBar) throws InterruptedException {
            for (int i = 0; i < n; i++) {
                synchronized (this) {
                    while (fooTurn) wait();
                    printBar.run();
                    fooTurn = true;
                    notifyAll();
                }
            }
        }
    }

    interface Body { void run() throws InterruptedException; }
    static Thread start(Body b) {
```

```
        Thread t = new Thread(() -> { try { b.run(); } catch (InterruptedException e) {
Thread.currentThread().interrupt(); } });
        t.start();
        return t;
    }

    public static void main(String[] args) throws InterruptedException {
        StringBuffer out1 = new StringBuffer();               // StringBuffer is synchronized
        FooBarSemaphore s = new FooBarSemaphore(4);
        Thread b1 = start(() -> s.bar(() -> out1.append("bar")));   // start bar FIRST on purpose
        Thread a1 = start(() -> s.foo(() -> out1.append("foo")));
        a1.join(); b1.join();
        System.out.println("semaphores : " + out1);

        StringBuffer out2 = new StringBuffer();
        FooBarMonitor m = new FooBarMonitor(4);
        Thread b2 = start(() -> m.bar(() -> out2.append("bar")));
        Thread a2 = start(() -> m.foo(() -> out2.append("foo")));
        a2.join(); b2.join();
        System.out.println("monitor    : " + out2);
        System.out.println("both correct: " + (out1.toString().equals("foobar".repeat(4)) &&
out2.toString().equals("foobar".repeat(4))));
    }
}
```

Output:

```
semaphores : foobarfoobarfoobarfoobar
monitor    : foobarfoobarfoobarfoobar
both correct: true
```

Why it's correct

- **Invariant:** the permits in `fooTurn` + `barTurn` always total exactly 1 (each thread releases the *other* semaphore only after acquiring its own). So at most one thread can be printing, and the turns strictly alternate.
- Starting `bar` first doesn't matter: it blocks on `barTurn` (0 permits) until `foo` has printed.
- **Visibility:** a `release()` happens-before the `acquire()` it enables, so each thread sees the other's appends.
- **Termination:** both loops run exactly *n* times, and each acquire has a matching release.

Pitfalls

- Using one semaphore for both threads — a thread can re-acquire its own release and print twice.
- The monitor version with `if` instead of `while`, or `notify()` in more complex variants.
- **Busy-waiting** (spinning in a loop that keeps re-checking a flag) on a `volatile` flag (a field whose writes are immediately visible to other threads) works but burns a CPU core.

Real-world examples

Strict two-party hand-offs: ping-pong protocols, request/acknowledge stages, **double-buffering** (one buffer is filled while the other is read, then they swap) where a renderer and a producer alternate buffers.

In the interview

30-second answer: "Two semaphores as a baton: foo's starts at 1, bar's at 0. Each thread acquires its own, prints, and releases the other's. The total permits are always one, so they alternate."

Follow-ups:

- *Three threads printing A, B, C in order?* Three semaphores in a ring: A(1), B(0), C(0); each releases the next.
- *Without semaphores?* A monitor with a turn variable and `wait/notifyAll`, or `Lock` + `Condition`.

Self-check

- **Q:** What happens if `barTurn` starts with 1? **A:** bar can print first → output may begin with "bar".

TL;DR

Two semaphores, one permit total, passed back and forth.

13.2 Print Zero Even Odd (LeetCode 1116)

Problem

Three threads share a `ZeroEvenOdd(n)` object. `zero()` may only print 0, `even()` only even numbers, `odd()` only odd numbers. Together they must print `0 1 0 2 0 3 … 0 n` — e.g. *n* = 5 → `0102030405`.

Approach

The zero thread acts as a **dispatcher**: after printing a 0 for position *i*, it releases `oddTurn` if *i* is odd, else `evenTurn`. The odd/even thread prints its number and hands control back via `zeroTurn`.

- `zeroTurn = 1`, `oddTurn = 0`, `evenTurn = 0`.
- zero loops *n* times; odd loops over 1, 3, 5…; even over 2, 4, 6….

Java solution

```java
// File: code/lld/ch13/zeroevenodd/Main.java
package lld.ch13.zeroevenodd;

import java.util.concurrent.Semaphore;
import java.util.function.IntConsumer;

/**
 * LeetCode 1116 - Print Zero Even Odd.
 * Three threads: zero() prints only 0s, even() only even numbers, odd() only odd numbers.
 * Together they must print 0 1 0 2 0 3 ... 0 n  (e.g. n=5 -> "0102030405").
 */
public class Main {

    static class ZeroEvenOdd {
        private final int n;
        private final Semaphore zeroTurn = new Semaphore(1);
        private final Semaphore oddTurn = new Semaphore(0);
        private final Semaphore evenTurn = new Semaphore(0);

        ZeroEvenOdd(int n) { this.n = n; }

        void zero(IntConsumer print) throws InterruptedException {
            for (int i = 1; i <= n; i++) {
                zeroTurn.acquire();
                print.accept(0);
                // The zero thread is the "dispatcher": it decides who prints next.
                if (i % 2 == 1) oddTurn.release(); else evenTurn.release();
            }
        }
        void odd(IntConsumer print) throws InterruptedException {
            for (int i = 1; i <= n; i += 2) {
                oddTurn.acquire();
                print.accept(i);
                zeroTurn.release();
            }
        }
        void even(IntConsumer print) throws InterruptedException {
            for (int i = 2; i <= n; i += 2) {
                evenTurn.acquire();
                print.accept(i);
                zeroTurn.release();
            }
        }
    }

    interface Body { void run() throws InterruptedException; }
    static Thread start(Body b) {
        Thread t = new Thread(() -> { try { b.run(); } catch (InterruptedException e) {
Thread.currentThread().interrupt(); } });
        t.start();
        return t;
    }

    public static void main(String[] args) throws InterruptedException {
        for (int n : new int[] {1, 2, 5, 10}) {
            StringBuffer out = new StringBuffer();
            ZeroEvenOdd z = new ZeroEvenOdd(n);
            Thread e = start(() -> z.even(out::append));
            Thread o = start(() -> z.odd(out::append));
            Thread zt = start(() -> z.zero(out::append));
            zt.join(); o.join(); e.join();
            System.out.println("n=" + n + " -> " + out);
        }
    }
}
```

Output:

```
n=1 -> 01
n=2 -> 0102
n=5 -> 0102030405
n=10 -> 01020304050607080910
```

Why it's correct

- Exactly one semaphore holds a permit at any moment → exactly one thread may print.
- The zero thread's loop index *i* decides the parity of the next number, so the right thread is woken.
- Each thread's loop count matches the number of permits it will receive: zero gets *n*, odd gets ⌈n/2⌉, even gets ⌊n/2⌋. So nobody waits forever and everyone exits (e.g. *n* = 1: even's loop runs zero times).

Pitfalls

- Letting odd/even threads compute "the next number" from a shared counter without synchronization.
- Loop bounds that don't match the permits (e.g. even looping `n/2 + 1` times) → a thread waits forever and the program hangs.

Real-world examples

Dispatcher/worker designs where one coordinator routes each step to a specialised worker (e.g. an interpreter routing **opcodes** — the numeric codes of individual instructions — a scheduler assigning alternating tasks).

In the interview

> **30-second answer:** "Three semaphores. Zero starts with one permit. After each 0 it releases odd or even depending on the index, and they release zero back. One permit total in the system, so the order is forced."

Follow-up: *Could you use one lock + condition?* Yes: a shared `state` (ZERO/ODD/EVEN) and `current` number, each thread waits `while (state != mine)`, acts, updates state, `signalAll()`.

Self-check

- **Q:** For *n* = 4, how many times does `odd()` acquire? **A:** Twice (1 and 3).

TL;DR

Zero is the dispatcher; one permit circulates among three semaphores.

13.3 Fizz Buzz Multithreaded (LeetCode 1195)

Problem

Four threads share a `FizzBuzz(n)` object and must together output 1..n where: multiples of 15 → `fizzbuzz` (thread C), multiples of 3 only → `fizz` (thread A), multiples of 5 only → `buzz` (thread B), everything else → the number (thread D).

Approach

Keep one shared counter `current` guarded by the object's monitor. Each thread runs the same loop with its own predicate:

1. `while (current <= n && !mine(current)) wait();`
2. If `current > n` → `notifyAll()` and exit.
3. Print, `current++`, `notifyAll()` (the next number may belong to anyone).

This is the **condition variable** pattern (12.13) with a different predicate per thread. The helper `runWhile(predicate, action)` avoids writing the loop four times (DRY: Don't Repeat Yourself).

Java solution

```java
// File: code/lld/ch13/fizzbuzz/Main.java
package lld.ch13.fizzbuzz;

import java.util.ArrayList;
import java.util.List;
import java.util.function.IntConsumer;
import java.util.function.IntPredicate;

/**
 * LeetCode 1195 - Fizz Buzz Multithreaded.
 * Four threads share one counter 1..n: fizz() prints "fizz" (divisible by 3 only), buzz() "buzz"
 * (by 5 only), fizzbuzz() "fizzbuzz" (by 15), number() prints the number otherwise.
 */
public class Main {

    static class FizzBuzz {
        private final int n;
        private int current = 1;                            // guarded by 'this'

        FizzBuzz(int n) { this.n = n; }

        /** Shared loop: wait until 'current' is mine (or we're done), act, advance, wake everyone. */
        private void runWhile(IntPredicate mine, IntConsumer action) throws InterruptedException {
            while (true) {
                synchronized (this) {
                    while (current <= n && !mine.test(current)) wait();
                    if (current > n) { notifyAll(); return; }     // done: wake others so they can exit too
                    action.accept(current);
                    current++;
                    notifyAll();                                  // the next number may belong to anyone
                }
            }
        }

        void fizz(Runnable printFizz) throws InterruptedException {
            runWhile(i -> i % 3 == 0 && i % 5 != 0, i -> printFizz.run());
        }
        void buzz(Runnable printBuzz) throws InterruptedException {
            runWhile(i -> i % 5 == 0 && i % 3 != 0, i -> printBuzz.run());
        }
        void fizzbuzz(Runnable printFizzBuzz) throws InterruptedException {
            runWhile(i -> i % 15 == 0, i -> printFizzBuzz.run());
        }
        void number(IntConsumer printNumber) throws InterruptedException {
            runWhile(i -> i % 3 != 0 && i % 5 != 0, printNumber);
        }
    }

    interface Body { void run() throws InterruptedException; }
    static Thread start(Body b) {
        Thread t = new Thread(() -> { try { b.run(); } catch (InterruptedException e) {
Thread.currentThread().interrupt(); } });
        t.start();
        return t;
    }

    public static void main(String[] args) throws InterruptedException {
        int n = 15;
        List<String> out = new ArrayList<>();          // only touched inside the FizzBuzz monitor
        FizzBuzz fb = new FizzBuzz(n);
        List<Thread> ts = List.of(
                start(() -> fb.fizz(() -> out.add("fizz"))),
                start(() -> fb.buzz(() -> out.add("buzz"))),
                start(() -> fb.fizzbuzz(() -> out.add("fizzbuzz"))),
                start(() -> fb.number(i -> out.add(String.valueOf(i)))));
        for (Thread t : ts) t.join();                  // join() makes the list's contents visible to main
```

```
            System.out.println(String.join(", ", out));
        }
    }
```

Output:

```
1, 2, fizz, 4, buzz, fizz, 7, 8, fizz, buzz, 11, fizz, 13, 14, fizzbuzz
```

Why it's correct

- Every number satisfies **exactly one** predicate (they partition 1..n), so exactly one thread can act on each value.
- `current` is read and written only inside `synchronized (this)` → no races, full visibility.
- `notifyAll()` (not `notify()`): four different predicates wait on the same monitor; `notify()` could wake a thread whose predicate is false, which then waits again — and the right thread is never woken → hang.
- **Termination:** when `current` exceeds *n*, every waiting thread is woken (by the last `notifyAll`) and sees `current > n` in its loop condition, so all four exit.
- The output list is only modified inside the monitor, and `join()` makes it visible to `main`.

Pitfalls

- `notify()` instead of `notifyAll()` → lost wake-ups, random hangs.
- Forgetting the `current > n` exit check inside the wait loop → threads wait forever after the last number.
- Overlapping predicates (e.g. fizz = `i % 3 == 0` without excluding 15) → two threads compete for 15.

Real-world examples

"Workers wait until a shared state matches their role" — e.g. pipeline stages each waiting for a job to reach their stage in a shared state machine.

In the interview

> **30-second answer:** "One monitor, one shared counter. Each thread waits in a while loop until the counter matches its predicate or passes n, prints, increments and notifies all. The predicates partition the numbers, so exactly one thread acts per number."

Follow-up: *Semaphore version?* Possible: the number thread acts as dispatcher and releases the fizz/buzz/fizzbuzz semaphore for the next value — more efficient (no **thundering herd** — many threads woken at once when only one can proceed) but more code.

Self-check

- **Q:** Why `notifyAll`? **A:** Threads wait for *different* conditions on the same monitor; only waking all guarantees the right one wakes.

TL;DR

Shared counter + per-thread predicate + `while`-wait + `notifyAll`.

13.4 Building H2O (LeetCode 1117)

Problem

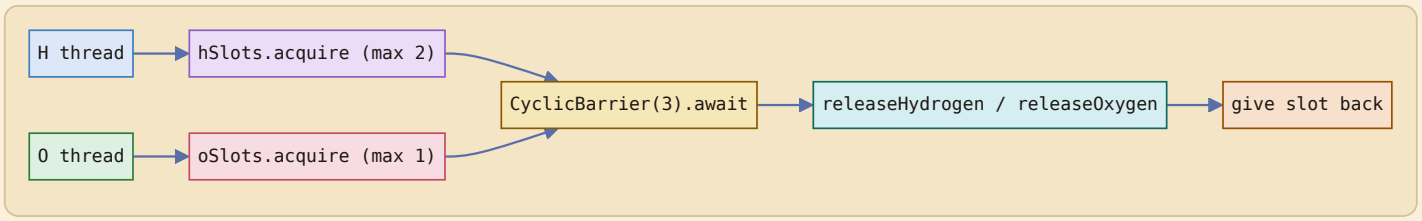
Hydrogen and oxygen threads arrive in any order. Each must pass a barrier in groups of three that form one water molecule: exactly **2 H + 1 O**. Threads from one molecule must all pass before any thread of the next molecule passes.

Approach

Combine two tools:

- **Slots** — `hSlots = Semaphore(2)`, `oSlots = Semaphore(1)`: at most 2 H and 1 O can be "in" the current molecule.

- **Group** — `CyclicBarrier(3)`: the three atoms wait for each other, then all go.
- A thread returns its slot permit **after** it has been released (printed), so the next molecule can only form once this one is finished.



Java solution

```java
// File: code/lld/ch13/h2o/Main.java
package lld.ch13.h2o;

import java.util.ArrayList;
import java.util.List;
import java.util.concurrent.BrokenBarrierException;
import java.util.concurrent.CyclicBarrier;
import java.util.concurrent.Semaphore;

/**
 * LeetCode 1117 - Building H2O.
 * Hydrogen and oxygen threads arrive in any order. They must leave in groups of three:
 * exactly 2 H + 1 O per group, and a group must fully leave before the next one starts.
 */
public class Main {

    static class H2O {
        private final Semaphore hSlots = new Semaphore(2);    // at most 2 H in the current molecule
        private final Semaphore oSlots = new Semaphore(1);    // at most 1 O in the current molecule
        private final CyclicBarrier bond = new CyclicBarrier(3);   // wait until all 3 atoms are present

        void hydrogen(Runnable releaseHydrogen) throws InterruptedException {
            hSlots.acquire();
            try {
                bond.await();
            } catch (BrokenBarrierException e) { throw new IllegalStateException(e); }
            releaseHydrogen.run();
            hSlots.release();                                 // free my slot only after I have "left"
        }
        void oxygen(Runnable releaseOxygen) throws InterruptedException {
            oSlots.acquire();
            try {
                bond.await();
            } catch (BrokenBarrierException e) { throw new IllegalStateException(e); }
            releaseOxygen.run();
            oSlots.release();
        }
    }

    public static void main(String[] args) throws InterruptedException {
        // 16 H + 8 O = 8 molecules, arriving in a scrambled (but reproducible) order.
        List<Character> atoms = new ArrayList<>();
        for (int i = 0; i < 8; i++) { atoms.add('H'); atoms.add('H'); atoms.add('O'); }
        java.util.Collections.shuffle(atoms, new java.util.Random(7));
        StringBuilder in = new StringBuilder();
        atoms.forEach(in::append);
        String input = in.toString();
        System.out.println("arrival order   : " + input);
        StringBuffer out = new StringBuffer();
        H2O h2o = new H2O();
        List<Thread> ts = new ArrayList<>();
        for (char c : input.toCharArray()) {
            Thread t = new Thread(() -> {
                try {
                    if (c == 'H') h2o.hydrogen(() -> out.append('H'));
                    else h2o.oxygen(() -> out.append('O'));
                } catch (InterruptedException e) { Thread.currentThread().interrupt(); }
            });
            ts.add(t);
            t.start();
        }
        for (Thread t : ts) t.join();

        // Output order varies run to run (HHO, HOH, OHH are all fine), so we verify it instead.
        String s = out.toString();
        boolean valid = s.length() == input.length();
```

```
        for (int i = 0; valid && i < s.length(); i += 3) {
            String g = s.substring(i, i + 3);
            valid = g.chars().filter(ch -> ch == 'H').count() == 2 && g.indexOf('O') >= 0;
        }
        System.out.println("molecules formed: " + s.length() / 3 + ", every group of 3 has 2 H + 1 O: " + valid);
    }
}
```

Output:

```
arrival order   : OHOOOHHHHOHHHHHOOHHHHHOH
molecules formed: 8, every group of 3 has 2 H + 1 O: true
```

Why it's correct

- **At most 2 H and 1 O** can reach the barrier in each round because of the slot semaphores; the barrier needs 3 parties, so each trip is exactly `H, H, O`.
- **No mixing between molecules:** a new molecule needs all three slots free again. Each slot is freed only after its thread printed. So the next group can't trip the barrier (and print) until all three of the previous group have printed.
- The barrier resets automatically (it's *cyclic*) for the next molecule.
- The demo checks every consecutive group of 3 in the output instead of printing it, because `HHO`, `HOH` and `OHH` are all valid orders.

Pitfalls

- Releasing the slot **before** printing → a new H might print before the previous O, mixing molecules.
- Using only semaphores without the barrier → the 2 H and 1 O aren't forced to leave "together".
- If the thread counts aren't exactly 2:1, the last threads wait forever (the problem guarantees they are).

Real-world examples

Batching: gather exactly N items of certain types before dispatching (e.g. matchmaking 2 players + 1 server slot, assembling an order that needs parts from different producers).

In the interview

30-second answer: "Two semaphores cap the molecule at 2 H and 1 O; a CyclicBarrier of 3 makes the three wait for each other; each atom returns its slot only after it's released, so molecules never interleave."

Follow-up: *Without a barrier?* Use a lock with counters of waiting H and O; when 2 H + 1 O are available, the thread completing the set signals exactly those. More code, same idea.

Self-check

- **Q:** Why is `hSlots` initialised to 2, not 1? **A:** A molecule needs two hydrogens simultaneously inside the barrier.

TL;DR

Slots (semaphores) decide *who* can join; the barrier decides *when* they leave; free slots only after leaving.

13.5 Dining Philosophers (LeetCode 1226)

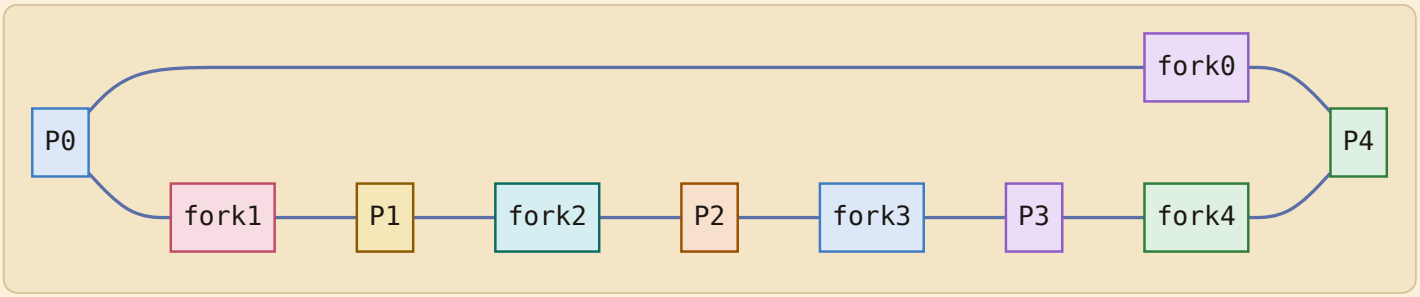
Problem

Five philosophers sit at a round table with one fork between each pair (5 forks). To eat, a philosopher needs **both** adjacent forks. If everyone picks up their left fork first, everyone may hold one fork and wait forever for the right one — **deadlock** (all four **Coffman conditions** hold — mutual exclusion, hold-and-wait, no preemption and circular wait; 12.17).

Approach

Break a Coffman condition:

1. **Resource ordering** (breaks circular wait): number the forks 0–4; always pick up the **lower-numbered** fork first. Philosopher 4 (forks 4 and 0) picks fork 0 first, so the cycle is impossible.
2. **Waiter / limited seats** (also breaks circular wait): a semaphore lets at most **n − 1** philosophers try at once — with 4 people and 5 forks, at least one can get both forks. Make the semaphore **fair** to prevent starvation.
3. (Other known solutions: `tryLock` both forks and put down on failure with random **back-off** (waiting a random short time before retrying); the Chandy–Misra algorithm for distributed settings.)



Java solution

```java
// File: code/lld/ch13/philosophers/Main.java
package lld.ch13.philosophers;

import java.util.ArrayList;
import java.util.List;
import java.util.concurrent.Semaphore;
import java.util.concurrent.atomic.AtomicIntegerArray;
import java.util.concurrent.locks.ReentrantLock;

/**
 * Dining Philosophers (LeetCode 1226 variant): 5 philosophers, 5 forks, each needs both
 * neighbouring forks to eat. Naive "everyone picks up the left fork first" can deadlock.
 */
public class Main {

    interface Table { void eat(int p, Runnable eatAction) throws InterruptedException; }

    /** Fix 1 - resource ordering: always pick up the LOWER-numbered fork first (breaks circular wait). */
    static class OrderedForks implements Table {
        private final ReentrantLock[] forks;
        OrderedForks(int n) { forks = new ReentrantLock[n]; for (int i = 0; i < n; i++) forks[i] = new
ReentrantLock(); }

        public void eat(int p, Runnable eatAction) {
            int left = p, right = (p + 1) % forks.length;
            ReentrantLock first = forks[Math.min(left, right)], second = forks[Math.max(left, right)];
            first.lock();
            try {
                second.lock();
                try { eatAction.run(); } finally { second.unlock(); }
            } finally { first.unlock(); }
        }
    }

    /** Fix 2 - a "waiter" lets at most n-1 philosophers try at once (breaks circular wait too). */
    static class Waiter implements Table {
        private final ReentrantLock[] forks;
        private final Semaphore seats;
        Waiter(int n) {
            forks = new ReentrantLock[n];
            for (int i = 0; i < n; i++) forks[i] = new ReentrantLock();
            seats = new Semaphore(n - 1, true);                // fair: nobody starves waiting for a seat
        }
        public void eat(int p, Runnable eatAction) throws InterruptedException {
            seats.acquire();
            try {
                ReentrantLock left = forks[p], right = forks[(p + 1) % forks.length];
                left.lock();
                try {
                    right.lock();
                    try { eatAction.run(); } finally { right.unlock(); }
                } finally { left.unlock(); }
            } finally { seats.release(); }
        }
    }

    static String dine(Table table, int n, int meals) throws InterruptedException {
        AtomicIntegerArray eaten = new AtomicIntegerArray(n);
        List<Thread> ts = new ArrayList<>();
        for (int p = 0; p < n; p++) {
            final int id = p;
            Thread t = new Thread(() -> {
                try {
                    for (int m = 0; m < meals; m++) {
                        Thread.onSpinWait();                                // "think"
                        table.eat(id, () -> eaten.incrementAndGet(id));
```

```
                    }
                } catch (InterruptedException e) { Thread.currentThread().interrupt(); }
            });
            ts.add(t); t.start();
        }
        for (Thread t : ts) t.join();
        return eaten.toString();
    }

    public static void main(String[] args) throws InterruptedException {
        System.out.println("resource ordering, meals per philosopher: " + dine(new OrderedForks(5), 5, 10_000));
        System.out.println("waiter (4 seats),  meals per philosopher: " + dine(new Waiter(5), 5, 10_000));
    }
}
```

Output:

```
resource ordering, meals per philosopher: [10000, 10000, 10000, 10000, 10000]
waiter (4 seats),  meals per philosopher: [10000, 10000, 10000, 10000, 10000]
```

Why it's correct

- **Ordering:** every philosopher acquires forks in increasing index order. A cycle of waiting would need someone to hold a higher fork while waiting for a lower one — impossible. No circular wait → no deadlock.
- **Waiter:** with at most 4 philosophers competing for 5 forks, by the **pigeonhole principle** (if there are more items than boxes, some box must get two) at least one of them can get both forks, eat, and release — so progress is always possible. The fair semaphore gives waiting philosophers seats in FIFO (first in, first out) order.
- Forks are `ReentrantLock`s released in `finally`, so an exception can't leave a fork held.
- 5 × 10,000 meals complete with each philosopher eating exactly 10,000 times.

Pitfalls

- "Everyone picks left then right" → deadlock.
- `tryLock` both forks and immediately retry without random back-off → livelock.
- Unfair strategies can starve one philosopher in theory (neighbours keep winning). The fair semaphore makes *seat* access first-come-first-served; for a strict no-starvation guarantee on the forks as well, make the fork locks fair too (`new ReentrantLock(true)`), at a throughput cost.

Real-world examples

Any time a task needs **two or more locks** at once: bank transfers (two accounts), moving an item between two inventories, database transactions updating several rows — solved by ordering (account id), or by the DB's deadlock detection aborting one transaction.

In the interview

> **30-second answer:** "Naively everyone takes the left fork and waits for the right — circular wait, deadlock. I break circular wait by always taking the lower-numbered fork first, or by a waiter semaphore allowing only n−1 philosophers to try; fairness prevents starvation."

Follow-ups:

- *Which Coffman condition does each fix break?* Both break circular wait; the tryLock variant breaks hold-and-wait.
- *Maximum parallelism?* With 5 forks, at most 2 philosophers can eat at the same time.

Self-check

- **Q:** With resource ordering, which philosopher behaves "differently"? **A:** The one between forks 4 and 0 — they pick fork 0 (right) first.

TL;DR

Break circular wait: global fork order, or allow only n−1 diners.

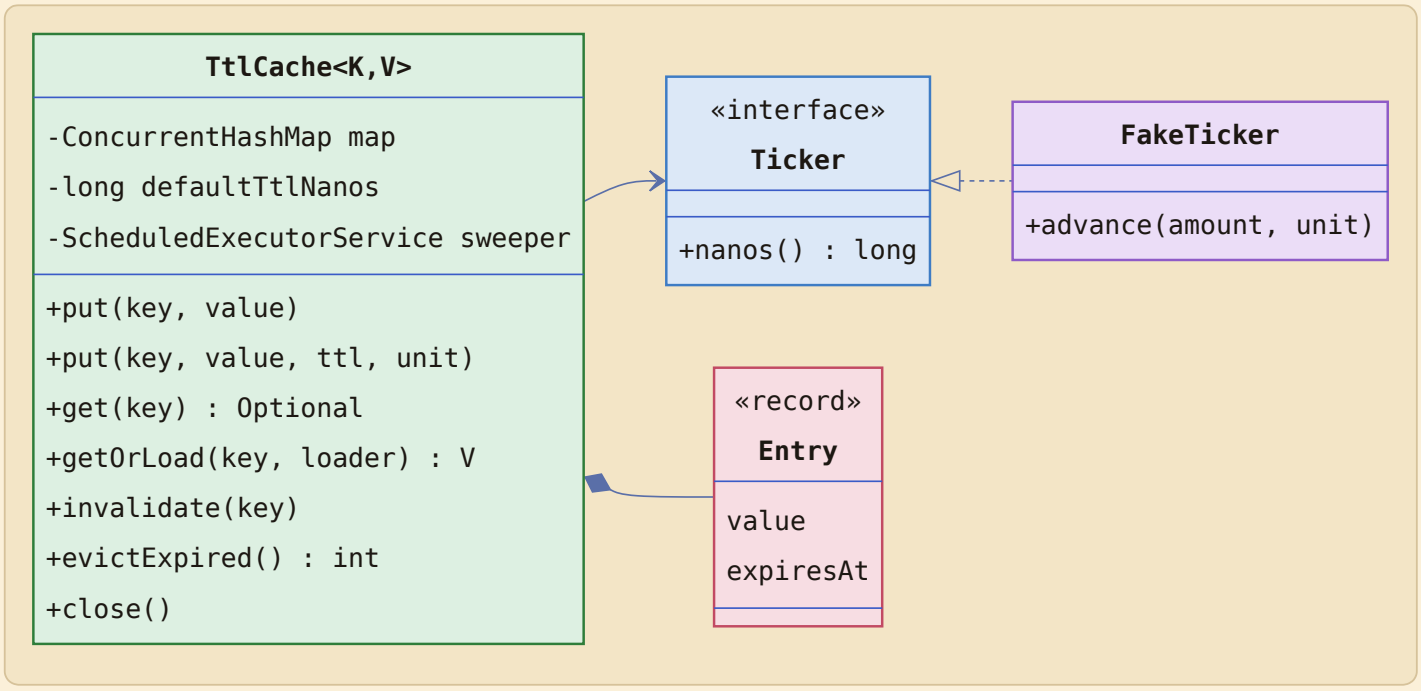
13.6 Thread-safe cache with TTL

Problem

Design an in-memory key-value **cache** (a fast store that keeps copies of data for quick reads; see System Design Fundamentals) used by many threads where each entry expires after a **time-to-live** (TTL). Requirements: `put(k, v)` (with default or per-entry TTL), `get(k)` returns nothing for expired entries, `getOrLoad(k, loader)` loads on a miss without a **cache stampede** (many threads loading the same key at once), expired entries are eventually removed from memory, and it's testable without sleeping.

Approach

- Store `Entry(value, expiresAt)` records (immutable) in a `ConcurrentHashMap`.
- **Lazy expiry**: `get` checks `expiresAt`; if expired, removes it with the **conditional** `remove(key, entry)` so it never deletes a fresher value another thread just put.
- **Active expiry**: a **daemon** (background thread that does not keep the JVM — Java Virtual Machine — running) `ScheduledExecutorService` (a JDK thread pool that runs tasks on a timer) periodically calls `evictExpired()` so keys nobody reads again don't leak memory.
- **No stampede**: `getOrLoad` uses `map.compute(...)`, which runs the function atomically per key; concurrent callers for the same key wait and the loader runs once.
- **Testability**: time comes from an injected `Ticker` (a `FakeTicker` in tests) — a small application of **Dependency Inversion** (depending on an interface rather than a concrete class, so the real clock can be swapped for a fake one).



Java solution

```java
// File: code/lld/ch13/ttlcache/Main.java
package lld.ch13.ttlcache;

import java.util.ArrayList;
import java.util.List;
import java.util.Map;
import java.util.Objects;
import java.util.Optional;
import java.util.concurrent.ConcurrentHashMap;
import java.util.concurrent.CountDownLatch;
import java.util.concurrent.Executors;
import java.util.concurrent.ScheduledExecutorService;
import java.util.concurrent.TimeUnit;
import java.util.concurrent.atomic.AtomicInteger;
import java.util.concurrent.atomic.AtomicLong;
import java.util.function.Function;

/** Thread-safe key-value cache where every entry expires after a time-to-live (TTL). */
public class Main {

    /** Time source. Injected so tests can move time forward without sleeping. */
    @FunctionalInterface interface Ticker { long nanos(); }

    static final class FakeTicker implements Ticker {
        private final AtomicLong now = new AtomicLong();
        public long nanos() { return now.get(); }
        void advance(long amount, TimeUnit unit) { now.addAndGet(unit.toNanos(amount)); }
    }

    static final class TtlCache<K, V> implements AutoCloseable {
        private record Entry<V>(V value, long expiresAt) { }

        private final ConcurrentHashMap<K, Entry<V>> map = new ConcurrentHashMap<>();
        private final long defaultTtlNanos;
        private final Ticker ticker;
        private final ScheduledExecutorService sweeper;       // null = lazy expiry only

        TtlCache(long ttl, TimeUnit unit, Ticker ticker, long sweepEveryMillis) {
            this.defaultTtlNanos = unit.toNanos(ttl);
            this.ticker = ticker;
            if (sweepEveryMillis > 0) {
                sweeper = Executors.newSingleThreadScheduledExecutor(r -> {
                    Thread t = new Thread(r, "ttl-sweeper");
                    t.setDaemon(true);                          // never blocks JVM shutdown
                    return t;
                });
                // 'this' escapes to the sweeper thread before the constructor ends (a pattern 12.6 warns
                // about). It is safe HERE only because every field evictExpired() uses (map, ticker) is
                // already assigned and handing a task to an executor is a happens-before edge. In
                // production code prefer a static factory that starts the sweeper after construction.
                sweeper.scheduleAtFixedRate(this::evictExpired, sweepEveryMillis, sweepEveryMillis,
TimeUnit.MILLISECONDS);
            } else {
                sweeper = null;
            }
        }

        private boolean expired(Entry<V> e) { return ticker.nanos() - e.expiresAt() >= 0; }   // overflow-safe
compare

        void put(K key, V value) { put(key, value, defaultTtlNanos, TimeUnit.NANOSECONDS); }

        void put(K key, V value, long ttl, TimeUnit unit) {
            Objects.requireNonNull(key); Objects.requireNonNull(value);
            map.put(key, new Entry<>(value, ticker.nanos() + unit.toNanos(ttl)));
        }
```

```
        Optional<V> get(K key) {
            Entry<V> e = map.get(key);
            if (e == null) return Optional.empty();
            if (expired(e)) {
                map.remove(key, e);   // conditional remove: never deletes a FRESH value another thread just put
                return Optional.empty();
            }
            return Optional.of(e.value());
        }

        /**
         * Read-through: if missing/expired, load it. compute() locks the key's bin, so concurrent callers
         * for the SAME key wait and the loader runs once (no "cache stampede").
         * The loader must be fast and must not touch this cache.
         */
        V getOrLoad(K key, Function<? super K, ? extends V> loader) {
            return map.compute(key, (k, old) ->
                    old != null && !expired(old) ? old : new Entry<>(loader.apply(k), ticker.nanos() +
defaultTtlNanos)
            ).value();
        }

        void invalidate(K key) { map.remove(key); }

        /** Active expiry: drop every expired entry. Safe to run concurrently with readers and writers. */
        int evictExpired() {
            int removed = 0;
            for (Map.Entry<K, Entry<V>> me : map.entrySet()) {
                if (expired(me.getValue()) && map.remove(me.getKey(), me.getValue())) removed++;
            }
            return removed;
        }

        int rawSize() { return map.size(); }   // includes not-yet-swept expired entries

        @Override public void close() { if (sweeper != null) sweeper.shutdownNow(); }
    }

    public static void main(String[] args) throws Exception {
        FakeTicker clock = new FakeTicker();
        try (TtlCache<String, String> cache = new TtlCache<>(100, TimeUnit.MILLISECONDS, clock, 0)) {
            cache.put("session:42", "alice");
            cache.put("otp:alice", "913377", 30, TimeUnit.MILLISECONDS);   // per-entry TTL
            clock.advance(50, TimeUnit.MILLISECONDS);
            System.out.println("t=50ms  session=" + cache.get("session:42").orElse("<expired>")
                    + ", otp=" + cache.get("otp:alice").orElse("<expired>"));
            clock.advance(60, TimeUnit.MILLISECONDS);
            System.out.println("t=110ms session=" + cache.get("session:42").orElse("<expired>"));

            for (int i = 0; i < 5; i++) cache.put("k" + i, "v" + i);
            clock.advance(200, TimeUnit.MILLISECONDS);
            System.out.println("before sweep raw size=" + cache.rawSize() + ", swept=" + cache.evictExpired()
                    + ", after=" + cache.rawSize());

            // Stampede test: 16 threads miss the same key at the same moment.
            AtomicInteger loads = new AtomicInteger();
            CountDownLatch go = new CountDownLatch(1);
            List<Thread> ts = new ArrayList<>();
            List<String> results = java.util.Collections.synchronizedList(new ArrayList<>());
            for (int i = 0; i < 16; i++) {
                Thread t = new Thread(() -> {
                    try { go.await(); } catch (InterruptedException e) { return; }
                    results.add(cache.getOrLoad("user:7", k -> { loads.incrementAndGet(); return "profile-of-" + k;
}));
                });
                ts.add(t); t.start();
            }
            go.countDown();
```

```
            for (Thread t : ts) t.join();
            System.out.println("16 concurrent misses -> loader ran " + loads.get() + " time(s), all got same value:
"
                    + results.stream().allMatch("profile-of-user:7"::equals));
        }

        // Background sweeper with the real clock.
        try (TtlCache<Integer, Integer> real = new TtlCache<>(30, TimeUnit.MILLISECONDS, System::nanoTime, 10)) {
            for (int i = 0; i < 1_000; i++) real.put(i, i * i);
            System.out.println("real clock: size right after puts=" + real.rawSize());
            Thread.sleep(200);
            System.out.println("real clock: size after 200 ms (sweeper ran)=" + real.rawSize());
        }
    }
}
```

Output:

```
t=50ms  session=alice, otp=<expired>
t=110ms session=<expired>
before sweep raw size=5, swept=5, after=0
16 concurrent misses -> loader ran 1 time(s), all got same value: true
real clock: size right after puts=1000
real clock: size after 200 ms (sweeper ran)=0
```

Why it's correct

- All shared state is inside one `ConcurrentHashMap`; entries are immutable records, so a reader sees either the old or the new entry, never a half-written one.
- `remove(key, e)` removes only if the mapping is still *that exact entry*. If another thread replaced it with a fresh one after our read, the fresh one survives.
- `compute` executes the remapping function atomically for that key, so 16 simultaneous misses cause one load (the output shows `loader ran 1 time(s)`).
- Expiry uses `now - expiresAt >= 0` rather than `now >= expiresAt`, which stays correct even if `System.nanoTime()` values **overflow** (wrap around after passing the largest value a `long` can hold) (the JDK recommends comparing nano times by subtraction).
- The sweeper is a **daemon** thread and is shut down in `close()`, so it never keeps the JVM alive.
- The constructor hands `this::evictExpired` to the sweeper before it returns (`this` escapes). That is normally a bug (12.6), and it is safe here only because the fields the sweeper uses are already set and submitting to an executor creates a happens-before edge; a **static factory method** (a static method that builds and returns the object) that starts the sweeper after construction is the cleaner production choice.

Pitfalls

- Using `System.currentTimeMillis()` for TTL: wall-clock time can jump (NTP adjustments — the Network Time Protocol corrects the system clock). `System.nanoTime()` is **monotonic** (it only ever moves forward) for measuring durations.
- A slow loader inside `compute` blocks other keys that share the same hash bin, and a loader that touches the same map can throw or deadlock. For slow loads, store a `CompletableFuture<V>` (a JDK placeholder for a value that an asynchronous task will fill in later) in the map instead (`computeIfAbsent(k, key -> supplyAsync(...))`) so the bin lock is held only briefly.
- Only lazy expiry → memory leak for keys never read again. Only active expiry → a `get` could return a stale value between sweeps. Use both.
- No size limit: a real cache also needs a maximum size and an **eviction policy** (the rule for which entry to throw out when full: LRU = least recently used, LFU = least frequently used).

Real-world examples

- **Caffeine** (the de-facto Java caching library) offers `expireAfterWrite`/`expireAfterAccess`, size-based eviction, and a loading cache that prevents stampedes — the production version of this design. Guava's (Google's core Java library) `CacheBuilder` is its predecessor.

- **Redis** `EXPIRE` / `SET … EX` uses the same combination: lazy expiry on access plus periodic active sampling of keys with TTLs.
- Sessions, OTPs (one-time passwords), DNS caches (DNS is the internet's lookup from names to IP addresses), and seat holds in booking systems (a hold is a TTL entry).

In the interview

> **30-second answer:** "A ConcurrentHashMap of immutable entries holding value and expiry time. Get checks expiry lazily and removes with a conditional remove; a daemon scheduled sweeper removes expired keys nobody reads. getOrLoad uses compute so concurrent misses load once. Time is injected for testing."

Follow-ups (with answers):

- *Add max size with LRU?* Combine with an access-ordered `LinkedHashMap` under a lock, or a `ConcurrentHashMap` plus a concurrent linked **deque** (double-ended queue) of keys updated on access — or just use Caffeine (Window-TinyLFU).
- *Refresh without blocking readers?* "Refresh-ahead": serve the old value while one thread reloads asynchronously when the entry is close to expiring.
- *Distributed?* Redis/Memcached (in-memory cache servers shared by many machines) with TTLs; keep a small local cache in front for hot keys.

Self-check

- **Q:** Why `remove(key, e)` and not `remove(key)` on expiry? **A:** To avoid deleting a new value written between our read and our remove.

TL;DR

CHM (`ConcurrentHashMap`) + immutable (value, expiry) entries; lazy + scheduled expiry; `compute` for **single-flight** loads (one load per key, shared by every waiting caller); injected clock.

13.7 Design a (simplified) Concurrent HashMap — lock striping

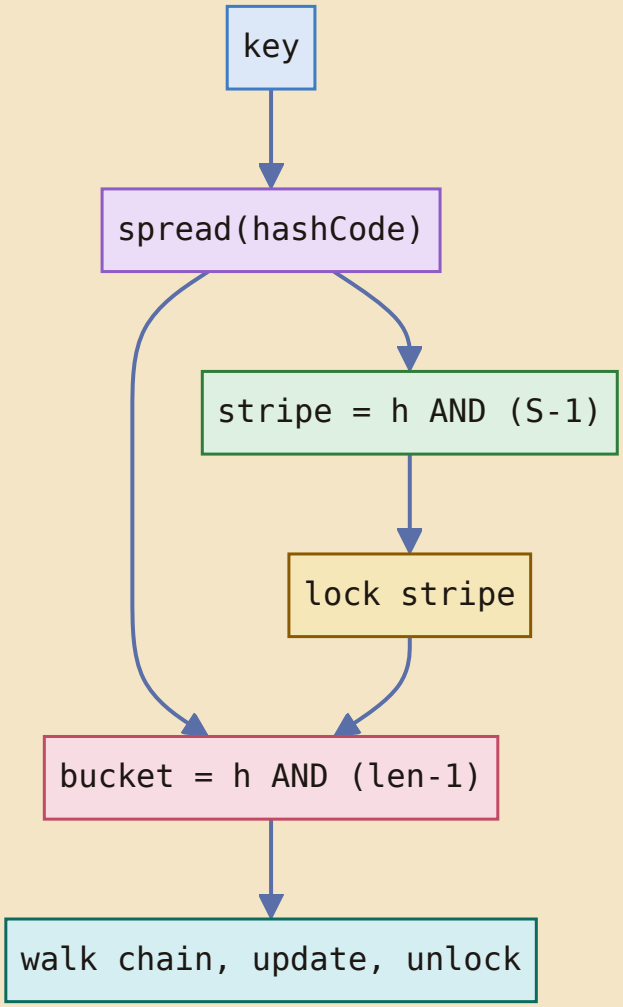
Problem

Implement a hash map that many threads can use at once with `get`, `put`, `remove`, `compute` and automatic resizing — faster than one global lock around a `HashMap`.

Approach

Lock striping (12.11):

- Buckets: an array of linked lists (**separate chaining**: each bucket holds a list of all entries whose hash lands there).
- Stripes: a fixed array of `S` locks (power of two). Key with hash *h* uses stripe `h & (S − 1)` and bucket `h & (tableLength − 1)`.
- Because the stripe depends only on the hash — **not** on the table length — a key's stripe never changes after a resize.
- Every operation locks only its stripe; threads on different stripes run in parallel.
- **Resize** (when size > 0.75 × buckets): acquire **all** stripe locks in index order (a global order → no deadlock), re-check the condition, **rehash** (recompute every key's bucket) into a table twice as big, publish via a `volatile` field, release in reverse.
- Size tracked with an `AtomicInteger`.



key
spread(hashCode)
stripe = h AND (S-1)
lock stripe
bucket = h AND (len-1)
walk chain, update, unlock

Java solution

```java
// File: code/lld/ch13/stripedmap/Main.java
package lld.ch13.stripedmap;

import java.util.ArrayList;
import java.util.List;
import java.util.Objects;
import java.util.concurrent.atomic.AtomicInteger;
import java.util.concurrent.locks.ReentrantLock;
import java.util.function.BiFunction;

/**
 * A simplified concurrent hash map using LOCK STRIPING: the buckets are guarded by a small array
 * of locks, so threads touching different stripes never block each other.
 * (Java 7's ConcurrentHashMap used this idea with "segments".)
 */
public class Main {

    static final class StripedHashMap<K, V> {
        private static final class Node<K, V> {
            final K key; final int hash; V value; Node<K, V> next;
            Node(K key, int hash, V value, Node<K, V> next) { this.key = key; this.hash = hash; this.value = value;
this.next = next; }
        }

        private volatile Node<K, V>[] table;               // replaced (never mutated in place) only while ALL
locks are held
        private final ReentrantLock[] stripes;
        private final AtomicInteger size = new AtomicInteger();

        System.out.println("after concurrent removes size=" + map.size());
    }
}
```

Output:

```
put a=1, put a=2 returns old=1, get a=2, remove a=2, get a=null
8 threads x 20,000 puts -> size=160000, missing=0, table grew from 16 to 262144 buckets
atomic compute on 10 hot keys: each=8000, total=80000 (expected 80000)
after concurrent removes size=0
```

Why it's correct

- **Every bucket belongs to exactly one stripe.** Both the stripe count S and the table length are powers of two and $S \le$ table length, so the stripe index (`h & (S-1)`) is just the low bits of the bucket index (`h & (len-1)`). All keys in one bucket therefore share one stripe lock, and two threads can never modify the same chain at the same time. Two operations on the same key obviously share it too.
- **Resize safety:** resize holds *every* stripe lock, so no other operation is in progress; it re-checks the load condition (another thread may have resized first) and publishes the new table with a `volatile` write. Any

later operation acquires a stripe lock that the resizer released → happens-before → it sees the new table and moved nodes.

- **No deadlock:** normal operations hold one lock; resize acquires all locks in ascending order and is started only *after* the caller released its own stripe.
- **Atomic compute:** read-modify-write of one key happens entirely under its stripe lock (the demo's 80,000 increments on 10 hot keys are exact).

Pitfalls

- Deriving the stripe from the *bucket index of the current table* — after a resize a key could move to a different lock while another thread holds the old one.
- Resizing while holding one stripe lock and then taking all locks → deadlock with another resizer. Release first, then resize.
- Reading `table` without a lock or `volatile` → a stale table after resize.
- Allowing `null` keys/values makes `get() == null` ambiguous (the JDK's `ConcurrentHashMap` forbids them too).

How the real `ConcurrentHashMap` goes further

Aspect	This design	JDK 8+ `ConcurrentHashMap`
Reads	Lock the stripe	Lock-free (volatile reads of nodes)
Write locking	One of S stripe locks	CAS into empty bins; `synchronized` on the bin's first node otherwise
Long chains	Linked list	Converted to a red-black tree beyond 8 nodes (when table ≥ 64)
Resize	Stop-the-world (all locks; everything else pauses)	Incremental: threads help transfer bins concurrently
Size	`AtomicInteger`	`LongAdder`-style counter cells

Real-world examples

Java 7's `ConcurrentHashMap` used **segments** (16 by default) — the same striping idea. Guava's `Striped<Lock>` offers striped locks for your own data; Caffeine uses striped buffers to record reads.

In the interview

> **30-second answer:** "An array of buckets plus a small array of locks; each key maps to a stripe by its hash bits, so different stripes work in parallel. Every bucket belongs to exactly one stripe. Resize takes all stripe locks in order, rehashes and publishes the new table through a volatile field."

Follow-ups:

- *How to make `get` lock-free?* Make `Node.value` and `next` volatile, publish nodes safely, and never mutate a chain in a way a reader could see half-done (the JDK copies/reorders carefully during transfer).
- *How many stripes?* Around the number of threads expected to write concurrently (JDK 7 default 16); more stripes = less contention but more memory.

Self-check

- **Q:** Why must stripe count divide the table length? **A:** So every bucket maps to exactly one stripe (stripe index = low bits of bucket index).

TL;DR

N locks for M buckets, stripe by hash bits, resize under all locks in order, publish via volatile.

13.8 Thread-safe bounded Blocking Queue (two ways)

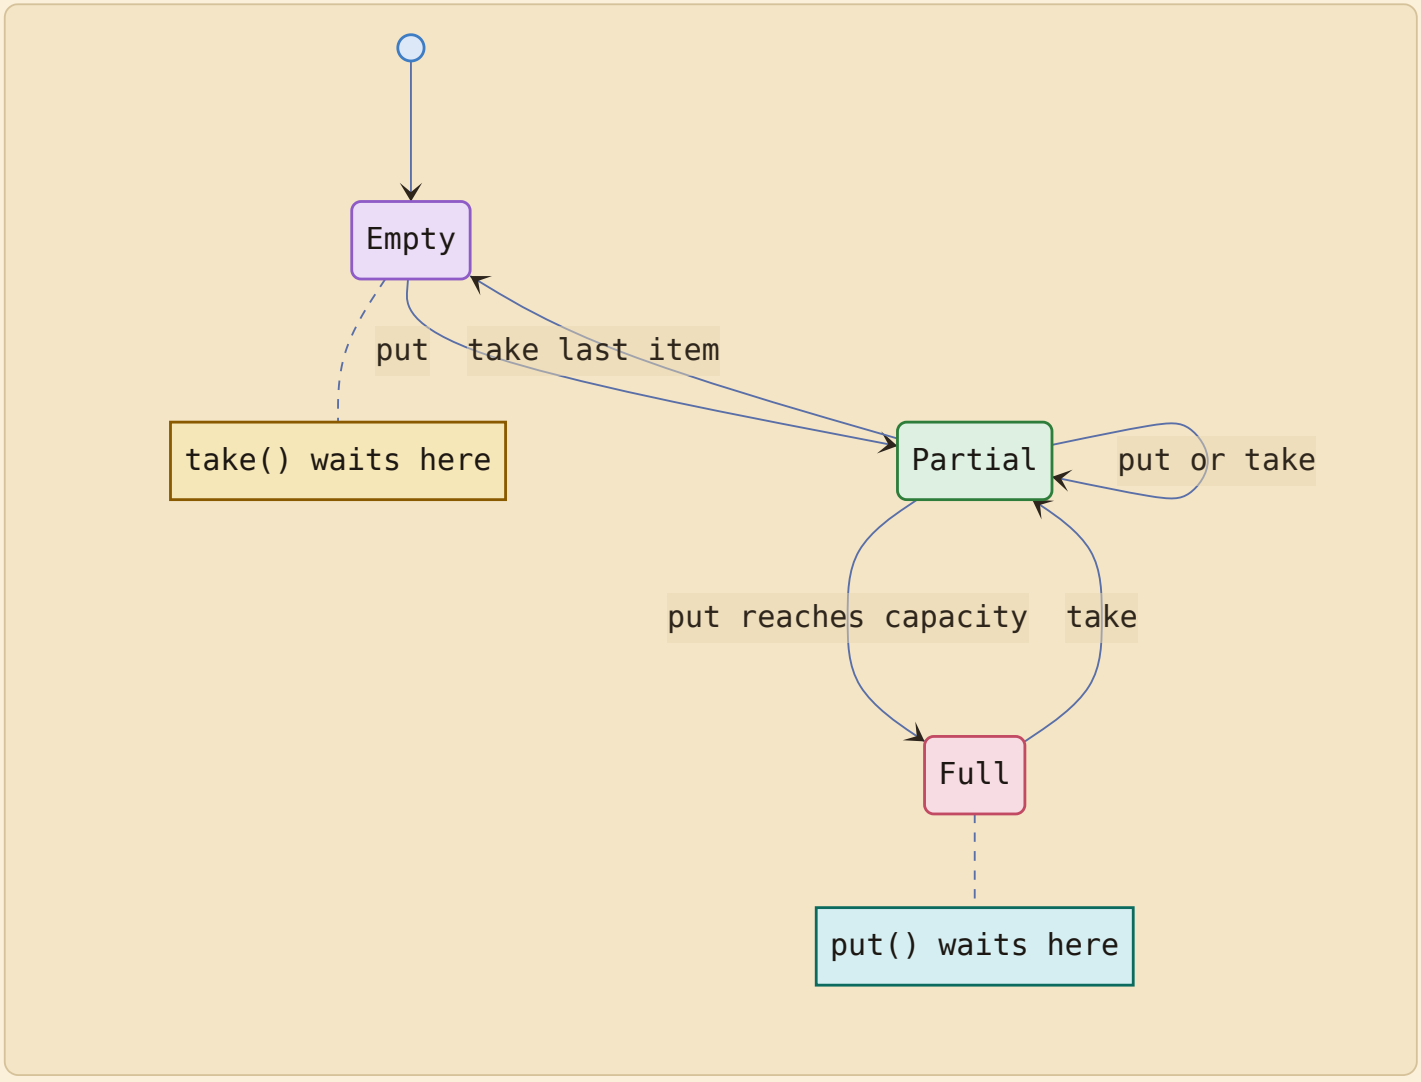
Problem

Implement a fixed-capacity FIFO queue for producer-consumer use: `put` blocks while full, `take` blocks while empty, plus `offer(item, timeout)` and `poll(timeout)` that give up after a timeout.

Approach

Storage: a **circular array** (an array whose end wraps around to the start; `head`, `tail`, `count`). Two synchronisation designs:

	Way 1: monitor	**Way 2: `ReentrantLock` + 2 `Condition`s**
Lock	`synchronized` methods	`lock.lockInterruptibly()`
Wait	`while (full) wait();`	`while (full) notFull.await();`
Wake	`notifyAll()` — producers and consumers share one wait set	`notEmpty.signal()` after enqueue, `notFull.signal()` after dequeue
Timed wait	`TimeUnit.timedWait(this, nanos)` + deadline loop	`awaitNanos(nanos)` returns the time left
Efficiency	Wakes everyone (thundering herd)	Wakes exactly one thread of the right kind



Java solution

```java
// File: code/lld/ch13/blockingqueue/Main.java
package lld.ch13.blockingqueue;

import java.util.ArrayList;
import java.util.List;
import java.util.concurrent.TimeUnit;
import java.util.concurrent.atomic.AtomicLong;
import java.util.concurrent.locks.Condition;
import java.util.concurrent.locks.ReentrantLock;

/** A bounded blocking queue built two ways: monitor (wait/notifyAll) and Lock + two Conditions. */
public class Main {

    interface BoundedBlockingQueue<T> {
        void put(T item) throws InterruptedException;          // blocks while full

consumedCount.incrementAndGet(); } }
                catch (InterruptedException e) { Thread.currentThread().interrupt(); }
            });
            ts.add(t);
        }
        ts.forEach(Thread::start);
        for (Thread t : ts) t.join();
        long expected = (long) PRODUCERS * PER_PRODUCER * (PER_PRODUCER + 1) / 2;
        System.out.println(name + ": consumed " + consumedCount.get() + " items, sum ok=" + (consumedSum.get() ==
expected)
                + ", left in queue=" + q.size());

        System.out.println(name + ": poll(30ms) on empty -> " + q.poll(30, TimeUnit.MILLISECONDS));
        q.put(1); q.put(2);                                     // capacity is 2 in this demo
        System.out.println(name + ": offer(30ms) on full -> " + q.offer(3, 30, TimeUnit.MILLISECONDS));
    }

    public static void main(String[] args) throws InterruptedException {
        stressTest("wait/notifyAll  ", new MonitorQueue<>(2));
        stressTest("Lock+Conditions ", new ConditionQueue<>(2));
    }
}
```

Output:

```
wait/notifyAll  : consumed 60000 items, sum ok=true, left in queue=0
wait/notifyAll  : poll(30ms) on empty -> null
wait/notifyAll  : offer(30ms) on full -> false
Lock+Conditions : consumed 60000 items, sum ok=true, left in queue=0
Lock+Conditions : poll(30ms) on empty -> null
Lock+Conditions : offer(30ms) on full -> false
```

Why it's correct

- All fields are accessed only while holding the single lock → no races; the lock gives visibility.
- **Waiting in `while` loops** handles spurious wake-ups and "someone else took the item first".
- **Way 1** must use `notifyAll()`: with one wait set, `notify()` might wake a producer when a consumer was needed (or vice versa), and the right thread might never wake → deadlock-like hang.
- **Way 2** can use `signal()` because producers only wait on `notFull` and consumers only on `notEmpty`; every enqueue makes exactly one more consumer able to proceed, every dequeue exactly one producer.
- Timed versions track the *remaining* time so repeated spurious wakeups can't extend the total wait.
- Stress test: 3 producers × 20,000 items, 3 consumers, capacity 2 (maximum blocking) → all 60,000 items consumed, sum correct, queue empty.

Pitfalls

- `if` instead of `while`.
- `notify()` with a single monitor shared by producers and consumers.
- Forgetting `items[head] = null` after dequeue → the array keeps references alive (memory leak for large objects).
- Accepting `null` items when `null` means "timed out" in `poll`.
- Using `lock()` instead of `lockInterruptibly()` makes cancellation harder (the JDK's queues use `lockInterruptibly` in blocking methods).

Real-world examples

`java.util.concurrent.ArrayBlockingQueue` is built exactly like Way 2 (one lock, `notEmpty`/`notFull`). `LinkedBlockingQueue` uses **two** locks (`putLock`, `takeLock`) so a producer and a consumer can work at the same time. Thread pools, logging frameworks, and Kafka's producer internals all rely on blocking hand-off.

In the interview

> **30-second answer:** "A circular array with head, tail and count guarded by one lock. put waits while count == capacity, take waits while count == 0, both in while loops. With synchronized I must use notifyAll because both sides share one wait set; with ReentrantLock I use two Conditions, notFull and notEmpty, and signal just the right side."

Follow-ups:

- *Higher throughput?* Two-lock queue (linked list, separate put/take locks, atomic count) like `LinkedBlockingQueue`, or a lock-free ring buffer (LMAX Disruptor, a high-performance Java messaging library) for single producer/consumer.
- *Unbounded?* Remove the "full" condition — but then there's no back-pressure.

Self-check

- **Q:** Why is `signal()` safe in Way 2 but `notify()` unsafe in Way 1? **A:** Separate condition queues guarantee the woken thread is of the right kind.

TL;DR

Circular buffer + one lock + "wait while full/empty" in loops. Monitor → `notifyAll`; Lock → `notFull`/`notEmpty` + `signal`.

13.9 Concurrent Bloom Filter

Problem

Design a thread-safe **Bloom filter** — a compact probabilistic set that answers *"definitely not present"* or *"probably present"* — that many threads can add to and query at the same time.

Approach

How a Bloom filter works (first-time explanation):

1. Keep an array of m bits, all 0.
2. To **add** an item, compute k hash positions and set those k bits to 1.
3. To **query**, compute the same k positions: if **any** bit is 0 the item was **definitely never added**; if all are 1 it was **probably** added (the bits might have been set by other items → a *false positive*).
4. No false negatives, no deletion (clearing a bit could erase other items; a *counting* Bloom filter with small counters supports deletes).

Sizing for n expected items and target false-positive rate p:

- bits: $m = \lceil -n \cdot \ln p / (\ln 2)^2 \rceil$
- hashes: $k = \text{round}((m / n) \cdot \ln 2)$

For n = 80,000 and p = 1% → $m \approx$ 766,805 bits (≈ 93.6 KiB — kibibytes of 1,024 bytes; the demo prints 93 because it uses integer division) and k = 7 — about 9.6 bits per item, whatever the item size.

Double hashing (Kirsch–Mitzenmacher): compute two hashes $h1$, $h2$ once and use positions $h1 + i \cdot h2$ for i = 0..k−1 — as good as k independent hashes in practice.

Thread safety without locks:

- Bits live in an `AtomicLongArray` (64 bits per word).
- Adding a bit = **atomic OR** via `getAndAccumulate(word, mask, (a, b) -> a | b)` (a CAS loop inside). Two threads setting different bits in the same word both succeed.
- Queries are plain volatile reads of words. Bits only ever go 0 → 1, so a concurrent query can at worst miss an item whose `add` hasn't finished — which is fine, because that add hadn't happened yet. After `add` returns, every later query sees its bits (happens-before of atomic operations).

Java solution

```java
// File: code/lld/ch13/bloomfilter/Main.java
package lld.ch13.bloomfilter;

import java.util.ArrayList;
import java.util.List;
import java.util.concurrent.atomic.AtomicLongArray;

/**
 * A thread-safe Bloom filter: a compact set that answers "definitely NOT present" or
 * "PROBABLY present". No false negatives; a tunable rate of false positives.
 * Lock-free: bits live in an AtomicLongArray and are set with an atomic OR.
 */
public class Main {

    static final class ConcurrentBloomFilter {
        private final AtomicLongArray words;     // m bits packed into 64-bit words
        private final int numBits;               // m
        private final int numHashes;             // k

        /** Size the filter for 'expectedItems' at the target false-positive probability. */
        ConcurrentBloomFilter(int expectedItems, double falsePositiveRate) {
            double ln2 = Math.log(2);
            long m = (long) Math.ceil(-expectedItems * Math.log(falsePositiveRate) / (ln2 * ln2));
            if (m > Integer.MAX_VALUE - 63) throw new IllegalArgumentException("too large");
            this.numBits = (int) m;
            this.numHashes = Math.max(1, (int) Math.round((double) m / expectedItems * ln2));
            this.words = new AtomicLongArray((numBits + 63) / 64);
        }

        /** Adds the item. Returns true if at least one bit changed (i.e. it was definitely new). */
        boolean add(String item) {
            long base = fnv1a64(item);
            long h1 = fmix64(base), h2 = fmix64(base ^ 0x9E3779B97F4A7C15L) | 1;   // h2 odd
            boolean changed = false;
            for (int i = 0; i < numHashes; i++) {
                int bit = (int) Math.floorMod(h1 + i * h2, (long) numBits);        // double hashing
                long mask = 1L << (bit & 63);
                long before = words.getAndAccumulate(bit >>> 6, mask, (cur, m) -> cur | m);  // atomic OR (CAS
loop)
                if ((before & mask) == 0) changed = true;
            }
            return changed;
        }

        boolean mightContain(String item) {
            long base = fnv1a64(item);
            long h1 = fmix64(base), h2 = fmix64(base ^ 0x9E3779B97F4A7C15L) | 1;
            for (int i = 0; i < numHashes; i++) {
                int bit = (int) Math.floorMod(h1 + i * h2, (long) numBits);
                if ((words.get(bit >>> 6) & (1L << (bit & 63))) == 0) return false;   // definitely absent
            }
            return true;
        }

        int numBits() { return numBits; }
        int numHashes() { return numHashes; }

        // 64-bit FNV-1a over the string's chars, then a strong bit-mixer (MurmurHash3's finalizer).
        private static long fnv1a64(String s) {
            long h = 0xcbf29ce484222325L;
            for (int i = 0; i < s.length(); i++) { h ^= s.charAt(i); h *= 0x100000001b3L; }
            return h;
        }
        private static long fmix64(long k) {
            k ^= k >>> 33; k *= 0xff51afd7ed558ccdL;
            k ^= k >>> 33; k *= 0xc4ceb9fe1a85ec53L;
```

```
            k ^= k >>> 33;
            return k;
        }
    }

    public static void main(String[] args) throws InterruptedException {
        final int THREADS = 8, PER_THREAD = 10_000, N = THREADS * PER_THREAD;
        ConcurrentBloomFilter bf = new ConcurrentBloomFilter(N, 0.01);
        System.out.println("sized for n=" + N + ", p=1%: m=" + bf.numBits() + " bits (" + bf.numBits() / 8 / 1024
                + " KiB), k=" + bf.numHashes() + " hashes");

        List<Thread> ts = new ArrayList<>();
        for (int t = 0; t < THREADS; t++) {
            final int id = t;
            Thread th = new Thread(() -> { for (int i = 0; i < PER_THREAD; i++) bf.add("user-" + id + "-" + i); });
            ts.add(th); th.start();
        }
        for (Thread th : ts) th.join();

        int falseNegatives = 0;
        for (int t = 0; t < THREADS; t++) for (int i = 0; i < PER_THREAD; i++) if (!bf.mightContain("user-" + t +
"-" + i)) falseNegatives++;
        System.out.println("false negatives after 8-thread insert: " + falseNegatives);

        int probes = 100_000, falsePositives = 0;
        for (int i = 0; i < probes; i++) if (bf.mightContain("stranger-" + i)) falsePositives++;
        System.out.printf("false-positive rate on %,d unseen keys: %.2f%% (target 1%%)%n", probes, 100.0 *
falsePositives / probes);
        System.out.println("add(\"user-0-0\") again changes bits? " + bf.add("user-0-0"));
    }
}
```

Output:

```
sized for n=80000, p=1%: m=766805 bits (93 KiB), k=7 hashes
false negatives after 8-thread insert: 0
false-positive rate on 100,000 unseen keys: 1.01% (target 1%)
add("user-0-0") again changes bits? false
```

Why it's correct

- **No lost updates:** a plain `words[i] |= mask` on a `long[]` is read-modify-write and two threads could overwrite each other's bits → false negatives. The atomic OR retries on conflict, so every bit set survives.
- **Monotonic state:** bits never go back to 0, so there's no ABA issue and no need for locks.
- **Deterministic result:** OR is commutative, so the final bit array is the same whatever the thread interleaving — the demo's false-positive rate (≈1%) is identical every run.
- The measured false-positive rate matches the formula's target.

Pitfalls

- Non-atomic bit setting → false negatives (the one thing a Bloom filter must never produce).
- Poor hash functions (e.g. using `String.hashCode()` directly with `i * 31` offsets) → clustered bits and much higher false-positive rates. Mix bits (here FNV-1a + MurmurHash3's finalizer — two fast, non-cryptographic hash functions).
- Adding far more than n items → false-positive rate climbs quickly; resize by creating a larger filter (or a "scalable" chain of filters).
- `Math.floorMod` on `long` to avoid negative indices.

Real-world examples

- **Apache Cassandra, HBase, RocksDB, LevelDB** (databases and storage engines): Bloom filters per **SSTable** (Sorted String Table — an immutable sorted data file on disk)/file to skip disk reads for keys that aren't there.
- **Google Guava** `BloomFilter` (its `put`/`mightContain` are thread-safe since Guava 23 using atomic long arrays).
- **Redis** (RedisBloom module / Redis Stack) offers `BF.ADD`/`BF.EXISTS`.

- Checking whether a username is already taken, or a URL already crawled, before hitting the database; Medium has described using Bloom filters to avoid recommending already-read articles.

In the interview

> **30-second answer:** "A bit array of size m with k hash positions per item from double hashing; add sets k bits, query checks them — any zero means definitely absent. For concurrency I store bits in an AtomicLongArray and set them with an atomic OR; since bits only go from 0 to 1, reads need no lock. m and k come from n and the target false-positive rate."

Follow-ups:

- *Deletions?* Counting Bloom filter (small counters instead of bits, atomic increments/decrements) or a Cuckoo filter (a Bloom-filter alternative that supports deletion).
- *Distributed?* Keep it in Redis (RedisBloom) or rebuild per node from a shared source.

Self-check

- **Q:** Can a Bloom filter say "absent" for an item that was added? **A:** No — no false negatives (assuming atomic, completed adds).
- **Q:** Bits per element for 1% FPR (false-positive rate)? **A:** About 9.6.

TL;DR

Bits + k hashes; "no" is certain, "yes" is probable. `AtomicLongArray` + atomic OR = lock-free and correct.

13.10 Multi-threaded Merge Sort (Fork/Join)

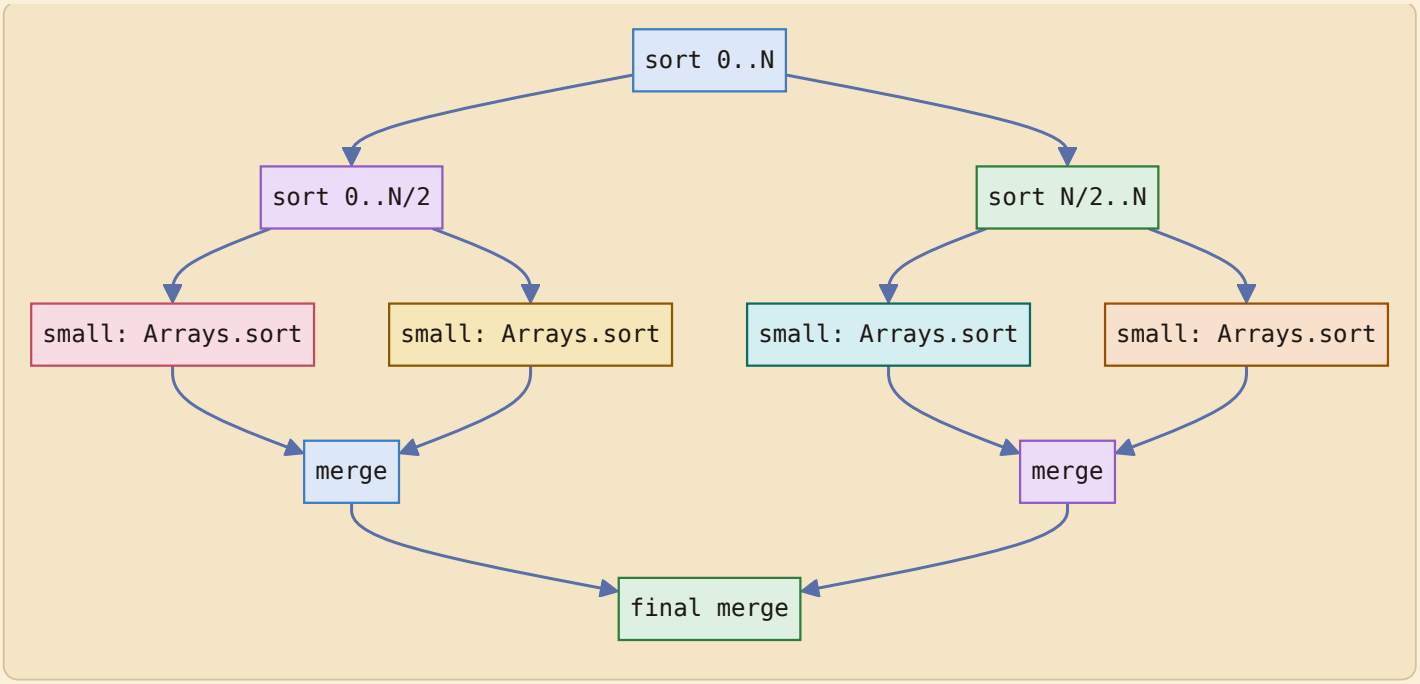
Problem

Sort a large `int[]` using all CPU cores.

Approach

Merge sort is naturally **divide and conquer**: sort the left half and right half *independently* (in parallel), then merge. Java's **Fork/Join framework** (`ForkJoinPool`, `RecursiveAction`/`RecursiveTask`) is built for this:

1. If the range is small (≤ 8,192 elements) → sort it sequentially (`Arrays.sort`); splitting further costs more than it saves.
2. Otherwise split at `mid = (lo + hi) >>> 1` and `invokeAll(left, right)` — forks both halves and waits for both.
3. Merge the two sorted halves using a **shared scratch buffer**; each task only uses its own `[lo, hi)` slice, so there's no sharing between concurrent tasks.
4. **Work stealing:** each pool thread has its own deque of tasks; idle threads steal tasks from the other end of busy threads' deques, keeping all cores busy.



sort 0..N
sort 0..N/2
sort N/2..N
small: Arrays.sort
small: Arrays.sort
small: Arrays.sort
small: Arrays.sort
merge
merge
final merge

Java solution

```java
// File: code/lld/ch13/mergesort/Main.java
package lld.ch13.mergesort;

import java.util.Arrays;
import java.util.Random;
import java.util.concurrent.ForkJoinPool;
import java.util.concurrent.RecursiveAction;

/** Multi-threaded merge sort with the Fork/Join framework (divide and conquer + work stealing). */
public class Main {

    static final class ParallelMergeSort extends RecursiveAction {
        private static final long serialVersionUID = 1L;
        static final int THRESHOLD = 1 << 13;   // below ~8K elements, splitting costs more than it saves
        private final int[] a, buf;             // buf = one shared scratch array; tasks use disjoint ranges
        private final int lo, hi;               // sorts a[lo, hi)

        ParallelMergeSort(int[] a, int[] buf, int lo, int hi) { this.a = a; this.buf = buf; this.lo = lo; this.hi =
hi; }

        @Override protected void compute() {
            if (hi - lo <= THRESHOLD) {
                Arrays.sort(a, lo, hi);                         // sequential base case
                return;
            }
            int mid = (lo + hi) >>> 1;                          // overflow-safe midpoint
            invokeAll(new ParallelMergeSort(a, buf, lo, mid),   // fork both halves, wait for both
                      new ParallelMergeSort(a, buf, mid, hi));
            merge(mid);
        }

        private void merge(int mid) {
            if (a[mid - 1] <= a[mid]) return;                   // already in order: skip
            System.arraycopy(a, lo, buf, lo, hi - lo);
            int i = lo, j = mid, k = lo;
            while (i < mid && j < hi) a[k++] = buf[i] <= buf[j] ? buf[i++] : buf[j++];   // <= keeps it stable
            while (i < mid) a[k++] = buf[i++];
            // right-half leftovers are already in place
        }
    }

    static void parallelSort(int[] a) {
        ForkJoinPool.commonPool().invoke(new ParallelMergeSort(a, new int[a.length], 0, a.length));
    }

    public static void main(String[] args) {
        int[] small = {38, 27, 43, 3, 9, 82, 10, 3};
        parallelSort(small);
        System.out.println("small: " + Arrays.toString(small));

        int n = 4_000_000;
        int[] data = new Random(42).ints(n).toArray();
        int[] expected = data.clone();
        Arrays.sort(expected);

        int[] mine = data.clone();
        parallelSort(mine);
        System.out.println(n + " random ints: matches Arrays.sort = " + Arrays.equals(mine, expected));

        int[] jdk = data.clone();
        Arrays.parallelSort(jdk);                               // the JDK's own parallel sort
        System.out.println("Arrays.parallelSort agrees        = " + Arrays.equals(jdk, expected));
    }
}
```

Output:

```
small: [3, 3, 9, 10, 27, 38, 43, 82]
4000000 random ints: matches Arrays.sort = true
Arrays.parallelSort agrees        = true
```

Why it's correct

- The two subtasks work on **disjoint** ranges of both `a` and `buf` → no data race between them.
- `invokeAll` returns only when both subtasks completed; Fork/Join's `join` establishes happens-before, so the parent's merge sees the children's writes.
- The merge takes from the left run on ties (`<=`), so it's **stable** (equal elements keep their original order; matters for objects, not for ints).
- The early exit `a[mid-1] <= a[mid]` skips merging already-ordered halves.
- The result is compared with `Arrays.sort` on 4 million random ints (seeded, so reproducible).

Pitfalls

- No threshold → millions of tiny tasks; overhead dominates.
- Allocating a new buffer in every merge → heavy GC (garbage collection — the JVM's automatic freeing of unused memory); allocate once.
- Calling `fork()` on both halves and `join()`ing in the wrong order, or doing blocking I/O inside Fork/Join tasks (it's meant for CPU work).
- `(lo + hi) / 2` can overflow for huge arrays; `>>> 1` avoids it.
- Expecting speed-up on tiny arrays or on a single core (Amdahl's law: the part that must run sequentially caps the total speed-up — here the final merge).

Real-world examples

- `Arrays.parallelSort` (Java 8+) splits the array, sorts the pieces in parallel on the common Fork/Join pool and merges them (the demo cross-checks against it).
- Parallel streams (`list.parallelStream()`) run on `ForkJoinPool.commonPool()`.
- Big-data sorts (Hadoop MapReduce's — a model that maps over data in parallel, then combines the results — sort/shuffle, Spark's `sortBy`) apply the same divide-sort-merge idea across machines.

In the interview

30-second answer: "A RecursiveAction splits the range in half until it's below a threshold, sorts small pieces sequentially, then merges using one preallocated buffer. invokeAll runs both halves in parallel on the ForkJoinPool, whose work stealing keeps cores busy. Subtasks touch disjoint ranges, so no locks are needed."

Follow-ups:

- *`RecursiveAction` vs `RecursiveTask`?* `RecursiveTask<V>` returns a value (e.g. parallel sum); `RecursiveAction` returns nothing (in-place sort).
- *Can the merge be parallel too?* Yes — split the merge by binary-searching the median of one run in the other (parallel merge), which is how fully parallel merge sorts scale further.

Self-check

- **Q:** Why is a shared `buf` safe? **A:** Concurrent tasks use non-overlapping index ranges of it.

TL;DR

Split until small, sort sequentially, merge; Fork/Join + work stealing; disjoint ranges = no locks.

13.11 Rate limiter — token bucket (thread-safe)

Problem

Limit how often clients may call an **API** (Application Programming Interface — here, a web service that clients send requests to): allow short **bursts** up to *B* requests, and a sustained rate of *R* requests per second. Must be correct under many concurrent requests, per client (user id / API key — a secret string that identifies the caller / IP address).

Approach

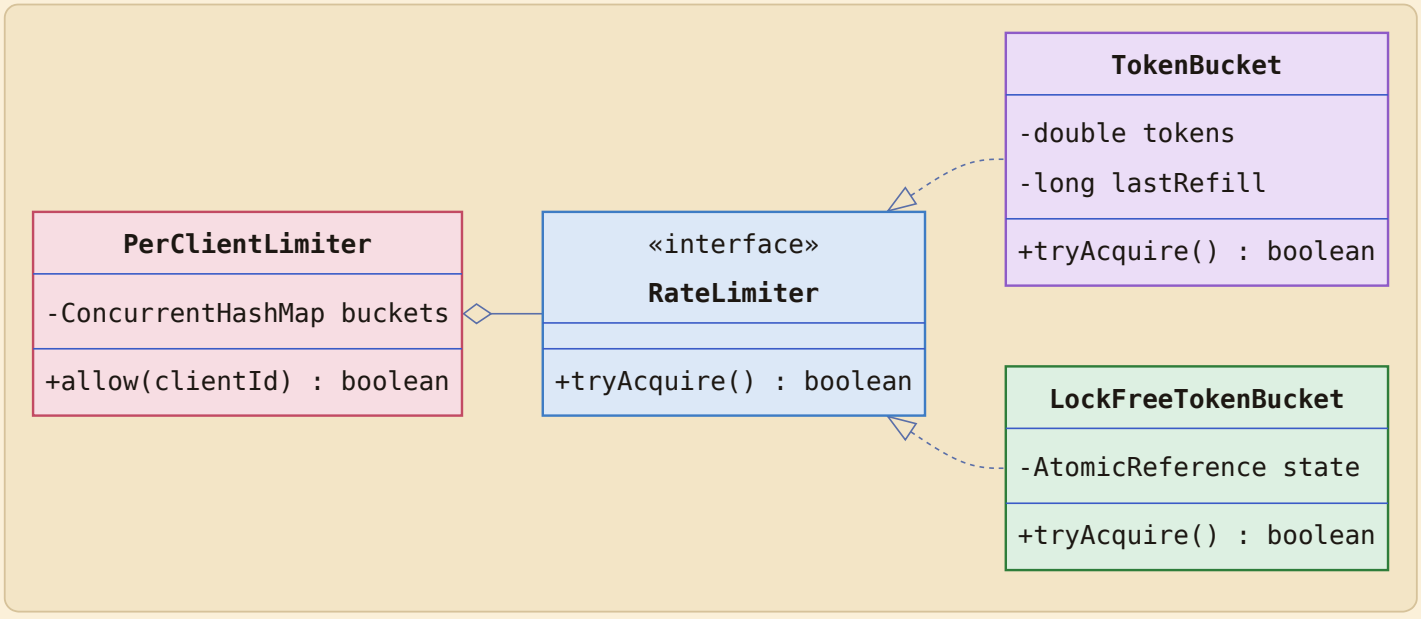
Token bucket (first-time explanation):

1. A bucket holds up to *capacity* tokens (the allowed burst) and starts full.
2. Tokens drip in at *refillRate* per second, never exceeding capacity.
3. Each request takes one token. No token → reject (HTTP 429 "Too Many Requests"; HTTP is the web's request/response protocol — see System Design Fundamentals).
4. Implement refill **lazily**: store `tokens` and `lastRefill`; on each request add `elapsed × rate` tokens. No background thread needed.

Thread safety: "refill + check + take" must be **one atomic step** — otherwise two threads can both see 1 token and both take it.

- Version 1: `synchronized tryAcquire()` — simple and correct.
- Version 2: **lock-free** — put `(tokens, lastRefill)` into one immutable `State` record inside an `AtomicReference` and CAS the whole state (the "several fields → one immutable object → one CAS" trick from 12.15).
- Per client: `ConcurrentHashMap.computeIfAbsent(clientId, …)` creates exactly one bucket per client.
- Time comes from an injected `Ticker` so the demo is deterministic.

Algorithm	Bursts	Memory	Notes
Token bucket	Allows up to capacity	2 numbers	Most common for APIs
Leaky bucket	Smooths to constant output rate	Queue	Good for shaping traffic (evening out bursts)
Fixed window counter	Allows 2× burst at window edges	1 counter	Simplest
Sliding window log	Exact	One timestamp per request	Memory-heavy
Sliding window counter	Approximate, smooth	2 counters	Good compromise



Java solution

```java
// File: code/lld/ch13/ratelimiter/Main.java
package lld.ch13.ratelimiter;

import java.util.ArrayList;
import java.util.List;
import java.util.concurrent.ConcurrentHashMap;
import java.util.concurrent.CountDownLatch;
import java.util.concurrent.TimeUnit;
import java.util.concurrent.atomic.AtomicInteger;
import java.util.concurrent.atomic.AtomicLong;
import java.util.concurrent.atomic.AtomicReference;
import java.util.function.Supplier;

/** Thread-safe token-bucket rate limiter: a lock-based version, a lock-free version, and per-user limits. */
public class Main {

    @FunctionalInterface interface Ticker { long nanos(); }

    static final class FakeTicker implements Ticker {
        private final AtomicLong now = new AtomicLong();

            clock.advance(1, TimeUnit.SECONDS);
            System.out.println("  t=1.0s  3 requests : " + burst(rl, 3));
            clock.advance(250, TimeUnit.MILLISECONDS);
            System.out.println("  t=1.25s 1 request  : " + burst(rl, 1) + "  (only 0.5 token so far)");
            clock.advance(250, TimeUnit.MILLISECONDS);
            System.out.println("  t=1.5s  1 request  : " + burst(rl, 1));
            clock.advance(1, TimeUnit.HOURS);
            System.out.println("  after 1 idle hour  : allowed " + concurrentBurst(rl, 100) + " of 100 concurrent
requests (burst capped at 5)");
        }

        FakeTicker clock = new FakeTicker();
        PerClientLimiter api = new PerClientLimiter(() -> new TokenBucket(3, 1, clock));
        StringBuilder alice = new StringBuilder(), bob = new StringBuilder();
        for (int i = 0; i < 4; i++) { alice.append(api.allow("alice") ? 'Y' : 'n'); }
        for (int i = 0; i < 2; i++) { bob.append(api.allow("bob") ? 'Y' : 'n'); }
        System.out.println("per-client (3 burst): alice " + alice + ", bob " + bob + "  (alice's spam doesn't hurt
```

```
bob)");
    }
}
```

Output:

```
[synchronized] capacity 5, refill 2/s
  t=0.0s  7 requests : YYYYYnn
  t=1.0s  3 requests : YYn
  t=1.25s 1 request  : n  (only 0.5 token so far)
  t=1.5s  1 request  : Y
  after 1 idle hour  : allowed 5 of 100 concurrent requests (burst capped at 5)
[lock-free] capacity 5, refill 2/s
  t=0.0s  7 requests : YYYYYnn
  t=1.0s  3 requests : YYn
  t=1.25s 1 request  : n  (only 0.5 token so far)
  t=1.5s  1 request  : Y
  after 1 idle hour  : allowed 5 of 100 concurrent requests (burst capped at 5)
per-client (3 burst): alice YYYn, bob YY  (alice's spam doesn't hurt bob)
```

Why it's correct

- **Atomic decision:** in `TokenBucket`, refill, check and decrement happen inside one `synchronized` method. In `LockFreeTokenBucket`, the new state is computed from one snapshot and installed with `compareAndSet`; if another thread changed the state first, the CAS fails and we recompute — so each token is granted at most once.
- **Burst cap:** tokens are clamped to `capacity`, so after an idle hour only 5 of 100 simultaneous requests pass (as the output shows for both versions).
- **Rate:** at 2 tokens/s, after 1 s exactly 2 new tokens exist; at +0.25 s only 0.5 token → rejected; at +0.5 s → 1 token → allowed.
- **Per-client isolation:** `computeIfAbsent` is atomic, so two concurrent first requests from the same client can't create two buckets (which would double their limit).
- The lock-free version clamps `now` with `Math.max(..., lastRefill)` so a thread that read the clock slightly earlier can't move time backwards.

Pitfalls

- Separate `refill()` and `take()` calls → race; two threads spend the same token.
- A background thread per bucket to add tokens → thousands of threads/timers; lazy refill needs none.
- Using `currentTimeMillis()` (wall clock can jump) instead of `nanoTime()`.
- An unbounded map of buckets → memory leak for one-off clients; evict idle buckets (e.g. with the TTL cache from 13.6).
- In a multi-server deployment an in-memory limiter only limits per server. For a global limit, keep the bucket in **Redis** (an in-memory data store shared by all servers) and update it atomically with a Lua script (a small script that Redis runs as one uninterruptible step) (or use a sliding-window counter in Redis).

Real-world examples

- **Stripe** has described using token buckets (backed by Redis) for its API rate limits.
- **Amazon API Gateway** (AWS's managed front door for APIs) **throttling** (deliberately rejecting or delaying excess requests) is configured with a *rate* and a *burst* — token-bucket parameters.
- **Guava** `RateLimiter`, **Bucket4j** (token bucket for Java, with Redis/JCache — the standard Java caching API — back-ends), and **Resilience4j** `RateLimiter` are production Java libraries; NGINX's (a popular web server and reverse proxy) `limit_req` uses a leaky-bucket approach.

In the interview

30-second answer: "Token bucket: capacity for bursts, refill rate for the average. I refill lazily from elapsed nanoTime on each request, and make refill-check-take one atomic step — synchronized, or lock-free by CASing an immutable state record. A ConcurrentHashMap gives one bucket per client via computeIfAbsent; across servers I'd move the bucket into Redis with a Lua script."

Follow-ups (with answers):

- *How do you tell the client when to retry?* Compute `(1 − tokens) / rate` seconds and return it in a `Retry-After` header (a response header that tells the client how many seconds to wait).
- *Different limits per plan (free vs paid)?* The factory creates buckets with capacity/rate from the client's plan (Strategy pattern).
- *Blocking instead of rejecting?* Compute the wait time and sleep/park until a token will exist (Guava's `acquire()` does this).

Self-check

- **Q:** Capacity 5, rate 2/s, bucket empty at t=0. How many requests pass at t=3s? **A:** min(5, 3 × 2) = 5.
- **Q:** Why one immutable `State` in the lock-free version? **A:** `tokens` and `lastRefill` must change together; one CAS on one reference updates both atomically.

TL;DR

Bucket of tokens: capacity = burst, rate = average. Lazy refill; refill+take atomic (lock or CAS on immutable state); one bucket per client; Redis for multi-server.

13.12 Chapter summary

Problem	Key primitive	The one invariant to state in the interview
FooBar	2 semaphores	Exactly one permit exists across both
Zero Even Odd	3 semaphores	Zero dispatches; one permit circulates
FizzBuzz	monitor + `notifyAll`	Predicates partition 1..n
H2O	2 semaphores + barrier	≤2 H and ≤1 O per round; slot freed after release
Dining Philosophers	ordered locks / n−1 semaphore	No circular wait
TTL cache	CHM + `compute` + conditional remove	Never return or keep expired data; load once per key
Striped map	lock array	Each bucket belongs to exactly one stripe
Blocking queue	lock + 2 conditions	0 ≤ count ≤ capacity; wait in loops
Bloom filter	atomic OR	Bits only go 0 → 1; no false negatives
Merge sort	Fork/Join	Subtasks touch disjoint ranges
Rate limiter	lock or CAS on immutable state	Refill + take is one atomic step

13.13 Chapter self-check

1. **Q:** In FooBar, why doesn't it matter which thread starts first? **A:** The one without a permit blocks until the other releases it.
2. **Q:** In FizzBuzz, what bug appears with `notify()`? **A:** The wrong thread may be woken and go back to sleep; the right one never wakes → hang.
3. **Q:** In H2O, why release the slot after printing? **A:** So the next molecule cannot form (and print) until this one has fully left.
4. **Q:** Two ways to prevent Dining Philosophers deadlock? **A:** Always take the lower-numbered fork first; or allow at most n−1 philosophers to try at once.
5. **Q:** Why does the TTL cache use `remove(key, entry)`? **A:** To avoid deleting a fresh value written concurrently.
6. **Q:** Why must the striped map's stripe depend only on the hash? **A:** So a key's lock doesn't change when the table resizes.
7. **Q:** When is `signal()` safe instead of `signalAll()`? **A:** When each condition queue holds only threads waiting for the same thing and one state change enables exactly one waiter.
8. **Q:** What would a non-atomic OR do to a Bloom filter? **A:** Lose bits → false negatives.
9. **Q:** Why a threshold in parallel merge sort? **A:** Small tasks cost more to schedule than to sort.

10. **Q:** How do you make a token bucket global across 10 servers? **A:** Store it in Redis and update it atomically with a Lua script.

13.14 Chapter TL;DR

- **Ordering puzzles** (FooBar, ZeroEvenOdd, H2O): semaphores as batons, barriers for groups; keep "exactly one permit" style invariants.
- **Predicate waiting** (FizzBuzz, blocking queue): lock + `while (!condition) wait/await` + `notifyAll` or targeted `signal`.
- **Multi-lock problems** (philosophers): break circular wait with ordering or limiting.
- **Thread-safe data structures** (cache, map, queue, Bloom filter, rate limiter): immutable entries, atomic compound operations, striping, CAS on immutable state, and injected clocks for testable time.
- **Parallel algorithms** (merge sort): Fork/Join with thresholds and disjoint data.

Chapter 14 — Case Studies: Everyday Objects

> **Where this fits.** Chapters 1–13 gave you the tools: OOP (object-oriented programming: building software from objects that bundle data with the methods that act on it), UML (Unified Modeling Language, the standard way to draw classes and their links), SOLID (five principles for designing classes), clean code, the 23 GoF patterns (the "Gang of Four" design patterns, named after the four authors of the 1994 book *Design Patterns*) and concurrency (several pieces of work running at the same time). From this chapter to Chapter 21 you use those tools on real interview questions. This chapter starts with **physical machines you have used yourself**: a parking lot, a vending machine, a coffee machine, an ATM, an elevator, a traffic light and a parcel locker. You already know how they behave, so all your attention can go to the design.

What you will learn in this chapter

#	Problem	The one idea the interviewer is really testing	Main patterns
14.1	Parking Lot	**Resource allocation** under concurrency: two cars must never get the same spot	Strategy (spot finding, pricing), Factory, Observer (display boards)
14.2	Vending Machine	A **state machine**: the order in which actions are allowed	State
14.3	Coffee Vending Machine	**Atomic, all-or-nothing** deduction from a shared inventory; recipes as data	Observer (low-stock alerts), data-driven recipes, sealed result types
14.4	ATM	**Security + money correctness**: authenticate, never lose money, never double-spend	State, Chain of Responsibility (cash dispenser), Command (transactions)
14.5	Elevator System	**Scheduling** (SCAN/LOOK: sweep orders for visiting stops, see 14.5) and **dispatching** many cars	Strategy (dispatch), State-like modes
14.6	Traffic Signal Control	**Timed state machine** with a hard safety invariant and emergency override	State, Strategy (timing), Observer (safety monitor)
14.7	Shipping Locker System	**Best-fit allocation + deadlines + a secret**: reserve a door atomically, expire holds and uncollected parcels, single-use hashed pickup codes	Strategy (door choice), Observer (SMS), enum state machines, sealed results

> **Key terms — the pattern names in this table.** These are design patterns (proven, named shapes for arranging classes) from the earlier chapters. **Strategy**: a swappable rule (how to price, which car to send) hidden behind an interface. **Factory**: one place that creates objects, so callers need not know how they are built. **Observer**: an object keeps a list of listeners and tells each of them when something changes. **State**: each situation a machine can be in is its own class. **Chain of Responsibility**: a request is passed along a line of handlers, each doing what it can. **Command**: an action wrapped in an object, so it can be run, logged or queued. **Sealed result types**: a Java type whose possible variants form a fixed, known list (for example "served" or "refused"), so the compiler can check that callers handle each one.

What these problems test

These seven questions look different, but interviewers use them to check three skills:

1. **State machines.** A machine behaves differently depending on what has happened so far. A vending machine must not dispense before it is paid. An ATM must not allow a withdrawal before the PIN is checked. A traffic light must never go from green straight to green on the crossing road. A **state machine** is a model with a fixed set of situations (states) and rules for moving between them (transitions). The **State pattern** (Chapter 11) turns each state into its own class, so every button has a defined answer in every state.
2. **Resource allocation.** A limited set of things (parking spots, notes in a cassette, millilitres of milk, elevator cars, locker doors) must be handed out correctly: never twice, never below zero, and fairly.
3. **Concurrency.** Many actors act at the same moment: several entrance gates, two ATMs on one joint account, ten customers tapping "Latte" at once, a timer thread and an emergency thread (a **thread** is one independent line

of execution inside a program; many threads can run at once and touch the same objects). The design must stay correct when calls overlap (Chapters 12–13).

> **Key insight.** In every one of these problems, the hardest part is small: one method that picks a spot, one method that makes change, one method that deducts ingredients, one method that picks the next elevator stop. Find that method early, name it out loud, and spend your time there.

How each case study is laid out

Every problem follows the same template, which is also a good order to speak in during an interview:

Problem & clarifying questions → Requirements → Use cases → Core entities → Class diagram → Key flows → Design decisions & patterns → Java implementation → Concurrency & edge cases → Extensions & follow-ups → In the interview → Self-check → TL;DR.

How to read the course diagrams

The course draws its class diagrams in stages. Classes added in earlier stages are drawn in grey; the new ones are in colour. The legend below explains every arrow used in those diagrams (it is the same for all four course case studies in this chapter).

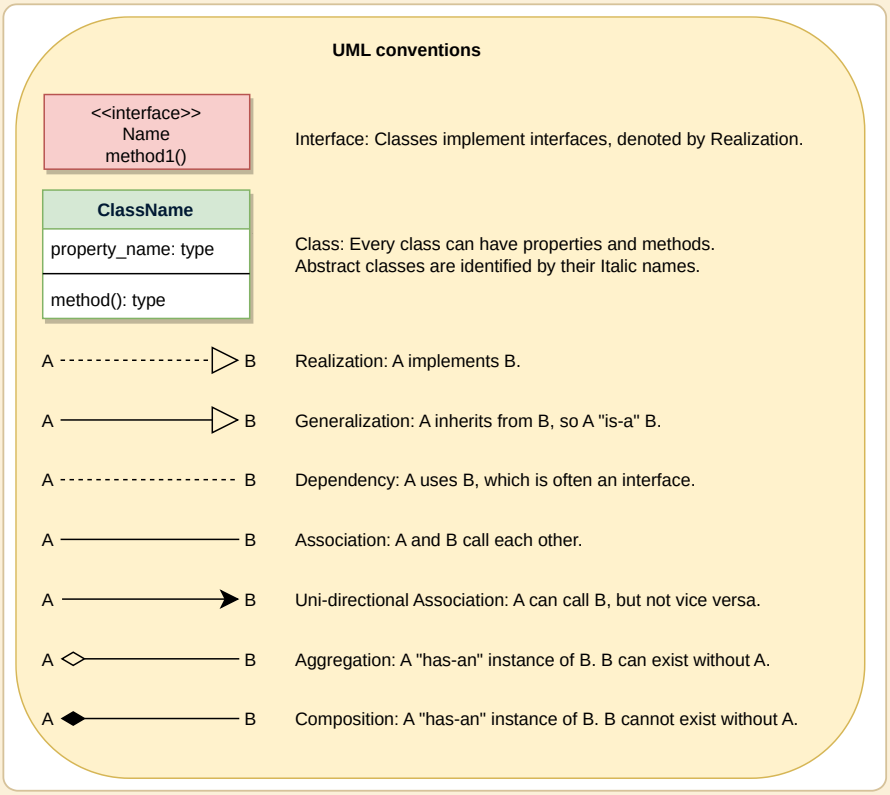

Figure — Legend for the course class diagrams: interface, class, realization, association, inheritance, composition and the other arrow kinds (course diagram)

Read the figure above once: a **hollow triangle** means inheritance ("is a"), a **dashed line with a hollow triangle** means "implements an interface" (an **interface** is a list of methods that a class promises to provide, without saying how), a **filled diamond** means composition (the part dies with the whole), and a **plain arrow** means association (one object refers to another without owning it). Chapter 3 covers these relationships in depth.

How to run every example in this chapter

```
cd chapters/14-case-everyday-objects/code
javac --release 21 -d /tmp/lld_14 $(find . -name '*.java')
java -cp /tmp/lld_14 lld.ch14.parkinglot.Main      # or vendingmachine, coffeemachine, atm, elevator, trafficsignal, locker
```

Here `javac` is the Java compiler (it turns `.java` source files into `.class` files of bytecode), `--release 21` targets Java 21, `-d` says where to put the compiled classes, and `java -cp` runs a class using the given

classpath (the folder where the JVM, the Java Virtual Machine that runs bytecode, looks for classes).

All seven `Main` classes compile with Java 21 (standard library only) and run. The output printed under each implementation is the real output of that program.

> **Code-style note.** To keep each design readable in one place, a file sometimes holds several small package-private types (types declared without `public`, visible only inside their own package) (for example `Vehicles.java` holds `SpotType`, `VehicleType` and `Vehicle`). That is legal Java, and the code compiles with no warnings under `-Xlint:all` (the compiler switch that turns on every optional warning, or *lint* check) except the `auxiliaryclass` lint, which exists precisely to flag this style (a type used from outside the file it is declared in). In production you would usually give each top-level type its own file.

14.1 Design a Parking Lot

Figure — A large multi-level car park, the kind of building this design models (course diagram)

A **parking lot** (car park) is an area set aside for parking vehicles. Malls, stadiums, airports and office towers have large multi-floor lots with gates, ticket machines and boards showing free spaces. The photo above is the kind of lot we are modelling: many floors, many spot sizes, and several ways in and out.

This is the most-asked LLD question (low-level design: designing the classes, their responsibilities and how they talk to each other) of all. It looks easy, which is exactly why it is useful to an interviewer: they can watch how you **scope** it, how you **model the fit rule** (which vehicle may use which spot), and whether you notice that **two gates can hand out the same spot** at the same moment.

Problem & clarifying questions

Ask these before drawing anything. The answers in the right column are the ones this design assumes.

Question	Assumed answer
One lot or a chain of lots?	One lot, many floors.
How many entrances and exits?	Several of each, all working at the same time.
Which vehicle types?	Car, truck, van, motorcycle, electric car.
Which spot types?	Compact, large, handicapped (accessible), motorcycle, electric.
How do customers pay?	Cash or card, at the exit panel, to an attendant, or earlier at an info portal on each floor.
How is the fee computed?	Per hour, with tiers: $4 for the first hour, $3.50 for hours 2 and 3, $2.50 for each hour after. A started hour counts as a full hour.
Do EVs charge?	Yes: electric spots have a panel where the driver pays for charging.
Reservations, monthly passes, number-plate recognition?	Out of scope (mentioned as extensions).
What happens when the lot is full?	The entrance panel and the ground-floor board show a "full" message; no more vehicles are admitted.

Requirements

Functional

1. The lot has **multiple floors**.
2. It has **multiple entry and exit points**.
3. A customer **collects a ticket at the entrance** and **pays at the exit**.
4. Payment at the **automated exit panel** or to a **parking attendant**.
5. Payment by **cash or credit card**.
6. Payment is also possible at a **customer info portal on each floor**; a ticket paid there is not charged again at the exit.
7. The lot **never admits more vehicles than its capacity**. When full, a message shows on the entrance panel and on the ground-floor display board.
8. Each floor has many spots of several **types**: compact, large, handicapped, motorcycle (and electric, below).
9. Some spots are for **electric cars**; each has an **electric panel** where the customer can pay for and charge the vehicle.
10. Many **vehicle types**: car, truck, van, motorcycle (and electric car).
11. Each floor has a **display board** showing free spots per spot type.
12. A **per-hour fee model** with tiers ($4 / $3.50 / $3.50 / $2.50 …).

Non-functional

- **Correctness under concurrency:** two entrance gates working at the same instant must never be given the same spot, and a ticket must never be paid twice.
- **Low latency at the gate:** finding a spot must not scan thousands of spots; taking one from a sorted set of free spots is O(log n). (**Latency** is how long one request takes from start to finish; see System Design Fundamentals. **O(log n)** is Big-O notation for cost: the work grows with the logarithm of the number of spots n, so even 10,000 spots need only about 14 steps.)
- **Extensibility:** a new pricing rule, a new spot-finding rule or a new vehicle type should be a small, local change.
- **Testability** (how easily automated tests can check the code)**:** time must be injectable (passed in from outside rather than read inside the code, here as a fake clock), so fee tests do not wait for hours.

Use cases

Actors (an actor is anyone or anything outside the system that uses it):

- **Admin** — adds, removes and edits floors, spots, entrance/exit panels; adds and removes attendants; sets the hourly rate.
- **Customer** — takes a ticket, pays, leaves.
- **Parking attendant** — can do everything a customer can, on the customer's behalf, and can accept cash.
- **System** — shows messages on panels and boards, assigns a vehicle to a spot and frees it again.

Top use cases: add/remove/edit a floor (each floor with its own display board); add/remove/edit a spot; add/remove an attendant; **take ticket**; **scan ticket** (to find the total charge); **credit-card payment**; **cash payment**; add/modify the parking rate.

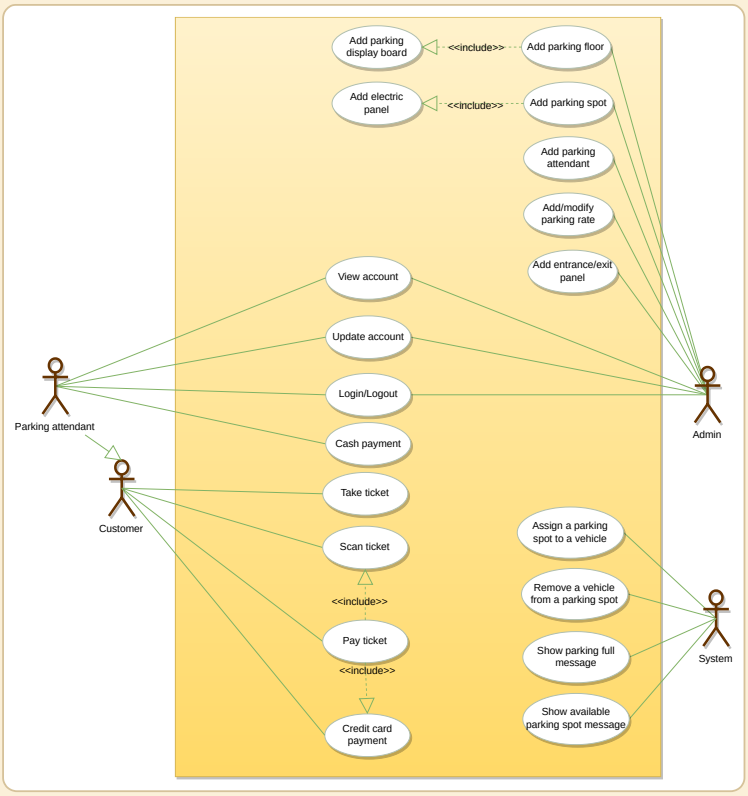

Figure — Use case diagram of the parking lot: Admin, Customer, Parking attendant and System, with their use cases (course diagram)

In the figure above, notice that the attendant's use cases overlap the customer's: the attendant is a customer "proxy" who can also take cash. The System actor is what assigns spots and updates the boards.

Core entities

Class	Responsibility
`VehicleType` (enum)	The kinds of vehicle and, for each, the spot types it fits in, **best fit first**.
`SpotType` (enum)	The kinds of spot: motorcycle, compact, large, handicapped, electric.
`Vehicle` (record)	Plate, type, accessibility permit. Knows its preferred spot types.
`ParkingSpot`	One physical spot: id, floor, type, and who occupies it (atomic).
`ChargingPanel`	The pay-and-charge panel owned by an electric spot.
`SpotFactory`	Builds spots; the only place that knows an electric spot needs a panel.
`ParkingFloor`	Holds the **free** spots per type in a thread-safe sorted set; notifies boards.
`DisplayBoard`	Shows free spots per type on one floor (an observer).
`SpotAllocationStrategy`	*How* to choose a spot (nearest floor first, least busy floor first, …).
`PricingStrategy`	*How much* a stay costs (hourly tiers, flat rate, weekend rate, …).
`Ticket`	Proof of entry: vehicle, the actual spot, entry time, status (ACTIVE → PAID → EXITED).
`PaymentMethod`	Cash or card.
`ParkingLot`	Ties it together: admit, price, pay, exit.
`EntrancePanel`, `ExitPanel`, `CustomerInfoPortal`	The devices customers touch. They hold **no rules**; they call the lot.

In the table, an **enum** is a Java type with a fixed list of named constants (such as `SpotType.COMPACT`), and a **record** is a short Java class that only carries a few values and cannot be changed after it is created. **Thread-safe** means an object stays correct even when several threads use it at the same moment.

The course also models **`Account`** with **`Admin`** and **`ParkingAttendant`** subclasses (both sign in). They carry no parking logic, so they are omitted from the code below; the attendant simply uses the same `pay` method as an exit panel.

Class diagram

The course grows the design in five steps. Every step adds a handful of classes and leaves you with a feature that runs. Use the same order in an interview: if the clock stops you early, what you have drawn already works, instead of being an unfinished picture.

Stage	What it adds	What works after it
1	Vehicle and spot types	The system can answer "may this vehicle use this spot?"
2	Floors and display boards	A floor can hand out a free spot and report counts
3	Ticket, rate card, payment	A stay can be turned into a price and settled
4	The `ParkingLot`	A full visit works: enter, park, pay, leave
5	Entrance/exit panels, info portal, electric panel	Drivers use the flow through physical devices

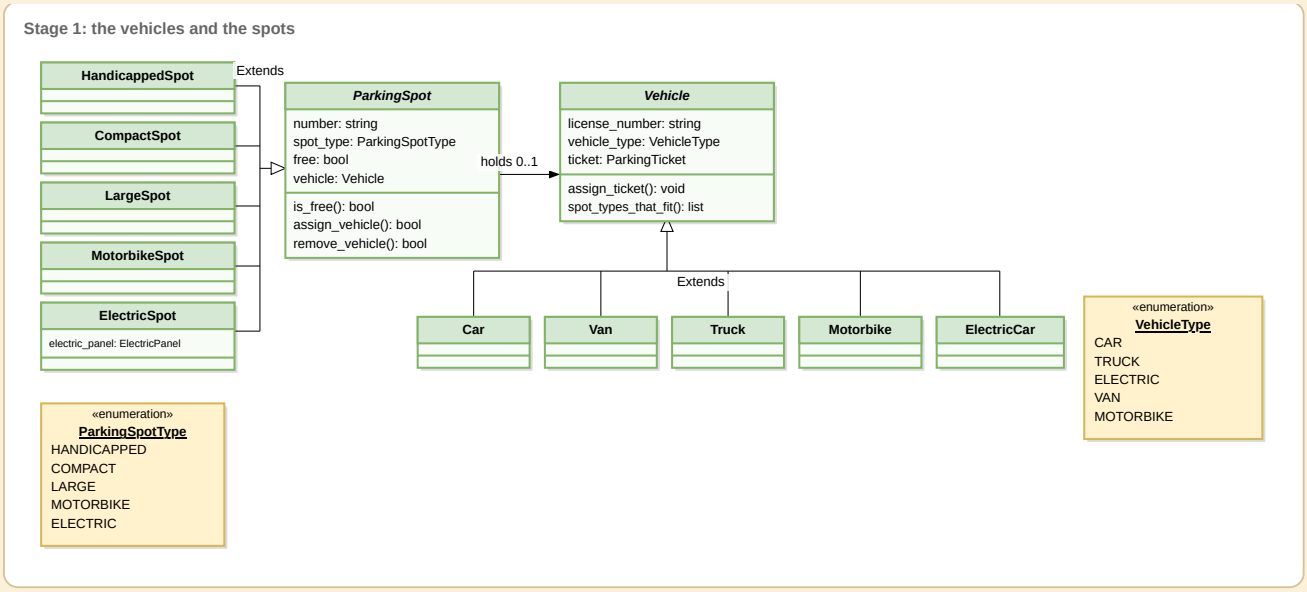

Figure — Stage 1: the vehicle and spot hierarchies, and the "holds 0..1" link from a spot to a vehicle (course diagram)

Stage 1 — vehicles and spots. Requirements 8 and 10 produce two small families of types and one link: a spot holds **at most one** vehicle (`0..1`). The most important rule of the whole design — *which spot types can this vehicle use?* — lives on the **vehicle** side. Because of that, introducing another kind of vehicle is a change to the vehicle types only; the lot code stays untouched. The fit rules: a motorcycle uses a motorcycle spot, trucks and vans use only large spots, and an electric car tries an electric spot first, then compact, then large.

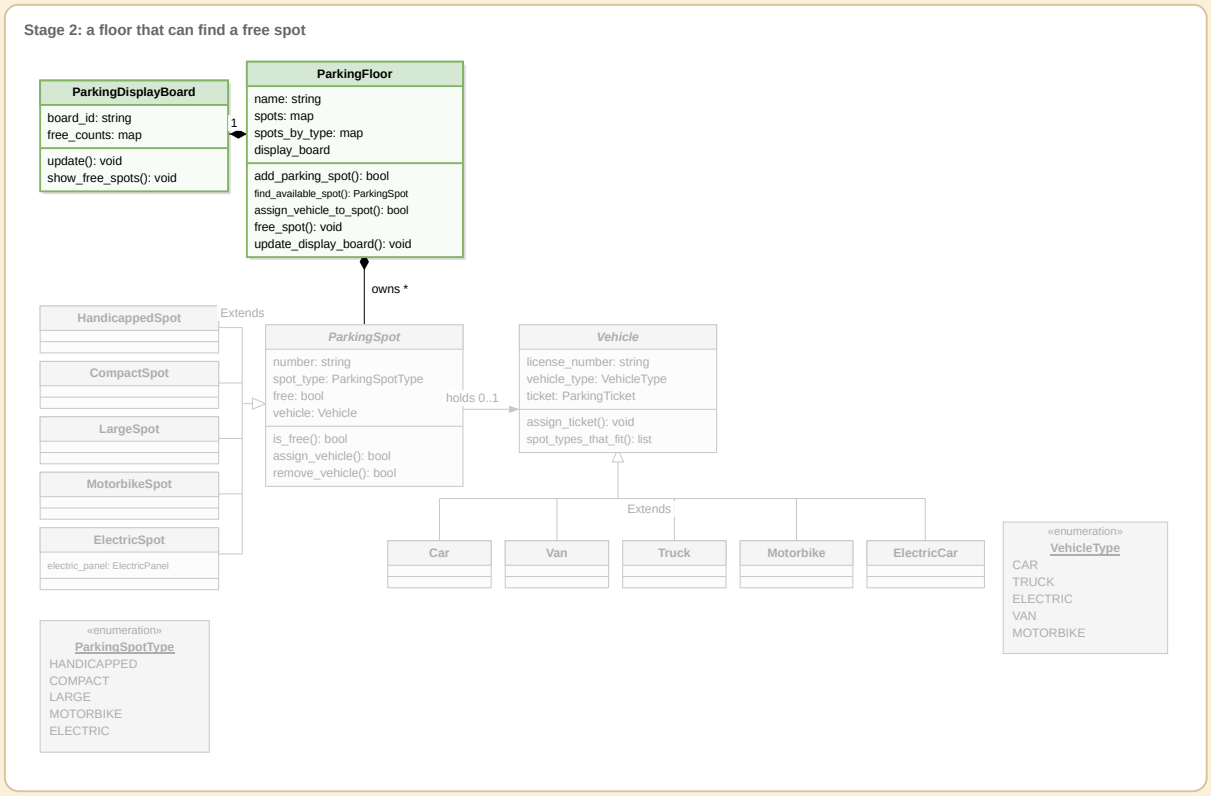

Figure — Stage 2: a floor owns its spots and its display board (composition) (course diagram)

Stage 2 — a floor that can find a free spot. Requirements 1, 8 and 11. Both new links are **composition** (filled diamond): deleting a floor deletes its spots and its board. The board stores **how many** spots of each type are free, not a pointer to "a sample free spot" of each type; such a pointer goes stale the moment that spot is taken and must be hunted for again. The course's floor keeps a map of all its spots plus an index by spot type (our code keeps a single map from spot type to its free spots). The rejected alternative is one separate

collection per type: every method would then need a five-way `if`, and adding a sixth type would touch all of them.

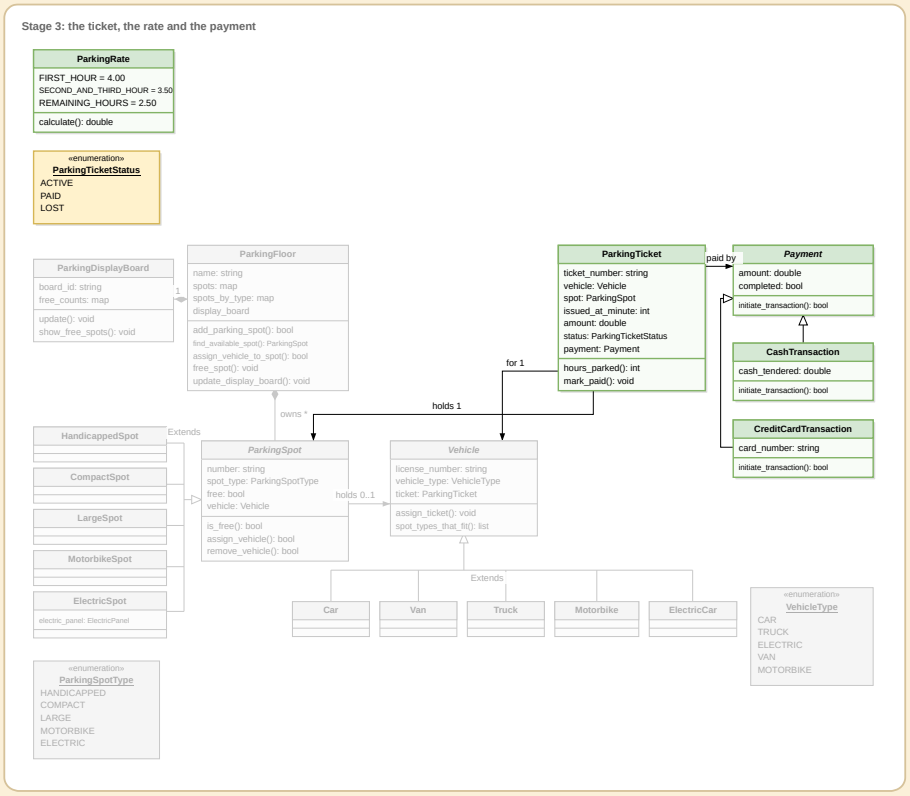

Figure — Stage 3: ticket, parking rate and the abstract payment with cash and card subclasses (course diagram)

`Stage 3 — ticket, rate, payment.` Requirements 3, 5 and 12. The key decision: **the ticket stores a reference to the exact spot**, not just "one more spot is taken". At the exit, that reference is how the system knows which spot to free and where the car was. A ticket merely points at the vehicle and the spot (it does not own them), so both links are plain associations. `Payment` is an abstract class (it cannot be created directly) with cash and card subclasses; this inheritance is justified because either subclass can stand in wherever "a payment" is expected (the Liskov Substitution Principle from Chapter 4).

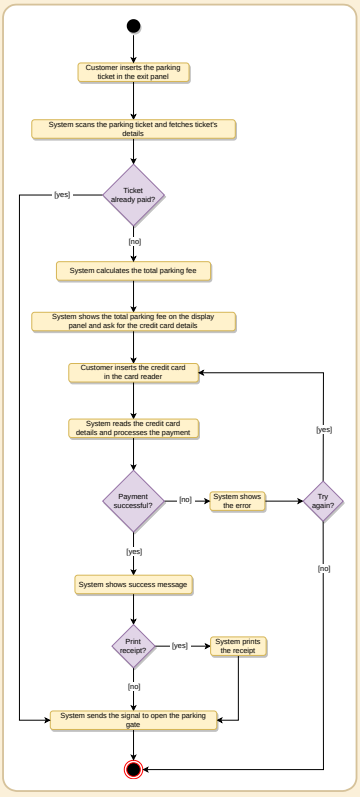

Figure — Activity diagram: the customer inserts the ticket at the exit, the system computes the fee, the customer pays by card or cash, and the barrier opens (course diagram)

The activity diagram above is the exit flow; the ticket, rate and payment classes between them handle each of its steps.

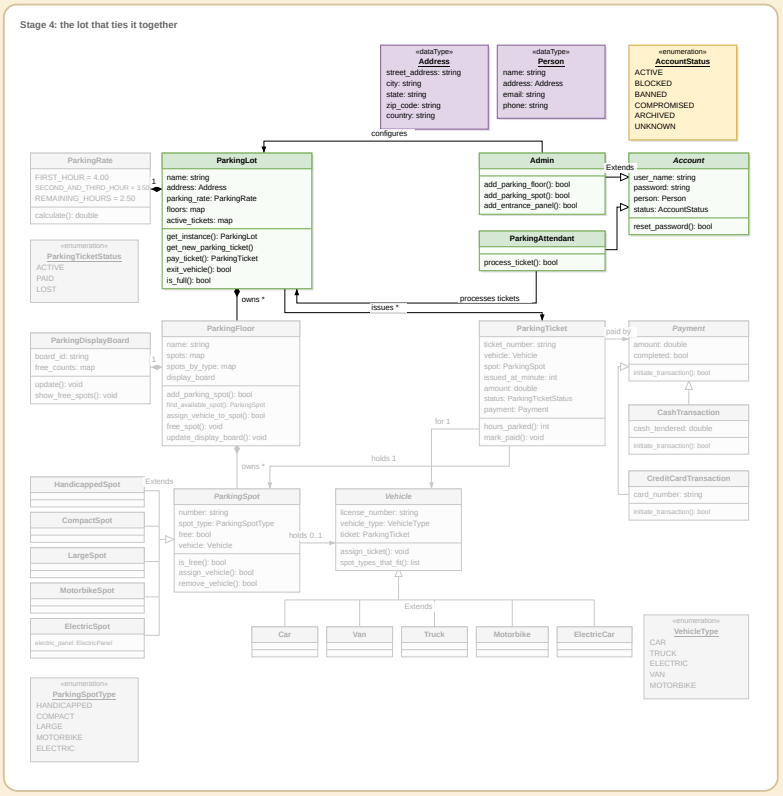

Figure — Stage 4: the parking lot owns floors and the rate; Admin and ParkingAttendant accounts connect to it (course diagram)

Stage 4 — the lot. Requirement 7 and the actor list. The lot has a **name** and an **address** (so one lot can be told apart from another) and owns its floors and its rate card (filled diamonds). The two account types, `Admin` and `ParkingAttendant`, are linked with plain arrows: they work *on* the lot (setting it up, handling tickets) without owning any part of it. The course makes the lot a **Singleton** (only one instance may exist) and serialises spot assignment (**one caller at a time**), since two entrances assigning in parallel could pick the same spot.

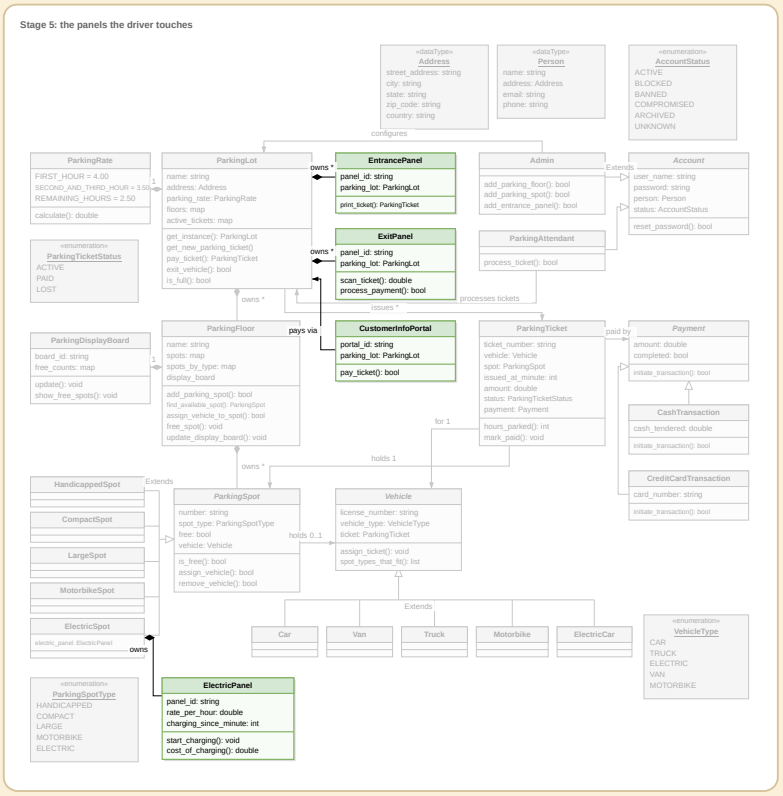

Figure — Stage 5: entrance and exit panels (owned by the lot), the customer info portal (refers to the lot) and the electric panel (owned by an electric spot) (course diagram)

Stage 5 — the panels. Requirements 2, 4, 6 and 9. The panels are thin: they forward every request to the lot, so all business rules sit in a single class. The entrance panel prints tickets, the exit panel scans a ticket and takes payment, the info portal lets a driver settle early (marking the ticket paid), and the electric panel bills for charging. The lot owns its entrance and exit panels (composition). It keeps no list of info portals, so a portal just holds a reference to the lot (association). The electric panel is owned by its electric spot, the only composition hanging off a spot.

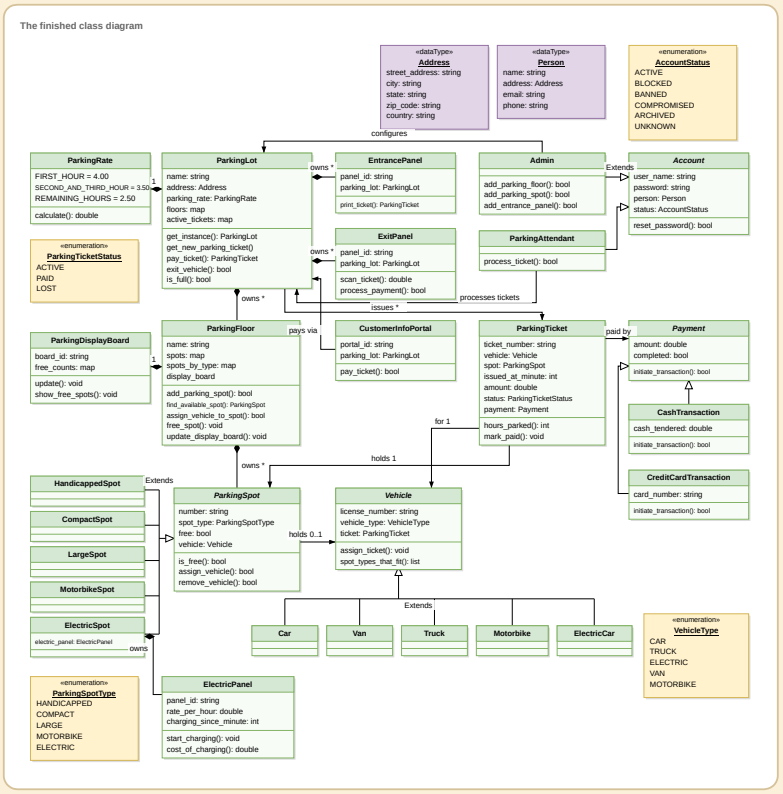

Figure — The finished class diagram of the parking lot (course diagram)

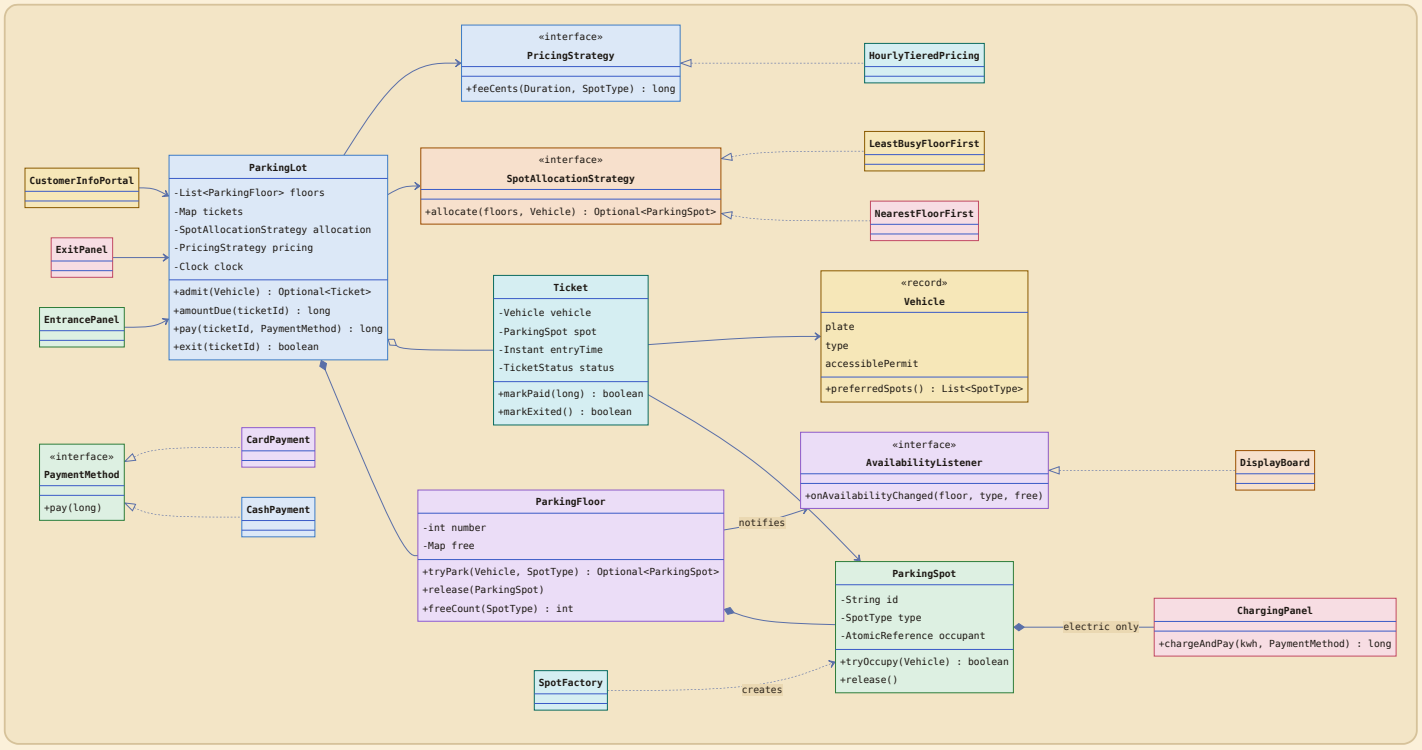
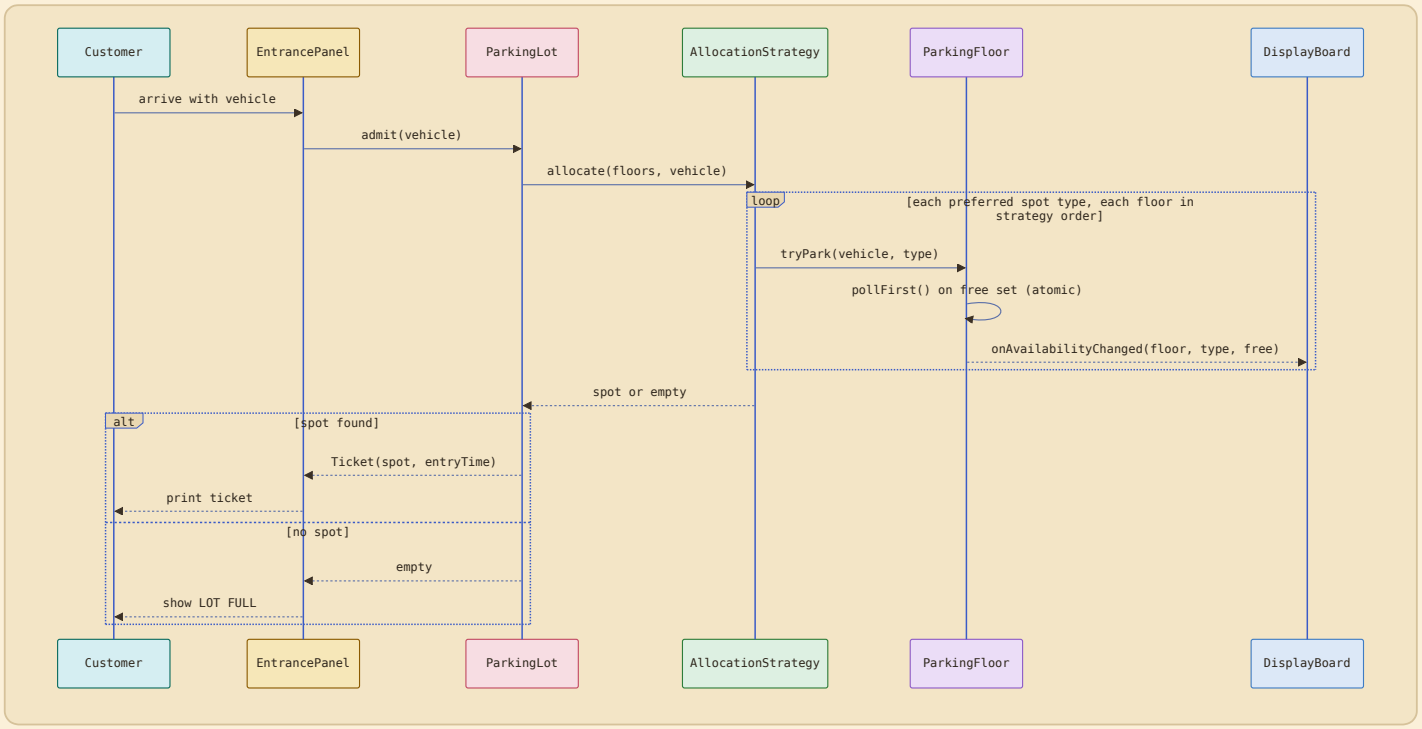
The finished diagram above is simply all five stages in colour; nothing new appears in it. Here is the class diagram of **the Java code in this chapter**. It keeps the same shape but makes three changes that interviewers usually push for: spot types are an enum instead of five empty subclasses, pricing and spot-finding are Strategies, and the display board is an Observer.



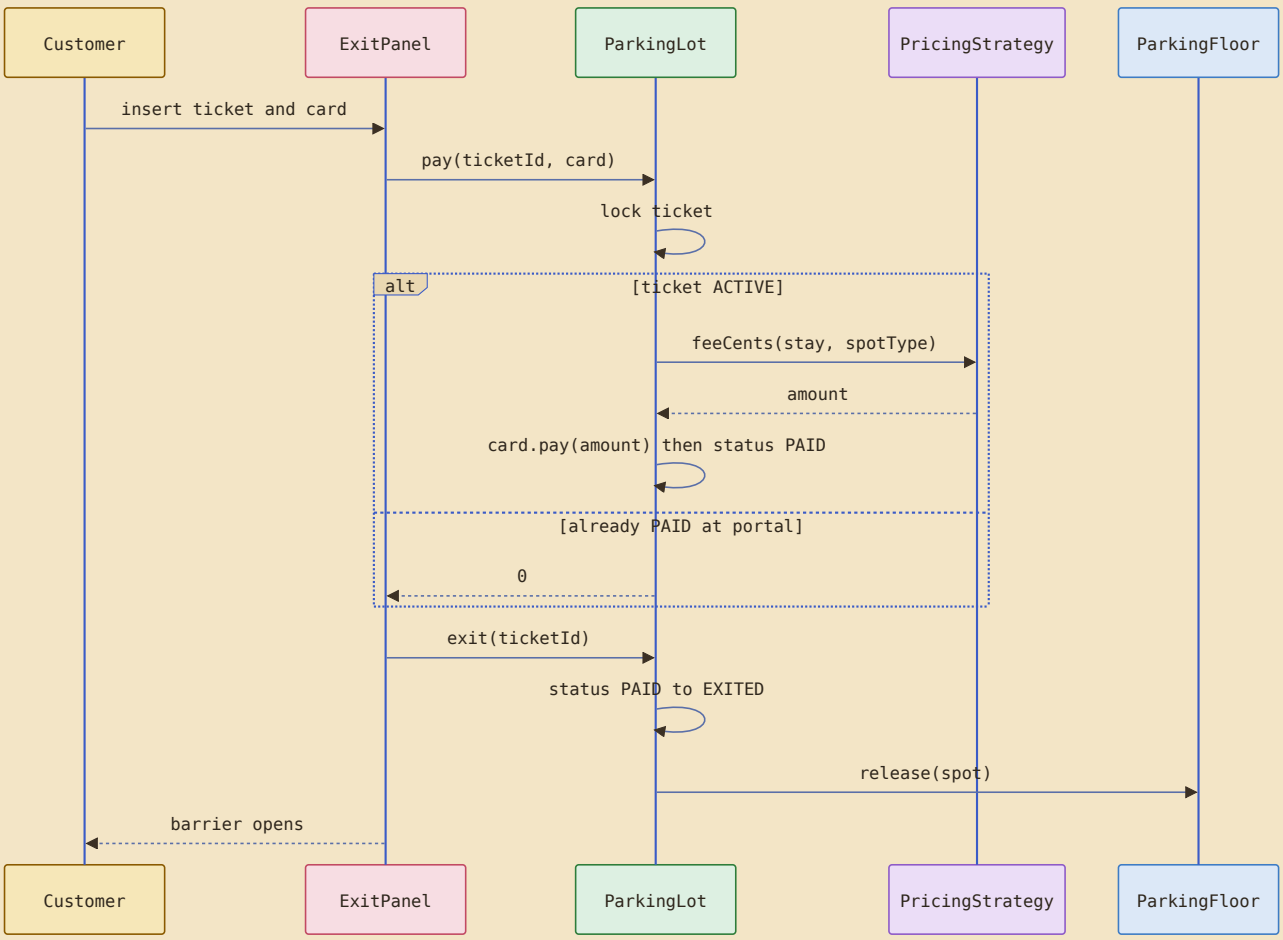
In this Mermaid diagram (Mermaid is a text format that renders as a diagram), `-` marks a private field (hidden inside its class), `+` a public method, `~T~` a generic type such as `List<ParkingFloor>`, `*--` composition, `o--` aggregation (a looser "has a" where the parts can live on their own), `-->` association, `<|..` "implements", and `..>` "uses or creates".

Key flows

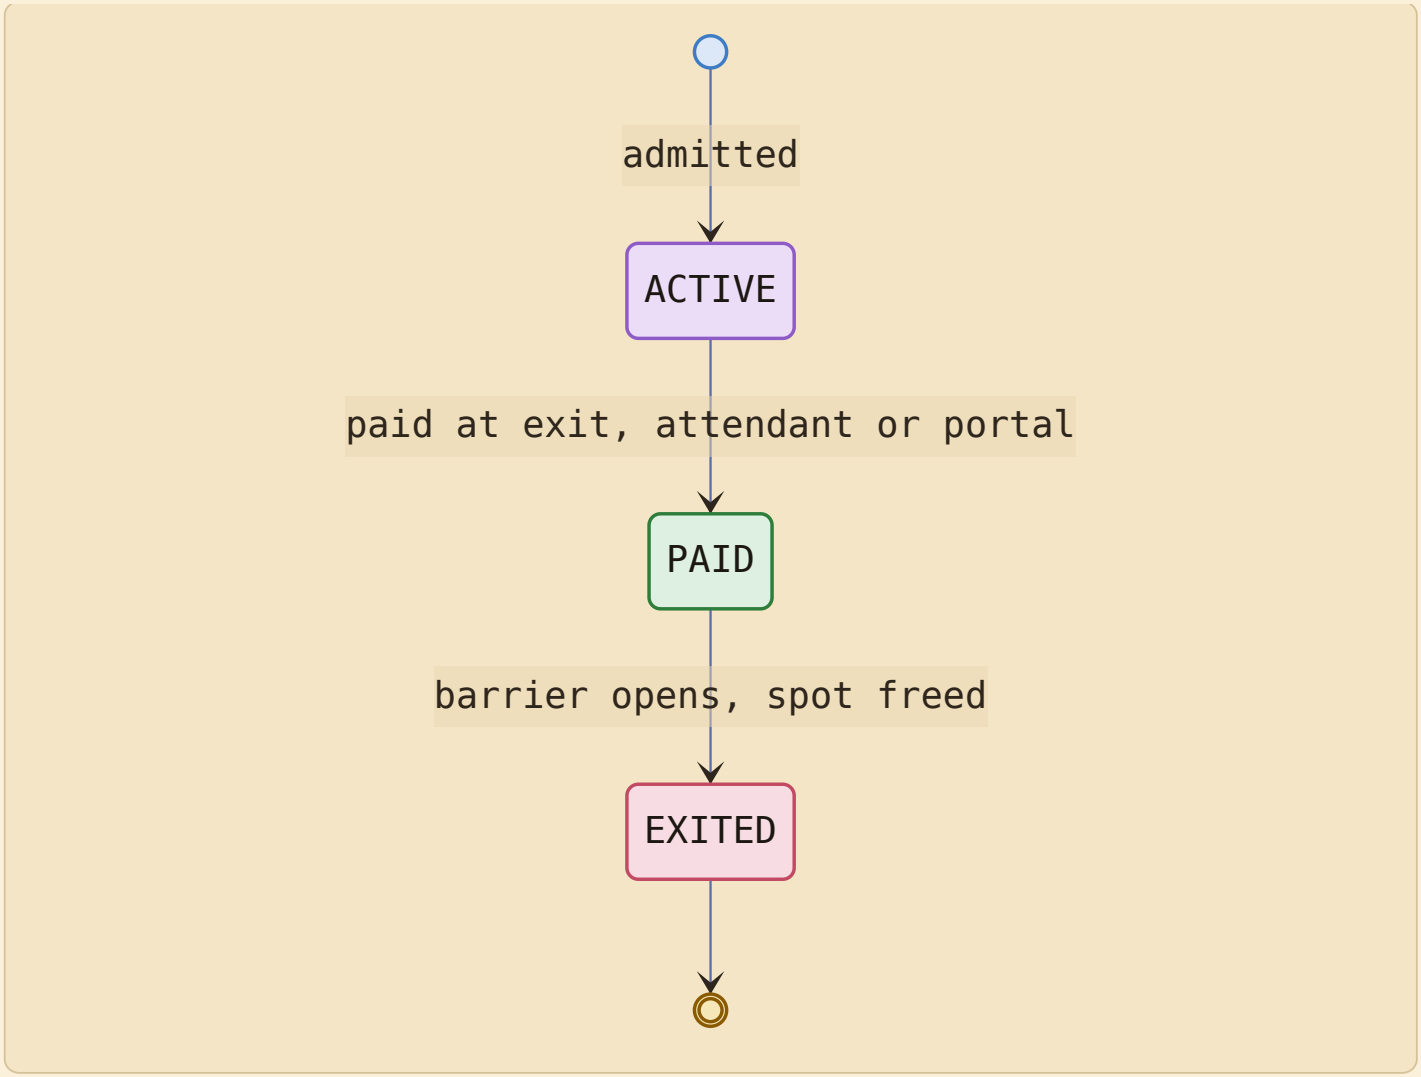
Entry (take ticket). The important step is that the spot is taken **atomically** (as one indivisible step that no other thread can interrupt halfway): `pollFirst()` on a concurrent sorted set removes the spot for exactly one caller. The **sequence diagram** below shows the messages between objects in time order, from top to bottom.



Exit (scan, pay, leave). Payment is guarded per ticket so the info portal and the exit panel cannot both charge.



Ticket life cycle.



admitted
ACTIVE
paid at exit, attendant or portal
PAID
barrier opens, spot freed
EXITED

Design decisions & patterns used

Decision	Pattern / principle	Why	Alternative rejected
The fit rule lives on `VehicleType`	Information Expert (give a job to the class that owns the data), Open/Closed (extend without editing)	Adding a vehicle type is one enum constant; the lot never changes	A big `switch(vehicleType)` inside the lot
Spot type is an **enum field**, not 5 subclasses	Composition over inheritance (hold a field instead of subclassing)	The 5 course subclasses carried no behaviour; a new type is one constant	`CompactSpot`, `LargeSpot`… (reviewers flag these as empty classes)
How to pick a spot is a `SpotAllocationStrategy`	**Strategy**	Nearest floor, least busy floor, closest to the lift, VIP floors… all swap without touching the lot	`if (mode == NEAREST) … else …` in the lot
How much to charge is a `PricingStrategy`	**Strategy**	The course's "what if pricing changes?" follow-up; admin swaps the rate at run time (the demo swaps to a flat rate)	Hard-coded tiers inside `Ticket`
Electric spots get a `ChargingPanel` in `SpotFactory`	**Factory** (simple static factory)	One place knows the construction rule "electric ⇒ has a panel"	Every caller remembers to attach a panel
Boards subscribe to floors	**Observer**	A floor change updates every board (and could update an app or a sensor light) without the floor knowing who listens	The lot pushing into boards directly
Ticket holds the **spot**, not a count	—	The exit can find and free the exact spot	Counting occupied spots
`ParkingLot` is **not** a hard-coded Singleton	Dependency injection (pass collaborators in from outside)	The course uses a Singleton ("there is one car park"). It is a global in disguise: tests cannot build two lots, and every class that calls `getInstance()` hides a dependency. We create one lot in `main` and pass it to the panels.	`ParkingLot.getInstance()`
`Clock` is injected	Testability	The demo moves time forward by hours instantly	`Instant.now()` inside the code

> **Honest note on "Strategy".** The course points out that a cash/card subclass pair is just an abstract base class, and calling it "Strategy" would be loose use of the word. Strategy means an object **holds** a behaviour and can **swap** it. In our code `ParkingLot` holds a `PricingStrategy` and a `SpotAllocationStrategy` and `setPricing(...)` swaps it at run time — that is genuinely Strategy.

The course also admits that `ParkingLot` does two jobs (finding spots and issuing tickets). Here spot-finding has moved into the strategy and the floors, so the lot is mostly a coordinator; in a longer design you would also move ticket storage into a `TicketRepository`.

Java implementation

Package `lld.ch14.parkinglot`. Amounts are in **cents** (`long`) to avoid floating-point rounding (a `double` stores numbers in binary and cannot hold values such as 0.10 exactly, so sums drift by tiny amounts).

```java
// File: lld/ch14/parkinglot/Vehicles.java
package lld.ch14.parkinglot;

import java.util.ArrayList;
import java.util.List;

/** The kinds of spot a floor can have. */
enum SpotType { MOTORCYCLE, COMPACT, LARGE, HANDICAPPED, ELECTRIC }

/** The kinds of vehicle the lot accepts, each with the spot types it fits, best fit first. */
enum VehicleType {
    MOTORCYCLE(List.of(SpotType.MOTORCYCLE)),
    CAR(List.of(SpotType.COMPACT, SpotType.LARGE)),
    ELECTRIC_CAR(List.of(SpotType.ELECTRIC, SpotType.COMPACT, SpotType.LARGE)),
    VAN(List.of(SpotType.LARGE)),
    TRUCK(List.of(SpotType.LARGE));

    private final List<SpotType> fits;

    VehicleType(List<SpotType> fits) { this.fits = fits; }

    List<SpotType> fits() { return fits; }
}

/** A vehicle is a value: plate + type + whether it carries an accessibility permit. */
record Vehicle(String plate, VehicleType type, boolean accessiblePermit) {

    Vehicle(String plate, VehicleType type) { this(plate, type, false); }

    /** Spot types this vehicle may use, most preferred first. The rule lives here, not in the lot. */
    List<SpotType> preferredSpots() {
        List<SpotType> order = new ArrayList<>();
        if (accessiblePermit && type != VehicleType.MOTORCYCLE && type != VehicleType.TRUCK) {
            order.add(SpotType.HANDICAPPED);
        }
        order.addAll(type.fits());
        return order;
    }
}
```

```java

    }
}
```

How the code works, part by part

- `Vehicle.preferredSpots()` returns the spot types in order of preference. An accessibility permit puts `HANDICAPPED` first; nobody else can ever get a handicapped spot.
- `ParkingFloor` keeps a `ConcurrentSkipListSet` (a thread-safe set from `java.util.concurrent` that keeps its elements sorted) of **free** spots per type, sorted by id. `pollFirst()` removes and returns the lowest id **atomically**: if 20 threads call it at once, each spot goes to exactly one of them. The lowest id stands for "nearest to the entrance".
- `ParkingSpot.tryOccupy` is a second safety net: an `AtomicReference.compareAndSet(null, v)` succeeds only if the spot was empty. This is **CAS** (compare-and-set): "change the value to *v* only if it is still *null*", done as one atomic step without any lock.
- `NearestFloorFirst` and `LeastBusyFloorFirst` are two interchangeable allocation strategies.
- `HourlyTieredPricing.standard()` encodes $4 / $3.50 / $3.50 / then $2.50, rounding a started hour up.
- `ParkingLot.admit` also reserves the **plate** with `putIfAbsent` (adds a key to a map only if it is not there yet, atomically), so the same car cannot be admitted twice.
- `ParkingLot.pay` locks **one ticket** (not the whole lot; a **lock** lets only one thread at a time run a piece of code, and Java's `synchronized` keyword is the built-in lock that every object carries), so payments for different tickets run in parallel while the portal and the exit panel cannot both charge the same ticket.
- `Main` uses a `TestClock` (a subclass of `java.time.Clock`) to jump forward in time, then races 20 threads for the last 5 car spots.

Output:

```
== Arrivals ==
[entry-A] CAR-1 -> ticket T1, spot F1-C01(COMPACT)
[entry-A] EV-1 -> ticket T2, spot F1-E01(ELECTRIC)
[entry-A] BIKE-1 -> ticket T3, spot F1-M01(MOTORCYCLE)
[entry-A] CAR-2 -> ticket T4, spot F1-H01(HANDICAPPED)
[entry-A] TRUCK-1 -> ticket T5, spot F1-L01(LARGE)
[entry-A] VAN-1 -> ticket T6, spot F2-L01(LARGE)
[entry-A] TRUCK-2 -> SORRY, LOT FULL for TRUCK
Floor 1 board: MOTORCYCLE=FULL COMPACT=1 LARGE=FULL HANDICAPPED=FULL ELECTRIC=FULL
Floor 2 board: COMPACT=3 LARGE=FULL

== EV charging at the spot ==
EV-1 charged 20 kWh, paid $6.00

== Departures ==
[exit-A] T1: paid $4.00 by cash $5.00, barrier OPEN
[portal] T2 due $16.00, charged $16.00
[exit-A] T2: already paid, barrier OPEN
Unpaid exit attempt: barrier opens? false

== Admin changes the rate: flat $5/hour ==
[exit-A] T3: paid $25.00 by card ****9999, barrier OPEN

== 20 cars race for the remaining CAR spots ==
free compact before: F1=2 F2=3, large: F1=0 F2=0
cars admitted: 5, distinct spots: 5
full for cars now? true
[entry-A] LATE-CAR -> SORRY, LOT FULL for CAR
Floor 2 board: COMPACT=FULL LARGE=FULL
```

Read the output: the truck is turned away because the only large spots are taken; T2 stayed 4 h 50 min, which rounds up to 5 hours = $4 + $3.50 + $3.50 + $2.50 + $2.50 = **$16.00**, paid at the portal, so the exit charges nothing; an unpaid ticket cannot open the barrier; after the admin switches to a flat $5/hour, the motorcycle pays $25 for 5 hours; 20 racing cars get exactly 5 distinct spots.

Concurrency & edge cases

Situation	What could go wrong	How the design handles it
Two gates want the last compact spot	Both get it (double booking)	`pollFirst()` is atomic; `tryOccupy` uses CAS as a second check
Portal and exit panel pay the same ticket at once	Customer charged twice	`synchronized (ticket)` around price-charge-mark; a PAID ticket costs 0
Same plate enters twice (cloned ticket, sensor glitch)	Two tickets for one car	`ticketByPlate.putIfAbsent`
Payment fails (card declined)	Ticket marked paid anyway	`method.pay` throws **before** `markPaid`; ticket stays ACTIVE
Car leaves without paying	Spot never freed or fee lost	`exit` only succeeds from PAID; the barrier stays closed
Customer pays at the portal and then stays 3 more hours	Free parking	Real lots give a **grace period** (e.g. 15 min) after payment; add `paidAt` and re-price after the grace period
Display board shows a slightly old number	Two notifications arrive out of order	Acceptable for a display; if exactness matters, have the board **pull** `freeCount` when it renders
Lost ticket	No entry time	Charge a daily maximum, or look up the plate (the plate map already exists)
Stay of 0 minutes	Fee of $0	Minimum of one hour (`Math.max(1, minutes)`)
Lock scope	One global lock would serialise all gates	Locks are per spot (CAS) and per ticket; no global lock

`ConcurrentSkipListSet.size()` is not constant-time (it walks the whole set instead of reading a stored number) and is only an estimate while other threads change the set; that is fine for a display board, but never use it to decide whether a spot is free — use `pollFirst()`.

Extensions & follow-up questions

1. **"What if pricing changes (weekend rate, per spot type, surge)?"** — Write a new `PricingStrategy` (for example `WeekendPricing`, or a decorator (a wrapper object with the same interface that adds behaviour around another object) that multiplies another strategy for large spots) and call `setPricing`. No other class changes.
2. **"Two cars arrive at the same instant — what happens?"** — Spot handout is atomic (`pollFirst` + CAS). Show the 20-thread race in the output.
3. **"Add reservations."** — Add a `Reservation(plate, spotType, from, to)` and a reserved set per floor; the allocation strategy checks the reservation first. Hold the spot with a timeout (release it if the car does not arrive within, say, 30 minutes).
4. **"Add monthly passes / season tickets."** — A `PricingStrategy` that returns 0 for plates with a valid pass, or a `PassHolderPricing` decorator around the normal pricing.
5. **"Number-plate recognition (ticketless)."** — The entrance camera becomes another kind of entrance panel that calls the same `admit`; the ticket id is keyed by plate. No core class changes.
6. **"How would you store this in a database?"** — Tables: `floor`, `spot(id, floor_id, type, occupied_by)`, `ticket(id, plate, spot_id, entry_time, status, paid_cents)`, `payment(id, ticket_id, method, amount)`. Claim a spot with a conditional update (`UPDATE spot SET occupied_by=? WHERE id=? AND occupied_by IS NULL`) — the database equivalent of our CAS. Candidates who have been asked this report that interviewers like to see **cardinalities** (how many of one thing can link to another; `1..*` means one or more) (a floor has 1..* spots, a spot holds 0..1 vehicles, a ticket has 1 spot) and then add a new entity to see how you rewire the model.
7. **"Many lots in a city?"** — A `ParkingLot` per site plus a `ParkingNetwork` that routes drivers to the lot with free spots. This is another reason not to make the lot a Singleton.
8. **"EV idle fees?"** — Add a charging session to `ChargingPanel` (start, end, kWh) and charge a per-minute fee after charging completes.

Real-world example

Many modern malls and airports use **parking guidance systems**: a sensor above each bay drives a small green/red light, and the boards at each entrance and floor show the free count per level — exactly our `DisplayBoard` observers fed by spot changes. Airports and many city garages increasingly use **automatic number-plate recognition** instead of paper tickets, and apps such as SpotHero and ParkMobile let drivers pre-book a spot, which is the "reservations" extension. Tesla Superchargers charge **idle fees** when a car stays plugged in after charging finishes — the EV extension above.

In the interview

Plan for 45 minutes

Minutes	What you do
0–5	Clarifying questions; write the 12 requirements and an out-of-scope list
5–10	Actors and use cases (take ticket, pay, exit, admin)
10–20	Stages 1–2: vehicle/spot fit rule, floors, board. Say "the fit rule lives on the vehicle"
20–25	Stage 3–4: ticket holds the spot; lot with admit/pay/exit; Strategy for pricing
25–38	Code `admit`, `tryPark`, `pay`, `exit`, and the tiered pricing
38–45	Concurrency (atomic spot handout, per-ticket lock), extensions

> **30-second answer:** "I'll model vehicles and spot types as enums with the fit rule on the vehicle, floors that keep a concurrent sorted set of free spots per type, and a lot that admits, prices and releases. Tickets point at the real spot. Pricing and spot-finding are Strategies so they can change without touching the lot. Handing out a spot is atomic — `pollFirst` plus a CAS on the spot — so two gates can never get the same spot, and payment locks only the one ticket."

Follow-ups with answers

- *"Why not a Singleton?"* — There is one lot in production, but a Singleton is a hidden global: it makes testing two lots impossible. I create one instance and inject it. If the interviewer insists, a lazy holder-class Singleton (the single instance lives in a nested class that Java loads only on first use, which the JVM makes thread-safe for free) is thread-safe and simple.
- *"Why is the fit rule on the vehicle?"* — Because it changes when vehicle types change; putting it there keeps the lot closed for modification (OCP).
- *"How do you make finding a spot fast?"* — Keep only the free spots, indexed by type, in a sorted set; taking one is O(log n) and needs no scan.
- *"What if the display board and the real count disagree?"* — The board is informational; the atomic `pollFirst` is the source of truth. The board can pull the count on render if needed.

Self-check

1. **Q:** Why must the ticket store a reference to the spot? **A:** So the exit can free exactly that spot; a count cannot tell you which spot to release.
2. **Q:** What makes spot assignment thread-safe here? **A:** `ConcurrentSkipListSet.pollFirst()` removes a spot for exactly one caller, and `AtomicReference.compareAndSet` on the spot double-checks it.
3. **Q:** Where would you add a weekend price? **A:** A new `PricingStrategy` implementation; set it with `setPricing`. Nothing else changes.
4. **Q:** Why did we replace the five spot subclasses with an enum? **A:** They had no behaviour of their own; an enum field does the same job and a new type is one constant (composition over inheritance).
5. **Q:** A customer paid at the portal. What does the exit panel charge? **A:** Nothing: `amountDue` returns 0 for a PAID ticket, and `exit` moves it from PAID to EXITED.
6. **Q:** How does the design stop a car from being admitted twice? **A:** `ticketByPlate.putIfAbsent(plate, …)` reserves the plate before allocating.

TL;DR

- Fit rule on the **vehicle**, spot type as an **enum**, free spots per type in a **concurrent sorted set**.
- **Ticket → spot** reference makes the exit possible; status goes ACTIVE → PAID → EXITED.
- **Strategy** for pricing and spot-finding, **Factory** for electric spots, **Observer** for boards; inject the lot instead of a Singleton.
- Concurrency: atomic `pollFirst` + CAS for spots, per-ticket lock for payment, `putIfAbsent` for plates.

14.2 Design a Vending Machine

Figure — A vending machine: slots with codes, a keypad, a coin/note slot and a tray at the bottom (course diagram)

A **vending machine** is an unattended shop: you key in a slot code, pay, and pull your item out of the tray at the bottom. Because everyone has used one, the interviewer can skip the domain and look at one thing only: **which actions are legal at which moment**. Taking a coin when nothing has been chosen is a bug; handing out two items for one payment is a bug. No amount of tidy code elsewhere makes up for getting that order wrong.

Problem & clarifying questions

Question	Assumed answer
Select first, or pay first?	Select a slot code first, then pay.
Which money?	A fixed set of coins and notes (5¢, 10¢, 25¢, $1, $5). Anything else is returned.
Card or contactless?	Out of scope (an extension).
Can it give change?	Yes. If it cannot make **exact** change, it refuses the sale and returns everything.
Can the customer cancel?	Any time before the product is dispensed, with a full refund.
One customer at a time?	Yes (one physical machine).
Who restocks?	An operator: restocks slots, loads coins for change, collects the takings.

Requirements

Functional (the course's twelve)

1. The machine has many **slots**. A slot has a code (`A1`, `B2`, …), holds items of a **single** product, and tracks its remaining **count**.
2. A product has a **name** and a **price in cents**.
3. Order of use: **choose a slot, then pay**.
4. Only a **known set of coins and notes** is accepted; any other piece is given back.
5. After **every** customer action the **display** says what to do next.
6. When the amount paid covers the price, the machine **releases the item and the change**.
7. When **exact change is impossible**, the sale is **refused** and every cent paid is **returned**.

8. Until the item drops, the customer may **cancel** and receive a **full refund**.
9. A slot whose count is **zero cannot be chosen**.
10. One payment buys **exactly one** item, never two.
11. An **operator** refills slots, adds coins for change, and removes the takings.
12. After every sale, cancel and refusal, **both** the item counts and the cash counts must be **exactly right**.

Non-functional

- **No illegal transitions**: every button must have a defined answer in every situation.
- **Exact money**: integer cents only — no floating-point.
- **Extensible**: a new payment device (card reader) or a new state (maintenance) should not require editing every existing class.

Use cases

Actors: Customer (selects, pays, cancels, takes the product), **Operator** (restocks, loads change, collects money), **System** (decides which actions are allowed now, works out change, shows messages).

Top use cases: select a product · insert money · dispense · collect (take from the tray) · cancel · restock a slot · load change and collect takings.

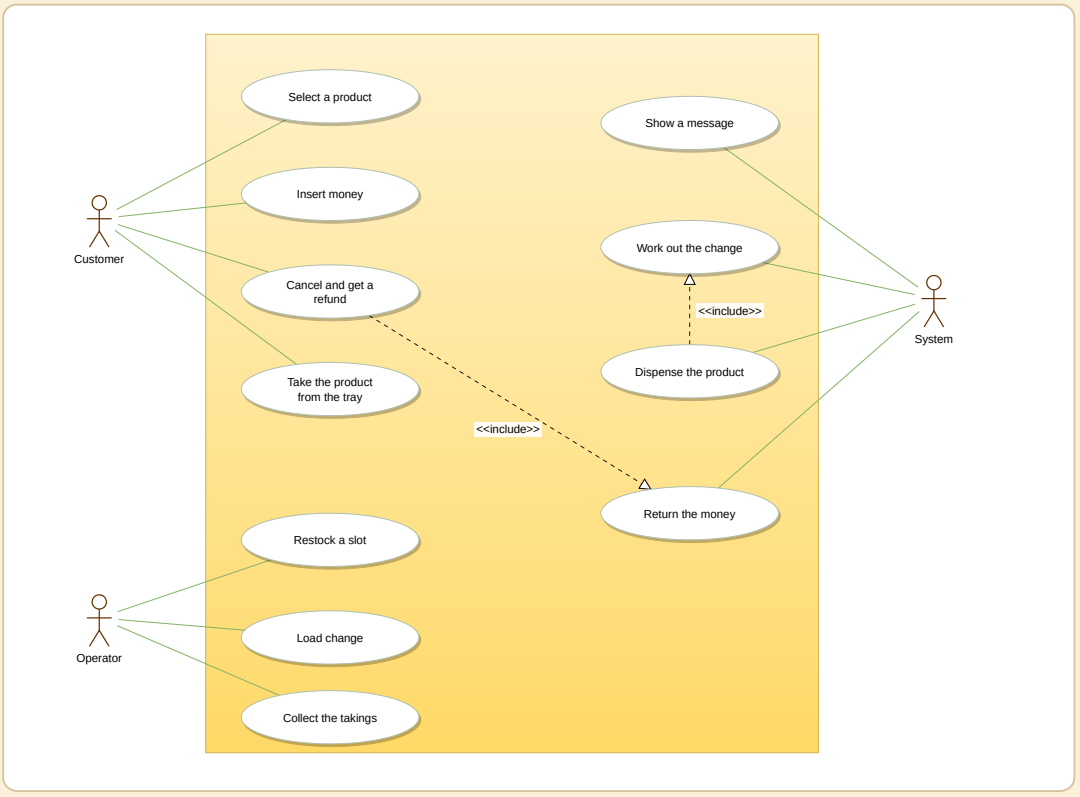

Figure — Use case diagram of the vending machine: Customer, Operator and System (course diagram)

In the figure above, "dispense" is a System use case, not a customer one: the customer only *causes* it by paying enough.

Core entities

Class	Responsibility
`Product` (record)	Name and price in cents. Describes *what* is sold.
`Slot`	One physical column: a code, one product, and the **count** left.
`Inventory`	All slots, looked up by code.
`Denomination` (enum)	The accepted coins and notes and their values in cents.
`CashBox`	Counts pieces by value; plans exact change; reports when it cannot.
`VendingState` (interface)	One method per customer button: `select`, `insert`, `cancel`, `take`.
`IdleState`, `SelectedState`, `HasMoneyState`, `DispensingState`, `OutOfStockState`	The situations the machine can be in (the course has the first four, calling `HasMoneyState` `PaidState`); each answers every button and names the next state.
`Display`	The message the customer currently sees. In our code, `VendingMachine.show(...)` plays this part.
`Keypad`, `CashSlot`, `Dispenser`	The hardware the customer touches; each calls the machine and holds no rules. In our code they are folded into the machine's public methods.
`Operator`	Restocks, loads change, collects takings. In our code: `restock`, `loadChange`, `collectTakings`.
`VendingMachine`	Holds the parts, the current state, the selection and the balance; forwards each button to the state. Also exposes operator actions.

Why is the count on the **slot**, not on the product? `Product` answers "what is it?"; `Slot` is the physical column it sits in. The same product may be loaded into two columns (the course even allows different prices), and emptying one column must leave the other untouched. That is the first real design decision in this question.

Class diagram

The course builds the machine in five stages:

Stage	What it adds	What works after it
1	`Product`, `Slot`, `Inventory`	Look up a code and learn what it holds and whether it is empty
2	`Coin`, `Note`, `CashBox`	Decide whether a given amount of change can be paid exactly
3	A class for each state	Each button press gets a defined reaction in each situation
4	`Display` and `VendingMachine`	A complete sale, from choosing to picking up the item
5	`Keypad`, `CashSlot`, `Dispenser`, `Operator`	Real hardware drives the same flow

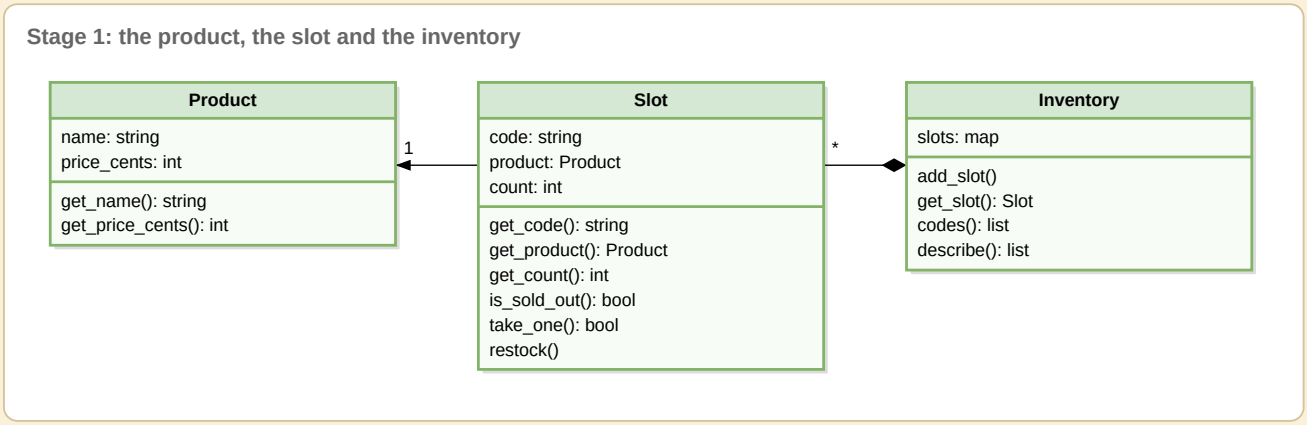

Figure — Stage 1: Product, Slot (association to Product) and Inventory (composition of Slots) (course diagram)

Stage 1. Requirements 1, 2 and 9. `Slot → Product` is an **association**: a product can appear in several slots, so removing a slot must leave the product alone. `Inventory ◆ Slot` is **composition** (filled diamond): slots are parts of the machine and do not outlive it.

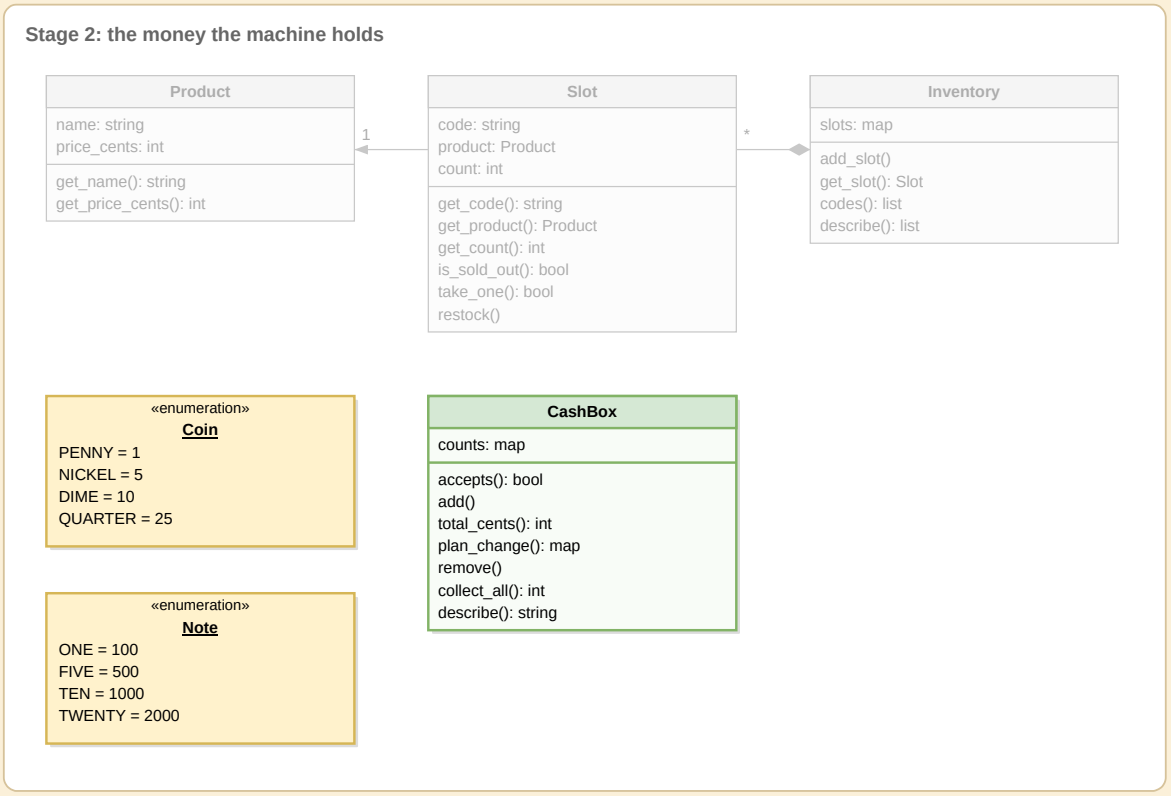

Figure — Stage 2: Coin and Note enumerations and the CashBox that counts pieces by value (course diagram)

Stage 2. Requirements 4, 6 and 7. All amounts are whole cents, so rounding errors cannot happen. `Coin` and `Note` are enumerations (fixed lists of named values; our code merges them into one `Denomination` enum), and fixed sets like these have no relationship arrows. The choice to defend here: **a piece goes into the cash box the moment it is inserted**, not into a holding area. Those pieces are then available for change, and a refund becomes nothing more than "pay out exact change equal to what was inserted". The box stores a **count per value**; which

physical quarter comes back does not matter. Its change planner either returns an exact plan or says "impossible"; it never approximates, and that is what makes requirement 7 implementable.

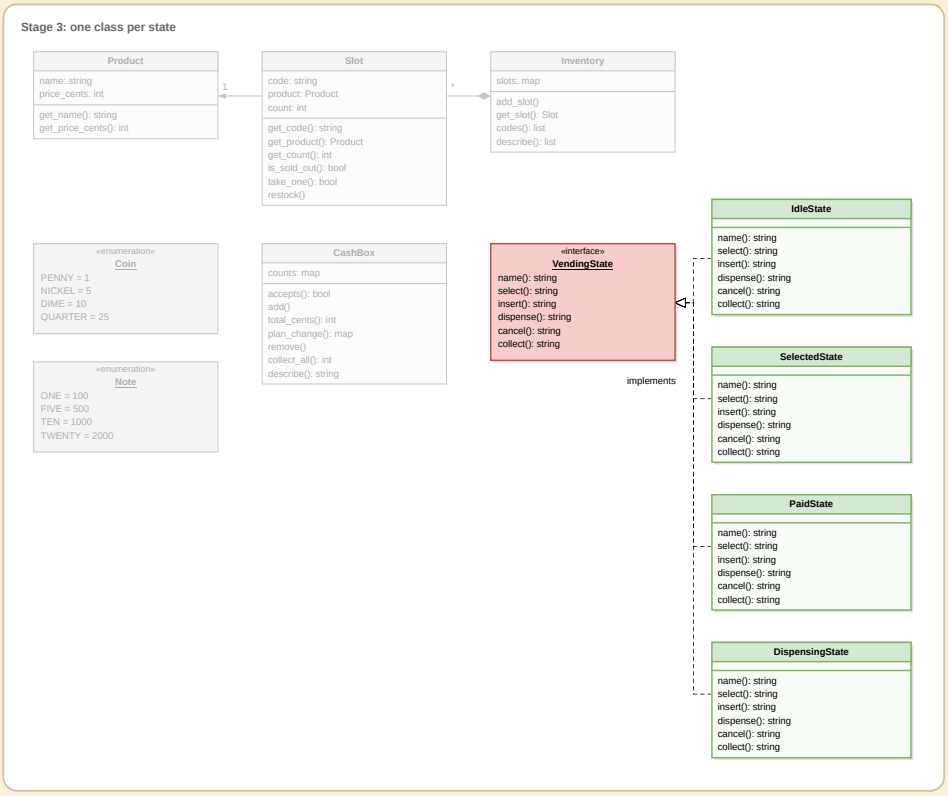

Figure — Stage 3: one class per state, all implementing the VendingState interface (course diagram)

Stage 3 — the heart of the question. Requirements 3, 8 and 10. The obvious first attempt is one class with a few boolean flags and nested `if`s; that version is exactly where double dispensing and swallowed coins come from. Use the **State pattern** instead: each situation becomes a class, and all of them implement one interface on which **each customer button is a method**. A state class that forgets a button does not compile. Picture the states as a **grid**, buttons down the side and situations across the top: the design is finished when every cell holds a response. The state classes carry no fields, and none of them checks which state is active; each handles its own buttons and hands over to the next state, so a new state can be added without editing the existing ones.

The course draws **four** states: `IdleState`, `SelectedState`, `PaidState` and `DispensingState`. Our code keeps those four (its `HasMoneyState` is the course's `PaidState`: some money is in, not yet enough) and adds a fifth, `OutOfStockState`, so that an empty machine refuses every customer button until an operator restocks it.

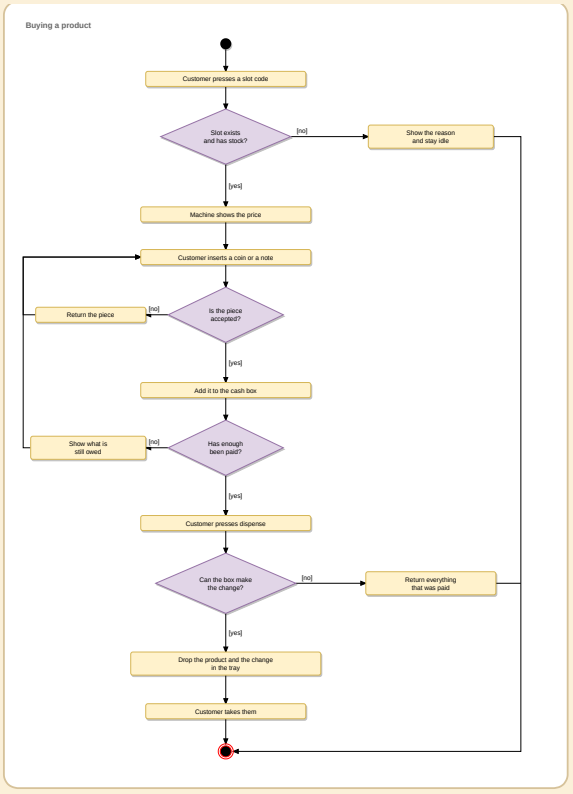

Figure — Activity diagram "Buying a product": select, check stock, insert money until enough, check change, dispense, take (course diagram)

Each decision diamond in the activity diagram above corresponds to one state choosing whether to accept an action.

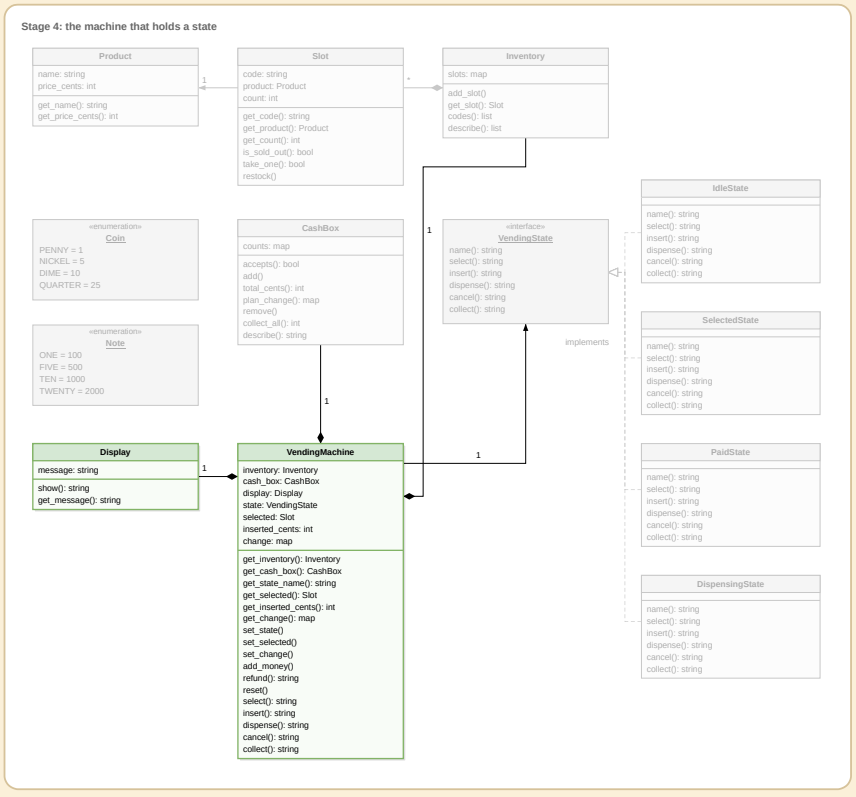

Figure — Stage 4: VendingMachine owns its display, cash box and inventory, and points at the current VendingState (course diagram)

Stage 4. Requirements 5, 6, 8 and 12. `VendingMachine` remembers the chosen slot and the money inserted so far, and passes every button press to its current state. It **owns** its `Display`, `CashBox` and `Inventory` (composition) and merely **refers to** the current state object (association). Look at what the class does *not* contain: any `if`

that tests which state is active. The refund method shows why stage 2 pays off: since inserted money is already in the box, refunding is just a request for exact change equal to the balance.

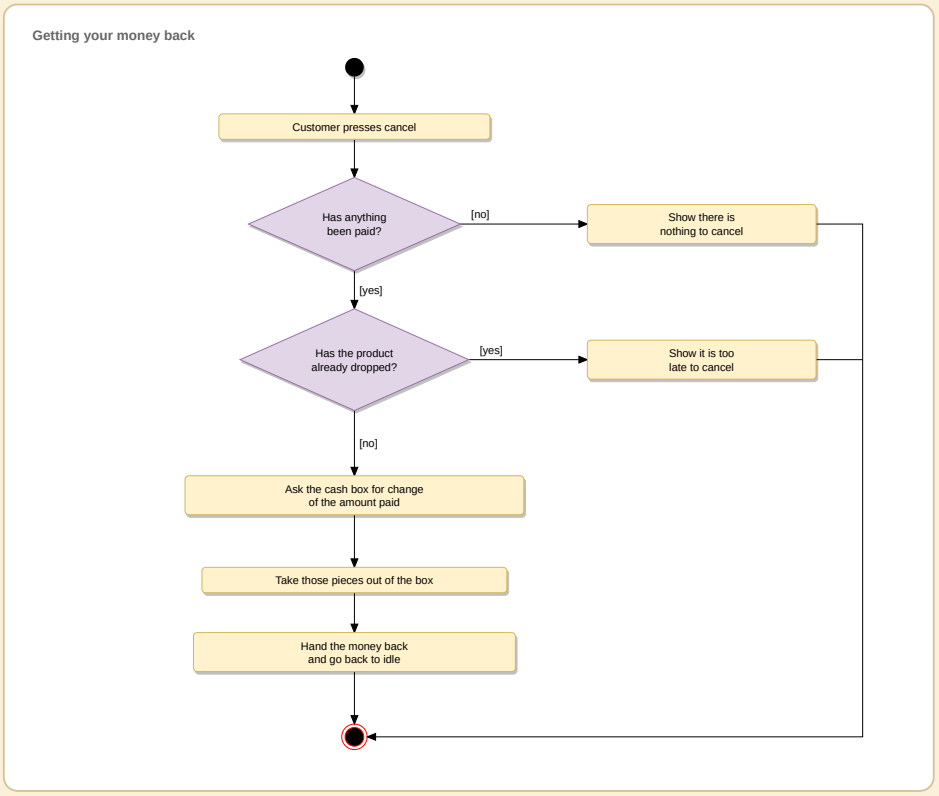

Figure — Activity diagram "Getting your money back": cancel and "cannot make change" end in the same refund path (course diagram)

As the figure above shows, a cancel and a "no exact change" refusal finish identically, so the design needs a **single** refund method.

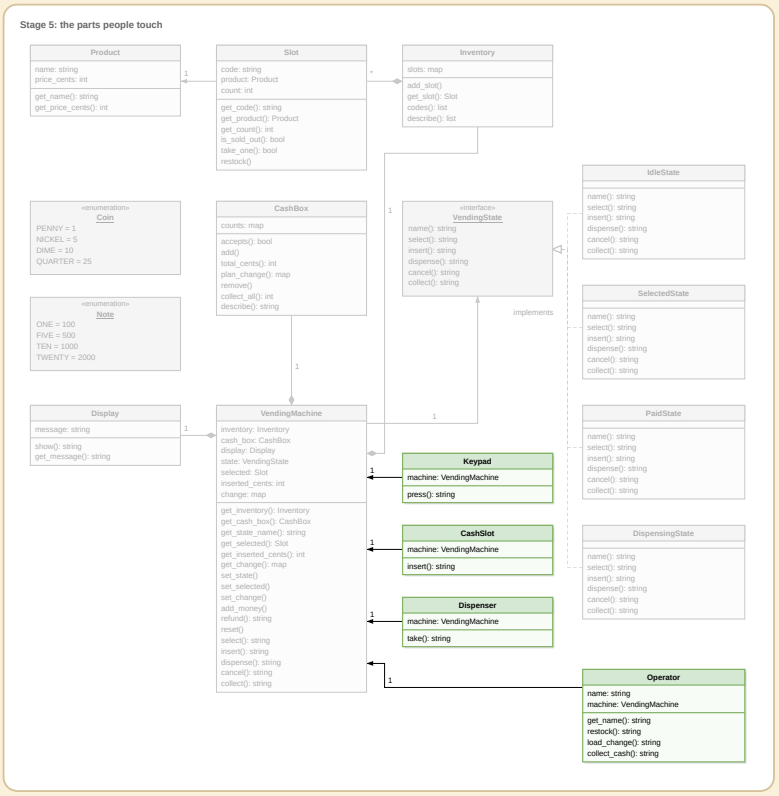

Figure — Stage 5: Keypad, CashSlot, Dispenser and Operator, all pointing at the machine (course diagram)

Stage 5. Requirements 3, 4 and 11. All four new classes hold references **to** the machine, never the reverse: the keypad calls the machine, but the machine has no idea a keypad exists. Swapping the keypad for a touch screen, or the coin slot for a card reader, therefore touches no other class. The `Dispenser` is the tray; pulling the item out of it is what finishes a sale, which is why `take` is a customer button on the state interface.

`Operator` is intentionally kept **off** that interface: refilling, loading change and emptying the box are not customer actions and are permitted whatever state the machine is in (if they were on the interface, every state class would have to answer them).

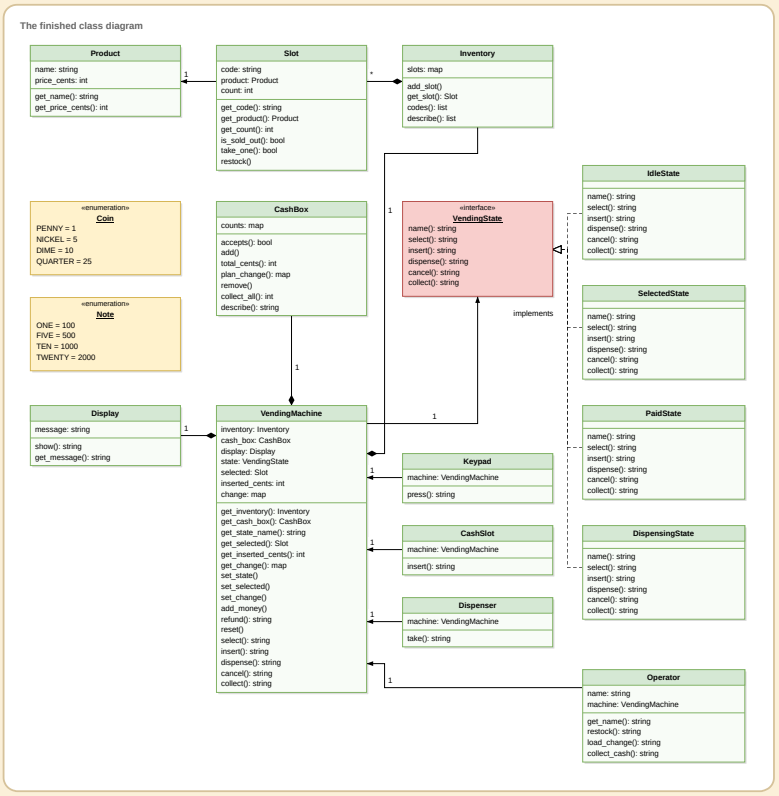

Figure — The finished class diagram of the vending machine (course diagram)

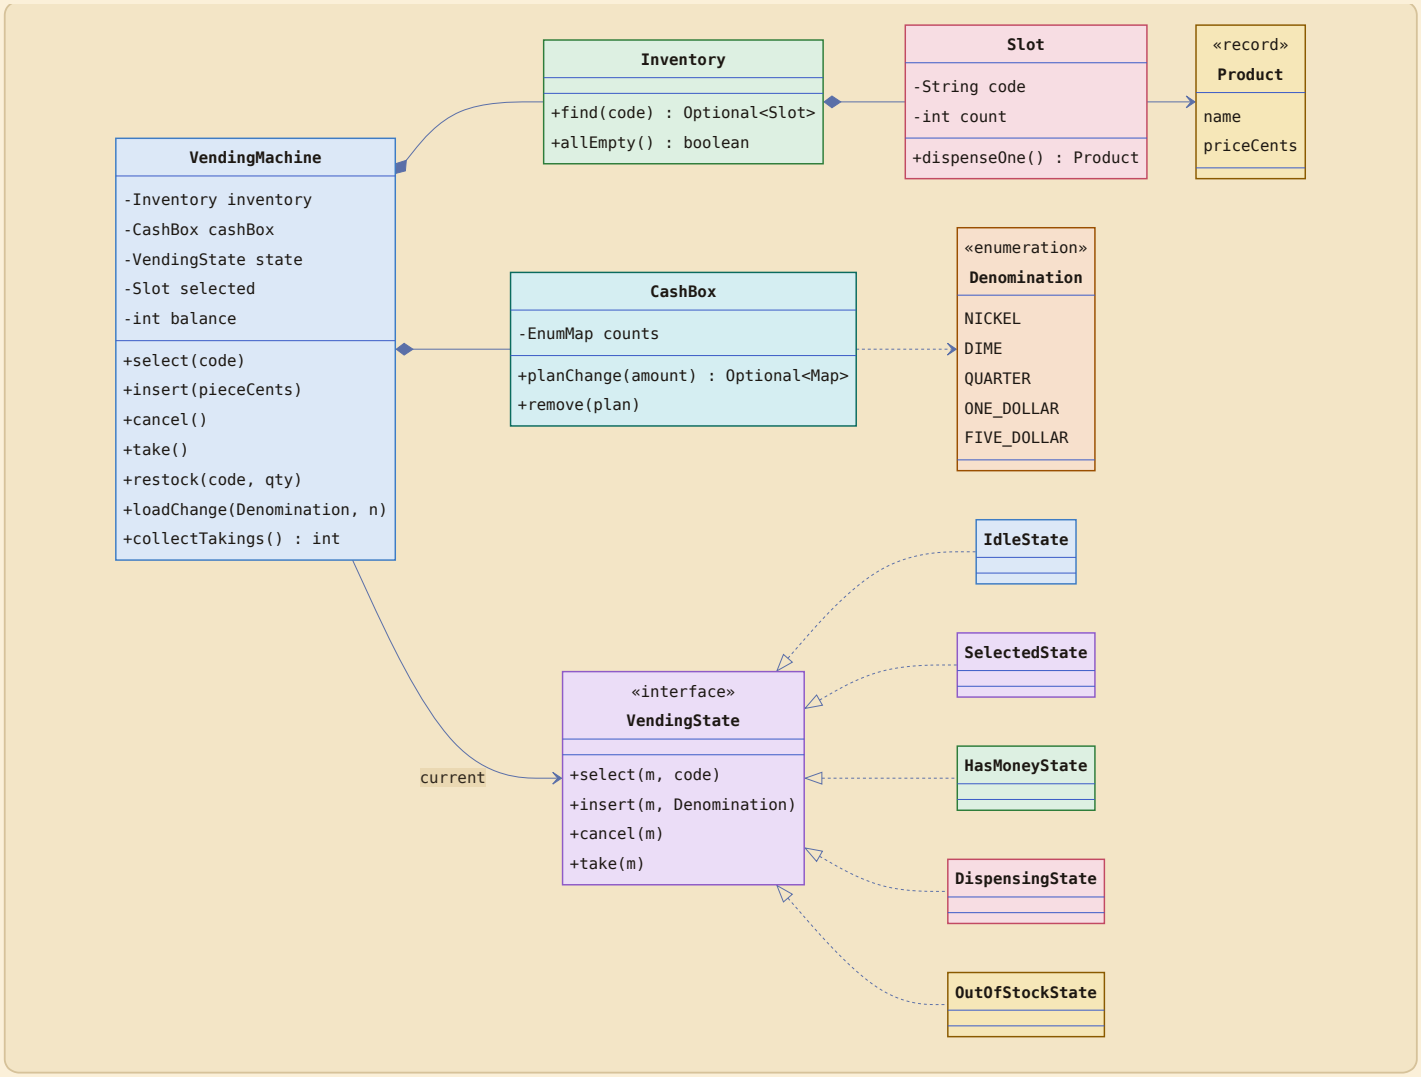
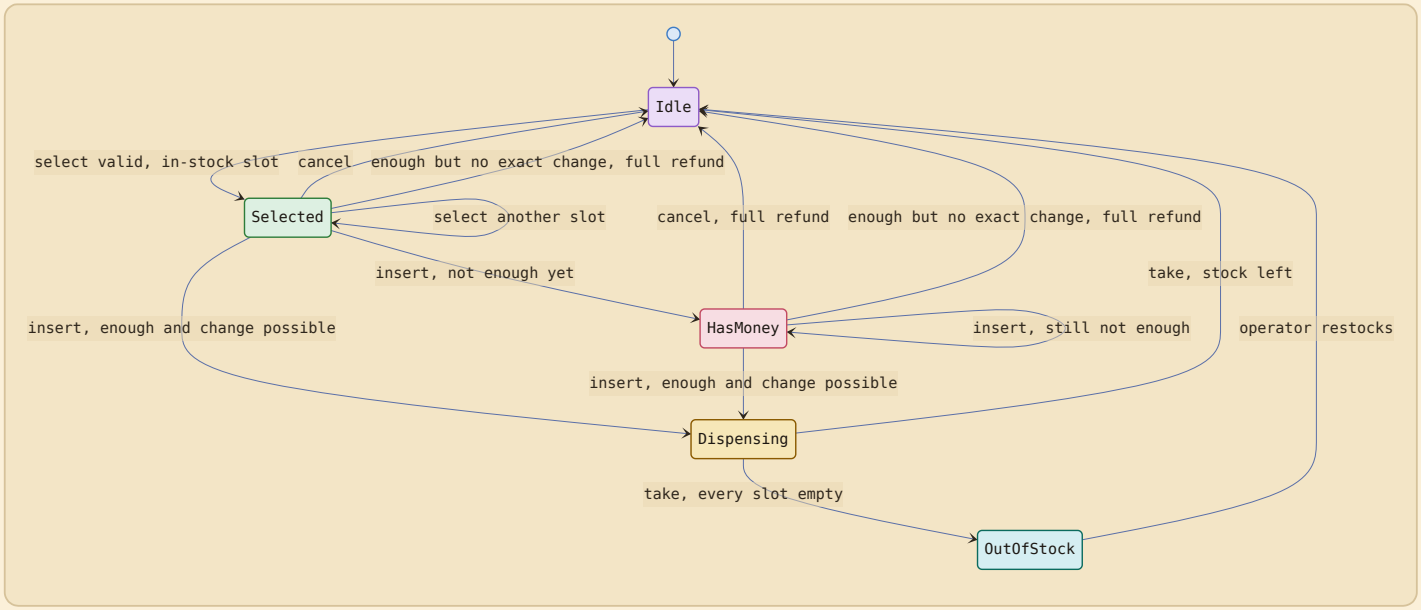
Class diagram of **our Java code** (hardware classes folded into the machine's public methods to keep the code short):



Key flows

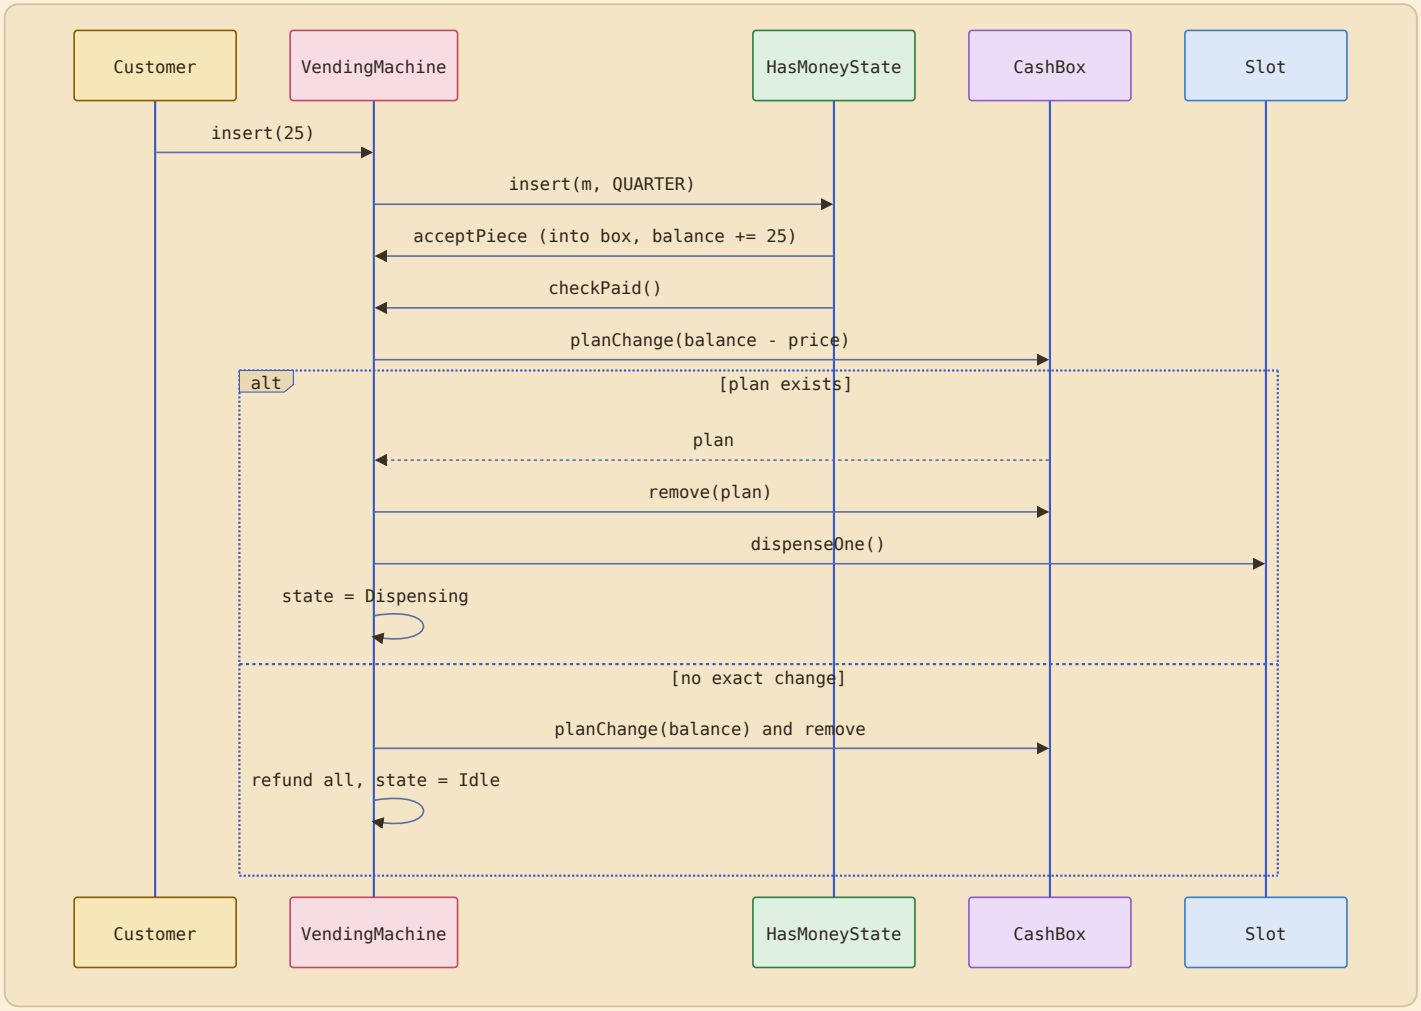
State machine. This diagram *is* the design; draw it before writing code.



The state table (rows = buttons, columns = states). Every cell has an answer:

Button ↓ / State →	Idle	Selected	HasMoney	Dispensing	OutOfStock
`select`	choose slot (reject empty/unknown)	change choice	"cancel first"	"take your product first"	"out of stock"
`insert`	return piece	accept; check paid	accept; check paid	return piece	return piece
`cancel`	"nothing to cancel"	clear choice → Idle	**refund all** → Idle	"too late"	"nothing to cancel"
`take`	"tray empty"	"pay first"	"pay the rest"	give product + change → Idle/OutOfStock	"tray empty"

Paying enough.



Design decisions & patterns used

Decision	Pattern / principle	Why	Alternative rejected
One class per situation behind `VendingState`	**State**	Every button × situation cell is answered; the compiler enforces completeness; no `if (state == …)`	Flags + `if/else` chains (the classic source of double-dispense bugs)
States are shared **stateless singletons** (`INSTANCE`; no fields, so one copy serves everyone)	Flyweight-style sharing (one shared object instead of many identical ones)	The course notes that creating a new state object on each transition is readable but wasteful; the states hold no data, so one instance each is enough	`new IdleState()` on every transition
Operator actions are **not** on the state interface	Interface Segregation (no class is forced to implement methods it does not need)	Restocking is allowed in every state; forcing five classes to answer it would be noise	Adding `restock` to `VendingState`
Money counted by value in an `EnumMap` (a fast map keyed by enum constants)	—	The machine never cares which physical quarter it returns	A list of coin objects
Inserted money goes straight into the box	—	Refund = "make change for the balance"; one refund path	A separate escrow pile (a holding area for inserted money)
Exact change with dynamic programming	Correctness	Greedy can fail when the box is short of one coin (see output part 6)	Greedy only
Refuse the sale if exact change is impossible	Requirement 7	Never short-change the customer	Give "close enough" change

> **About the change algorithm.** The course's planner is **greedy** (largest piece first, never looks back) and honestly says so: greedy is correct for standard coin sets when the box is well stocked, but when the box is short of one piece it can fail for an amount that smaller pieces could make. The exact fix is **dynamic programming** — the "coin change with limited coins" problem, where you build the answer for each amount from the answers for smaller amounts. Our `CashBox.planChange` implements that (bounded coin change, fewest pieces), and `greedyPlan` is kept only to show the difference: for 30¢ from {1 quarter, 3 dimes}, greedy takes the quarter and gets stuck at 5¢; DP returns three dimes.

Java implementation

Package `lld.ch14.vendingmachine`.

```

```
    }
}
```

How the code works, part by part

- `VendingMachine.insert(int)` first maps the raw piece to a `Denomination`; an unknown piece (a 3¢ token) is returned without ever reaching a state.
- `SelectedState` and `HasMoneyState` both call `acceptPiece` then `checkPaid`. `checkPaid` either moves to `HasMoney`, or completes the sale (plan change → remove pieces → dispense one → `Dispensing`), or refunds everything if exact change is impossible.
- `refundAll` is the **single** refund path used by cancel and by "cannot make change". It can never fail, because the pieces just inserted are in the box, so an exact plan always exists.
- `DispensingState.take` empties the tray and moves to `Idle` or `OutOfStock` — the sale ends when the customer takes the product, which is why `take` is a customer button.
- All public methods are `synchronized`. A single physical machine has one customer, but a networked controller (remote price change, telemetry — status data sent automatically to a remote server — or a second input device) must not interleave two actions.

Output:

```
state=IDLE cash=60c stock=[A1:Colax2 B1:Chipsx1 C1:Candyx0]

1) Happy path: Cola with $1 + 25c. Extra coins and a late cancel are refused
 > select A1   (IDLE)
   [display] Cola costs 125 c. Insert money.
 > insert 100c   (SELECTED)
   [display] Paid 100 c, 25 c to go.
 > insert 25c   (HAS_MONEY)
   [display] Dispensed. Please take: [Cola]
 > insert 25c   (DISPENSING)
   [display] QUARTER returned: take your product first.
 > insert 10c   (DISPENSING)
   [display] DIME returned: take your product first.
 > cancel   (DISPENSING)
   [display] Too late to cancel: product already dispensed.
 > take   (DISPENSING)
   [display] Customer took [Cola]

2) Wrong order and bad input
 > insert 25c   (IDLE)
   [display] QUARTER returned: select a product first.
 > select C1   (IDLE)
   [display] C1 is sold out. Choose another.
 > select Z9   (IDLE)
   [display] Unknown code Z9
 > select B1   (IDLE)
   [display] Chips costs 50 c. Insert money.
 > insert 3c   (SELECTED)
   [display] Unknown piece of 3c returned.

3) Cancel with money in: full refund
 > insert 25c   (SELECTED)
   [display] Paid 25 c, 25 c to go.
 > select A1   (HAS_MONEY)
   [display] Cancel first to change your choice.
 > cancel   (HAS_MONEY)
   [display] Cancelled. Refunded 25 c as {QUARTER=1}

4) Cannot make exact change -> sale refused, everything refunded
 > select B1   (IDLE)
   [display] Chips costs 50 c. Insert money.
 > insert 500c   (SELECTED)
   [display] Cannot make exact change. Refunded 500 c as {FIVE_DOLLAR=1}
state=IDLE cash=185c stock=[A1:Colax1 B1:Chipsx1 C1:Candyx0]

5) Last items sold -> OUT_OF_STOCK -> operator restocks
 > select B1   (IDLE)
   [display] Chips costs 50 c. Insert money.
 > insert 25c   (SELECTED)
   [display] Paid 25 c, 25 c to go.
 > insert 25c   (HAS_MONEY)
   [display] Dispensed. Please take: [Chips]
 > take   (DISPENSING)
   [display] Customer took [Chips]
 > select A1   (IDLE)
   [display] Cola costs 125 c. Insert money.
 > insert 100c   (SELECTED)
   [display] Paid 100 c, 25 c to go.
 > insert 25c   (HAS_MONEY)
   [display] Dispensed. Please take: [Cola]
 > take   (DISPENSING)
   [display] Customer took [Cola]
state=OUT_OF_STOCK cash=360c stock=[A1:Colax0 B1:Chipsx0 C1:Candyx0]
 > select A1   (OUT_OF_STOCK)
   [display] Machine is out of stock.
   [display] Operator restocked C1 +5
 > select C1   (IDLE)
   [display] Candy costs 65 c. Insert money.
```

```
  > insert 100c   (SELECTED)
    [display] Dispensed. Please take: [Candy, change {DIME=1, QUARTER=1}]
  > take   (DISPENSING)
    [display] Customer took [Candy, change {DIME=1, QUARTER=1}]

6) Why the change planner is not greedy
30c from {1 quarter, 3 dimes}: greedy=Optional.empty dp=Optional[{DIME=3}]

Operator collects notes: 300 c
state=IDLE cash=125c stock=[A1:Colax0 B1:Chipsx0 C1:Candyx4]
```

Read the output: in part 1 the cola is paid exactly, and coins inserted while the product waits are returned, and a late cancel is refused; part 4 shows the refusal when 450¢ of change cannot be made from the box (so the $5 note comes straight back); part 5 shows the machine going to `OUT_OF_STOCK` and back to `IDLE` after a restock; part 6 shows greedy failing where DP succeeds.

Concurrency & edge cases

Edge case	Handling
Money inserted before selecting	`IdleState.insert` returns the piece
Unknown coin or foreign note	Returned before reaching the state
Selecting an empty slot	`IdleState.select` refuses; the state stays Idle
Changing the choice after paying	`HasMoneyState.select` says "cancel first" (prevents price confusion)
Paying more than the price	Change is planned **before** dispensing; if impossible, the sale is refused
Cancel after dispensing	"Too late" — the product is already in the tray
Two products for one payment	Impossible: after dispensing, the balance is 0 and the state is Dispensing, which accepts no money
Last item sold	`take` moves to `OutOfStock`; only a restock leaves it
Two threads pressing buttons	`synchronized` public methods; states run under the machine's lock
A bank of machines sharing one stock count	The course notes the design is not safe for that; the shared count on `Slot` would then need a lock or an atomic decrement
Power failure mid-sale	Real machines keep a transaction log (credit held) in non-volatile memory (memory that keeps its contents without power); out of scope

Extensions & follow-up questions

1. **"Where would you add contactless card payment?"** — One new input device beside the cash slot that calls the same machine (for example a `payByCard(amount)` that sets the balance to the price). No state class changes if the states only look at the balance.
2. **"What if it cannot give change?"** — The planner returns empty; the sale is refused and everything is refunded (requirement 7). Mention greedy vs DP.
3. **"Add a maintenance state."** — A new `MaintenanceState` class; the operator switches it on. The existing five states are untouched (Open/Closed).
4. **"Different price per slot for the same product?"** — Move the price from `Product` to `Slot` (the slot already owns the count).
5. **"Report empty slots to headquarters."** — Make `Inventory` notify an observer when a slot reaches 0; a telemetry client sends it over the network.
6. **"What did you leave out on purpose?"** — Card payment, reporting empty slots over a network, refrigeration (chilling) control and per-customer discounts. Say so explicitly: they are scope decisions, not oversights.
7. **"Timeout if the customer walks away with money in?"** — A timer that calls `cancel()` after, say, 60 seconds of inactivity; it goes through the same state machine.

Real-world example

Modern vending machines are often retro-fitted with cashless readers such as **Nayax** or **Cantaloupe (ePort)** units, which plug into the machine's controller as just another payment device — exactly extension 1: a new input beside the coin mechanism, with the dispensing logic unchanged. Coin mechanisms in real machines keep "change tubes" of each coin and show an **"exact change only"** light when a tube runs low — the physical version of our planner reporting that it cannot make change.

In the interview

Plan for 45 minutes: 5 min questions and requirements → 5 min entities (product, slot, inventory, cash box) → **10 min: draw the state diagram and the state table** → 15 min code the interface, two or three states and `checkPaid`/`refundAll` → 10 min edge cases and follow-ups.

> **30-second answer:** "The whole question is the order of events, so I'll use the State pattern: one class per situation — Idle, Selected, HasMoney, Dispensing, OutOfStock — all implementing an interface that lists every button. The machine just forwards to its current state. Money goes into the cash box as it is inserted, so a refund is just 'make exact change for the balance'; if exact change is impossible, the sale is refused and everything is returned. Amounts are integer cents."

Follow-ups with answers

- *"Why not an enum with a switch?"* — It works for tiny machines, but every new state means editing every switch; with the State pattern a new state is a new class, and the compiler forces it to answer every button.
- *"Is greedy change correct?"* — Only for well-stocked canonical coin sets (coin systems such as 1/5/10/25 where taking the largest coin first always gives the fewest coins). With limited coins it can fail; use bounded coin-change DP.
- *"Where does the operator fit?"* — Outside the state interface; restocking is allowed in any state and can move OutOfStock → Idle.

Self-check

1. **Q:** What makes the design "complete"? **A:** Every state class implements every button method, so every (state, button) cell has a defined answer.
2. **Q:** Why does inserted money go straight into the cash box? **A:** So the same pieces can be returned as change or refund; a refund is just planning exact change for the balance.
3. **Q:** Why is `restock` not in `VendingState`? **A:** It is not a customer action and is valid in every state (Interface Segregation).
4. **Q:** Give a case where greedy change fails. **A:** 30¢ with one quarter and three dimes: greedy takes 25¢ and cannot make 5¢; three dimes work.
5. **Q:** How is "two products for one payment" prevented? **A:** After dispensing, balance is reset to 0 and the Dispensing state returns any inserted money until the product is taken.

TL;DR

- **State pattern is the whole design**: five state classes, one interface listing every button, no `if` on state in the machine.
- Count lives on the **slot**; money in **integer cents**; inserted money goes **into the box immediately**.
- Change: **exact** or refuse; greedy can fail, **DP** (bounded coin change) is the correct planner.
- One refund path for cancel and "no change"; operator actions stay off the state interface.

14.3 Design a Coffee Vending Machine

A **coffee vending machine** makes drinks on demand — espresso, americano, latte, cappuccino, mocha, hot chocolate — from a shared stock of **ingredients** (beans, water, milk, chocolate, sugar). It looks like the previous problem, but the hard part is different. A snack machine hands out a finished item from a slot. A coffee machine **consumes several ingredients at once** from shared containers, and many drinks draw on the same milk. The interviewer wants to see three things:

1. **Recipes as data** — adding a drink should be a data change, not a new class.
2. **Atomic, all-or-nothing deduction** — a latte must take its beans, water *and* milk together, or take nothing; stock must never go negative, even when ten people order at once.
3. **Low-stock alerts** — the operator hears about milk running low *before* it runs out (Observer).

Problem & clarifying questions

Question	Assumed answer
Which drinks?	Espresso, Americano, Latte, Cappuccino, Mocha, Hot Chocolate — loaded from a menu file.
Customisation?	Extra espresso shot (+50¢) and sugar (grams).
Payment?	Amount paid in cents; change returned (coin handling was covered in 14.2).
Several screens / concurrent orders?	Yes: a large machine or a kiosk with several touch screens, so orders can overlap.
Who refills?	An operator, alerted when an ingredient falls to a threshold.
One alert or one per drink?	One alert per crossing of the threshold (re-armed after a refill).

Requirements

Functional

1. Several drink types, each with a **price** and a **recipe** (amount of each ingredient).
2. Show a **menu** with prices and availability.
3. Accept a selection and a **payment**; return **change**; refund in full if the drink cannot be made.
4. Track **ingredient inventory**; deduct exactly the recipe amounts per drink.
5. Raise **low-stock notifications** when an ingredient drops to its threshold.
6. Allow **refills**.
7. Support **customisation** (extra shot, sugar) without changing the menu.

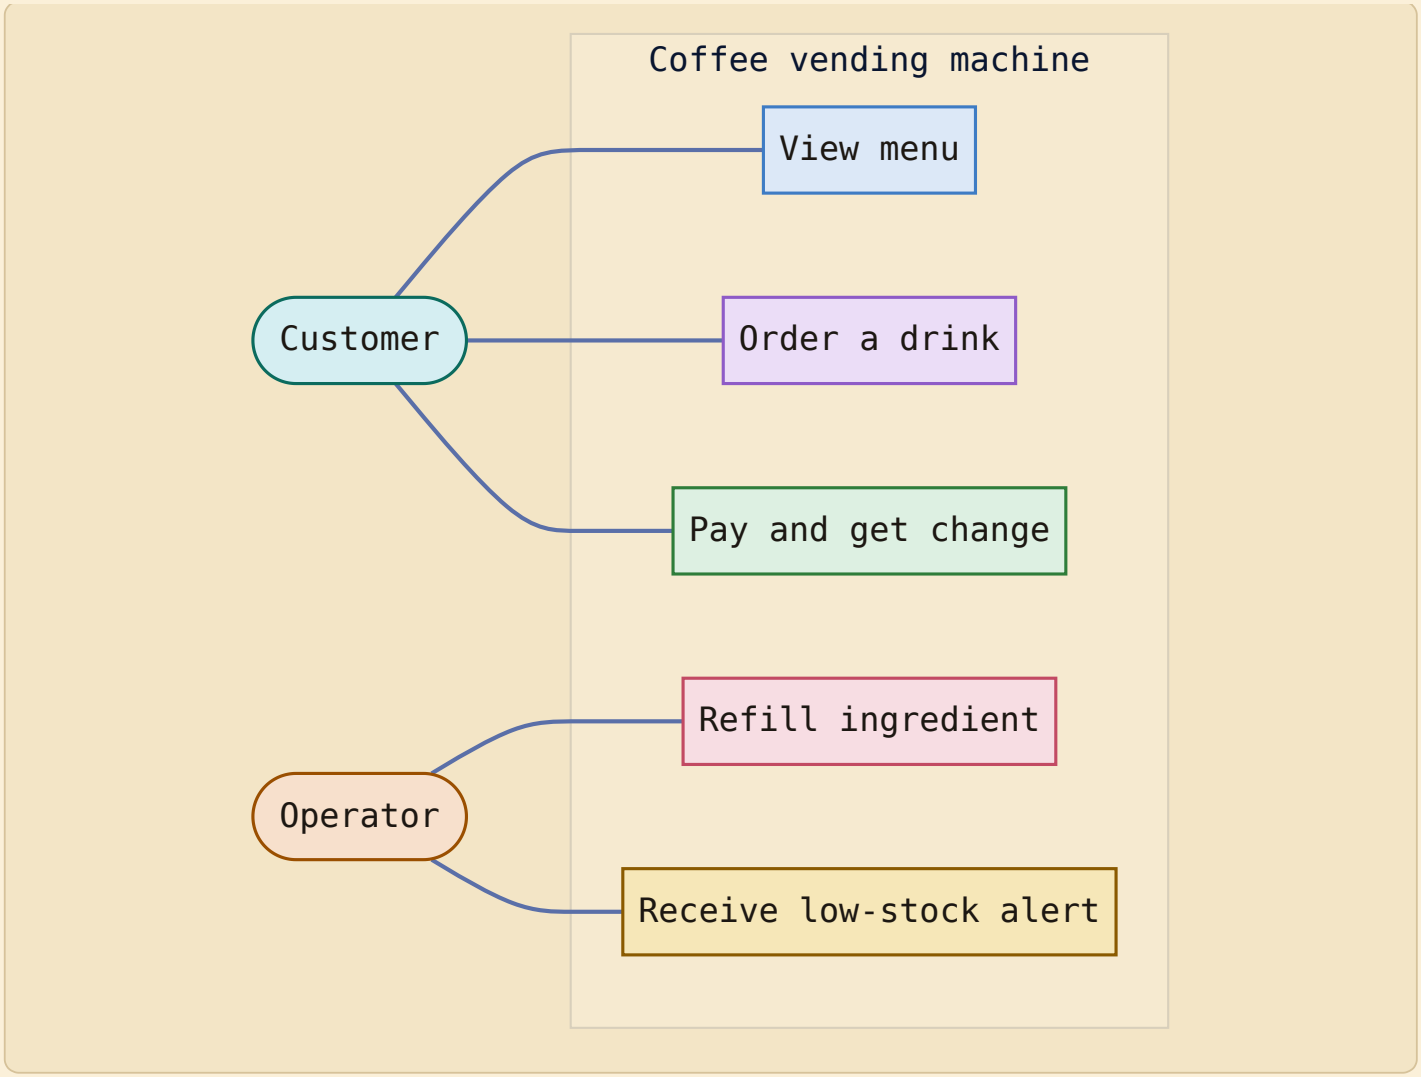
Non-functional

- **Thread-safe**: concurrent orders must never over-draw an ingredient or leave a half-deducted recipe.
- **Data-driven**: new drinks and recipe tweaks without code changes.
- **Observable**: operators, dashboards or a telemetry client can subscribe to alerts without the machine knowing about them.

Use cases

Actors: **Customer** (views menu, orders, pays, takes drink and change), **Operator** (refills, receives alerts), **System** (checks stock, deducts, brews, sends alerts).

Use cases: view menu · order drink (with customisation) · pay / get change / get refund · refill ingredient · receive low-stock alert.



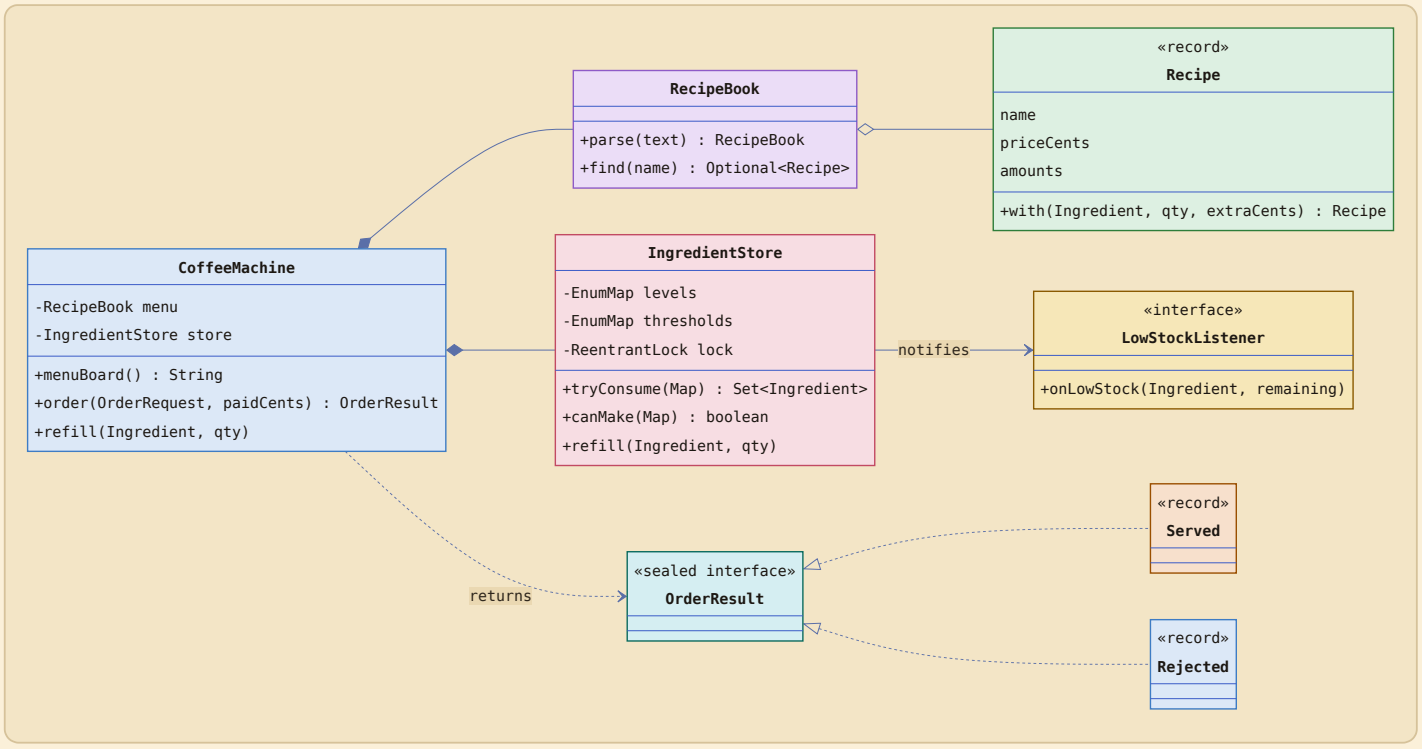
Core entities

Class	Responsibility
`Ingredient` (enum)	Beans, water, milk, chocolate, sugar — with the unit (g or ml).
`Recipe` (record)	**Data**: name, price, `Map<Ingredient, Integer>` amounts. Immutable (cannot change after creation). `with(...)` returns a customised copy.
`RecipeBook`	Parses the menu text into recipes; looks drinks up by name.
`IngredientStore`	Levels, thresholds, **one lock**; `tryConsume` = check all + deduct all atomically; alerts listeners.
`LowStockListener` (interface)	Observer called once when an ingredient crosses its threshold.
`OrderRequest` (record)	Drink name + extra shots + sugar grams.
`OrderResult` (sealed)	Either `Served(drink, price, change)` or `Rejected(reason, refund)`.
`CoffeeMachine`	Facade (one simple front object hiding the parts behind it): menu board, `order(...)`, `refill(...)`.

Mapping to the common problem statement. The widely used version of this problem (for example in the open-source *awesome-low-level-design* collection) asks for: several coffee types (espresso, cappuccino, latte) each with a price and a recipe, a menu with prices, selection and payment, dispensing with change, ingredient tracking with low-stock notifications, and thread-safe handling of concurrent requests. Its classes map onto ours as follows: `Coffee` (name, price, recipe) → our `Recipe`; `Ingredient` (name + quantity with `synchronized` update methods) → our `Ingredient` enum plus the levels inside `IngredientStore`; `Payment` (amount paid) → the `paidCents` argument and the change/refund in `OrderResult`; `CoffeeMachine` (a Singleton there) → our injected `CoffeeMachine`;

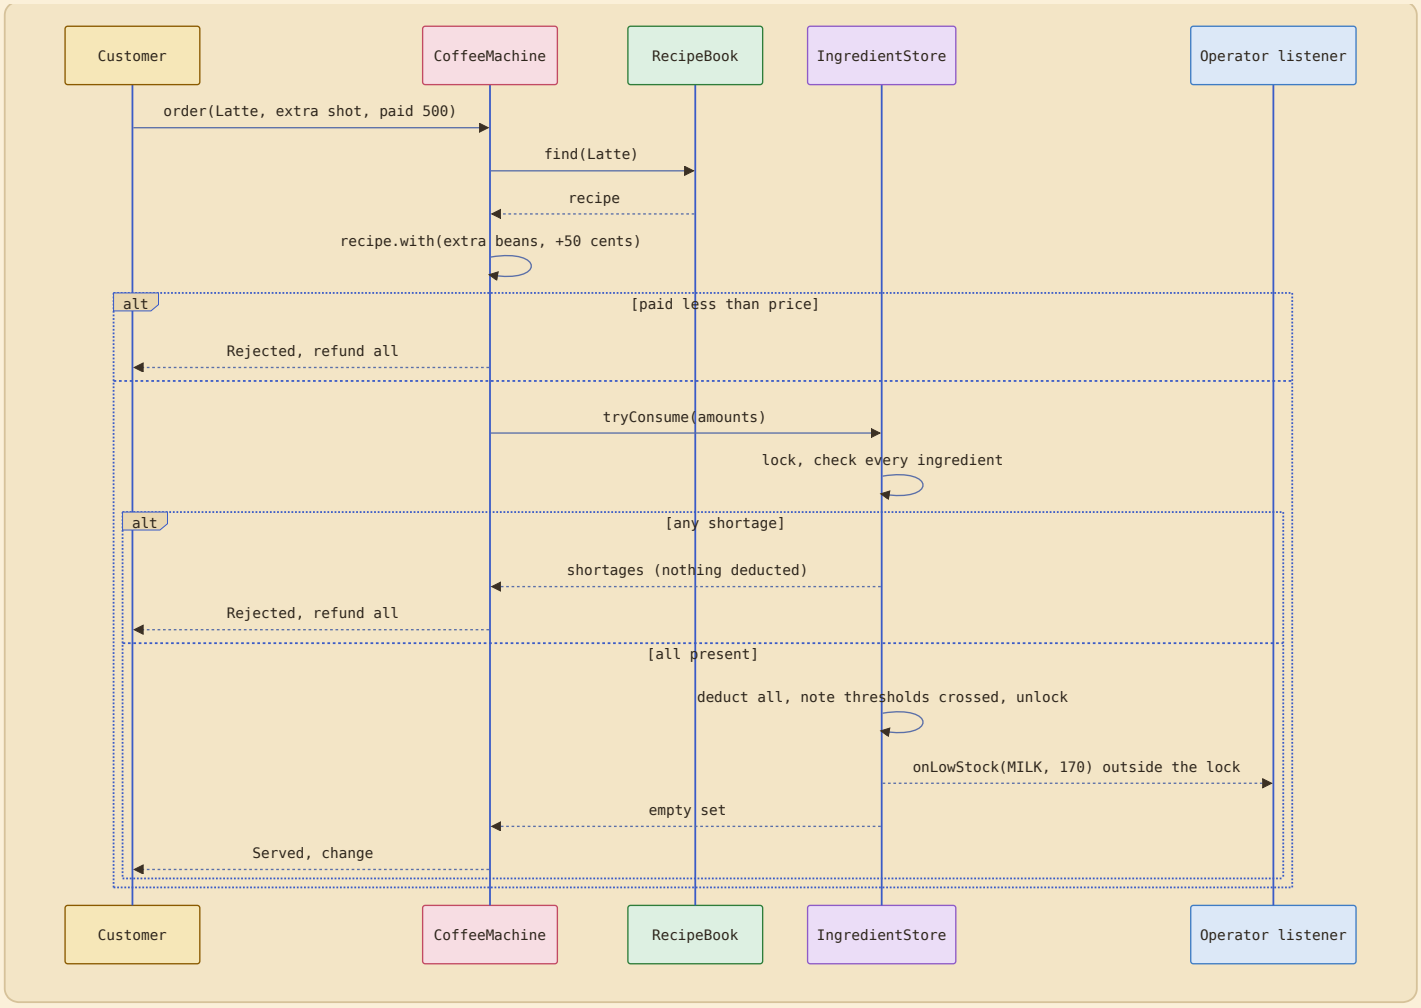
concurrent users simulated with an `ExecutorService` (a Java pool of worker threads that runs submitted tasks) → the 10-thread demo in our `Main`. Two deliberate differences: we lock the **whole recipe** rather than each ingredient separately (per-ingredient locking cannot make a multi-ingredient deduction all-or-nothing), and we avoid the Singleton (see the table below).

Class diagram

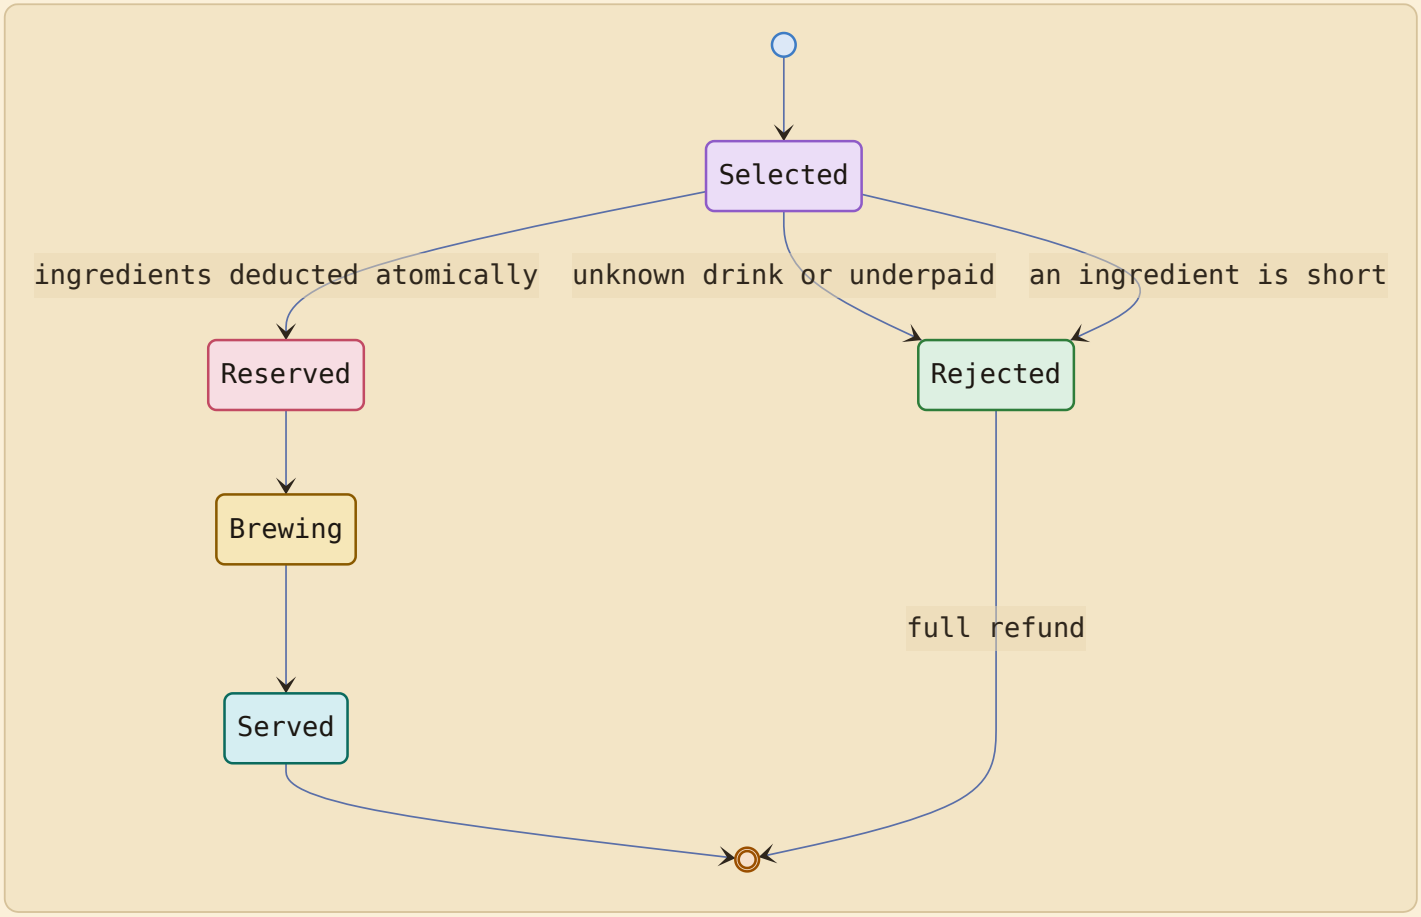


Key flows

Ordering a drink. The key point is that the stock check and the deduction happen **inside one critical section** (a piece of code that only one thread may run at a time), and alerts are sent **after** the lock is released.



Order life cycle.



Design decisions & patterns used

Decision	Pattern / principle	Why	Alternative rejected
Recipes are **data** parsed from a menu text	Data-driven design, Open/Closed	A new drink is a new line in the menu; no new class, no recompile of logic	One subclass per drink (`Latte extends Coffee`) — class explosion, and recipe tweaks need code changes
Check-and-deduct under **one lock**	Atomicity (Ch. 12)	Prevents two orders both seeing "enough milk" and both deducting (a check-then-act **race**: both check, then both act on an answer that is already stale)	Checking in one call and deducting in another; per-ingredient locks (a multi-ingredient recipe would need all of them, in order)
All-or-nothing	Transaction semantics (all steps take effect together, or none do)	Never leave a half-made recipe's ingredients missing	Deduct one by one and "roll back" on failure
Alerts via `LowStockListener`	**Observer**	Operator app, dashboard, telemetry can subscribe independently	The store calling a specific SMS class
Alert **once per crossing**, re-armed by refill	—	Prevents alert storms (one per drink)	Alerting on every order below threshold
Listeners called **outside** the lock	Concurrency hygiene	A slow listener (network call) must not block every order; it also avoids deadlocks (two threads each waiting forever for a lock the other holds) if a listener calls back into the store	Notifying inside the lock
Customisation returns a **new** immutable `Recipe`	Immutability	The menu recipe can never be corrupted by one order	Mutating the menu recipe; a Decorator chain (works, but heavier than needed for "extra X")
`OrderResult` is a **sealed** interface with records	Algebraic data type (a value that is exactly one of a fixed set of shapes; Java 17+ sealed, Java 21 pattern switch)	Callers must handle both Served and Rejected; `switch` is checked for exhaustiveness (the compiler complains if a case is missing)	Returning `null` or throwing for normal refusals
No Singleton	Dependency injection	The problem-set solutions often make `CoffeeMachine` a Singleton; we create one and pass it around, so tests can build fresh machines (the demo builds two)	`CoffeeMachine.getInstance()`

> **Decorator or data?** A classic textbook example (*Head First Design Patterns*) models coffee add-ons with the **Decorator** pattern: `new Whip(new Mocha(new DarkRoast()))`, each wrapper adding cost and description. That is a good fit when each add-on has **behaviour**. Here add-ons only change **quantities and price**, so a data change (`recipe.with(...)`) is simpler. Say both in the interview and pick one for a reason.

Java implementation

Package `lld.ch14.coffeemachine`.

```java

```
        }
        System.out.println("served=" + served + " rejected=" + rejected
                + " milk left=" + busy.level(Ingredient.MILK) + "ml (never negative)");
    }

    static void show(OrderResult r) {
        switch (r) {
            case Served s -> System.out.println("SERVED   %s for %d c, change %d c".formatted(s.drink(),
s.pricedCents(), s.changeCents()));
            case Rejected x -> System.out.println("REJECTED %s, refund %d c".formatted(x.reason(),
x.refundCents()));
        }
    }
}
```

How the code works, part by part

- `Main.MENU` is a Java text block (a multi-line string written between `"""` marks); `RecipeBook.parse` turns each line into a `Recipe`. Adding "Flat White" is one more line.
- `Recipe` copies the amounts into an unmodifiable `EnumMap` in its compact constructor (a record constructor written without a parameter list, used for checks and defensive copies), so a recipe can never be changed after creation.
- `IngredientStore.tryConsume` holds a `ReentrantLock` (an explicit lock object with `lock()` and `unlock()`; *re-entrant* means the thread already holding it may take it again) while it (1) collects shortages, (2) returns immediately if any, (3) deducts every ingredient, (4) records which thresholds were crossed. It releases the lock and **then** calls listeners.
- `alerted` is an `EnumSet` (a compact set of enum constants) that remembers which ingredients already raised an alert; `refill` clears the flag when the level goes back above the threshold.
- `CoffeeMachine.order` validates the drink, applies customisation, checks payment, then reserves ingredients. The `switch` in `Main.show` uses Java 21 pattern matching over the sealed `OrderResult`.

Output:

```
Menu:
  Espresso        250 c
  Americano       300 c
  Latte           400 c
  Cappuccino      380 c
  Mocha           450 c
  Hot Chocolate   300 c

== Orders ==
SERVED   Espresso for 250 c, change 50 c
SERVED   Latte for 450 c, change 50 c
REJECTED no such drink: Flat White, refund 400 c
REJECTED insufficient payment, need 450 c, refund 200 c
SERVED   Mocha for 450 c, change 0 c
   ALERT to operator: MILK low, 170ml left
   ALERT to operator: CHOCOLATE low, 5g left
SERVED   Hot Chocolate for 300 c, change 0 c
SERVED   Cappuccino for 380 c, change 20 c
REJECTED out of [MILK], refund 400 c
   beans left 410g (unchanged by the rejected latte)
Menu now:
  Espresso        250 c
  Americano       300 c
  Latte           400 c  (unavailable)
  Cappuccino      380 c  (unavailable)
  Mocha           450 c  (unavailable)
  Hot Chocolate   300 c  (unavailable)

== Operator refills milk ==
SERVED   Latte for 400 c, change 0 c

== 10 customers order a Latte at the same instant (milk for exactly 4) ==
   ALERT to operator: MILK low, 80ml left
served=4 rejected=6 milk left=80ml (never negative)
```

Read the output: the rejected latte left the beans at 410 g — nothing is deducted when any ingredient is short; the milk and chocolate alerts fire once each; in the last part ten threads order a latte at the same instant with milk for exactly four: four are served, six are refused, milk ends at 80 ml, never negative, and the alert fires exactly once.

Concurrency & edge cases

Situation	What could go wrong	How the design handles it
Ten concurrent orders, milk for four	Over-draw (negative stock) — classic check-then-act race	Check and deduct under one lock
Recipe needs several ingredients, one is short	Beans and water taken, milk missing	All-or-nothing: shortages are found before anything is deducted
Listener is slow (sends an SMS)	Every order waits on the network	Listeners run after `unlock()`
Many orders below the threshold	Alert storm	One alert per crossing; refill re-arms
Underpayment	Drink made, money short	Payment checked before reserving ingredients
Brewing fails after deduction (hardware fault)	Customer pays, gets nothing	Extension: refund and optionally `refill` the reserved amounts back (compensation: an action that undoes an earlier step)
Menu displays "available" and then the order fails	A race between display and order	The menu is advisory; `tryConsume` is the source of truth

A **single lock** is right here: the critical section is tiny (five map operations) and the machine brews one drink at a time anyway. If contention (many threads waiting for the same lock) mattered (a cloud-backed inventory shared by many machines), you would move to optimistic concurrency (work without a lock, then check at write

time that nobody changed the data, and retry if they did — e.g. version numbers / compare-and-set on a snapshot) or a database transaction (a group of database changes that succeed or fail together).

Extensions & follow-up questions

1. **"Add a new drink."** — Add one line to the menu data. No code change.
2. **"Sizes (small/medium/large)?"** — A `Size` enum with a multiplier; `recipe.scaled(size)` returns a new recipe with scaled amounts and price.
3. **"Several brewing units?"** — A pool of `Brewer` workers (a `BlockingQueue` — a thread-safe queue where a taker waits while it is empty — of orders consumed by N threads). Inventory stays in the one `IngredientStore`.
4. **"Remote monitoring?"** — Another `LowStockListener` that posts to a telemetry endpoint. The store does not change.
5. **"Brewing steps differ per drink (grind, tamp, steam milk)?"** — Template Method (a base class fixes the order of the steps and subclasses fill in some of them): a `BrewProcess` with fixed steps and hooks (optional steps a subclass may override), or a list of `Step` objects in the recipe data (Command).
6. **"Card payments and change?"** — Reuse the `CashBox` from 14.2 for cash; card payment is another payment device.

Real-world example

Professional espresso machines such as the Thermoplan Mastrena used in Starbucks stores store **drink recipes as configuration**, so a chain can roll out a new beverage without new hardware. Starbucks and Microsoft publicly described (in 2019) connecting store equipment, including espresso machines, to the cloud through Microsoft Azure Sphere, so that each shot's data is collected as telemetry and new recipes are pushed from the cloud instead of being carried to stores on USB drives — the "recipes as data" and "remote monitoring listener" ideas in this design. Many connected self-serve coffee kiosks also report stock levels remotely, so that a service visit is scheduled before the milk runs out — the low-stock Observer in this design.

In the interview

Plan for 40 minutes: 5 min questions → 5 min entities (ingredient, recipe, store, machine) → 5 min "recipes are data" and the menu format → 15 min code `tryConsume` (lock, all-or-nothing, alert outside the lock) and `order` → 10 min concurrency demo and extensions.

> **30-second answer:** "Recipes are data: a map from ingredient to amount, loaded from a menu, so a new drink is a new row. The ingredient store checks and deducts **every** ingredient of a recipe under one lock, so an order is all-or-nothing and stock never goes negative. When an ingredient crosses its threshold, the store notes it and, after releasing the lock, notifies observers once. Orders return a sealed Served/Rejected result, and a rejected order is refunded in full."

Follow-ups with answers

- *"Why not one class per drink?"* — Drinks differ only in data. Classes would multiply with every size and add-on (class explosion) and every recipe tweak would be a code change.
- *"Why not an `AtomicInteger` per ingredient?"* — Each atomic is safe alone, but a recipe updates several at once; without a common lock, two orders could each take the last milk and beans in different orders, leaving partial deductions.
- *"Why notify outside the lock?"* — A slow or re-entrant listener would block all orders or deadlock.

Self-check

1. **Q:** What does "all-or-nothing" mean for `tryConsume`? **A:** Either every ingredient of the recipe is deducted, or none is (shortages are detected first).
2. **Q:** What race does the single lock prevent? **A:** Check-then-act: two threads both see enough milk, then both deduct, going negative.
3. **Q:** How is an alert storm prevented? **A:** An `EnumSet` records ingredients already alerted; refill above the threshold re-arms them.
4. **Q:** Why is `Recipe.with` returning a new object important? **A:** Customising one order must not change the shared menu recipe.
5. **Q:** When would you use Decorator for add-ons? **A:** When add-ons carry behaviour (extra steps, special description or pricing logic), not just quantities.

TL;DR

- **Recipes are data** (`Map<Ingredient,Integer>` + price), parsed from a menu; customisation creates a new immutable recipe.
- **One lock, check-then-deduct, all-or-nothing**: stock never goes negative under concurrent orders.
- **Observer** for low-stock alerts, fired **once per crossing** and **outside** the lock.
- A **sealed** `OrderResult` makes callers handle Served and Rejected; refund in full on rejection.

14.4 Design an ATM

Figure — An automated teller machine with its card reader, keypad, screen, cash dispenser, deposit slot and printer (course diagram)

An **automated teller machine (ATM)** is a cashier-less machine, placed in a public spot, where a bank's customers can do everyday banking. It exists because branches keep limited hours and people cannot go to a branch every time they need cash or want to pay in money. The interviewer is checking whether you can keep **money correct** (never dispense without debiting, never debit without dispensing, never let two machines overdraw one account), **authenticate** before anything else, and model the machine's **session states** cleanly.

Problem & clarifying questions

Question	Assumed answer
Which transactions?	Balance inquiry, cash withdrawal, cash deposit, check deposit, transfer.
Which account types?	Checking and savings. Withdrawal is from checking (and savings within a daily cap).
How is the user identified?	ATM card + PIN (personal identification number, a short secret code). The card is the main security element.
Does the ATM talk to the bank?	Yes, on every transaction (assume the network is available).
Are deposits available at once?	A check is **not**: it waits for verification. We keep a *total* and an *available* balance.
Which notes are loaded?	$100, $50, $20, $10 cassettes.
Wrong PIN?	Three wrong attempts block the card and the ATM keeps it. The course lists PIN retry limits and card capture as deliberately left out, along with receipt-paper levels, an audit journal and other banks' networks; we add the first two and the journal.
How many customers at a time?	One per machine; the ATM must not shut down mid-session.

Requirements

Parts of the machine (from the course): **card reader** (reads the card), **keypad** (PIN, amounts), **screen** (messages; also used to pick a transaction), **cash dispenser**, **deposit slot** (cash or checks), **printer** (receipts), and a **network link** to the bank.

Functional

1. The customer inserts a card and enters a PIN; the ATM asks the **bank** to authenticate. No transaction is possible without authentication.
2. Five transactions: **balance inquiry** (each account), **deposit cash**, **deposit check**, **withdraw cash** (from checking), **transfer funds** to another account.
3. The ATM **keeps the card** for the whole session; the customer can **cancel** at any time and the card is ejected.
4. The ATM keeps an **internal log (journal)** of transactions, including hardware failures, for the operator to resolve issues.
5. A deposited **check is not added at once**: it waits for manual verification and bank approval. (The course assumes deposits in general are verified first; our code credits counted cash immediately and holds checks — see the trade-off below.)
6. The **bank manager** can see the ATM's system information (reports).

Actors' operations

- **Operator:** turn the ATM on/off with the key switch; refill cash; refill receipt paper and ink; take out deposited cash and checks.
- **Customer:** balance inquiry, withdraw, deposit (cash or check), transfer.
- **Bank manager:** reports of total deposits and total withdrawals; print them; check the cash remaining in the ATM.

Non-functional

- **Security:** PINs never stored or compared in clear on the ATM; limit PIN attempts.
- **Consistency:** debit and dispense happen together or not at all (compensate on failure).
- **Concurrency:** many ATMs act on the same account at once without overdrawing it or deadlocking.
- **Auditability** (every action can be traced afterwards)**:** every action is journaled.

Use cases

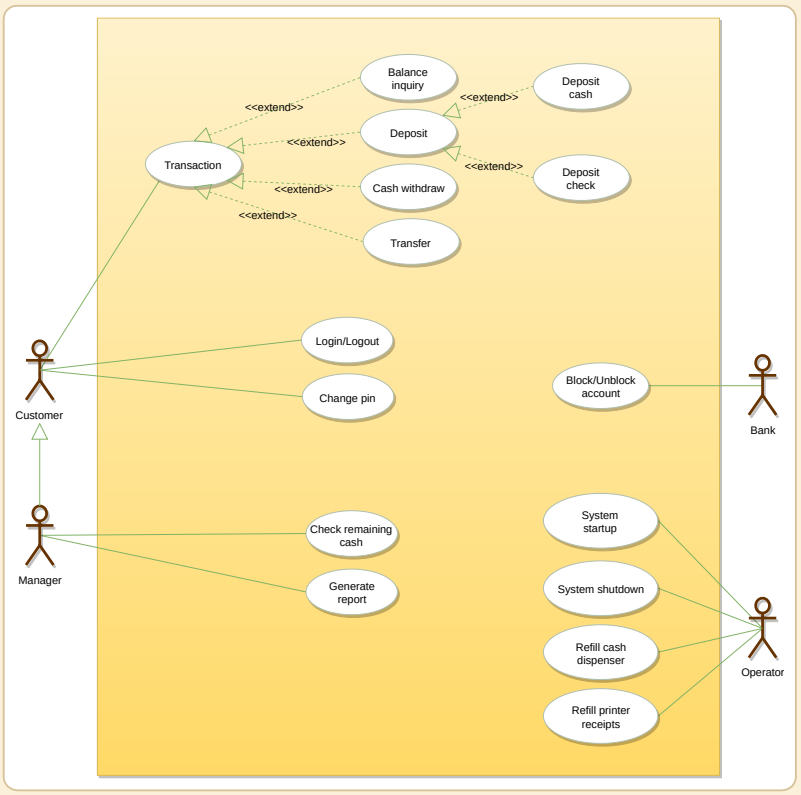

Figure — ATM use case diagram: Customer (balance, withdraw, deposit, transfer), Operator (on/off, refill cash, paper, ink, empty deposits) and Bank Manager (reports, check remaining cash) (course diagram)

The figure above shows three actors. Only the Customer's use cases go through PIN authentication; the Operator works with a physical key and the Bank Manager reads data held at the bank.

Customer authentication is the entry point of every session:

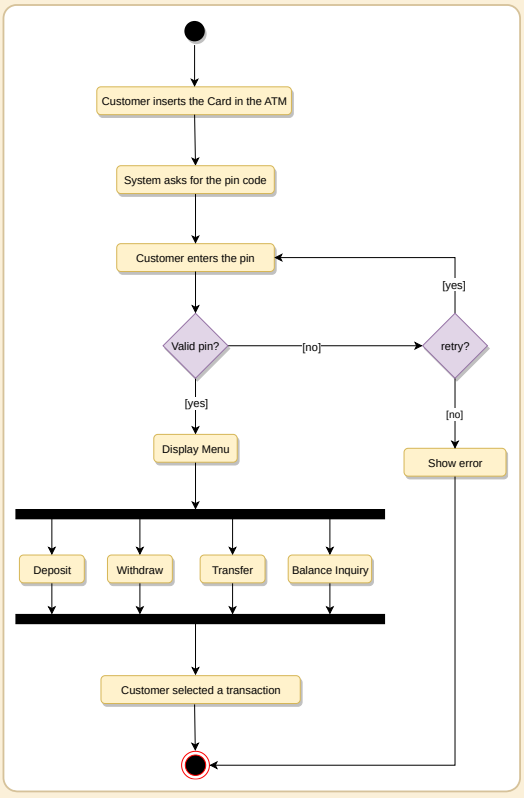

Figure — Activity diagram: insert card, the system asks for the PIN, the customer enters it; an invalid PIN shows an error and offers a retry; a valid PIN displays the menu (balance inquiry, deposit, withdraw, transfer) (course diagram)

Withdraw:

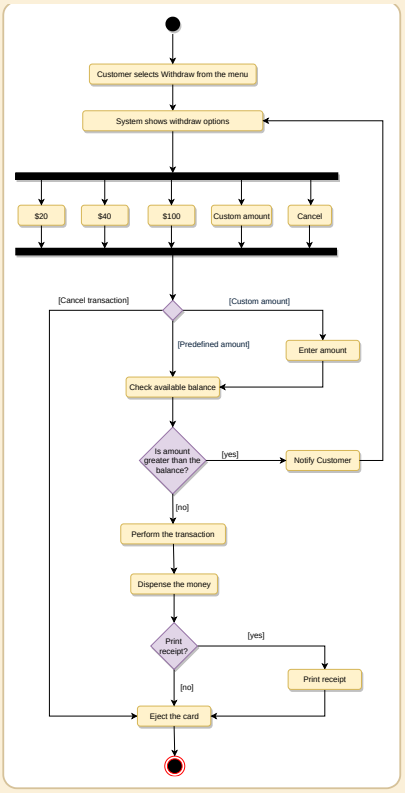

Figure — Activity diagram: choose Withdraw, pick a predefined amount ($20, $40, $100) or enter a custom one, check the available balance (notify the customer if the amount is greater), perform the transaction, dispense, optional receipt, eject the card (course diagram)

Deposit check:

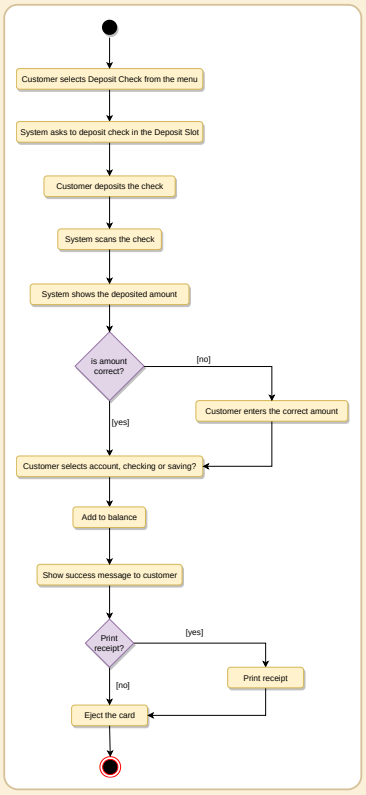

Figure — Activity diagram: choose Deposit Check, pick checking or savings, put the check in the deposit slot, the system scans it and shows the amount; if wrong the customer enters the correct amount; the amount is added, a success message and optional receipt follow, and the card is ejected (course diagram)

Transfer:

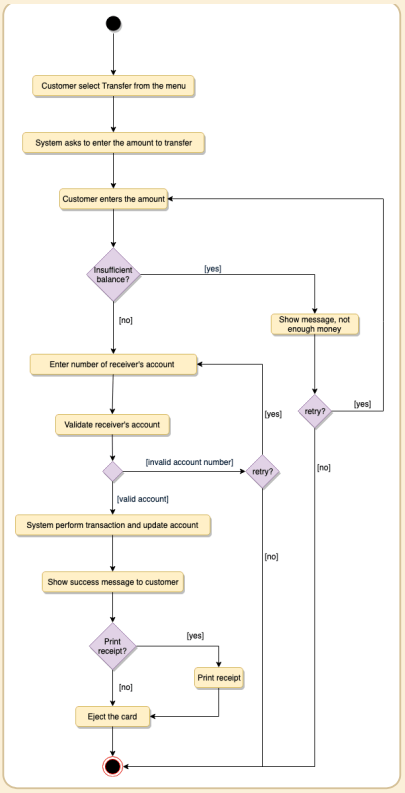

Figure — Activity diagram: enter the amount (retry if balance is insufficient), enter and validate the receiver's account (retry if invalid), perform the transfer, show success, optional receipt, eject card (course diagram)

In the transfer diagram above, note the two retry loops: one for "insufficient balance" and one for "invalid account number". If the customer declines to retry, the diagram goes straight to the end node without the "Eject the card" step; in a real design every exit path must still return the card, which is exactly the card-reader rule in stage 2 below.

Core entities

Class	Responsibility
`Card` (record)	Card number and holder name. (The course also has a `Customer` class with name and email, owning exactly one card; our code folds the holder's name into the card.)
`Account` (abstract)	Id, **total** and **available** balance, a lock; the withdrawal rule hook.
`CheckingAccount`, `SavingsAccount`	Savings overrides the rule to add a **daily withdrawal cap** — the only behavioural difference, which is why they are two classes.
`BankService` (interface)	What the ATM needs from the bank: authenticate, balances, withdraw, reverse, deposits, transfer.
`InMemoryBank`	A stand-in bank: PIN hashes (one-way fingerprints of PINs), failed-attempt counts, account locks, ordered-lock transfers.
`AuthResult` (sealed)	`Ok(accounts)`, `WrongPin(attemptsLeft)` or `Blocked`.
`NoteHandler` + 4 subclasses	**Chain of Responsibility** for $100 → $50 → $20 → $10.
`CashDispenser`	Plans a withdrawal from the chain (dry run: a trial that changes nothing), then dispenses; can jam (fault injection: a deliberately triggered failure, for testing).
`Transaction` (sealed) + 5 records	**Command**: each transaction has one `execute(ctx)`; its rules live only there.
`AtmState` + 4 states	**State**: Idle → CardInserted → Authenticated → Idle, plus OutOfService.
`Atm`	Has an id (the course also gives it a location); owns its parts, holds the session, forwards buttons to the state, keeps the journal.
`CardReader`, `Keypad`, `Screen`, `Printer`, `DepositSlot` (cash / check)	The course's hardware classes. Our code folds them into `Atm`: the `card` field is the reader's slot, `screen(...)` is the screen, the method arguments are the keypad, and printing a receipt would format a journal line.

Class diagram

The course builds the ATM in four stages:

Stage	What it adds	What works after it
1	`Customer`, `Card`, `Account` (checking, savings)	Verify a PIN and read a balance
2	Card reader, dispenser, keypad, screen, printer, deposit slots	Work out and count out a set of notes
3	`Transaction` and its five kinds	Move money, with each rule written in exactly one class
4	`Bank` and `ATM`	Run a full session for a single customer at a time

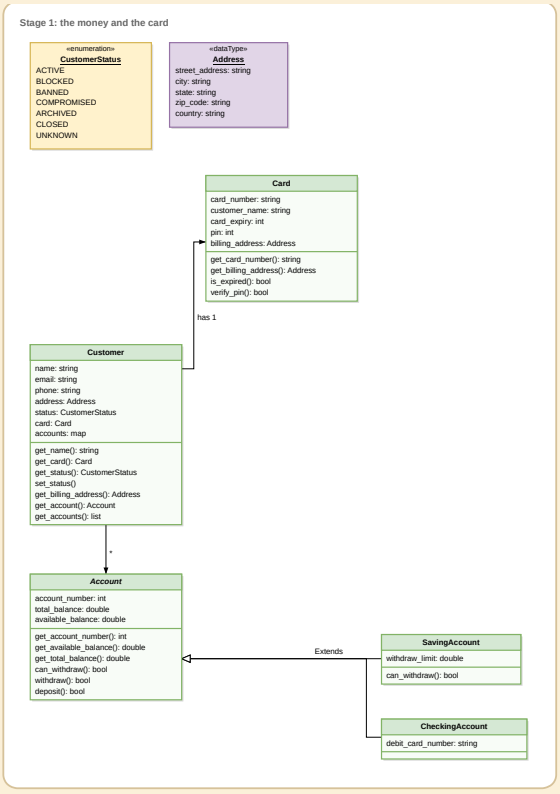

Figure — Stage 1: enumerations, Customer, Card and the abstract Account with Checking and Saving subclasses (course diagram)

Stage 1 — money and card. An account keeps **two balances**. The *total balance* is everything credited to it; the *available balance* is the part the customer may spend right now. A check deposit is the moment they diverge: the check raises the total at once, but the money becomes available only after the check clears. `Account` is abstract with `CheckingAccount` and `SavingsAccount` beneath it; savings overrides a single method to impose its withdrawal cap, and because that is a difference in **behaviour** (not just data) inheritance is justified here instead of a type field. `Customer` (name, email; each customer has **one** card) is linked to its card and accounts by plain associations, since none of them is deleted along with another.

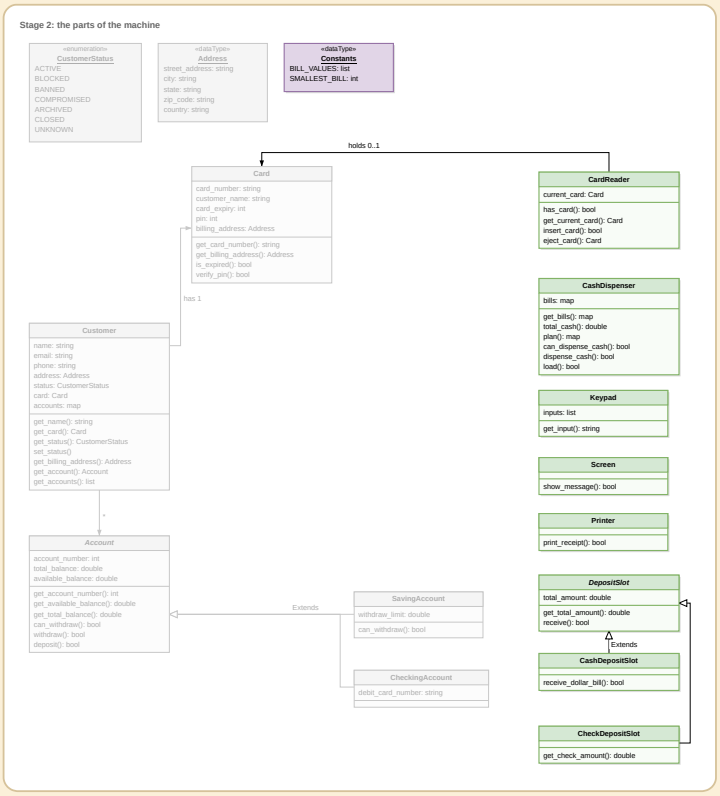

Figure — Stage 2: CardReader, CashDispenser, Keypad, Screen, Printer and the abstract DepositSlot with cash and check slots (course diagram)

Stage 2 — the parts. Six of the seven hardware parts become one class each (the seventh, the network link, is assumed rather than modelled), and none of them knows what a transaction is. Deciding whether an amount (say $85) can be paid from the notes **currently loaded** belongs to the **dispenser**, not to the withdrawal logic; it tries the largest note first and reports failure when the exact amount is impossible. The card reader has one rule of its own: it **keeps the card for the whole session** and releases it when the session ends, so every failed sign-in path must eject (or retain) the card before it returns; the reader's link to `Card` is the only arrow leaving this stage. `DepositSlot` is abstract, with a cash slot and a check slot below it. It is the physical opening money is pushed into; do not confuse it with the deposit *transaction* of stage 3.

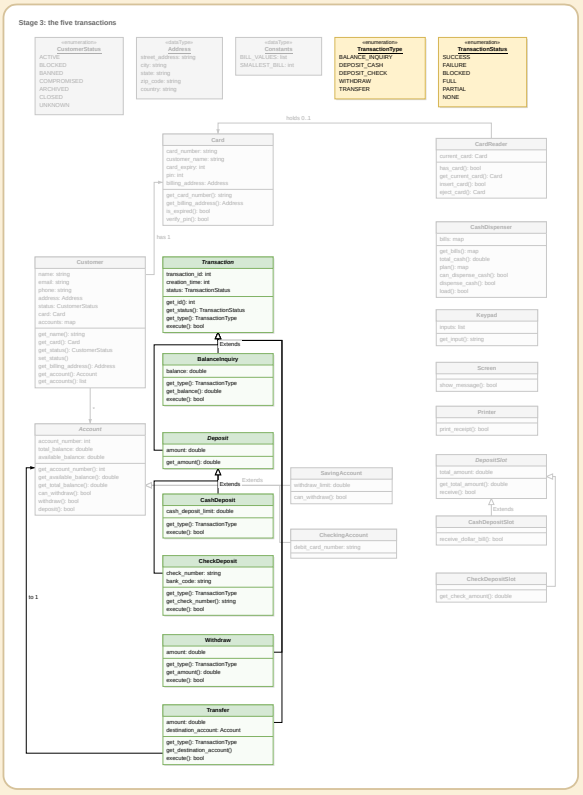

Figure — Stage 3: the abstract Transaction with BalanceInquiry, Deposit (CashDeposit, CheckDeposit), Withdraw and Transfer (course diagram)

Stage 3 — the five transactions. Every transaction type is a class with a single `execute` method, so each rule has exactly one home: nothing outside `Withdraw` needs to know the withdrawal rules. `Deposit` is an intermediate class: cash and check deposits share an amount but differ in when the money becomes spendable. `Transfer` is the only transaction with an outgoing arrow, to the destination account. Inside the course's `Withdraw`, the checks run in this order: **note denominations** first, then the **account**, then the **dispenser**, and the account is debited

only once the notes have been counted out. The reason for that order: if you take the money from the account first and the dispensing then fails, the customer has paid for cash they never received.

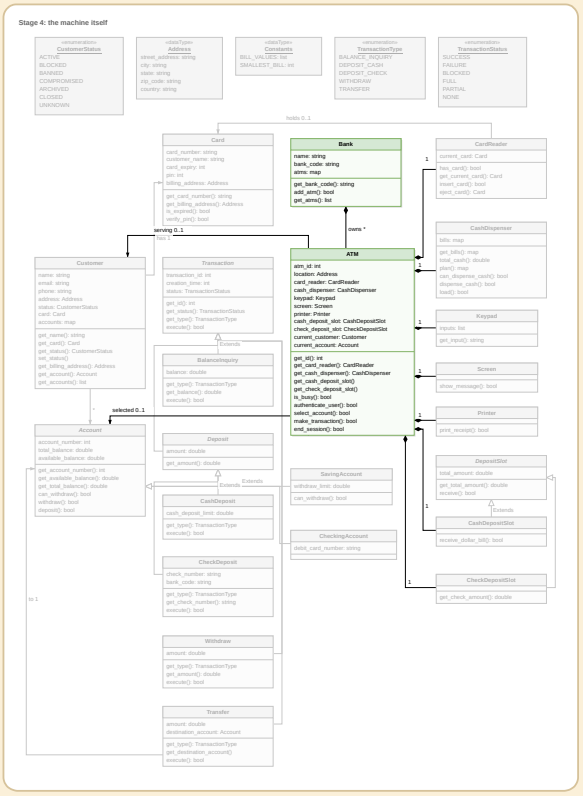

Figure — Stage 4: the ATM owns its parts (composition), refers to the current Customer and Account, and the Bank owns its ATMs (course diagram)

Stage 4 — the machine. The ATM has an **id** (`atmID`) and a **location**, and it **owns** its parts through composition: if the machine is scrapped, its reader, dispenser and screen go with it. Its links to the current `Customer` and `Account` are plain associations that change with each person at the machine. Because the ATM itself holds the current session, "one customer at a time" is enforced by the structure, not just promised in a comment. The `Bank` owns its ATMs and holds all account data; the ATM asks the bank to carry out every customer transaction.

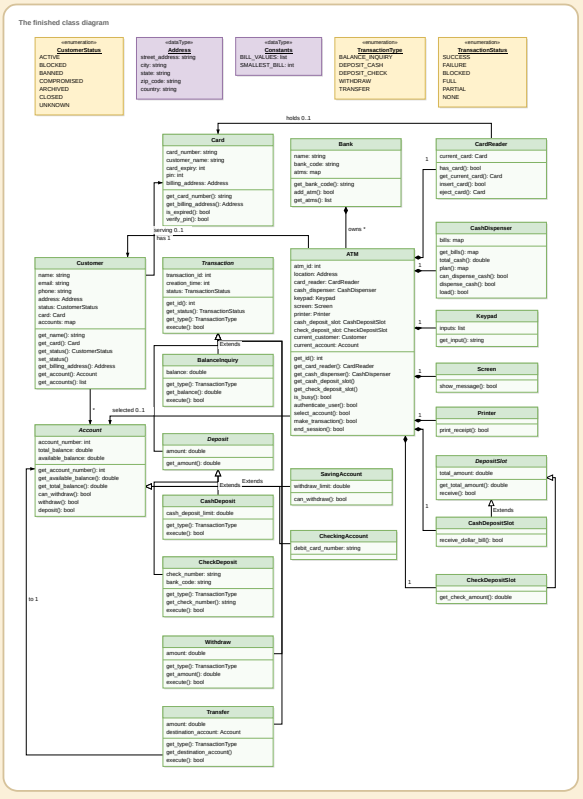

Figure — The finished class diagram of the ATM system (course diagram)

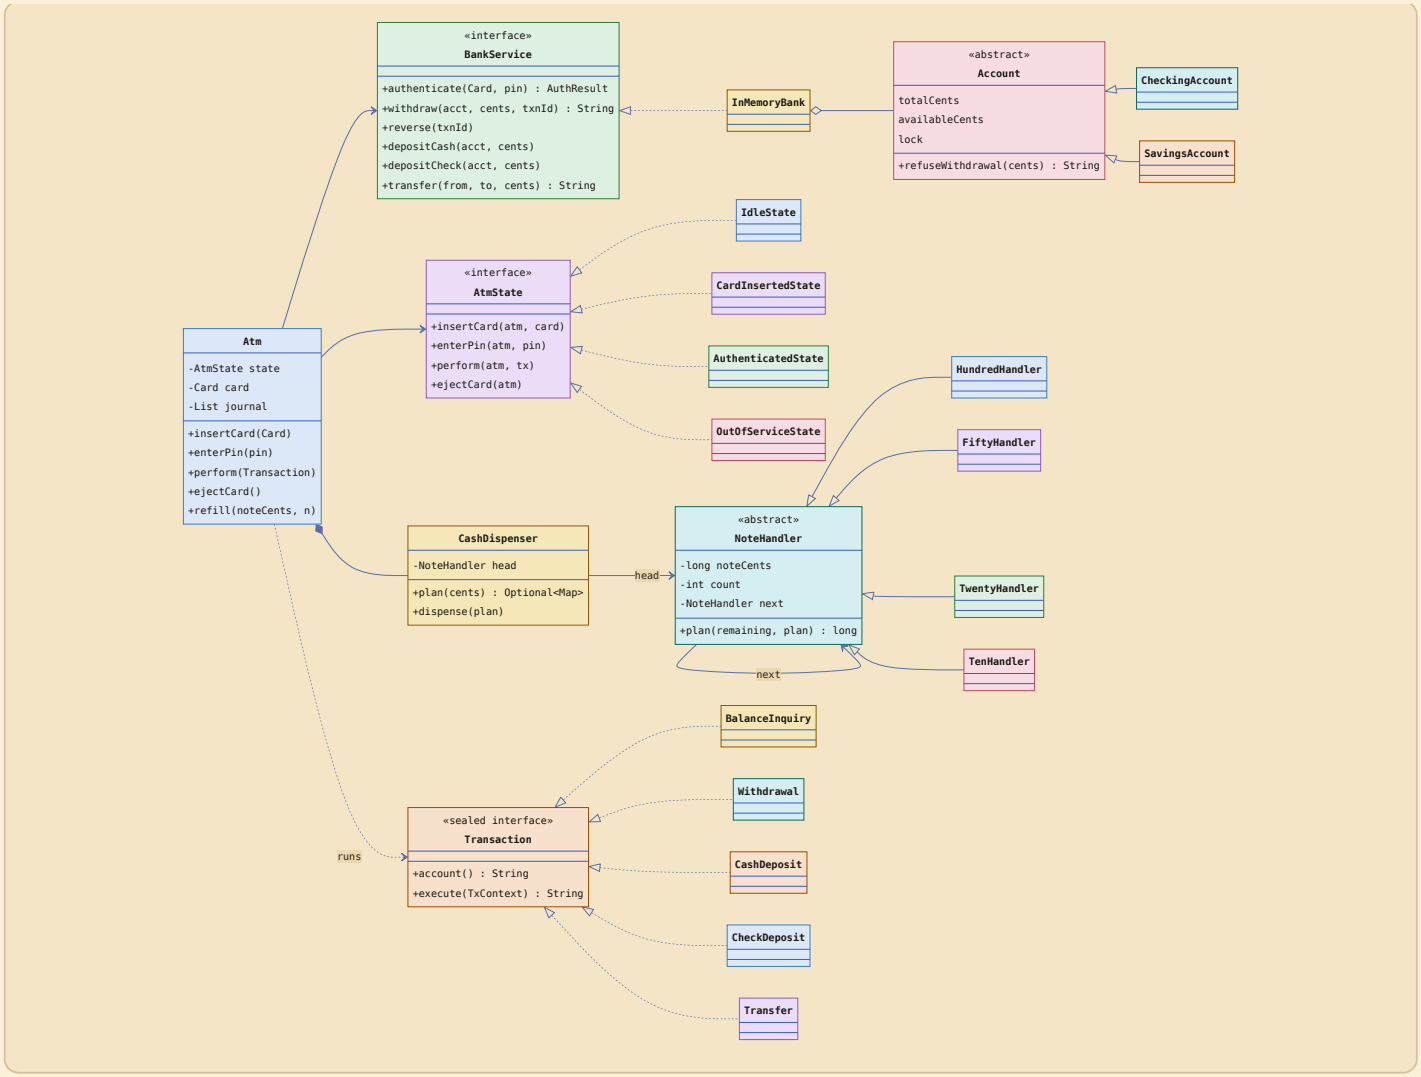
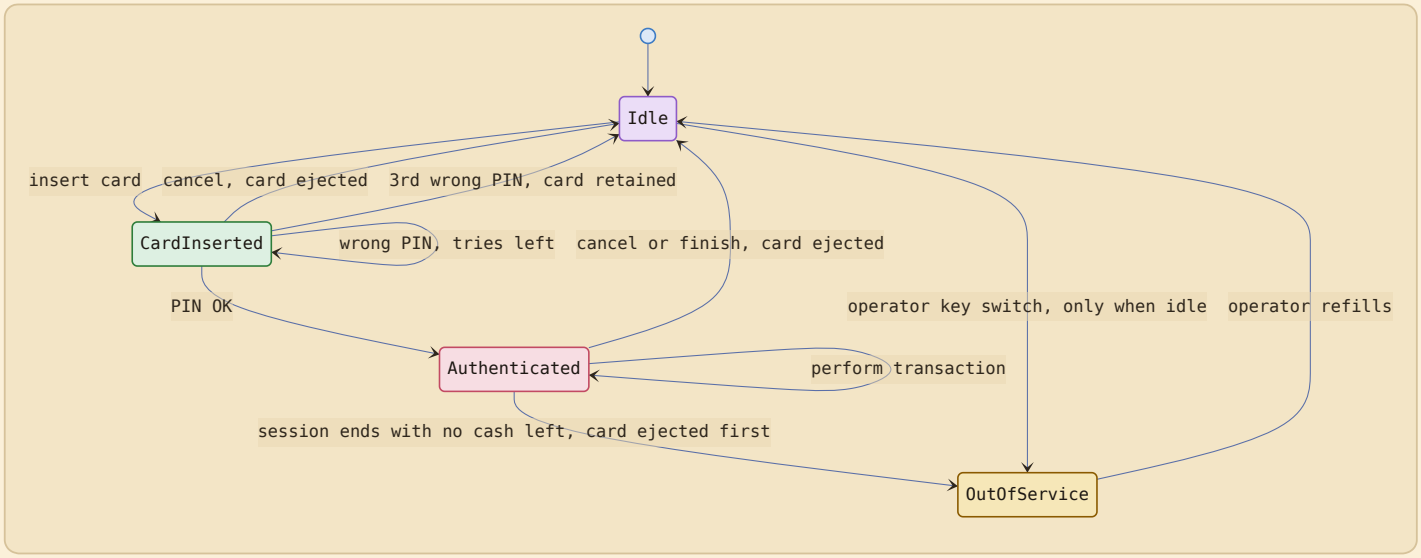
Class diagram of **our Java code**:



Key flows

Session states.



Balance inquiry (the course's sequence diagram):

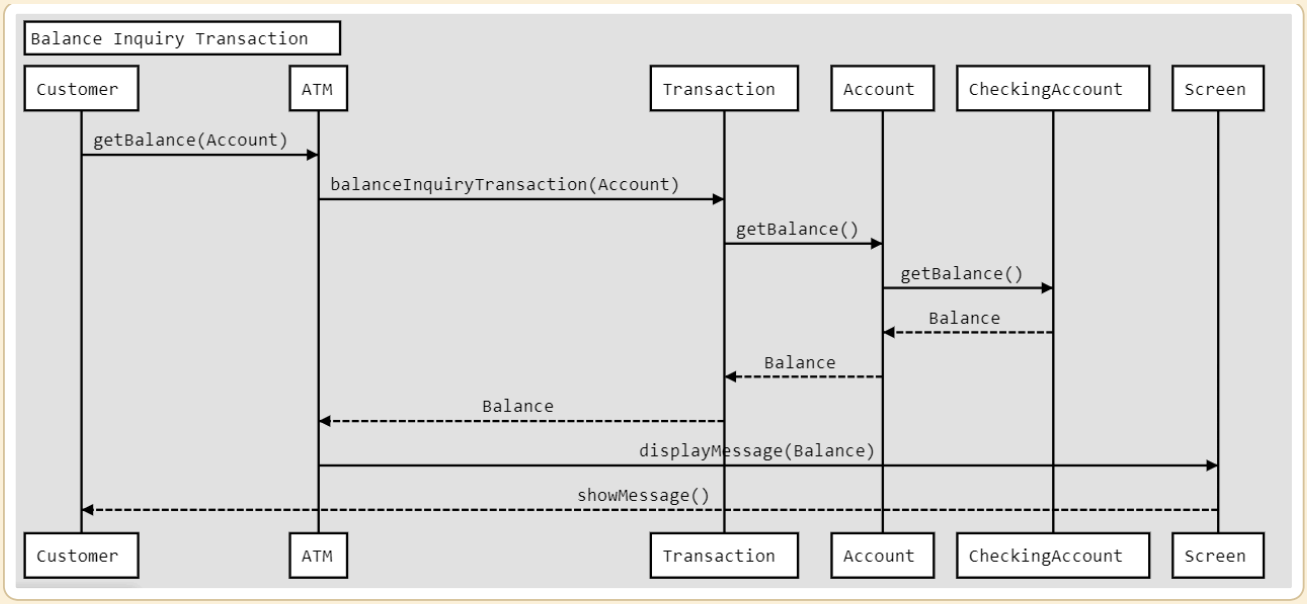


Figure — Sequence diagram of a balance inquiry: Customer → ATM → Transaction → Account → CheckingAccount, and the balance travels back to the Screen (course diagram)

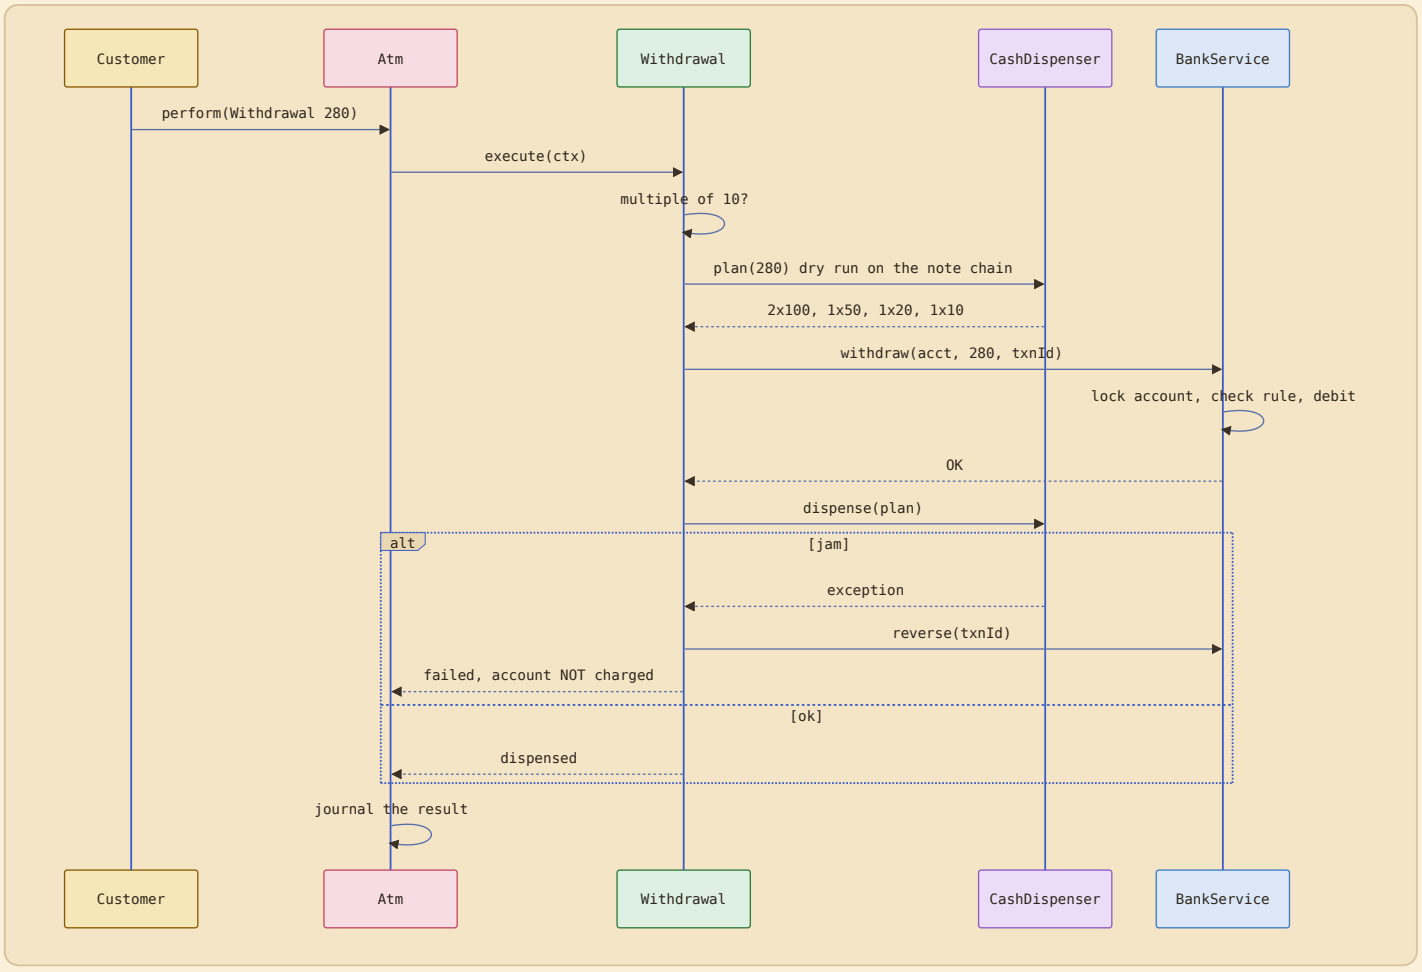
In the sequence above, the ATM never reads the balance itself: it creates a transaction, the transaction asks the account, and the result is shown on the screen.

Withdrawal with compensation (our code):



Design decisions & patterns used

Decision	Pattern	Why	Alternative rejected
Session flow as state classes	**State**	Insert-card/enter-PIN/perform/eject each mean something different per state; e.g. `perform` in Idle is simply refused	Booleans `cardInserted`, `authenticated` and nested `if`s
Dispenser as a chain of note handlers	**Chain of Responsibility**	Each handler takes what it can and passes the rest on; adding a $5 cassette is one new handler linked into the chain	One method with a hard-coded list of notes
Plan first, then dispense	—	The chain's dry run touches nothing; a failed plan leaves the cassettes intact	Removing notes while searching
Each transaction = one class with `execute`	**Command**	The rules of each transaction live in one place; transactions can be journaled, queued or replayed	A big `switch (type)` in the ATM
`Transaction` and `AuthResult` are **sealed**	Java 17+ sealed types	The compiler knows the full list; `switch` over `AuthResult` is exhaustive	Open hierarchies with `instanceof` chains
ATM talks to a `BankService` interface	Dependency Inversion (depend on an interface, not on a concrete class)	The ATM does not care whether the bank is in-memory, ISO 8583 (the standard card-payment message format) over a network, or a test fake	ATM changes balances directly
Total vs available balance	Domain modelling	Makes the check-hold rule correct, not merely convenient	A single balance
Savings is a subclass	Inheritance for **behaviour**	Its withdrawal rule differs (daily cap), so it overrides one hook	A `type` field and `if (type == SAVINGS)`

> **Debit before or after dispensing?** The course debits **after** the notes are counted out — the safer order for the customer — and admits the weakness: a crash between the two leaves the bank short. Our code does the opposite (debit, then dispense) and adds a **compensating action**: if the dispenser jams, `reverse(txnId)` puts the money back. Both are simplifications of what real systems do: make the pair atomic (a hold/authorisation, then a confirmation after dispensing), and **reconcile** (compare two sets of records afterwards and fix any difference) from the ATM's journal when something goes wrong in between. Say this out loud — it is the "power fails halfway through" follow-up.

> **Cash deposits.** The course assumes all deposits are verified before they count. Many banks make cash that the machine itself has counted available immediately (or up to a limit) and hold checks. Our `depositCash` credits both balances and `depositCheck` credits only the total; changing the policy is a one-line change in the bank, not the ATM.

Java implementation

Package `lld.ch14.atm`. Amounts are cents (`long`); notes are $100/$50/$20/$10.

```java
// File: lld/ch14/atm/Bank.java
package lld.ch14.atm;

import java.nio.charset.StandardCharsets;
import java.security.MessageDigest;
import java.security.NoSuchAlgorithmException;
import java.util.HexFormat;
import java.util.List;
import java.util.Map;
import java.util.concurrent.ConcurrentHashMap;
import java.util.concurrent.locks.ReentrantLock;

final class Money {
    private Money() {}
    static String fmt(long cents) { return "$%d.%02d".formatted(cents / 100, cents % 100); }
}

/** Total = everything credited. Available = what can be spent now (a check has not cleared yet). */
abstract class Account {
    final String id;
    final ReentrantLock lock = new ReentrantLock();   // one lock per account, shared by every ATM
    long totalCents;
    long availableCents;

    Account(String id, long openingCents) {
        this.id = id;
        this.totalCents = openingCents;
        this.availableCents = openingCents;
    }

    /** Hook that subclasses refine. Called with the lock held. Returns null if allowed, else the reason. */
    String refuseWithdrawal(long cents) {
        return cents > availableCents ? "insufficient funds" : null;
    }

    void recordWithdrawal(long cents) {}

        branch.perform(new Withdrawal("CHK-1", 180_00));  // takes every note in ATM-9
        System.out.println("   state after the last notes: " + branch.stateName() + " (card still inside)");
        branch.ejectCard();
        System.out.println("   state after the session: " + branch.stateName());
        branch.insertCard(alice);
        branch.refill(20_00, 10);
        System.out.println("   state after refill: " + branch.stateName() + ", cash " +
Money.fmt(branch.cashLeft()));

        System.out.println("\n== Journal of ATM-7 (for the operator and bank manager) ==");
        atm.journal().forEach(l -> System.out.println("   " + l));
    }
}
```

How the code works, part by part

- **PIN handling:** the bank stores a SHA-256 hash (a standard one-way function that turns any input into a fixed-length fingerprint that cannot practically be reversed) of card+PIN and counts failures; the third failure returns `Blocked` and the ATM **retains** the card. (The course's code compares the PIN inside `Card` and flags that as a simplification. Real banks never see the clear PIN: the PIN pad encrypts it into a PIN block and a hardware security module (HSM) verifies it. A plain hash of a 4-digit PIN is also easy to brute-force (try every possible value until one matches), which is one more reason it is demo-only.)
- **Account locks:** each `Account` has its own `ReentrantLock`, shared by every ATM. `withdraw` does check-and-debit under that lock, so two ATMs cannot both spend the same $500.
- **Transfers** lock both accounts in **id order**. Two opposite transfers (A→B and B→A) therefore always lock in the same order and cannot deadlock (Chapter 13).
- **Chain of Responsibility:** `HundredHandler → FiftyHandler → TwentyHandler → TenHandler`. `plan` fills a map and returns the uncovered remainder; `take` removes the planned notes.
- **Command:** each transaction record has `execute(TxContext)`. `AuthenticatedState.perform` first checks the transaction's account belongs to this card.
- **Journal:** the `Atm` logs card in/out, retained cards, every transaction result, operator actions and "cash empty".
- **Out of service:** `finishSession` (called after every eject or retain) chooses Idle or OutOfService, so the machine never changes to OutOfService while a card is still inside. The operator's key switch (`setOutOfService`) is refused during a session.
- **Input checks:** the bank refuses transfers and deposits of zero or negative amounts.

Output:

```
Cash loaded: $430.00

== Alice: wrong PIN, then right PIN ==
   [ATM-7 screen] Please sign in first.
   [ATM-7 screen] Hello Alice. Enter PIN.
   [ATM-7 screen] Wrong PIN. Tries left: 2
   [ATM-7 screen] PIN OK. Accounts: [CHK-1, SAV-1]
   [ATM-7 screen] Balance CHK-1: available $1000.00, total $1000.00
   [ATM-7 screen] Dispensed $280.00 as 2x$100 + 1x$50 + 1x$20 + 1x$10
   [ATM-7 screen] Withdrawal refused: amount must be a multiple of $10
   [ATM-7 screen] Withdrawal refused: savings daily limit $100.00
   [ATM-7 screen] Check $500.00 received: on hold until the bank clears it
   [ATM-7 screen] Balance CHK-1: available $720.00, total $1220.00
   [ATM-7 screen] Transferred $150.00 to CHK-2
   [ATM-7 screen] Account CHK-2 is not linked to this card.
   (dispenser jams on the next withdrawal)
   [ATM-7 screen] Withdrawal failed (note jam), account NOT charged
   [ATM-7 screen] Balance CHK-1: available $720.00, total $1220.00
   [ATM-7 screen] Card ejected. Goodbye.

== Bank clears the check overnight ==
   CHK-1 available now $1220.00

== Bob forgets his PIN three times ==
   [ATM-7 screen] Hello Bob. Enter PIN.
   [ATM-7 screen] Wrong PIN. Tries left: 2
   [ATM-7 screen] Wrong PIN. Tries left: 1
   [ATM-7 screen] Too many wrong PINs. Card retained. Contact your bank.
   [ATM-9 screen] Hello Bob. Enter PIN.
   [ATM-9 screen] Too many wrong PINs. Card retained. Contact your bank.

== Two ATMs, one account, same instant: $300 each from $500 ==
   cash handed out $300.00, JOINT left $200.00

== 2,000 opposite transfers in parallel (ordered locking: no deadlock) ==
   successful=2000, A+B=$2000.00

== ATM-9 runs out of cash; the operator refills it ==
   [ATM-9 screen] Hello Alice. Enter PIN.
   [ATM-9 screen] PIN OK. Accounts: [CHK-1, SAV-1]
   operator key switch mid-session accepted? false
   [ATM-9 screen] Dispensed $180.00 as 1x$100 + 1x$50 + 1x$20 + 1x$10
   state after the last notes: AUTHENTICATED (card still inside)
   [ATM-9 screen] Card ejected. Goodbye.
   state after the session: OUT_OF_SERVICE
   [ATM-9 screen] Out of service. Card returned.
   state after refill: IDLE, cash $200.00

== Journal of ATM-7 (for the operator and bank manager) ==
   card in ****1111
   ATM-7-1 BalanceInquiry: Balance CHK-1: available $1000.00, total $1000.00
   ATM-7-2 Withdrawal: Dispensed $280.00 as 2x$100 + 1x$50 + 1x$20 + 1x$10
   ATM-7-3 Withdrawal: Withdrawal refused: amount must be a multiple of $10
   ATM-7-4 Withdrawal: Withdrawal refused: savings daily limit $100.00
   ATM-7-5 CheckDeposit: Check $500.00 received: on hold until the bank clears it
   ATM-7-6 BalanceInquiry: Balance CHK-1: available $720.00, total $1220.00
   ATM-7-7 Transfer: Transferred $150.00 to CHK-2
   ATM-7-8 Withdrawal: Withdrawal failed (note jam), account NOT charged
   ATM-7-9 BalanceInquiry: Balance CHK-1: available $720.00, total $1220.00
   card out ****1111
   card in ****2222
   card RETAINED ****2222
```

Read the output: $280 comes out as 2×$100 + $50 + $20 + $10; $85 is refused (not a multiple of $10); the savings cap refuses $140; after the $500 check, *total* grows but *available* does not until the bank clears it; the jam leaves the balance unchanged; Bob's card is blocked at the bank, so even another ATM refuses the right PIN; two ATMs racing on a $500 joint account (one account shared by two people) hand out only $300; 2,000 opposite

transfers finish with no deadlock and the total conserved; ATM-9 refuses the key switch mid-session, pays out its last $180, ejects the card, and only then goes out of service until the operator refills it.

Concurrency & edge cases

Situation	Risk	Handling
Two ATMs withdraw from one account at once	Overdraft (check-then-act race)	Check and debit under the **account lock** at the bank
A→B and B→A transfers at once	**Deadlock** (each holds one lock, waits for the other)	Lock in a global order (account id)
Dispenser jams after the debit	Customer charged, no cash	Compensating `reverse(txnId)`; journal entry for reconciliation
Amount not makeable from loaded notes	Partial dispense	Dry-run `plan` first; refuse before touching the bank
Greedy chain misses a combination	e.g. $60 with one $50 and three $20 but no $10: greedy takes $50, then cannot make $10, though 3×$20 works	Acceptable for standard cassettes; mention a DP planner (as in 14.2) if asked
Wrong PIN many times	Brute force	3 tries, then block at the bank (so another ATM also refuses) and retain the card
Customer walks away mid-session	Next person uses the open session	Session timeout that ejects/retains the card (extension)
Transaction on an account not linked to the card	Unauthorised access	`AuthenticatedState` checks `sessionAccounts`
Cash runs out	Customer's card trapped, or the next customer gets refused mid-session	The session finishes normally (card ejected), then `finishSession` moves the ATM to `OutOfService`; an operator refill returns it to Idle
Operator turns the key mid-session	The machine shuts down while serving	`setOutOfService` is refused unless the ATM is idle (requirement: never shut down while serving)

Extensions & follow-up questions

1. **"What if the machine cannot make the amount?"** — The dispenser's plan fails and the withdrawal is refused before the bank is called.
2. **"What if the power fails halfway through a withdrawal?"** — Use a two-phase approach: authorise (hold) at the bank, dispense, then confirm; on restart the ATM reads its journal and either confirms or reverses. The bank reconciles against the journal.
3. **"Add a daily withdrawal limit for all accounts."** — Move the cap into `Account` or into a policy object the bank consults; the ATM does not change.
4. **"Receipts and PIN change?"** — Two more `Transaction` records (`PinChange`, and a `Printer` part that formats the journal entry).
5. **"Other banks' cards?"** — `BankService` gets a routing implementation that forwards to a card network (such as Visa or Mastercard, which passes requests between banks) for foreign cards (a Proxy — a stand-in object — or an Adapter — a translator between two interfaces — in front of the network).
6. **"Cardless / mobile withdrawals?"** — A new state path: `enterOneTimeCode` instead of `insertCard` → `enterPin`. The transactions do not change.
7. **"Bank manager reports?"** — Aggregate the journal (total deposits, total withdrawals, cash left = `dispenser.total()`).

Real-world example

Real ATMs (NCR, Diebold Nixdorf and others) control their devices through the **CEN/XFS** standard, which gives the card reader, PIN pad, dispenser and printer each a standard software interface — the same "parts behind interfaces" idea as our design. Messages between ATM networks and banks commonly use the **ISO 8583** message format, and PIN blocks are defined by **ISO 9564** and verified inside HSMs. Cash sits in **cassettes** of one denomination each, and the dispenser works out a note mix from what the cassettes hold, like our handler chain.

After a dispense error, ATMs routinely reverse the transaction, and banks reconcile disputed withdrawals from the machine's electronic journal.

In the interview

Plan for 45 minutes: 5 min parts, actors and transactions → 5 min total vs available balance → 10 min state diagram (Idle → CardInserted → Authenticated) → 15 min code: `Withdrawal.execute` (plan → debit → dispense → compensate) and the dispenser chain → 10 min concurrency (account lock, ordered transfer locks) and follow-ups.

> **30-second answer:** "The ATM has parts behind interfaces, a session modelled with the State pattern, and five transactions as Command objects with one `execute` each. It never touches balances: it calls a `BankService`. Accounts have total and available balances so checks can be held. Withdrawal plans the notes first through a Chain of Responsibility over the cassettes, debits the account atomically at the bank, dispenses, and reverses the debit if the hardware fails. The bank locks per account, and transfers lock in id order to avoid deadlock."

Follow-ups with answers

- *"Where is the PIN checked?"* — At the bank (in reality in an HSM, from an encrypted PIN block). The ATM never stores or compares it.
- *"How do you stop two ATMs overdrawing a joint account?"* — The check and the debit happen together under the account's lock at the bank (or in one database transaction).
- *"Why Chain of Responsibility for notes?"* — Each denomination handler decides how much it can cover and passes the rest on; adding or removing a cassette changes the chain, not the algorithm.

Self-check

1. **Q:** Why two balances? **A:** A deposited check increases the total immediately but must not be spendable until it clears; available tracks what can be withdrawn.
2. **Q:** Which order of debit and dispense is safe? **A:** Neither alone is safe against a crash; use a hold + confirm (or debit + compensating reverse) and reconcile from the journal.
3. **Q:** How does the design avoid deadlock in transfers? **A:** Both accounts are always locked in the same global order (by id).
4. **Q:** What does the dispenser's dry run protect against? **A:** Removing notes or debiting the account for an amount that cannot be made exactly.
5. **Q:** Why is `SavingsAccount` a subclass rather than a type field? **A:** It has different behaviour (a daily cap), which inheritance models by overriding one hook.
6. **Q:** What happens after the third wrong PIN? **A:** The bank blocks the card (so every ATM refuses it) and this ATM retains it.

TL;DR

- **State** for the session, **Command** for the five transactions, **Chain of Responsibility** for the note cassettes, `BankService` interface for the bank.
- **Total vs available** balance makes check deposits correct.
- Withdrawal = **plan notes → atomic debit at the bank → dispense → reverse on failure**, all journaled.
- Concurrency: **per-account lock**, transfers lock in **id order**, PIN attempts limited at the bank.

14.5 Design an Elevator System

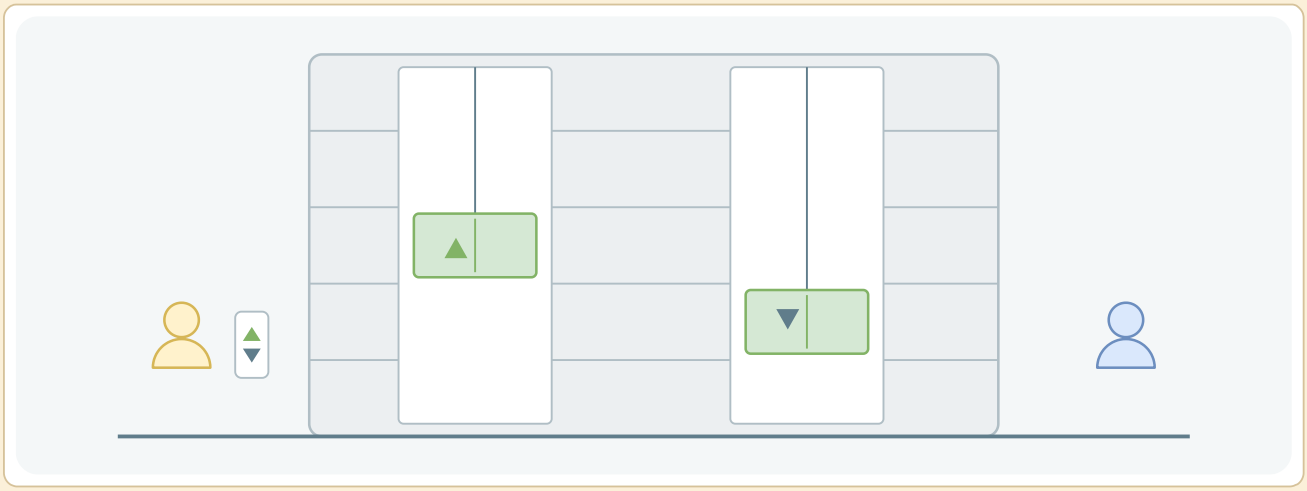

Figure — An elevator bank in a multi-floor building: several cars, hall buttons on each floor and displays (course diagram)

An **elevator** (lift) moves people up and down a building. A real building rarely has just one, and its cars are run as a **group** by a shared controller. That group control is what turns this from a small coding task into a design question. Two decisions carry the interview: **which car should answer a call from a floor** (dispatching) and **in what order a single car should visit its stops** (scheduling).

Problem & clarifying questions

Question	Assumed answer
How many floors and cars?	Many floors (0 … N-1), several cars serving all floors.
Which buttons?	Hall panel on each floor with UP and DOWN (no UP on the top floor, no DOWN on the ground floor); a car panel with one button per floor plus door-open and door-close.
Displays?	Inside each car: floor, direction, load. On each floor: one display per car showing where it is.
Scheduling rule?	A car serves every stop ahead in its direction before turning (the elevator algorithm; we use **LOOK**).
Dispatching rule?	Nearest suitable car; swappable.
Capacity?	Each car has a maximum load; an overloaded car does not move and says so.
Maintenance and emergencies?	A car can be taken out of service; fire alarm recalls all cars to the lobby.
Real time or simulated?	Simulated: one `step()` = one action. This makes the design testable without a clock.

Requirements

Functional (the course's twelve, plus emergency)

1. The building has **multiple floors** and **more than one elevator** serving all of them.
2. Each floor has a **hall panel** with UP and DOWN buttons (top floor: no UP; ground floor: no DOWN).
3. Each car has an **inside panel** with a button per floor, plus **door open** and **door close**.
4. Each car has a **display** showing its floor, direction and the weight it carries.
5. Each floor has a **display for every elevator** so a waiting rider can see where each car is.
6. When a rider presses a hall button, the system **picks one elevator** and sends it.
7. When a rider presses a floor button inside a car, the car **adds that floor** to its stops.
8. A car **serves the stops ahead of it** in its direction before turning around.
9. A car **does not move while its doors are open**.
10. Each car has a **maximum load**; an overloaded car does not move and **says so** on its display.
11. A car with no stops left **waits on the floor where it finished**.

12. An elevator can be **taken out of service** for maintenance; the system must not send riders to it.
13. *(Extension the course leaves out; we add it)* **Fire recall**: all cars go to the lobby, open their doors and ignore car calls.

Non-functional

- **Efficiency:** low average wait and ride time; no car runs to the end of the shaft for nothing.
- **Fairness / no starvation** (starvation = a request that waits forever because others keep being chosen first)**:** every accepted call is eventually served.
- **Safety:** doors, load limit and emergency modes always override scheduling.
- **Thread safety:** riders press buttons concurrently while a controller thread moves the cars.
- **Testability:** deterministic stepping (the same inputs always give the same results).

Use cases

Actors: Rider (calls a car, rides, chooses a destination), **Maintenance engineer** (takes a car out of service and back), **System** (chooses the car, moves cars, opens/closes doors, updates displays).

Top use cases: call an elevator · choose a destination · dispatch a car · move one floor · open and close the doors · report an overload · take a car out of service.

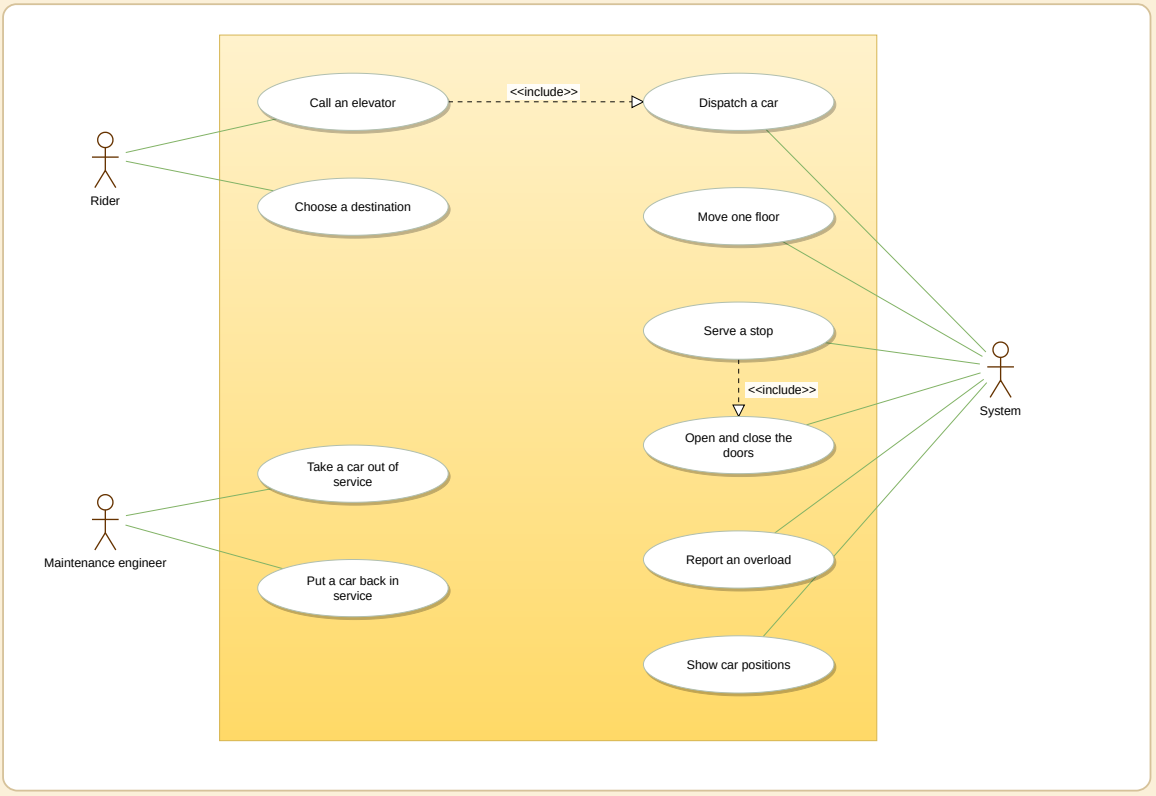

Figure — Use case diagram of the elevator system: Rider, Maintenance engineer and System (course diagram)

In the figure above, "dispatch a car" and "move one floor" belong to the System — the rider only triggers them.

Core entities

Class	Responsibility
`Direction` (enum)	UP, DOWN, IDLE.
`Stop` (record)	A floor **plus** the direction the car will travel when it leaves — two riders on floor 5 (one up, one down) are two stops.
`StopList`	The accepted stops in **two sorted sets** (`up`, `down`); `next(...)` implements LOOK.
`Door`	Open or closed.
`Elevator`	One car: floor, direction, mode, load, door, stop list. `step()` does exactly one action.
`Mode` (enum)	NORMAL, MAINTENANCE, FIRE_RECALL.
`Event` (record)	What one step did (moved, arrived, doors closed, overload, nothing).
`DispatchStrategy`	*Which car* answers a hall call. `NearestCarStrategy` is one rule.
`Dispatcher`	Holds the cars and one strategy; queues calls no car can take now.
`Building`	Owns hall-button lights, the cars and the dispatcher; ticks every car; clears hall lights on arrival; fire alarm.

The course additionally models the physical parts one-to-one: `Button` (with `HallButton`, `ElevatorButton`, `DoorButton`), `HallPanel`, `ElevatorPanel`, `Display` (with `ElevatorDisplay`, `FloorDisplay`) and `Floor`. Our code keeps the behaviour (lights, displays, door) with fewer classes; in a 45-minute interview either level of detail is fine as long as you say which you chose.

Class diagram

The course builds the design in five stages:

Stage	What it adds	What works after it
1	`Button` family and `Door`	Buttons light and reset; a door knows if it is open
2	`HallPanel`, `ElevatorPanel`, `Display` family, `Floor`	A floor accepts a call and shows each car's position
3	`Stop` and `StopList`	Given a floor and a direction, compute the next stop
4	`Elevator`	A car travels to all the stops it has accepted, one step at a time
5	`DispatchStrategy`, `Dispatcher`, `Building`	A call on floor 7 is handed to the most suitable car

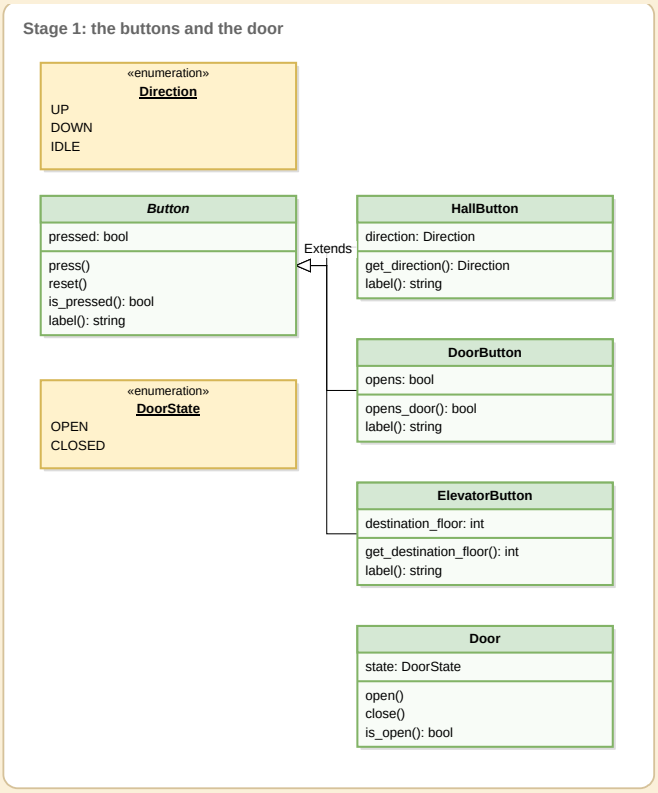

Figure — Stage 1: the Direction enum, the abstract Button with HallButton, ElevatorButton and DoorButton, and the Door (course diagram)

Stage 1. Requirements 2, 3 and 9. All buttons share one behaviour (light up on press, go dark once handled) and differ only in the value they carry: a hall button stores a **direction**, a car button a **floor number**, a door button **open or close**. That gives one abstract `Button` parent with three subclasses instead of three unrelated classes. `Door` has no owner yet; the car will own it in stage 4. Nothing can move at this point.

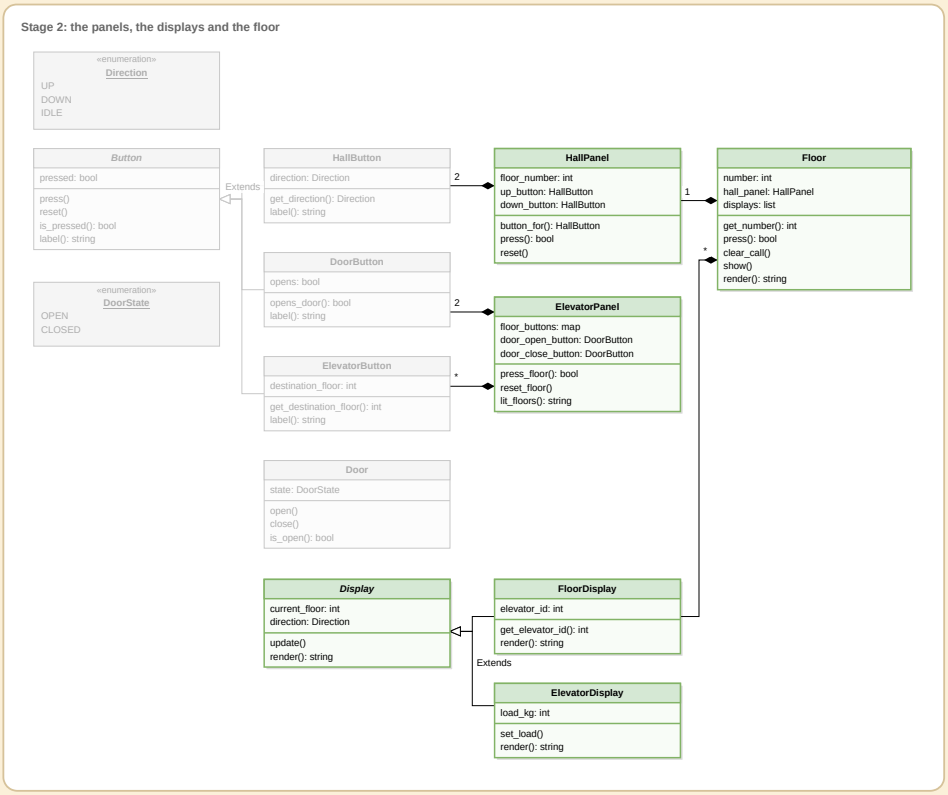

Figure — Stage 2: HallPanel, ElevatorPanel, the abstract Display with ElevatorDisplay and FloorDisplay, and Floor, all joined by composition (course diagram)

Stage 2. Requirements 2, 3, 4 and 5. Every new link is **composition**: a hall panel owns its buttons, and a floor owns its hall panel and its displays, so deleting a floor deletes them too. A hall panel has **at most two** buttons, and each is optional because the top and bottom floors lack one. The car panel creates one button per

floor from the list of floors it receives, so adding a floor needs no edit here. `Display` is abstract: both subclasses show a floor and a direction; the in-car `ElevatorDisplay` adds the load, the wall-mounted `FloorDisplay` adds which car it describes. The inheritance passes the substitution test (Chapter 4): either display can be asked to render itself wherever a `Display` is expected. After this stage a floor can register a call and show where the cars are, but nothing moves yet.

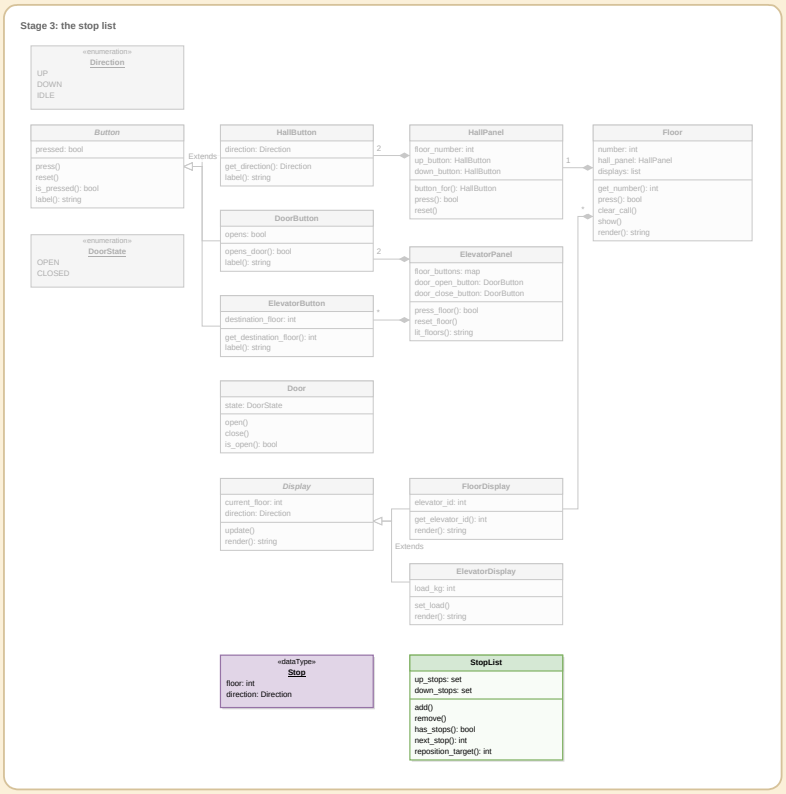

Figure — Stage 3: the Stop data type and the StopList with its up and down sets (course diagram)

Stage 3 — the most important stage. Requirement 8. The whole stage exists to answer: *knowing a car's floor and travel direction, which floor should it stop at next?* The key choice is to store stops in **two sets** (to serve going up, to serve going down) instead of one list. Picture two people waiting on floor 5, one heading up and one heading down: a plain list of floors records "5" once, so the car either stops there twice for no reason or picks up the wrong person. `Stop` is a small data type (a floor plus the direction the car will be moving when it stops there) with no relationships of its own. The next stop returned is always reachable **without reversing**; when nothing lies ahead, the car heads to the **farthest** waiting request rather than the closest one, so it sweeps

everyone up on the return trip. Putting this rule in `StopList` splits responsibilities cleanly: `Elevator` **moves**, `StopList` **chooses**.

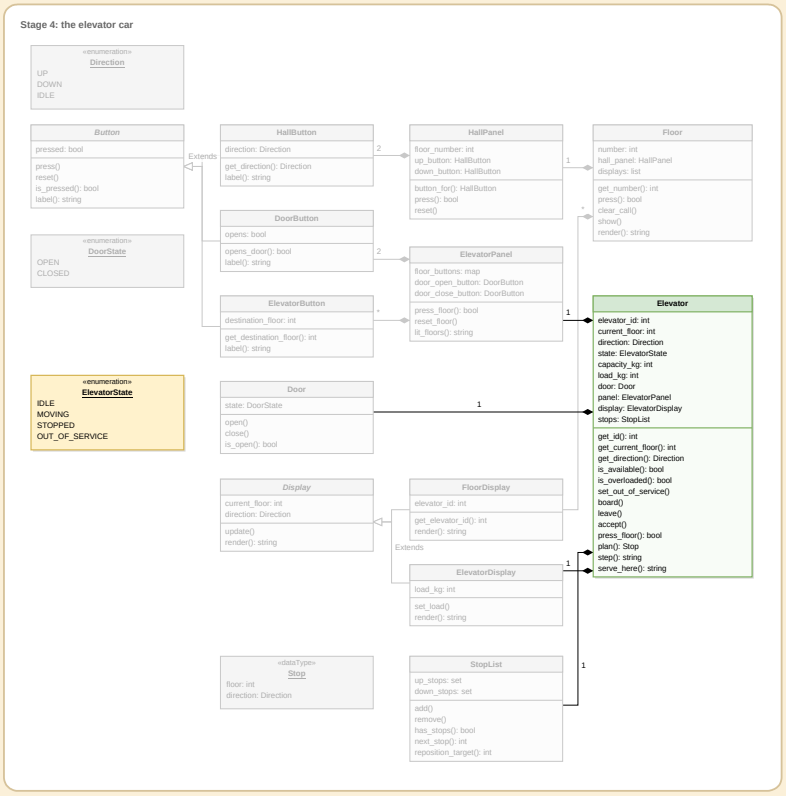

Figure — Stage 4: the Elevator owns its door, panel, display and stop list (course diagram)

Stage 4. Requirements 7, 9, 10 and 11. The car owns its door, panel, display and stop list (composition: none of them exists without the car). A single `step` does exactly **one** of four things: close the doors, refuse to move because of overload, move one floor, or stop and open the doors. Because each call does one action, a test can drive the car step by step with **no clock**. In the course, only one method reads the stop list and only `step` changes the car's position, and a car that is out of service simply does nothing on `step`, so it drops out of the building's rounds without special cases elsewhere (our `step()` returns a `NOTHING` event). Just as important

is what the car does **not** know: it never touches a `Floor` and never talks to another car, which leaves the choice of car to the dispatcher.

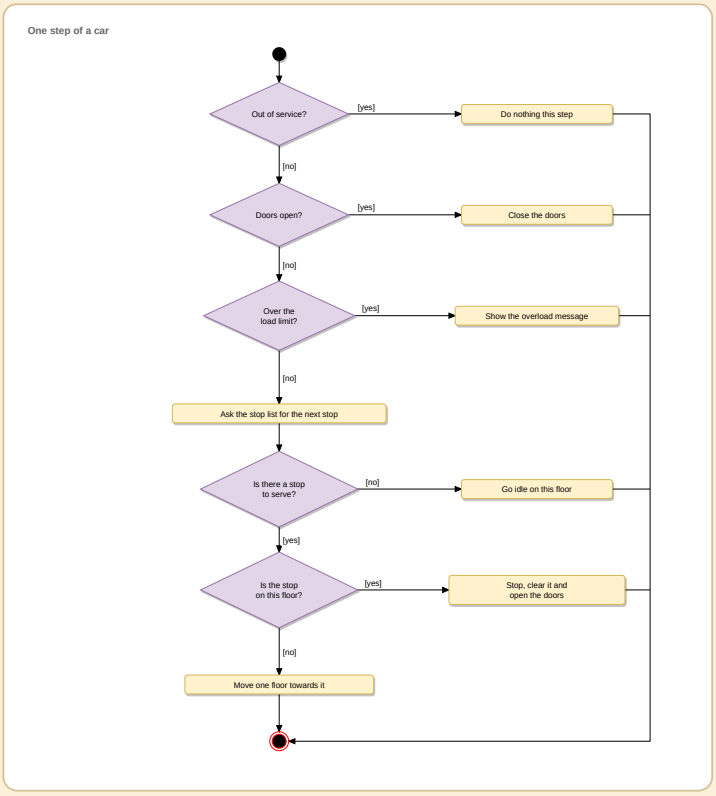

Figure — Activity diagram "One step of a car": out of service → nothing; doors open → overload check or close; otherwise ask the stop list, go idle, stop and open, or move one floor (course diagram)

The activity diagram above is our `Elevator.step()` drawn as a picture: every path ends in exactly one outcome, and only one outcome moves the car.

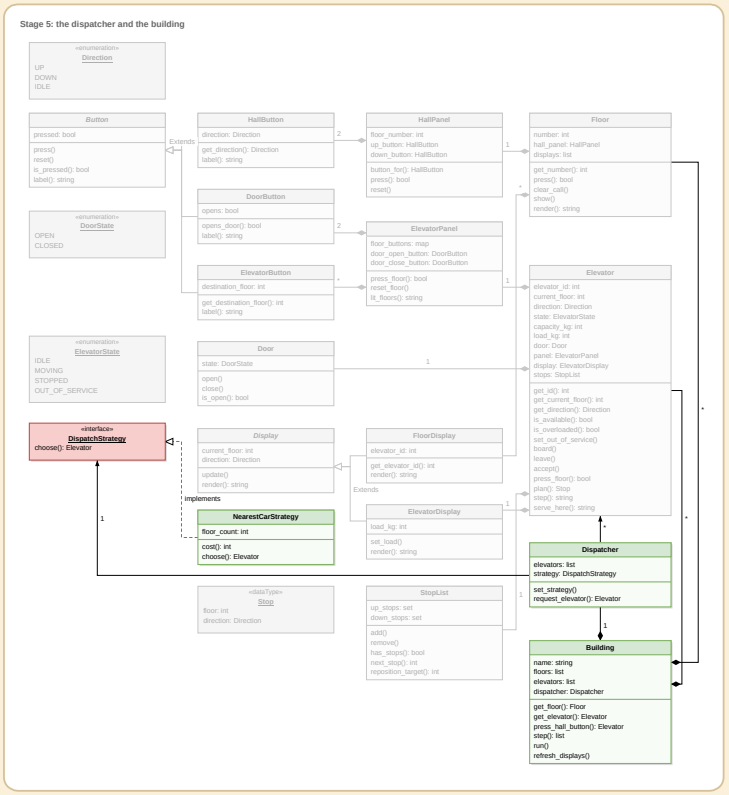

Figure — Stage 5: DispatchStrategy interface with NearestCarStrategy, the Dispatcher, and the Building that owns floors, cars and the dispatcher (course diagram)

Stage 5. Requirements 1, 6 and 12. The rule that picks a car lives **behind an interface** (`DispatchStrategy`), and the dispatcher depends only on that interface, drawn as a plain arrow to it; `NearestCarStrategy` implements it (dashed line, hollow triangle). Morning rush in an office block and a quiet night in a hotel call for different

rules, and swapping the rule touches one class only. The building owns its floors, cars and dispatcher (filled diamonds). It is also the only class that knows about both cars and floors, so switching off the hall-button light when a car opens its doors is the building's job.

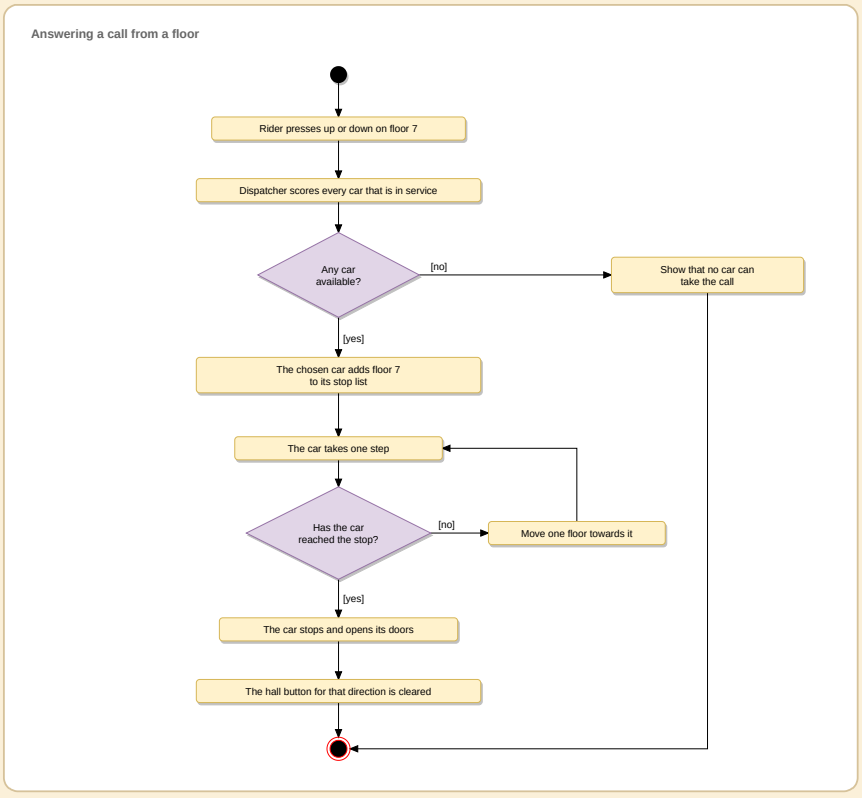

Figure — Activity diagram "Answering a call from a floor": rider presses up/down on floor 7, the dispatcher scores every in-service car, the chosen car adds floor 7, steps until it reaches the stop, opens its doors, and the hall button is cleared (course diagram)

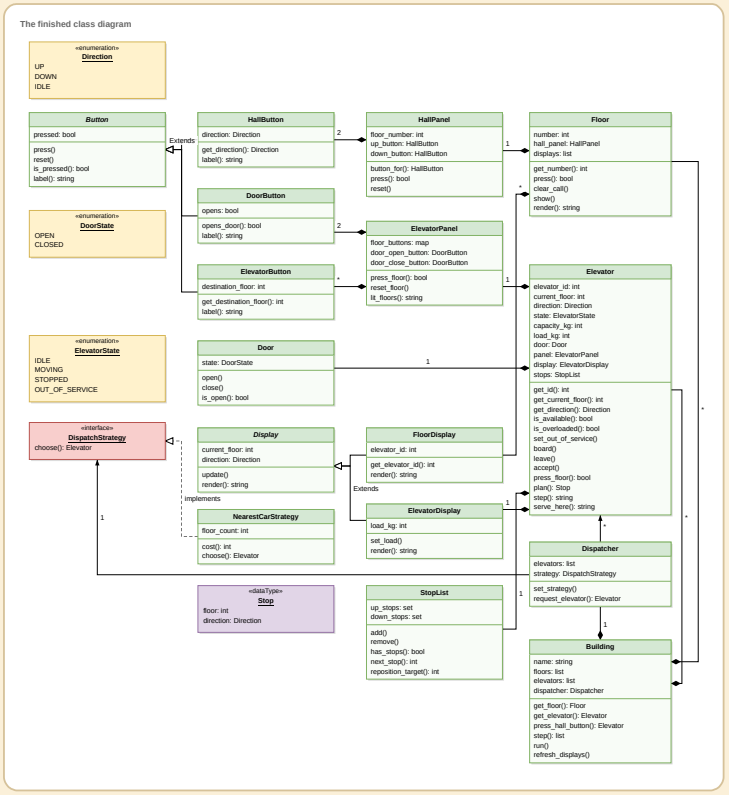

Figure — The finished class diagram of the elevator system (course diagram)

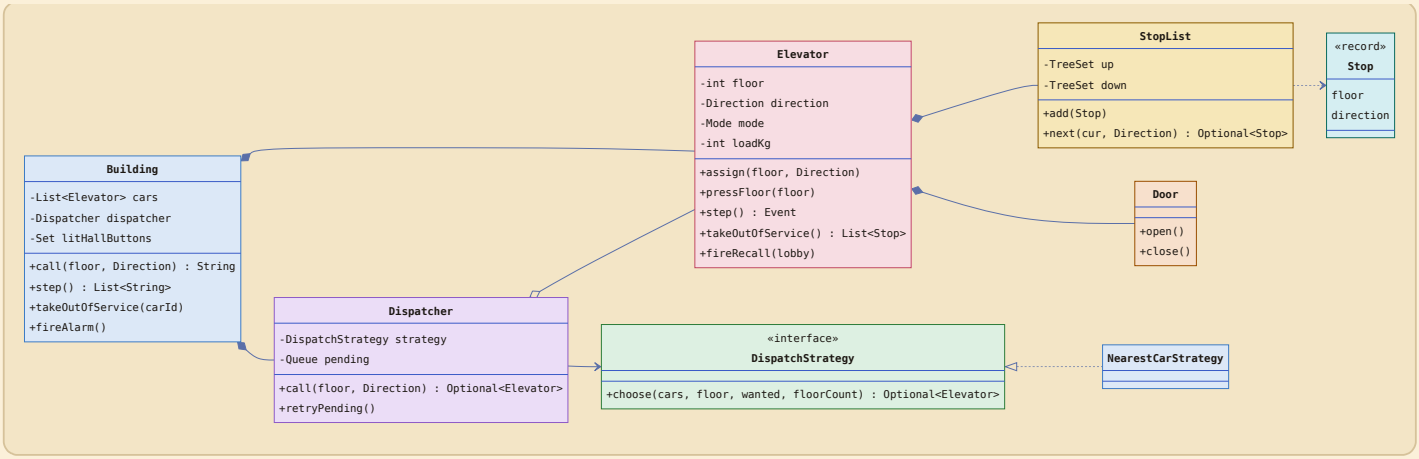
Class diagram of **our Java code**:



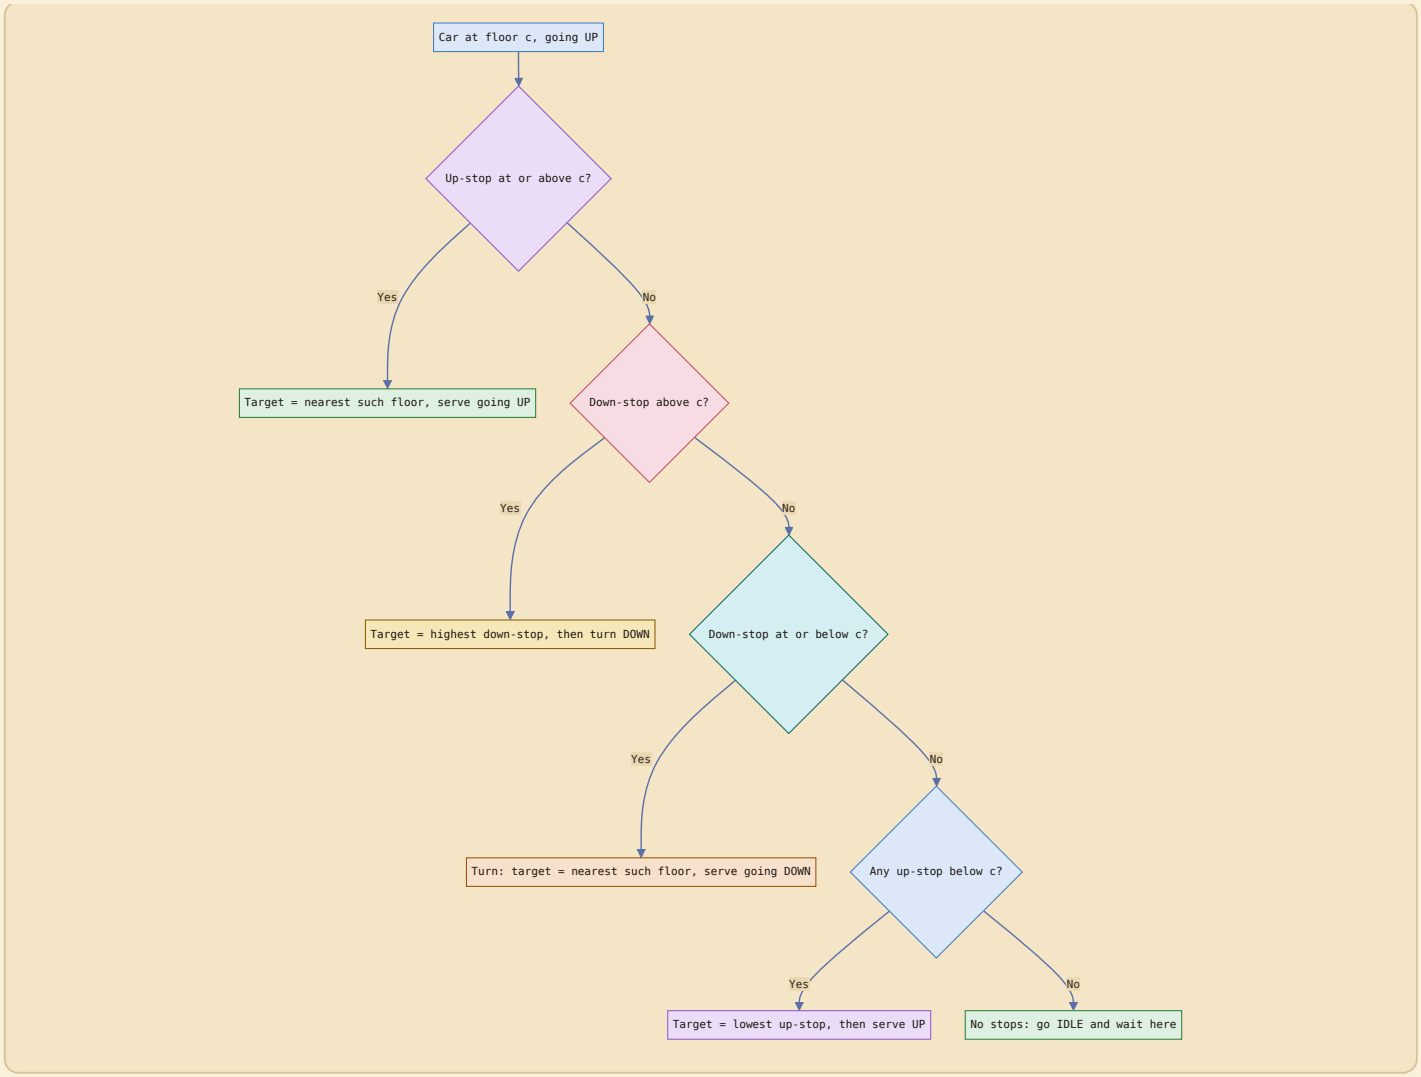
Key flows

Scheduling algorithms compared. "Scheduling" means choosing the order in which one car serves its stops. These algorithms come from disk-arm scheduling in operating systems (the order in which a hard disk's read head visits requested tracks), which has the same shape (a head moving along a line of requests).

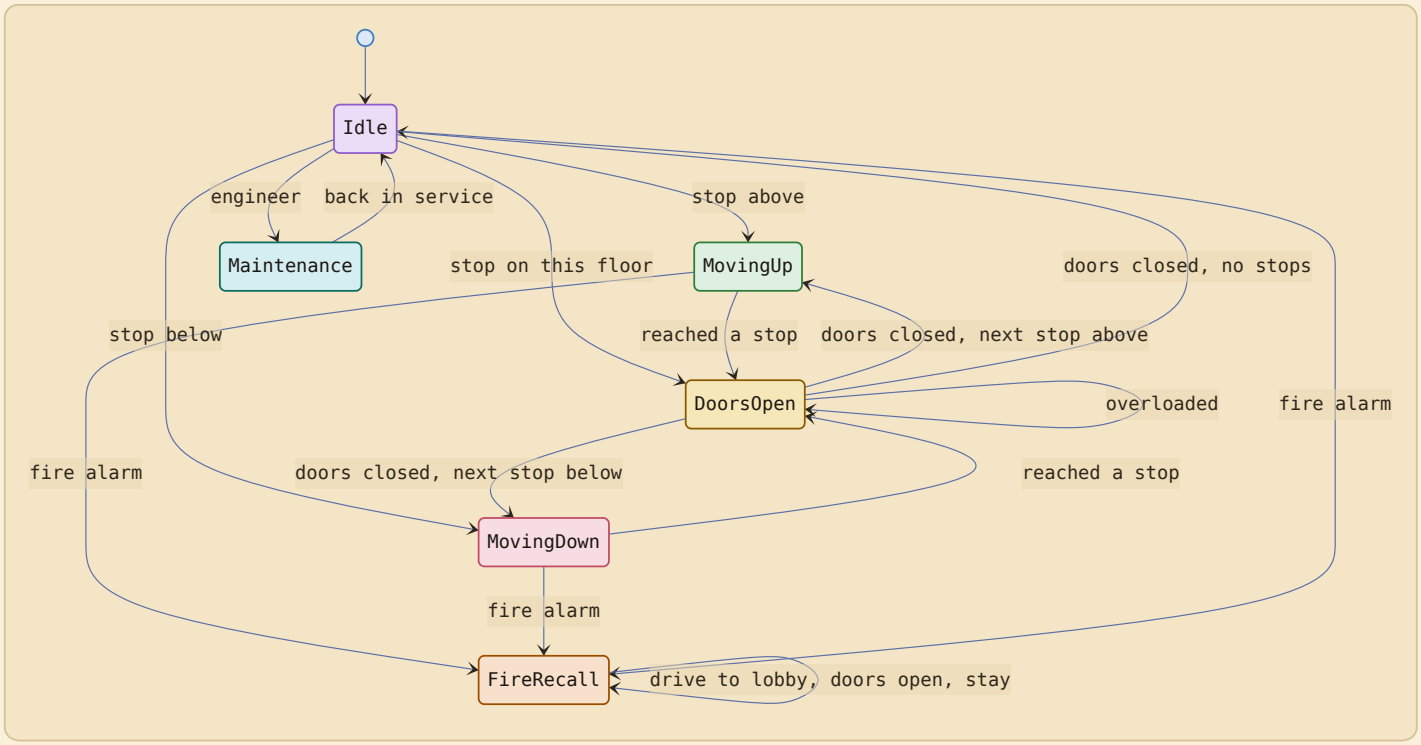
Algorithm	Rule	Good	Bad
FCFS (first come, first served)	Serve calls in arrival order	Simple, fair in order	Zig-zags up and down; very inefficient
SSTF (shortest seek time first)	Always go to the nearest stop	Short average trips	**Starvation**: a far floor may wait forever while nearby calls keep coming
SCAN ("elevator algorithm")	Sweep in one direction to the **end of the shaft**, then reverse	No starvation, predictable	Wastes travel going to the top/bottom floor even when nobody is there
LOOK	Sweep in one direction only **as far as the last request**, then reverse	No starvation, no wasted travel	Slightly more bookkeeping
C-SCAN / C-LOOK	Serve in one direction only; jump back to the start	More uniform waits	Empty return trips

Our `StopList.next` is **LOOK** with direction-aware stops:

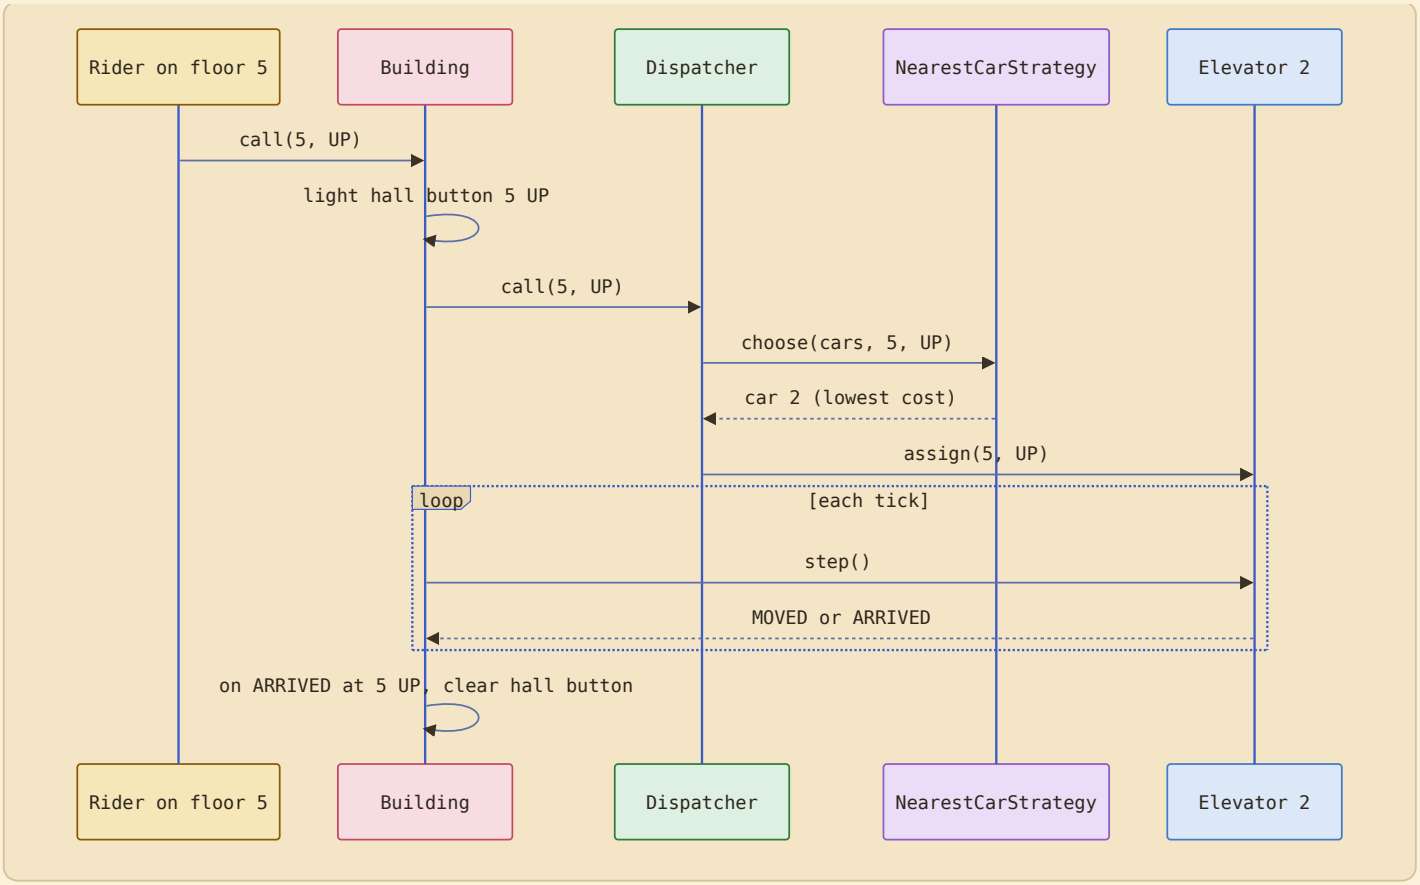
1. Going **UP**: the nearest up-stop at or above the car (`up.ceiling(cur)`).
2. None? If someone *above* wants to go **down**, go up to the **highest** such floor, then turn (collect the rest on the way down).
3. Otherwise turn: the nearest down-stop at or below the car (`down.floor(cur)`).
4. Otherwise the only work left is up-stops **below** the car: go down to the **lowest** one, then serve upward.
5. Going **DOWN** is the mirror image. An **IDLE** car picks the side of the nearest stop.



Car states.



A hall call.



Dispatch cost (`NearestCarStrategy`, from the course): an **idle** car costs its distance; a car **already coming this way in the same direction** costs its distance; any other car pays distance **+ two building heights**, so it wins only when nothing better is free. Cars out of service are skipped.

Design decisions & patterns used

Decision	Pattern / principle	Why	Alternative rejected
Choosing a car is a `DispatchStrategy`	**Strategy**	Different buildings and times of day want different rules; the course admits one implementation normally doesn't justify an interface, but here the *requirement* (swap the rule) does	`if (officeMode) … else …` in the dispatcher
Sweep rule in `StopList`, not in `Elevator`	Single Responsibility	The car drives; the stop list decides. Without this split, `Elevator` would do two jobs	Next-stop logic inside `step()`
Two sets of stops (up/down)	Data modelling	Distinguishes "5 going up" from "5 going down"	One list of floors
`step()` = one action	Deterministic simulation	Every scenario is a list of calls and an expected list of events; no clock, no flakiness (tests that pass or fail at random)	A thread per car with `sleep`
Modes as an enum inside the car	Lightweight State	Only three modes and a few checks; full State classes would add more code than they save here. If modes grew (fire phase II, independent service, VIP), switch to the State pattern	State classes from day one
Hall calls re-dispatched when a car leaves service	Robustness	A call accepted by a car must not be lost when that car is taken out	Silently clearing the car's stops
Queue calls when no car is available	—	"No car can take the call right now" is not the same as "rejected"	Dropping the call

The course lists three honest weak points, all worth saying: (1) one step per call means **no threads**; a real controller runs each car on its own thread and needs a lock around the stop list — our methods are `synchronized` for exactly that; (2) the dispatcher **decides once** and never re-evaluates, though real systems do (that is why a

busy building sometimes changes the car number while you wait); (3) `Elevator` is close to doing two jobs, which is why the sweep rule lives in `StopList`. The course also names only **one** pattern here (Strategy); `Button` and `Display` are ordinary abstract base classes and `StopList` is Single Responsibility, not a pattern. Its scope list deliberately leaves out emergency calls, fire service mode, express cars that skip floors, and door sensors that reopen for a hand (we add fire recall; the others are extensions below).

Java implementation

Package `lld.ch14.elevator`.

```java
// File: lld/ch14/elevator/StopList.java
package lld.ch14.elevator;

import java.util.Optional;
import java.util.TreeSet;

enum Direction { UP, DOWN, IDLE }

/** A floor plus the direction the car will travel when it leaves that floor. */
record Stop(int floor, Direction direction) {}

/**
 * The stops a car has accepted, kept in TWO sorted sets: floors to serve while going up,
 * and floors to serve while going down. Two riders on floor 5 (one up, one down) are two stops.
 * next() implements LOOK: keep going while there is work ahead, turn at the last request,
 * never travel to the end of the shaft for nothing (that would be SCAN).
 */
final class StopList {
    private final TreeSet<Integer> up = new TreeSet<>();
    private final TreeSet<Integer> down = new TreeSet<>();

    void add(Stop s) { (s.direction() == Direction.DOWN ? down : up).add(s.floor()); }
    void remove(Stop s) { (s.direction() == Direction.DOWN ? down : up).remove(s.floor()); }
    boolean isEmpty() { return up.isEmpty() && down.isEmpty(); }
    void clear() { up.clear(); down.clear(); }

    /** Removes and returns every stop (used when a car leaves service). */
    java.util.List<Stop> drain() {
        java.util.List<Stop> all = new java.util.ArrayList<>();
        up.forEach(f -> all.add(new Stop(f, Direction.UP)));
        down.forEach(f -> all.add(new Stop(f, Direction.DOWN)));
        clear();
        return all;
    }

    Optional<Stop> next(int cur, Direction dir) {
        if (isEmpty()) return Optional.empty();
        if (dir == Direction.IDLE) dir = nearestSide(cur);
        return Optional.of(dir == Direction.UP ? goingUp(cur) : goingDown(cur));
    }

    private Stop goingUp(int cur) {
        Integer f = up.ceiling(cur);
        if (f != null) return new Stop(f, Direction.UP);                          // work ahead
        if (!down.isEmpty() && down.last() > cur) return new Stop(down.last(), Direction.DOWN); // go up, then turn
        f = down.floor(cur);

}
```

How the code works, part by part

- `StopList` keeps two `TreeSet<Integer>`s (a `TreeSet` is a sorted set). `ceiling`, `floor`, `first` and `last` give O(log n) answers to "nearest stop at or above/below" — the core of LOOK.
- `Elevator.step()` checks, in order: maintenance → doors open (overload? fire parked? else close) → ask the stop list → arrive (remove the stop, open the doors) or move one floor. The car never moves with the doors open.
- `pressFloor` classifies a car call as an up- or down-stop relative to the current floor; during fire recall car buttons are ignored.
- `takeOutOfService` returns the car's accepted stops; `Building` re-dispatches the ones that are still lit hall calls.
- `Dispatcher.retryPending` runs every tick, so a queued call is dispatched as soon as any car becomes available.
- `Main` part 1 runs LOOK on one car in isolation; parts 2–5 run a two-car building; part 6 has eight threads press hall buttons at the same instant.

Output:

```
== 1. LOOK on one car: at floor 4 going up; stops 6(up) 9(car) 2(down) 1(up) ==
service order [6, 9, 2, 1]  (turns at 9 and at 1: never runs to 0 or to a floor above 9)

== 2. Building: floors 0-9, car1 at 0, car2 at 8 ==

display: car1@0 IDLE [open] 80kg FIRE_RECALL | car2@0 IDLE [open] 0kg FIRE_RECALL
```

```
== 6. 8 riders press hall buttons at the same instant (new building) ==
all 8 calls served: true (ticks=11 < 200)
```

Read the output: in part 1 the car serves 6 and 9 going up, turns at 9 (the highest request, not the top of the shaft), serves 2 going down, then 1 — LOOK, not SCAN. In part 2 the hall call on 3 goes to car 1 because it is below floor 3 and already going up. In part 3 the overloaded car keeps its doors open until two people step out. In part 4 the call held by car 1 moves to car 2 when car 1 goes out of service, then is queued when no car is available, and served as soon as car 1 returns. In part 5 car 2 reverses mid-trip and both cars park at the lobby with doors open.

Concurrency & edge cases

Situation	Handling
Riders press buttons while the controller steps cars	`Elevator` methods are `synchronized`; the dispatcher is `synchronized`; hall lights are a concurrent set
Same hall button pressed twice	`litHallButtons.add` returns false: "already lit", no second dispatch
Up and down requests on the same floor	Two different `Stop`s in two sets
Car call for the floor the car is on, doors open	Ignored (doors already open)
Overload	Doors stay open, display shows OVERLOAD, car does not move
Car taken out of service with accepted hall calls	Calls re-dispatched or queued; never lost
No car available	Call queued; retried every tick
Fire alarm	All stops dropped, lobby added, car buttons ignored, doors stay open at the lobby
Starvation	LOOK serves every accepted stop within one round trip (one sweep each way)
Invalid button (UP on the top floor)	`IllegalArgumentException` — that button does not exist

Extensions & follow-up questions

1. **"How do you choose which car?"** — `DispatchStrategy`; show `NearestCarStrategy` and mention alternatives: zoning (car 1 serves floors 0–10), **up-peak** mode (send idle cars to the lobby at 9 a.m.), and energy-saving rules.
2. **"What if two riders press at the same instant?"** — The dispatcher is synchronized, so calls are dispatched one at a time; each car's stop list is guarded by the car's lock. (The course's design leaves this lock out and says so.)
3. **"How would you test this?"** — Because one call = one step, every test is: a list of button presses, N steps, and an expected list of events. No sleeps, no flakiness.
4. **"Destination dispatch?"** — Riders enter their destination in the lobby keypad; the system groups riders with nearby destinations into the same car. Implement as another `DispatchStrategy` that receives (from, to) instead of (floor, direction).
5. **"Re-evaluate assignments?"** — Each tick, for unserved hall calls, ask the strategy again and move the call if a much better car is free now.
6. **"Real time?"** — A `ScheduledExecutorService` (a Java thread pool that runs tasks on a timer) calls `building.step()` every second (or per car on its own thread, with the car lock guarding the stop list).
7. **"Emergency stop button inside the car?"** — A new mode that halts movement immediately and raises an alarm; with more modes, refactor modes into State classes.
8. **"Express cars?"** — A car with a set of floors it may serve (e.g. lobby plus 30–40); the dispatch strategy skips cars whose served set does not include the call floor.
9. **"Door sensor that reopens for a hand?"** — A `DoorSensor` input; while it reports an obstruction, `step()` reopens the doors instead of closing them (same slot as the overload check).

Real-world example

Modern high-rise buildings use **destination dispatch** systems (for example Schindler's PORT, Otis CompassPlus and KONE's destination control): riders choose their floor in the lobby and the system tells them which car to take,

which cuts stops per trip — extension 4. Controllers switch between traffic modes such as **up-peak** in the morning. The fire behaviour in this design follows the idea of **Phase I emergency recall** in elevator safety codes such as ASME A17.1: on a fire alarm, cars return to the designated landing, open their doors and are removed from normal service.

In the interview

Plan for 45 minutes: 5 min requirements and scope (how many cars, which modes) → 5 min entities → **15 min on the stop list and LOOK** (two sets, the four cases) → 10 min car `step()` and dispatcher strategy → 10 min concurrency, testing and follow-ups.

> **30-second answer:** "Each car keeps its stops in two sorted sets, up-stops and down-stops, and uses LOOK: keep serving stops ahead in the current direction, turn at the last request, never run to the end of the shaft for nothing. A car's `step()` does one action — close doors, refuse to move if overloaded, move one floor, or stop and open — which makes the whole system testable without a clock. A dispatcher assigns hall calls through a `DispatchStrategy`, nearest suitable car by default, and queues calls when no car is available. Doors, load, maintenance and fire recall always override scheduling."

Follow-ups with answers

- *"Why LOOK and not SSTF?"* — SSTF can starve a distant floor; LOOK serves every accepted stop within one round trip (one sweep up, one sweep down).
- *"Why two sets and not one?"* — A floor can be requested going up and going down; one set cannot tell which rider to serve on which sweep.
- *"Where do you put the lock?"* — Around each car's stop list and state (the car's monitor — the built-in lock every Java object carries, taken by `synchronized`), and around the dispatcher's assignment. No global lock across cars.

Self-check

1. **Q:** Difference between SCAN and LOOK? **A:** SCAN runs to the end of the shaft before reversing; LOOK reverses at the last request.
2. **Q:** A car at 4 going up has stops 6(up), 9(car), 2(down), 1(up). Order? **A:** 6, 9, 2, 1.
3. **Q:** Why is the scheduling rule in `StopList` and not `Elevator`? **A:** Single Responsibility — the car drives, the stop list decides; each can be tested alone.
4. **Q:** What does the dispatcher do when every car is in maintenance? **A:** Queues the call and retries on every tick.
5. **Q:** Why does one `step()` do only one action? **A:** Deterministic, clock-free simulation: tests are sequences of calls with expected events.
6. **Q:** When would you convert modes into State classes? **A:** When there are many modes with different behaviour per action (fire phase I/II, independent service, VIP, emergency stop).

TL;DR

- **Two sorted sets** (up/down) of stops + **LOOK** = efficient, starvation-free scheduling.
- **`step()` = one action**; doors, load, maintenance and fire recall override scheduling.
- **Strategy** for dispatch (nearest car by default), with a pending queue and re-dispatch when a car leaves service.
- Thread safety: per-car lock, synchronized dispatcher, concurrent hall-light set.

14.6 Design a Traffic Signal Control System

A **traffic signal controller** decides which approaches of an intersection get green, for how long, and in what order. An **approach** is one road entering the intersection (north, south, east, west). A **phase** is a set of approaches that may be green together because their paths do not cross (for example north and south going straight). The controller cycles through phases, inserting **yellow** (warning) and **all-red** (clearance) intervals between them.

This question tests a **timed state machine** with a **hard safety rule** — *two crossing flows must never be green at the same time* — plus an **emergency override** that must interrupt the normal cycle *safely* (never by cutting a yellow short).

Problem & clarifying questions

Question	Assumed answer
How many roads?	A four-way intersection (N, S, E, W); phases are configurable.
Which signals?	Red, yellow, green; flashing red in fault mode.
Fixed or adaptive timing?	Configurable: fixed durations, or adaptive based on queue sensors.
Pedestrian signals, turn arrows?	Out of scope (extensions).
Emergency vehicles?	Yes: an approaching ambulance or fire truck gets green as soon as safely possible, held until it passes.
Many intersections?	Each intersection has its own controller; a central system can coordinate them (extension).
Real time?	A timer ticks once per second; the logic is tick-driven so it can also be simulated.

Requirements

Functional

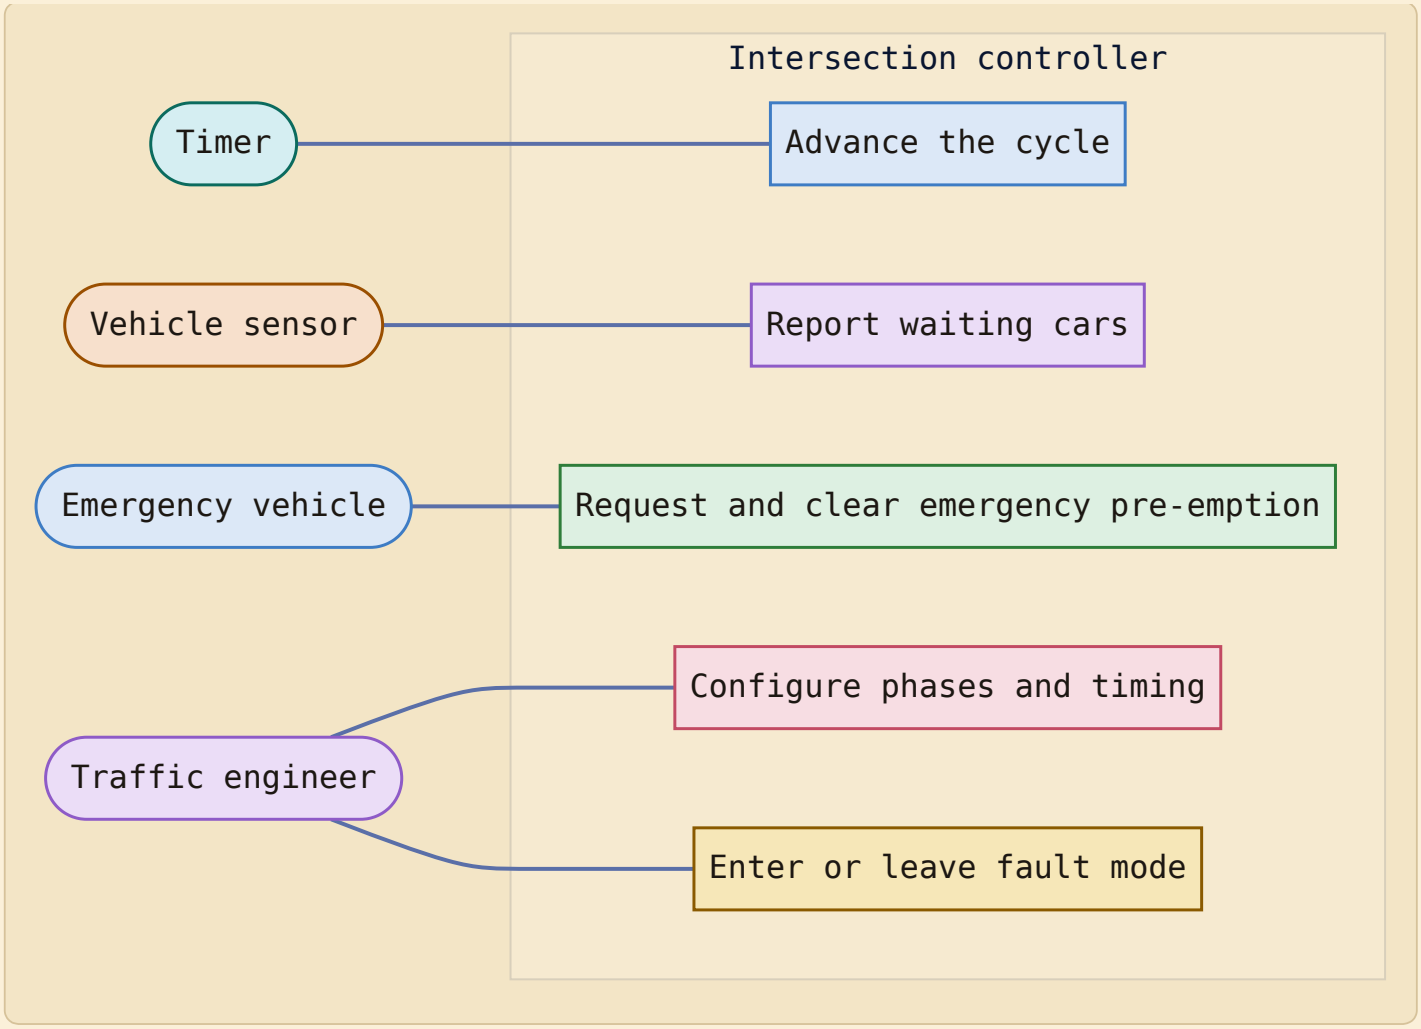
1. Control traffic at an intersection with **multiple roads**.
2. Support **red, yellow and green** signals.
3. Signal **durations are configurable** and can **adapt to traffic** conditions.
4. Transitions are **smooth and safe**: green → yellow → all-red → next green.
5. Handle **emergencies**: an approaching ambulance or fire truck gets priority.
6. Be **scalable and extensible** (more phases, more intersections, new features).
7. On a controller fault, fall back to a **safe mode** (all flashing red = treat as an all-way stop).

Non-functional

- **Safety invariant** (an invariant is a rule that must hold at every moment)**:** never conflicting greens, not even for an instant during a switch.
- **Deterministic timing:** a tick = one second; testable with a simulated clock.
- **Thread safety:** a timer thread ticks while sensor and emergency inputs arrive from other threads.
- **Observability** (the system's behaviour can be watched from outside)**:** displays, logs and monitors can subscribe to light changes.

Use cases

Actors: Timer (ticks every second), **Vehicle sensors** (report queue lengths), **Emergency vehicle / dispatch** (request and clear pre-emption — interrupting the normal cycle to serve a priority request), **Traffic engineer** (configures phases and timing), **Drivers** (see the lights).



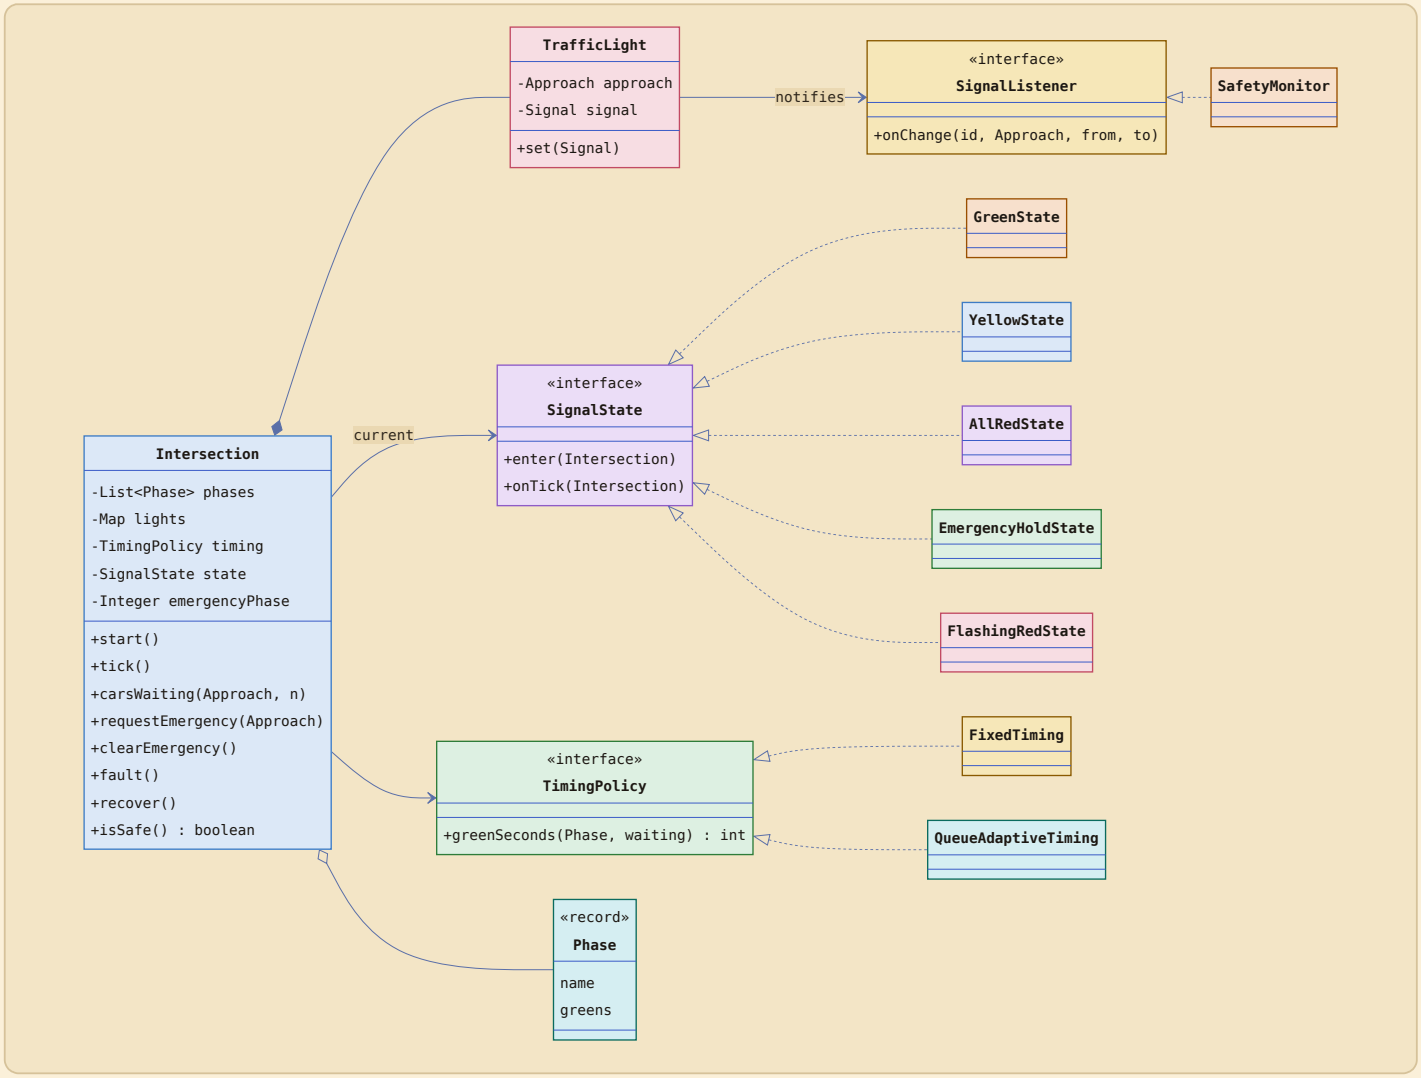
Core entities

Class	Responsibility
`Signal` (enum)	RED, YELLOW, GREEN, FLASHING_RED.
`Approach` (enum)	NORTH, SOUTH, EAST, WEST.
`Phase` (record)	A name and the set of approaches that may be green together.
`TrafficLight`	One signal head for one approach; notifies listeners on every change.
`SignalListener`	**Observer** interface for light changes.
`SafetyMonitor`	A listener that checks the safety invariant after every change to green.
`TimingPolicy`	**Strategy** for green duration: `FixedTiming`, `QueueAdaptiveTiming`.
`SignalState` + 5 states	**State**: `GreenState`, `YellowState`, `AllRedState`, `EmergencyHoldState`, `FlashingRedState`.
`Intersection`	The State context (the object that holds the current state and hands it each call): phases, lights, timing, sensors, emergency flag; `tick()`.

Mapping to the common problem statement. The widely used version of this problem (for example in the open-source *awesome-low-level-design* collection) asks for: an intersection with multiple roads, red/yellow/green signals, configurable durations that can adjust to traffic, smooth transitions, handling of emergency vehicles (ambulances, fire trucks), and a scalable, extensible design. Its classes map onto ours as follows: the `Signal` enum → our `Signal`; `Road` (id, name, and the traffic light facing it) → our `Approach` plus the `TrafficLight` stored for it; `TrafficLight` (current signal, durations, notifies observers) → our `TrafficLight` (signal + listeners) with the durations moved into `TimingPolicy` and the yellow/all-red settings; `TrafficController` (a Singleton managing all roads) → our `Intersection`, deliberately **not** a Singleton. What the reference leaves

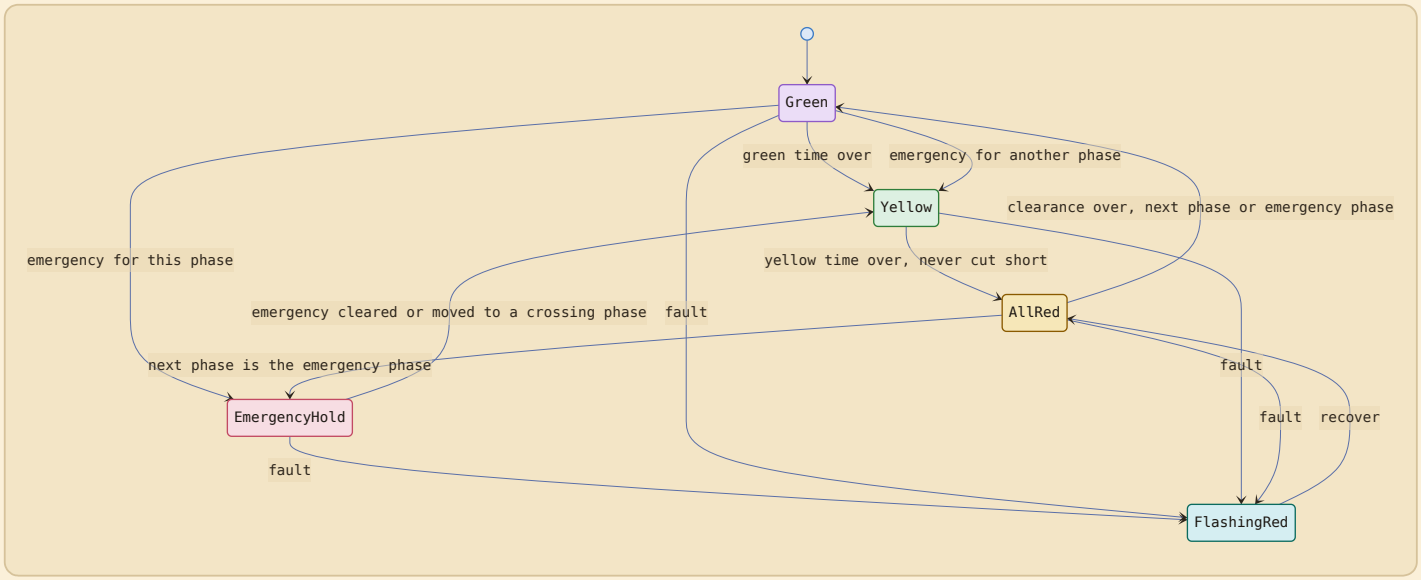
implicit, and we make explicit, is the phase model (which roads may be green together), the all-red clearance interval, and the safety check.

Class diagram

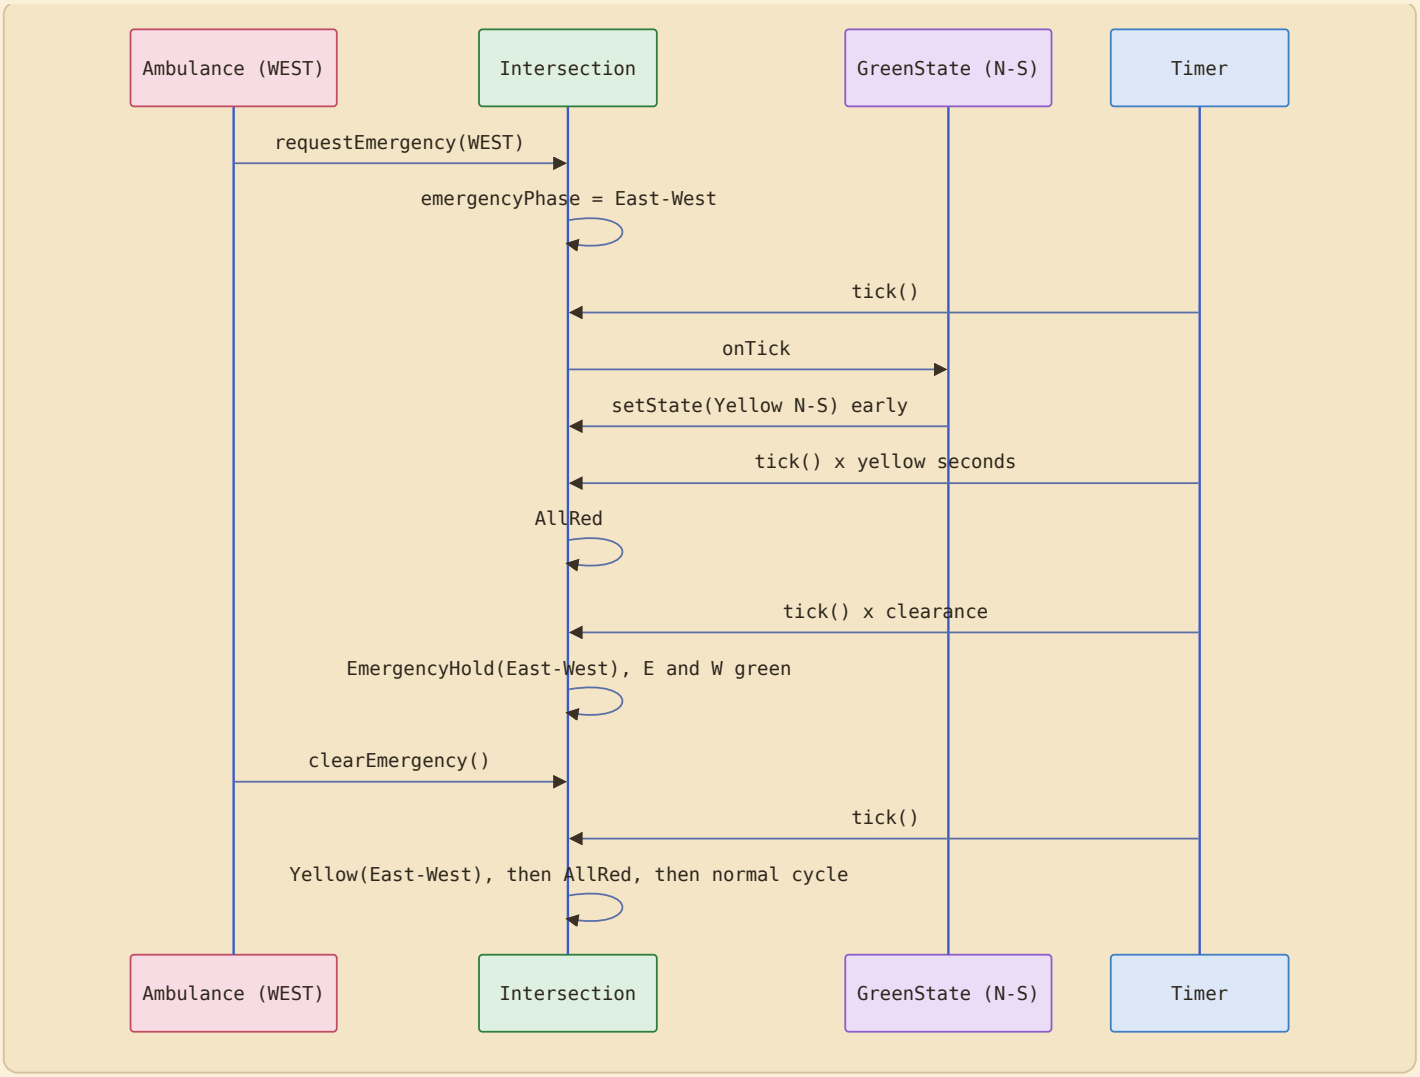


Key flows

The controller's state machine.



Emergency pre-emption.



One full fixed cycle (green 5 s, yellow 2 s, all-red 1 s): `N-S green (5) → N-S yellow (2) → all red (1) → E-W green (5) → E-W yellow (2) → all red (1) → …` — a 16-second cycle.

Design decisions & patterns used

Decision	Pattern	Why	Alternative rejected
Each interval is a state class with `enter` and `onTick`	**State**	What a tick means depends on the interval; the transitions (and the "yellow is never cut short" rule) live in one small class each	One `switch` over an enum with counters for every case
States **carry data** (remaining seconds) and are created per transition	State with per-instance data	Unlike the vending machine's stateless states, these hold a countdown, so they cannot be shared	Shared singletons with counters on the context
Green duration comes from a `TimingPolicy`	**Strategy**	Fixed, adaptive (queue sensors), time-of-day plans all swap at run time	Durations hard-coded in `GreenState`
Light changes are published to listeners	**Observer**	Displays, logs, a central monitoring system and the safety monitor subscribe independently	The intersection calling each consumer directly
`showPhaseGreen` turns others **red first**, then turns the phase green	Safety by construction	There is never an instant with conflicting greens	Setting lights in arbitrary order
A separate `SafetyMonitor` checks the invariant	Defence in depth (several independent safety layers)	Mirrors real hardware conflict monitors that force flash if a bug ever causes conflicting greens	Trusting the controller logic alone
Emergency is a **flag** the states read, not a direct jump	Safety	A request only *shortens* green; yellow and all-red still run in full	Jumping straight to the emergency green (a crash risk)
The awesome-lld reference makes the controller a **Singleton**	Rejected	A city has many intersections, each with its own controller; the demo runs two. A per-city `TrafficControlCenter` can own them	`TrafficController.getInstance()`

Java implementation

Package `lld.ch14.trafficsignal`.

```java
// File: lld/ch14/trafficsignal/Model.java
package lld.ch14.trafficsignal;

import java.util.List;
import java.util.Map;
import java.util.Set;
import java.util.concurrent.CopyOnWriteArrayList;

enum Signal { RED, YELLOW, GREEN, FLASHING_RED }

enum Approach { NORTH, SOUTH, EAST, WEST }

/** A phase = the set of approaches that may be green together (they never cross). */
record Phase(String name, Set<Approach> greens) {}

/** Observer: anyone who wants to hear about light changes (displays, logs, safety monitor). */
interface SignalListener {
    void onChange(String intersection, Approach approach, Signal from, Signal to);
}

/** One light head facing one approach. */
final class TrafficLight {
    private final String intersection;

            for (int i = 0; i < 20; i++) {
                y.requestEmergency(i % 2 == 0 ? Approach.EAST : Approach.NORTH);
                Thread.onSpinWait();
                y.clearEmergency();
            }
        });
```

```
        done.await();
        timer.shutdown();
        timer.awaitTermination(1, TimeUnit.SECONDS);
        dispatcher.join();
        System.out.println("ticks run: " + (y.clock() >= 500) + ", safety violations: " +
safety2.violations().size());

        System.out.println("\nlight changes seen by observer: " + changes.get()
                + ", safety violations: " + safety.violations().size());
    }

    static void run(Intersection x, int seconds) {
        String last = x.snapshot();
        for (int i = 0; i < seconds; i++) {
            x.tick();
            String now = x.snapshot();
            if (!now.equals(last)) System.out.printf("t=%-3d %s%n", x.clock(), now);
            last = now;
        }
    }
}
```

How the code works, part by part

- `Intersection.tick()` is `synchronized` and simply delegates to `state.onTick(this)`. A state changes the context with `setState(next)`, which immediately calls `next.enter(this)` so the new state can set lights and load its timer.
- `GreenState.enter` asks the `TimingPolicy` for the duration, and jumps straight to `EmergencyHoldState` if its phase is the emergency phase.
- `GreenState.onTick` ends the green **early** when an emergency is pending for another phase. `YellowState` never checks the emergency flag — yellow always runs in full.
- `AllRedState` chooses the emergency phase if one is pending, else the next phase in order.
- `QueueAdaptiveTiming` gives `secondsPerCar × waiting cars`, clamped between min and max.
- `SafetyMonitor` receives every change to GREEN and checks `isSafe()`: all green/yellow approaches must belong to one phase.
- Part 5 of `Main` drives a second intersection with a real `ScheduledExecutorService` (1 ms stands for 1 s) while a virtual thread (a lightweight Java 21 thread, cheap enough to create by the thousand) fires 20 emergency requests and clears; the synchronized methods keep every transition whole, and the monitor sees zero violations.

Output:

```
== 1. Fixed cycle: green 5s, yellow 2s, all-red 1s (printed when lights change) ==
t=0   N:G S:G E:R W:R  GREEN(0)
t=5   N:Y S:Y E:R W:R  YELLOW(0)
t=7   N:R S:R E:R W:R  ALL_RED
t=8   N:R S:R E:G W:G  GREEN(1)
t=13  N:R S:R E:Y W:Y  YELLOW(1)
t=15  N:R S:R E:R W:R  ALL_RED
t=16  N:G S:G E:R W:R  GREEN(0)

== 2. Adaptive timing: 12 cars waiting East-West, 2 North-South ==
t=21  N:Y S:Y E:R W:R  YELLOW(0)
t=23  N:R S:R E:R W:R  ALL_RED
t=24  N:R S:R E:G W:G  GREEN(1)
t=34  N:R S:R E:Y W:Y  YELLOW(1)
t=36  N:R S:R E:R W:R  ALL_RED

== 3. Ambulance from the WEST while North-South is green ==
t=37  N:G S:G E:R W:R  GREEN(0)
t=38  emergency request: WEST
t=39  N:Y S:Y E:R W:R  YELLOW(0)
t=41  N:R S:R E:R W:R  ALL_RED
t=42  N:R S:R E:G W:G  EMERGENCY_HOLD(1)
t=45  ambulance has passed: clear
t=46  N:R S:R E:Y W:Y  YELLOW(1)
t=48  N:R S:R E:R W:R  ALL_RED
t=49  N:G S:G E:R W:R  GREEN(0)

== 4. Controller fault -> flashing red, then recovery ==
t=50  N:F* S:F* E:F* W:F*  FLASHING_RED
t=51  N:G S:G E:R W:R  GREEN(0)

== 5. Real timer thread (1 ms = 1 s) + emergency from another thread ==
ticks run: true, safety violations: 0

light changes seen by observer: 48, safety violations: 0
```

Read the output: the fixed cycle is 5 s green, 2 s yellow, 1 s all-red; with 12 cars waiting east-west, the adaptive policy gives E-W a 10-second green (the maximum); the ambulance request at t=38 ends N-S green at the very next tick, but yellow (2 s) and all-red (1 s) still run before E-W goes green and is **held**; after the clear, the cycle resumes with N-S; a fault switches every head to flashing red; the observer counted every change and found no safety violation.

Concurrency & edge cases

Situation	Handling
Emergency request arrives between two ticks	Stored in a field under the intersection's lock; the next tick acts on it
Emergency arrives during yellow	Yellow runs in full; `AllRedState` then picks the emergency phase
Emergency for the phase that is already green	`GreenState.onTick` switches to `EmergencyHold` — no needless yellow
Two emergency vehicles from crossing directions	The latest request wins: if it arrives during a hold, `EmergencyHoldState` leaves through yellow and all-red and the new phase is then held. A real system queues requests by priority and arrival and serves them in turn (extension)
Emergency never cleared (lost message)	Add a maximum hold time after which the controller resumes the cycle
Timer thread and sensor thread overlap	All public methods are `synchronized`; listeners are in a `CopyOnWriteArrayList` (a thread-safe list that copies itself on every change)
Adaptive timing starves a quiet road	Minimum green time in `QueueAdaptiveTiming`; every phase still gets its turn in the cycle
Controller bug causes conflicting greens	`SafetyMonitor` detects it; real controllers then force flashing red
Timer drift (small delays adding up so ticks slowly fall behind)	`scheduleAtFixedRate` keeps a fixed rate; for real deployments use the controller's hardware clock

Extensions & follow-up questions

1. **"Pedestrian crossings?"** — Add pedestrian signal heads per phase (WALK during the phase's green, flashing DON'T WALK before yellow) and a push-button input that requests the phase.
2. **"Left-turn arrows?"** — More phases (e.g. N-S protected left, then N-S through); phases are data, so the state machine does not change.
3. **"Coordinate many intersections (green wave)?"** — A `TrafficControlCenter` sets each intersection's cycle length and **offset** so that a platoon (group travelling together) of cars driving at the speed limit meets greens in sequence.
4. **"Emergency corridor?"** — The centre pre-empts the next intersections along the ambulance's route, each through `requestEmergency`.
5. **"Night mode?"** — A time-of-day `TimingPolicy`, or a flashing-yellow state for the main road with flashing red for the side road.
6. **"How to test?"** — The tick-driven design is deterministic: call `tick()` N times and assert the snapshot, as `Main` does.

Real-world example

Adaptive systems such as **SCATS** (developed in Sydney) and **SCOOT** (developed in the UK) adjust green times and cycle lengths from road sensors across whole city networks — the `QueueAdaptiveTiming` strategy scaled up. **Emergency vehicle pre-emption** systems (for example infrared or GPS-based emitters on fire trucks) request green for the vehicle's approach; the controller still times out the current yellow and red clearance before serving it, exactly like our `EmergencyHoldState`. In North American cabinets, a **conflict monitor / malfunction management unit** watches the outputs and forces the intersection into flash if it ever sees conflicting greens — our `SafetyMonitor` observer.

In the interview

Plan for 40 minutes: 5 min requirements (phases, timing, emergency, fault) → 5 min entities → 10 min draw the state machine (green → yellow → all-red → next; emergency and fault edges) → 15 min code `GreenState` / `YellowState` / `AllRedState` and `tick()` → 5 min concurrency and follow-ups.

30-second answer: "An intersection has phases — sets of approaches that can be green together — and a controller that is a timed State machine: Green, Yellow, All-Red, plus Emergency-Hold and Flashing-Red. A timer calls `tick()` once a second; each state counts down and names the next one. Green duration comes from a swappable timing Strategy, fixed or queue-adaptive. An emergency request only shortens the current green: yellow and all-red always run in full, then the emergency phase is held green until cleared. Lights publish changes to observers, including a safety monitor that checks no crossing flows are ever green together."

Follow-ups with answers

- *"Why not jump straight to the emergency green?"* — Cars already in the intersection need the yellow and all-red intervals to clear it; skipping them causes crashes.
- *"Why is the controller not a Singleton?"* — There is one per intersection, and a city has thousands.
- *"How do you make the timing adaptive?"* — Sensors report queue lengths; a `TimingPolicy` turns them into green seconds within a min/max.

Self-check

1. **Q:** What is a phase? **A:** A set of approaches that may be green together because their paths do not cross.
2. **Q:** Why the all-red interval? **A:** To let vehicles still in the intersection clear it before the crossing flow gets green.
3. **Q:** What happens to an emergency request that arrives during yellow? **A:** Yellow finishes; all-red then picks the emergency phase instead of the normal next phase.
4. **Q:** Why do these states hold data while the vending states do not? **A:** Each interval has its own countdown, so each state instance carries remaining seconds.
5. **Q:** Which pattern lets you switch from fixed to adaptive timing at run time? **A:** Strategy (`TimingPolicy`).
6. **Q:** What does the `SafetyMonitor` check? **A:** That all green/yellow approaches belong to a single phase whenever a light turns green.

TL;DR

- **Timed State machine**: Green → Yellow → All-Red → next Green; plus Emergency-Hold and Flashing-Red.
- **Safety first**: red before green, yellow never cut short, conflict-monitor observer.
- **Strategy** for timing (fixed/adaptive), **Observer** for lights, emergency as a flag the states read.
- Tick-driven and synchronized: deterministic tests, safe with a timer thread plus emergency threads.

14.7 Design a Shipping Locker System

A **parcel locker** (also called a *pickup locker* or *shipping locker*) is a wall of numbered steel doors in a shop, station or apartment lobby. A courier puts a parcel behind one door; the customer later types a **pickup code** on the station's screen and that one door opens. Amazon Hub Locker, InPost's Paczkomat network in Poland and similar networks run by couriers and online shops in many countries all work this way. Lockers save the courier a failed doorstep delivery and let the customer collect at any hour.

This question looks like the parking lot (§14.1) — hand out a limited set of spaces of different sizes — but adds three things interviewers like to probe: **a lifecycle with deadlines** (a reservation that times out, a parcel that expires if nobody collects it), **a secret** (the pickup code, which must be hard to guess and never shown to the courier), and **a network** of stations (if the nearest one is full, suggest another).

Problem & clarifying questions

Question	Assumed answer
What sizes do doors come in?	A few fixed sizes (small, medium, large). A parcel may go into a bigger door if no door of its own size is free.
When is a door chosen — at the station, or before?	Before: the carrier's system **reserves** a door when the parcel is sorted for delivery, so the courier never arrives to a full station. The hold lasts 2 hours; if nothing is deposited, the door is released.
How does the customer open the door?	A 6-digit **one-time code** sent by SMS/app when the parcel is deposited. The courier never sees it.
How long can a parcel stay?	3 days after deposit. After that it **expires** and the carrier takes it back to the sender on the next visit.
What stops someone guessing codes?	Codes are random and single-use; after 5 wrong codes in a row the keypad locks for 15 minutes.
Returns (customer drops a parcel off)?	Same flow in reverse — a carrier-side "code"; treated as an extension.
Many stations?	Yes, a city-wide network. If the chosen station is full, offer the nearest station with space.
Broken doors?	A technician can take a free door **out of service**.
Payment at the locker (cash on delivery)?	Out of scope (extension).

Requirements

Functional

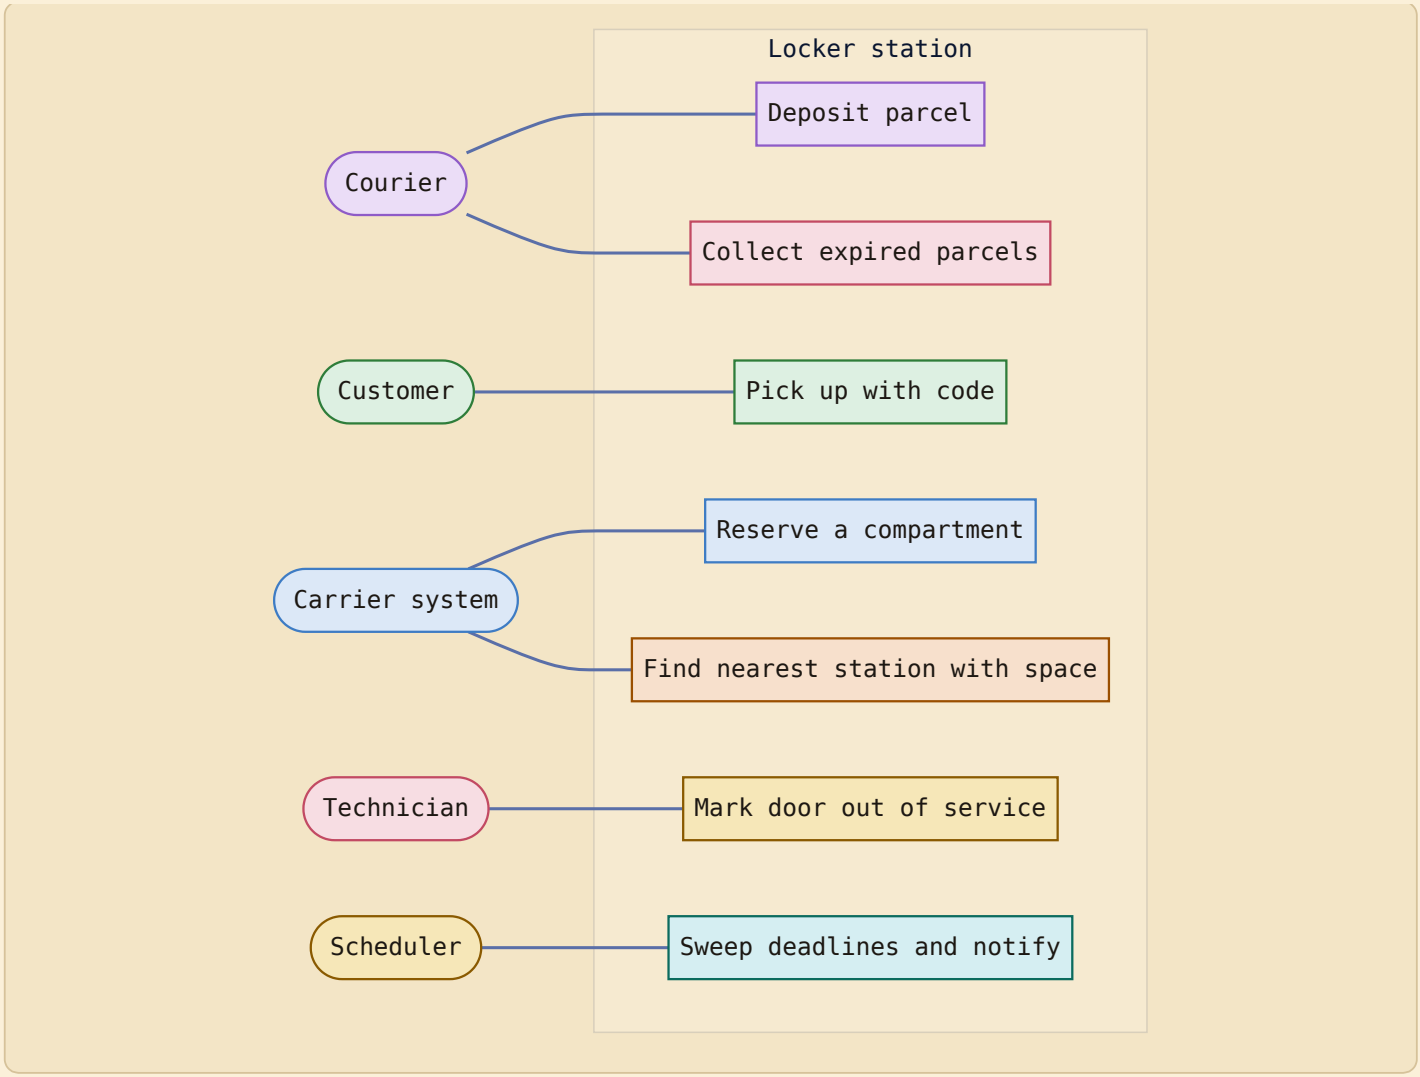
1. A station has numbered compartments of fixed sizes.
2. **Reserve** the best-fitting free compartment for a parcel (all-or-nothing); a reservation expires if the parcel is not deposited in time.
3. **Deposit**: the parcel goes in, a one-time pickup code is generated and **sent to the customer only**.
4. **Pickup**: a correct code opens exactly one door, frees the compartment and stops working.
5. **Expiry**: an uncollected parcel expires after the pickup window; the customer is told; the carrier **collects expired parcels** for return.
6. **Brute-force protection**: lock the keypad after too many wrong codes.
7. **Network search**: nearest station within a radius that has a free door this parcel fits.
8. Compartments can be taken out of service.

Non-functional

- **Never give one door to two parcels**, even when many carriers reserve at the same moment.
- **Security**: codes are unpredictable, single-use, stored only as a hash (the one-way fingerprint described in the ATM section).
- **Correct deadlines** without depending on a background timer being on time.
- **Testable**: time and randomness are injected (a fake clock and a seeded random generator in the demo — one started from a fixed seed, so it produces the same numbers every run).

Use cases

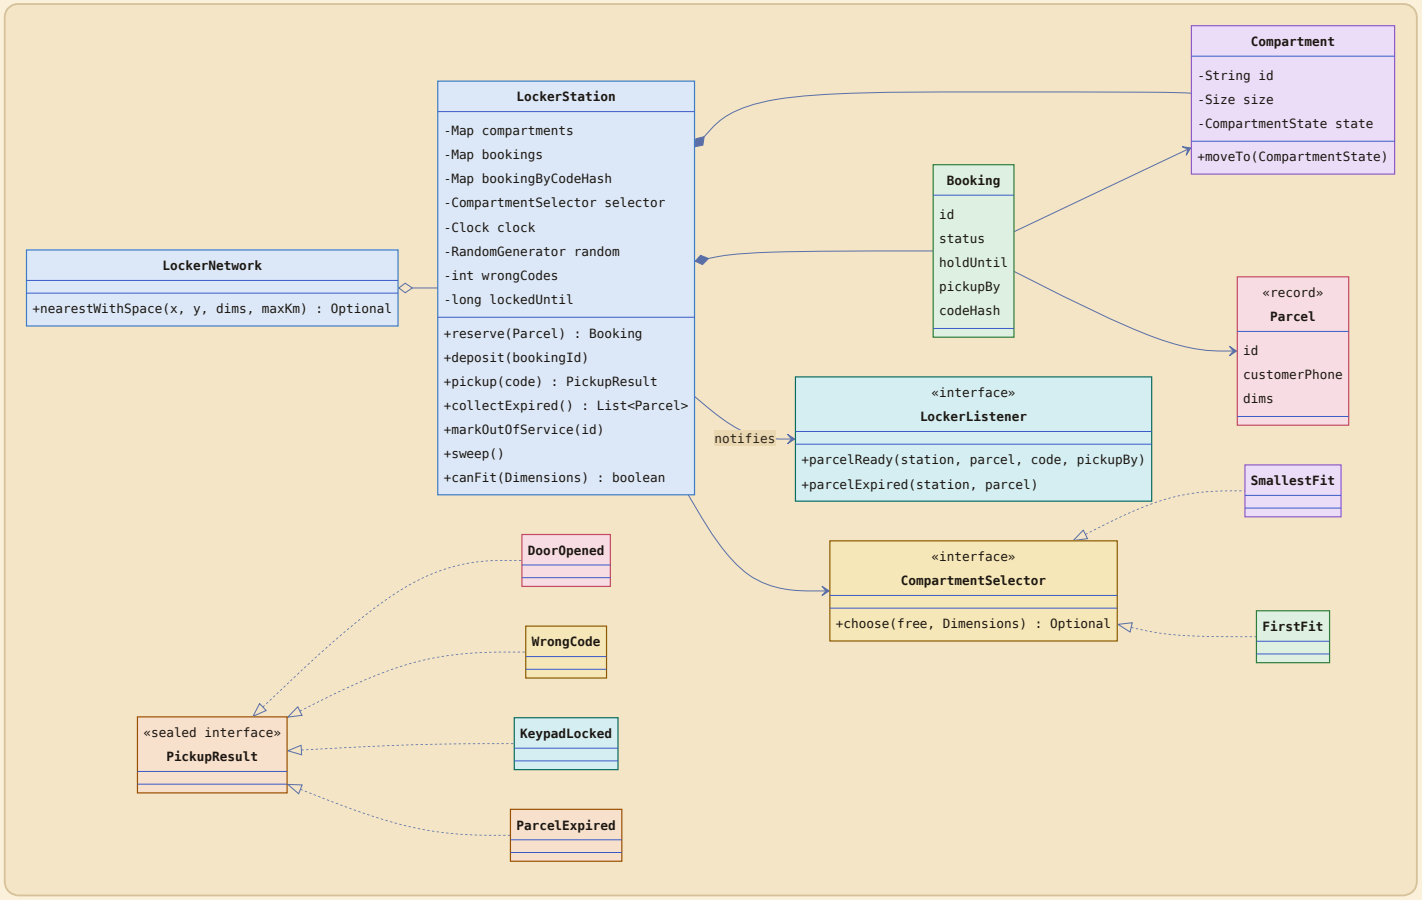
Actors: Carrier system (reserves doors), **Courier** (deposits, collects expired parcels), **Customer** (picks up), **Technician** (takes doors out of service), **Scheduler** (a component that runs a job at set times; here it runs the periodic sweep), **Notification service** (SMS/app).



Core entities

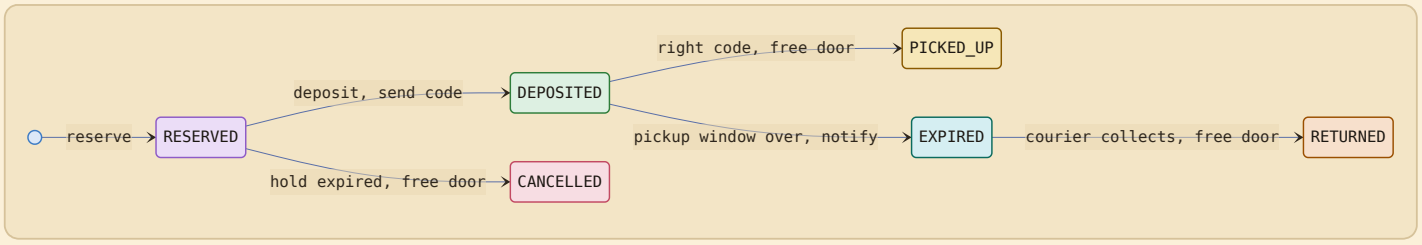
Class	Responsibility
`Size` (enum)	SMALL / MEDIUM / LARGE with inner dimensions; `fits(Dimensions)` checks a box against a door after sorting both sides.
`Dimensions` (record)	A parcel's three sides in cm (validated positive).
`Parcel` (record)	Parcel id, customer phone, dimensions.
`Compartment`	One door: id, size, `CompartmentState` (FREE, RESERVED, OCCUPIED, OUT_OF_SERVICE) with the legal moves inside `moveTo`.
`Booking` + `BookingStatus`	One parcel's stay in one door: RESERVED → DEPOSITED → PICKED_UP, or → EXPIRED → RETURNED, or RESERVED → CANCELLED. Holds the deadlines and the code **hash**.
`PickupResult` (sealed)	`DoorOpened`, `WrongCode`, `KeypadLocked`, `ParcelExpired` — every keypad outcome is a type, not a magic string (a bare text value whose meaning is known only by convention).
`CompartmentSelector`	**Strategy**: `SmallestFit` (default), `FirstFit`.
`LockerListener`	**Observer**: parcel ready (with the code), parcel expired.
`LockerStation`	The station: doors, bookings, code index, lockout counter, clock, random generator; every state change under one lock.
`LockerNetwork`	All stations; nearest station with space.

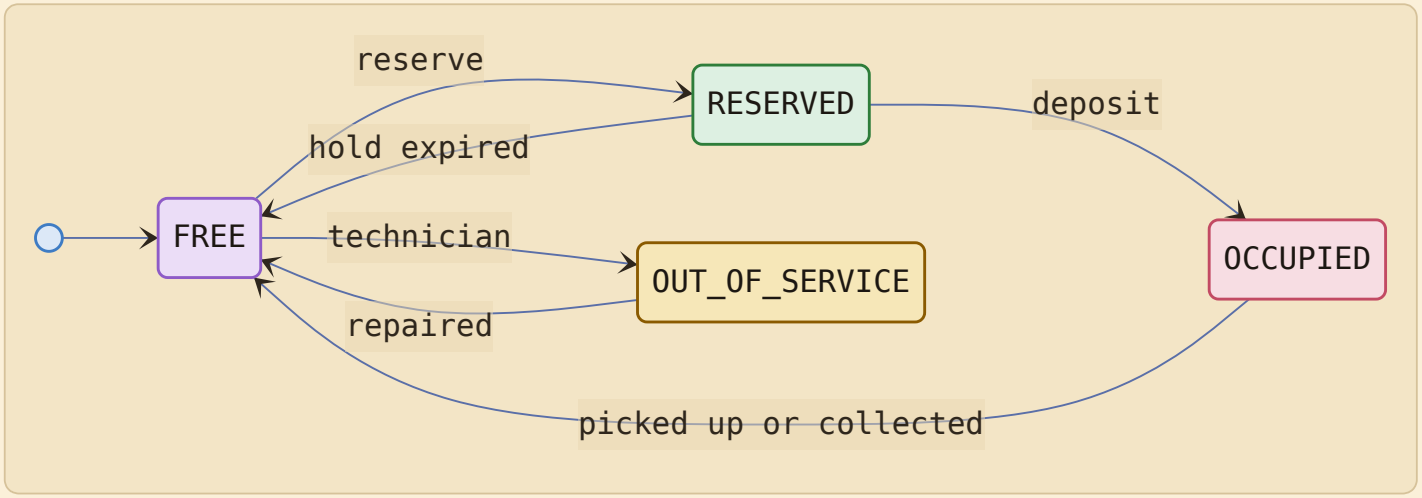
Class diagram



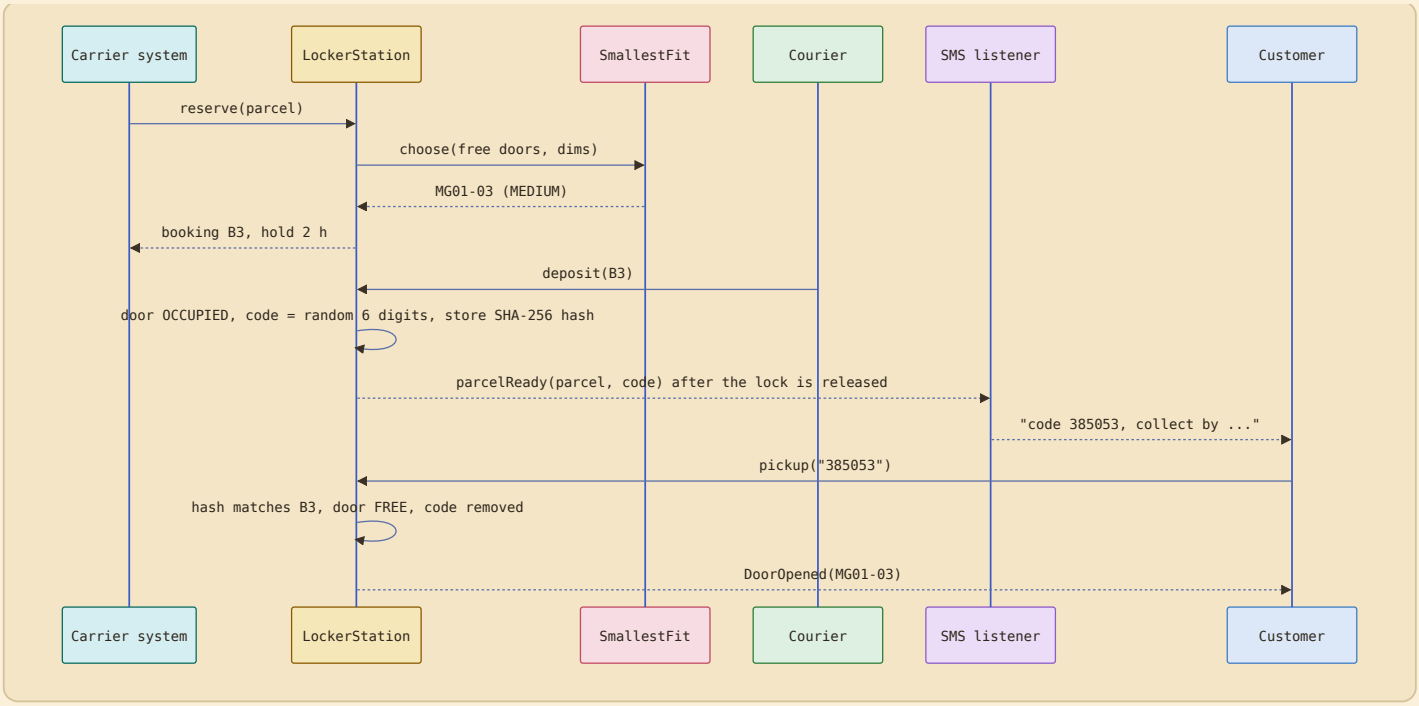
Key flows

The two state machines — first the booking, then the door. A compartment only knows whether it is free; a booking knows the parcel's story. Keeping them separate means a door can be reused while the old booking stays in the history.





Delivery and pickup.



Carrier system
LockerStation
SmallestFit
Courier
SMS listener
Customer
reserve(parcel)
choose(free doors, dims)
MG01-03 (MEDIUM)
booking B3, hold 2 h
deposit(B3)
door OCCUPIED, code = random 6 digits, store SHA-256 hash
parcelReady(parcel, code) after the lock is released
"code 385053, collect by ..."
pickup("385053")
hash matches B3, door FREE, code removed
DoorOpened(MG01-03)
Carrier system
LockerStation
SmallestFit
Courier
SMS listener
Customer

Design decisions & patterns used

Decision	Pattern	Why	Alternative rejected
Door choice is a `CompartmentSelector`	**Strategy**	"Smallest door that fits" keeps large doors for large parcels; a station may prefer "lowest door first" (fast for the courier) or "eye-level first" (accessibility). Each is a small class.	An `if (mode == ...)` inside `reserve`
Separate `Compartment` state and `Booking` status	Two small state machines	A door is reused many times; the booking keeps each parcel's history and deadlines	One status field on the door that mixes "free" with "expired parcel inside"
Transitions checked inside `moveTo` (a `switch` over the current state)	Enum state machine	An illegal move (e.g. taking an occupied door out of service) throws at once	Setting the field anywhere
Keypad outcomes as a **sealed** `PickupResult`	Sealed result types	The UI must handle every outcome; the compiler checks the `switch`	Returning `null`, `-1` or strings
Codes: random, single-use, unique per station, stored as a salted (mixed with a random value before hashing) **SHA-256** hash	Security by design	A database leak does not reveal live codes; the courier never sees them	Storing the plain code, or deriving it from the parcel id
Notify through `LockerListener` **after** releasing the lock	**Observer**	SMS, app push and audit log are independent; a slow SMS gateway (the service that actually sends text messages) must not block the keypad	Calling the SMS gateway inside `deposit` while holding the lock
Lazy expiry (deadlines checked whenever the data is next touched) at the start of every operation, plus a `sweep()` for notifications	Deadline checking on read	Correct even if the scheduler is late or down; the scheduler only sends messages	A reaper thread (a background thread that cleans up expired items) as the *only* thing that frees doors
`Clock` and `RandomGenerator` are injected	Dependency injection	Deterministic demo and tests; production passes `Clock.systemUTC()` and a `SecureRandom` (Java's cryptographically strong random generator)	`Instant.now()` and `new Random()` inside the class
One lock per station (`synchronized`)	Monitor	A station has tens of doors and each call is microseconds, so one lock is simple and never the bottleneck (the one part that limits overall speed); stations never share a lock	Per-door CAS like the parking lot — more code for no gain at this size

Java implementation

Package `lld.ch14.locker`.

```java
// File: lld/ch14/locker/Model.java
package lld.ch14.locker;

import java.util.Arrays;

/** Inner size of a compartment door, in centimetres (height x width x depth). */
enum Size {
    SMALL(10, 40, 60), MEDIUM(20, 40, 60), LARGE(40, 40, 60);

    private final int[] sorted;

    Size(int h, int w, int d) { sorted = new int[]{h, w, d}; Arrays.sort(sorted); }

    /** A box fits if, after sorting both sides, each parcel side is no longer than the matching compartment side.
*/
    boolean fits(Dimensions p) {
        int[] q = p.sorted();
        return q[0] <= sorted[0] && q[1] <= sorted[1] && q[2] <= sorted[2];
    }
}

/** Parcel box size in centimetres. */
record Dimensions(int a, int b, int c) {
    Dimensions {
        if (a <= 0 || b <= 0 || c <= 0) throw new LockerException("Dimensions must be positive");
    }
    int[] sorted() { int[] s = {a, b, c}; Arrays.sort(s); return s; }
    @Override public String toString() { return a + "x" + b + "x" + c + "cm"; }
}

record Parcel(String id, String customerPhone, Dimensions dims) { }

        System.out.println("   reserved=" + ok + " rejected=" + full + " distinct doors=" + doorsGiven.size());
    }
}
```

How the code works, part by part

- `Size.fits` sorts the three sides of both the box and the door, then compares smallest-to-smallest. That handles a parcel lying on its side without trying all six rotations.
- `reserve` first applies overdue deadlines, rejects a parcel that already has a door, asks the selector for a free door, moves it to RESERVED and creates a `Booking` whose hold ends in 2 hours. It is `synchronized`, so "find a free door" and "mark it reserved" are one atomic step.
- `deposit` does its state change inside a `synchronized (this)` block, generates a 6-digit code (retrying on the rare clash with another live code at this station), stores only its hash, and calls the listeners **after** the block ends.
- `pickup` checks the lockout, looks the code up by hash, counts wrong attempts (5 in a row locks the keypad for 15 minutes), refuses an expired parcel, and on success frees the door and deletes the code so it cannot be used twice.
- `expireOverdue` runs at the top of every public method: RESERVED past its hold → CANCELLED (door freed); DEPOSITED past its window → EXPIRED (door stays OCCUPIED until the courier collects). `sweep()` is what a scheduler calls every minute; it runs the same check and sends the "not collected" messages outside the lock.
- `LockerNetwork.nearestWithSpace` sorts stations by distance, keeps those within the radius and returns the first that can fit the parcel right now.

Output:

```
== 1. Carrier reserves doors (smallest door that fits) ==
   P1 3x10x18cm    -> MG01-01(SMALL)
   P2 4x16x24cm    -> MG01-02(SMALL)
   P3 9x12x12cm    -> MG01-03(MEDIUM)
   P4 14x22x34cm   -> MG01-04(MEDIUM)
   free now: {SMALL=0, MEDIUM=0, LARGE=1}  (the mug got a MEDIUM: both SMALL doors were taken)
   error: Parcel P1 already has a locker
   error: No free compartment fits 50x50x70cm at MG01

== 2. Deposit: the code goes to the customer by SMS, never to the carrier ==
   SMS to +91-98450-00001: parcel P1 is in locker MG01, code 694696, collect by 2026-10-04T09:00:00Z
   SMS to +91-98450-00002: parcel P2 is in locker MG01, code 607553, collect by 2026-10-04T09:00:00Z
   SMS to +91-98450-00003: parcel P3 is in locker MG01, code 385053, collect by 2026-10-04T09:00:00Z
   error: Booking MG01-B1 is DEPOSITED

== 3. Pickup ==
   typo 123456 -> WrongCode[attemptsLeft=4]
   right code  -> DoorOpened[compartmentId=MG01-01, parcelId=P1]
   same code again -> WrongCode[attemptsLeft=4]  (a code works once)

== 4. Someone guesses codes: keypad locks after 5 wrong tries in a row ==
   guess 000001 -> WrongCode[attemptsLeft=3]
   guess 000002 -> WrongCode[attemptsLeft=2]
   guess 000003 -> WrongCode[attemptsLeft=1]
   guess 000004 -> KeypadLocked[secondsLeft=900]
   real owner during lockout -> KeypadLocked[secondsLeft=900]
   15 min later -> DoorOpened[compartmentId=MG01-02, parcelId=P2]

== 5. Reservation hold runs out (carrier never came with the shoes) ==
   booking MG01-B4 is CANCELLED, free now: {SMALL=2, MEDIUM=1, LARGE=1}

== 6. Mug not collected within 3 days ==
   SMS to +91-98450-00003: parcel P3 was not collected and will be returned
   customer types the code -> ParcelExpired[parcelId=P3]
   carrier collects for return: [P3], free now: {SMALL=2, MEDIUM=2, LARGE=1}

== 7. Station full -> suggest the nearest station with space ==
   customer at (1.0, 0.4), box 8x20x30cm -> MG01
   same box, max 0.2 km -> none within 0.2 km

== 8. FirstFit vs SmallestFit: doors 01 = LARGE, 02 = SMALL ==
   station F: small parcel -> F-01(LARGE), then large parcel -> REJECTED
   station S: small parcel -> S-02(SMALL), then large parcel -> S-01(LARGE)

== 9. 50 carriers reserve at once on a 20-door station ==
   reserved=20 rejected=30 distinct doors=20
```

Reading the output: the mug (9 × 12 × 12 cm) fits a small door but both were taken, so it was upgraded to a medium one; a second reservation for the same parcel and an oversized box are refused. Codes went only to the customers' phones. The keypad counted the earlier typo, so the fourth guess in section 4 hit the limit of five and locked it — even the real owner had to wait 15 minutes. The shoes' reservation lapsed after 2 hours and the door came back. After 3 days the mug expired, the customer's code now says so, and the courier's visit freed the door. `FirstFit` put a tiny parcel in the only large door and then had to refuse a large parcel; `SmallestFit` served both. Fifty concurrent reservations on a 20-door station produced exactly 20 bookings on 20 different doors.

Concurrency & edge cases

Situation	Handling
Two carriers reserve the last medium door at once	`reserve` is `synchronized`: choose + mark RESERVED is one step; the loser gets "no free compartment" (or a larger door)
Courier arrives after the hold ran out	`deposit` sees CANCELLED and refuses; the carrier system reserves again (possibly at another station)
Same parcel reserved twice (retry after a timeout)	Rejected while it has an active booking — make the carrier's reserve call idempotent (repeating it has the same effect as calling it once) by parcel id
Two live parcels get the same random code	Generation retries until the code is unique among live codes at this station
Brute-force guessing	10^6 possible codes, 5 wrong tries then a 15-minute lockout per station; codes also expire
Scheduler down for an hour	Lazy expiry still frees doors on the next operation; only the "expired" SMS is late
Slow SMS gateway	Listeners run outside the lock; in production they hand off to a queue (a buffer that a separate worker drains)
`canFit` says yes but `reserve` then fails (someone else took the door)	Expected: `nearestWithSpace` is a hint; the caller reserves and, on failure, tries the next station
Door jammed / broken	Technician marks a **free** door OUT_OF_SERVICE; an occupied door must be emptied first (`moveTo` enforces it)
Power cut or network loss at the station	Real lockers keep a local copy of live code hashes and sync events later; the design already keeps the station self-contained

Extensions & follow-up questions

1. **"Returns (customer drops off)?"** — A `DropOffBooking`: the customer gets a drop-off code, the door opens empty, the courier collects later. Same states with the roles swapped.
2. **"Let the customer extend the pickup window?"** — A method that moves `pickupBy` once, only while DEPOSITED; a policy object can decide how many extensions are allowed.
3. **"Cash on delivery?"** — Payment at the station screen before the door opens: a `PaymentStep` inserted into `pickup` (Chain of Responsibility or a small state machine per session).
4. **"Fairness when the station is nearly full?"** — Keep a few large doors for large parcels only (a `ReservedCapacitySelector` that refuses to upgrade small parcels when fewer than k large doors are free).
5. **"Scale to thousands of stations?"** — Stations are independent, so shard by station id (sharding = splitting the data across several servers, each owning a slice; see System Design Fundamentals); the network search uses a geo index (an index for fast "what is near this point?" queries: a geohash turns a map cell into a short string, an R-tree is a tree of nested rectangles) instead of sorting every station.
6. **"How would you store this in a database?"** — `compartment(id, station_id, size, state)`, `booking(id, parcel_id, compartment_id, status, hold_until, pickup_by, code_hash)`; reserve with `UPDATE compartment SET state='RESERVED' WHERE id=? AND state='FREE'` and check that one row changed.

Real-world example

Amazon Hub Locker sends the customer a pickup code by email or app and gives a limited number of days to collect before the parcel goes back — the `DEPOSITED → EXPIRED → RETURNED` path. InPost's Paczkomat lockers in Poland let couriers load many parcels in one visit and customers open a door with a code or a phone app; the network is dense enough that "nearest locker with space" matters. In both, the door is chosen by the system, not the courier, which is our `CompartmentSelector`.

In the interview

Plan for 40 minutes: 5 min questions (sizes, holds, codes, expiry) → 5 min entities → 8 min the two state machines → 15 min code `reserve`, `deposit`, `pickup` with the lock and the listener call outside it → 7 min security, concurrency and follow-ups.

30-second answer: "A station has doors of a few sizes. A carrier reserves one ahead of time; a Strategy picks the smallest free door that fits, and the choose-and-mark step runs under the station's lock, so two carriers never get the same door. On deposit I generate a random single-use code, store only its hash, and notify the customer through an observer after releasing the lock. Pickup matches the hash, frees the door and deletes the code; five wrong codes lock the keypad. Holds and pickup windows are checked lazily on every call, so doors come back even if the scheduler is late, and a network object suggests the nearest station with space."

Follow-ups with answers

- *"Why not let the courier choose any empty door?"* — Couriers would use big doors for small parcels; the system also needs to know the door before the courier arrives.
- *"Why store only a hash of the code?"* — Anyone who reads the database or logs could otherwise open doors.
- *"Why a separate Booking instead of putting the parcel on the Compartment?"* — The door is reused; the booking keeps deadlines and history per parcel.

Self-check

1. **Q:** How does `Size.fits` handle a box lying on its side? **A:** It sorts the three sides of both box and door and compares them in order.
2. **Q:** What happens to an expired parcel's door? **A:** It stays OCCUPIED until the courier runs `collectExpired`, which frees it.
3. **Q:** Why is the listener called after the `synchronized` block in `deposit`? **A:** A slow or failing SMS call must not hold the station lock.
4. **Q:** What frees a door if the scheduler never runs? **A:** Lazy expiry at the start of every public method.
5. **Q:** Which pattern lets you switch from smallest-fit to first-fit? **A:** Strategy (`CompartmentSelector`).
6. **Q:** Why is one lock per station enough here but not in a parking lot of 5,000 spots with 20 gates? **A:** A station has tens of doors and few concurrent callers; the lock is held for microseconds.

TL;DR

- Doors of fixed sizes; a **Strategy** picks the smallest free door that fits; choose-and-mark is **atomic** under the station lock.
- Two small **state machines**: door (FREE/RESERVED/OCCUPIED/OUT_OF_SERVICE) and booking (RESERVED → DEPOSITED → PICKED_UP / EXPIRED → RETURNED / CANCELLED).
- Codes are **random, single-use, hashed**, sent only to the customer via an **Observer** outside the lock; lockout after 5 wrong tries.
- Deadlines are enforced **lazily** on every call; a sweep only sends messages. Inject clock and randomness.

Chapter summary

Problem	Core difficulty	Key data structure	Key patterns	Concurrency tool
Parking lot	Allocate spots without double booking	Concurrent sorted set of free spots per type	Strategy, Factory, Observer	`pollFirst` + CAS, per-ticket lock, `putIfAbsent`
Vending machine	Legal order of actions; exact change	`EnumMap` of coin counts; DP table	State	`synchronized` machine
Coffee machine	All-or-nothing multi-ingredient deduction	`EnumMap` levels, recipes as data	Observer, sealed results	One `ReentrantLock`; notify outside the lock
ATM	Money correctness and authentication	Total vs available balance; note chain	State, Chain of Responsibility, Command	Per-account lock; ordered locking for transfers
Elevator	Scheduling and dispatching	Two `TreeSet`s (up/down stops)	Strategy (+ modes)	Per-car lock, synchronized dispatcher
Traffic signal	Timed transitions with a safety invariant	Phases as data	State, Strategy, Observer	Synchronized tick; scheduled executor
Shipping locker	Best-fit door, holds and pickup windows, secret codes	Doors per station; bookings; code-hash index	Strategy, Observer, enum state machines, sealed results	One lock per station; lazy expiry; notify outside the lock

Chapter self-check

1. **Q:** Which two problems use the State pattern with *stateless* states, and which uses states *with data*? **A:** Vending machine and ATM share stateless singletons; the traffic signal's states hold countdowns, so a new instance is created per transition.
2. **Q:** Name the check-then-act race in each of parking, coffee and ATM, and its fix. **A:** Two gates take one spot (atomic `pollFirst`/CAS); two orders take the last milk (one lock around check+deduct); two ATMs overdraw one account (check+debit under the account lock).
3. **Q:** Where did we reject a Singleton, and why? **A:** Parking lot, coffee machine, traffic controller: a Singleton is a hidden global, blocks testing several instances, and real deployments have many (lots, machines, intersections).
4. **Q:** Where does greedy fail and what replaces it? **A:** Change-making with limited coins (vending) and note selection with limited cassettes (ATM); bounded coin-change dynamic programming.
5. **Q:** Which designs are tick-driven, and why is that useful? **A:** Elevator and traffic signal: deterministic, clock-free tests; a real timer just calls `tick()`/`step()`.
6. **Q:** Which case enforces deadlines *lazily*, and why? **A:** The shipping locker: every call first expires overdue holds and parcels, so doors come back even if the scheduler is late; the scheduled sweep only sends messages.

Chapter TL;DR

- Find the **one hard method** in each problem (spot allocation, change-making, ingredient deduction, withdrawal, next stop, next phase) and spend your time there.
- **State** for machines whose buttons mean different things over time; **Strategy** for rules that change (pricing, dispatch, timing); **Observer** for boards, alerts and monitors; **Chain of Responsibility** and **Command** for the ATM.
- Make every **check-then-act** atomic, lock at the **smallest** useful scope, lock in a **fixed order**, and call listeners **outside** locks.
- Prefer injected instances over Singletons, integer cents over doubles, and tick-driven logic over sleeps.
- For anything with a **deadline** (holds, pickup windows), check it on every call and keep secrets (pickup codes) **hashed and single-use**.

Chapter 15 — Case Studies: Booking & Inventory (Part 1)

> **Where this fits.** Chapter 14 designed small, self-contained objects. This chapter is the first of two on **booking systems**: software that sells or lends a limited thing (a book copy, a cinema seat, a concert place, a hotel night) to many people who all want it at once. Chapter 16 continues with more booking problems. Everything here uses the case-study template from Chapter 1 and the concurrency tools from Chapters 12–13.

Why booking problems are interview favourites

A booking problem looks like simple CRUD ("create, read, update, delete") until two people want the same thing. Then five hard questions appear, and every problem in this chapter is a different mix of them:

Theme	The question the interviewer is really asking	Where you will see it
Inventory	What exactly is the thing being sold or lent? A title or a copy? A seat or a seat *for one show*? A room or a room *on one night*?	`Book` vs `BookItem` (15.1), `HallSeat` vs `ShowSeat` (15.2), GA (general admission) count vs numbered seat (15.3), `Room` + booked nights (15.4)
Holds / locks	How do you keep something for a customer while they pay, without keeping it forever?	Seat lock with a TTL (time-to-live) (15.2), CAS holds + reaper (15.3)
Double-booking prevention	What stops two threads (or two servers) from both succeeding?	`synchronized` per item (15.1, 15.4), one monitor per show (15.2), lock-free compare-and-set (15.3)
Payments	What happens if payment fails? If it succeeds but the hold was lost meanwhile?	Release on decline, refund as **compensation** (15.2, 15.3)
Cancellations	Who gets the thing next, and how much money comes back?	Waitlists (15.1, 15.3), refund policies (15.2, 15.4)

Three words you will meet in every section:

- **Race condition** — two threads read the same data, both decide "it is free", and both act. One result silently overwrites the other.
- **Check-then-act** — the pattern "if free, then take it". It is only safe if the check and the act happen as one indivisible (atomic) step.
- **Hold** (also called a *lock*, *soft lock* or *reservation*) — a temporary claim with an expiry time, so an abandoned checkout does not block the item forever.

> **Key terms — the other words in the table above.** A **thread** is one independent line of execution inside a program; a server runs many at once, and they can all touch the same objects. A **lock** lets only one thread at a time run a piece of code; Java's `synchronized` keyword uses the built-in lock that every object carries, called its **monitor**. **Compare-and-set (CAS)** is a single atomic step that says "change this value to *new*, but only if it still equals *expected*"; code built on CAS instead of locks is called **lock-free**, because no thread ever waits for another. **Contention** means many threads competing for the same item or lock at the same moment. A **reaper** is a background job that sweeps away expired holds. **Compensation** is an action that undoes an earlier step after the fact — for money, a refund.

What you will learn

#	Problem	The one idea that carries the design
15.1	Library Management System	A *title* (`Book`) is not a *copy* (`BookItem`). Limits live with the member; the waitlist lives with the title.
15.2	Movie Ticket Booking (BookMyShow)	You book a `ShowSeat`, not a physical seat. Hold with TTL → pay → commit; refund if the hold was lost.
15.3	Concert Ticket Booking	Extreme contention: lock-free CAS, a counter for general admission, a fair virtual queue, per-user limits, a waitlist.
15.4	Hotel Management System	A status field is not availability. Each room remembers which nights are already sold.

How to run every example in this chapter

```
cd chapters/15-case-booking-1/code
javac --release 21 -d /tmp/lld_15 $(find . -name '*.java')
java -cp /tmp/lld_15 lld.ch15.library.Main        # or moviebooking, concert, hotel
```

All four `Main` classes compile with Java 21 (standard library only) and run. The output under each implementation is the real output of that program. In the concurrency demos, *which* thread wins a race changes from run to run; the *number* of winners never does.

> **Code-style note.** To keep each design readable in one place, a file sometimes holds several small package-private types (types declared without `public`, visible only inside their own package) (for example `Model.java` holds the enums and records of the library). That is legal Java. In a production codebase you would usually give each public type its own file. (If you compile with `-Xlint:all` — the switch that turns on every optional compiler warning — javac, the Java compiler, prints `[auxiliaryclass]` warnings for exactly this: a package-private type declared in one file and used from another. They are style warnings, not errors.)

> **Money.** Every amount (prices, fines, deposits, refunds) is a `java.math.BigDecimal` (Java's exact decimal-number type) built from a string such as `new BigDecimal("0.50")`, never a `double`: binary floating point cannot store 0.10 exactly, so sums drift. Comparisons use `compareTo`/`signum()`, not `equals` (which also compares the number of decimal places), and every rounding step names its `RoundingMode` (the rounding rule, for example half-up).

> **A time trick used in every demo.** Holds expire and fines grow with time. Instead of `Thread.sleep` (pausing for real time), every service takes a `java.time.Clock`. The demos pass a tiny `SimClock` (a `Clock` subclass whose `advance(Duration)` moves time forward). This is standard practice for testable time-dependent code: production passes `Clock.systemUTC()`, tests pass a controllable clock.

15.1 Design a Library Management System

Figure — Cover image for the library case study (course diagram)

Problem & clarifying questions

A **Library Management System** (LMS) is the software a library uses for its daily work: it tracks every book and every physical copy, who borrowed which copy and when it is due, each member's account and card, reservations, and fines. New stock is entered into it, and every loan is recorded with a due date.

Always clarify scope first. Good questions, with the answers we will design for:

Question	Answer we assume
Can a title have several physical copies?	Yes. Each copy is a **book item** with its own barcode and rack position.
How many books can one member hold?	At most **5** at a time.
How long can a member keep a book?	At most **10 days**, then a fine per day late.
Can a member reserve a book that is out?	Yes — and be told when a copy comes back.
How are people and books identified at the desk?	Every book item and every library card has a **unique barcode**; the system scans both.
Do we collect the fine money?	We *calculate and record* fines. Taking payment is out of scope (we say where it would go).
E-books, inter-library loans, lost-copy replacement?	Out of scope. Name them as extensions.

Requirements

Functional

1. Search the catalog by **title, author, subject category and publication date**.
2. Each book has a unique identification number (ISBN, the International Standard Book Number printed on every published book) and details; each copy has a **rack number** to find it physically.
3. A title can have **many copies** (book items); members check out and reserve copies.
4. Answer **"who took this copy?"** and **"which books does this member have?"**.
5. Limit: **max 5 books** per member.
6. Limit: **max 10 days** per loan.
7. **Fines** for books returned after the due date.

8. **Reserve** books that are not currently available.
9. **Notify** a member when a reserved book becomes available, and when a book is overdue.
10. **Barcodes** on every book item and every library card.

Non-functional

- **Correctness under concurrency:** two members at two desks can never both borrow the last copy; a member can never exceed 5 books even if two librarians scan for them at once.
- **Fast search:** searches are by far the most common operation, so they should be index lookups, not scans (an **index** is a lookup structure, such as a map from author name to books, that jumps straight to the matches instead of checking every book).
- **Extensibility:** fine rules and notification channels change; they should be swappable without editing the lending code.

Use cases

Three actors:

- **Librarian** — adds, edits and removes books, book items and members; can also issue, reserve and return items on a member's behalf.
- **Member** — searches the catalog; checks out, reserves, renews and returns books.
- **System** — sends notifications (overdue books, a reserved book is back, cancelled reservations).

Top use cases: add/remove/edit book (and book item); search catalog; register new account / cancel membership; **check out** a book; **reserve** a book that is out; **renew** (borrow the same copy again); **return** a book.

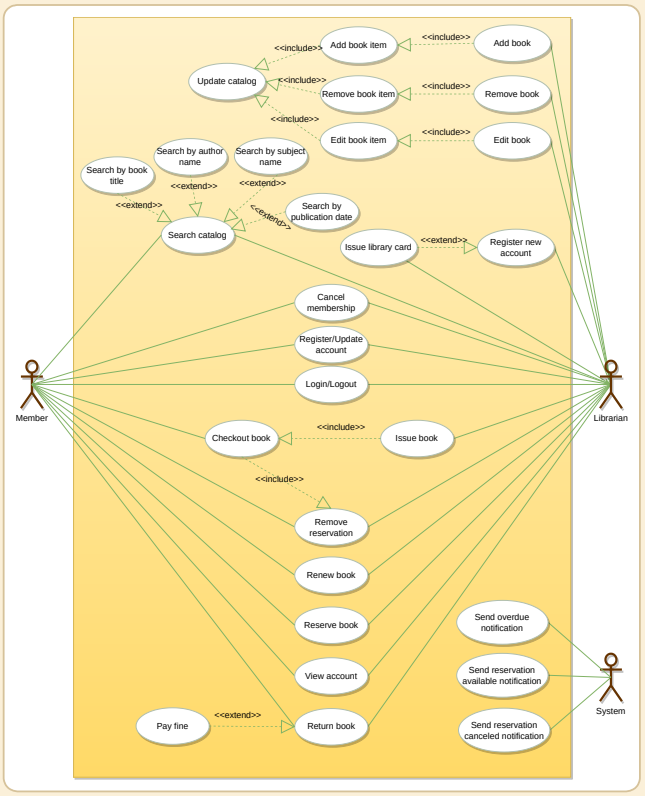

Figure — Library use cases: Member and Librarian share most of them (log in, search, check out, renew, reserve, return); the four "search by" use cases extend "Search catalog"; add/remove/edit book and book item feed "Update catalog"; "Checkout book" includes "Remove reservation"; the librarian's "Issue book" includes "Checkout book"; "Issue library card" is attached to "Register new account" (course diagram)

In the figure above, notice the two relationship kinds. `<<include>>` means a use case *always* performs another one as part of it — checking out a book always clears the member's reservation for it, if they had one. `<<extend>>` means an *optional variation* of a base use case — searching by author is one particular way a catalog search can go.

Core entities

Class	Responsibility
`Book` (record)	The **title**: ISBN, title, subject, publisher, publication date, authors. Immutable.
`BookItem`	One **physical copy**: barcode, format, rack, price, status (`AVAILABLE`, `RESERVED`, `LOANED`, `LOST`), and who it is held for.
`Author`, `Rack` (records)	An author's name; a rack's number and location.
`Account` (sealed, abstract) → `Member`, `Librarian`	People. An account **owns** its `LibraryCard` (composition). A member carries the loan count.
`LibraryCard` (record)	Card number, barcode, issue date.
`BookLending`	One loan: copy barcode, member id, creation date, **due date**, return date.
`Fine` (record)	Amount owed for one late return.
`Search` (interface) / `Catalog`	Four search methods; the catalog keeps one index per search and knows every copy of every title.
`LendingService`	The rules: check out, return, renew, reserve, overdue notices.
`FinePolicy` / `PerDayFine`	How much a late return costs (Strategy: a swappable rule behind an interface).
`Notifier` / `ConsoleNotifier`	Where messages go (email, SMS… here: console).
`Library`	Facade (one simple front object for the whole subsystem): owns the catalog and the lending service; only librarians may add stock.

In the table, a **record** is a short Java class that only carries values; **immutable** means it cannot change after it is created; an **enum** is a type with a fixed list of named constants; an **abstract** class cannot be created directly, only its subclasses can; and a **sealed** type lists exactly which subclasses it allows, so the compiler knows them all.

The course lists the same core classes: **Library** (name, address), **Book**, **BookItem**, **Account** (member or librarian), **LibraryCard**, **BookReservation**, **BookLending**, **Catalog** (searching by title, author, subject, publish date), **Fine**, **Author**, **Rack** (number + location identifier) and **Notification**. We keep every one of them; the only renames are `BookReservation` → a per-title waitlist inside `LendingService` (explained under *Design decisions*) and `Notification` → the `Notifier` interface.

Class diagram

The course builds its diagram in five stages, adding a few classes each time and greying out earlier ones. Walking through the stages is a good way to *present* a design in an interview, because every box arrives with a reason.

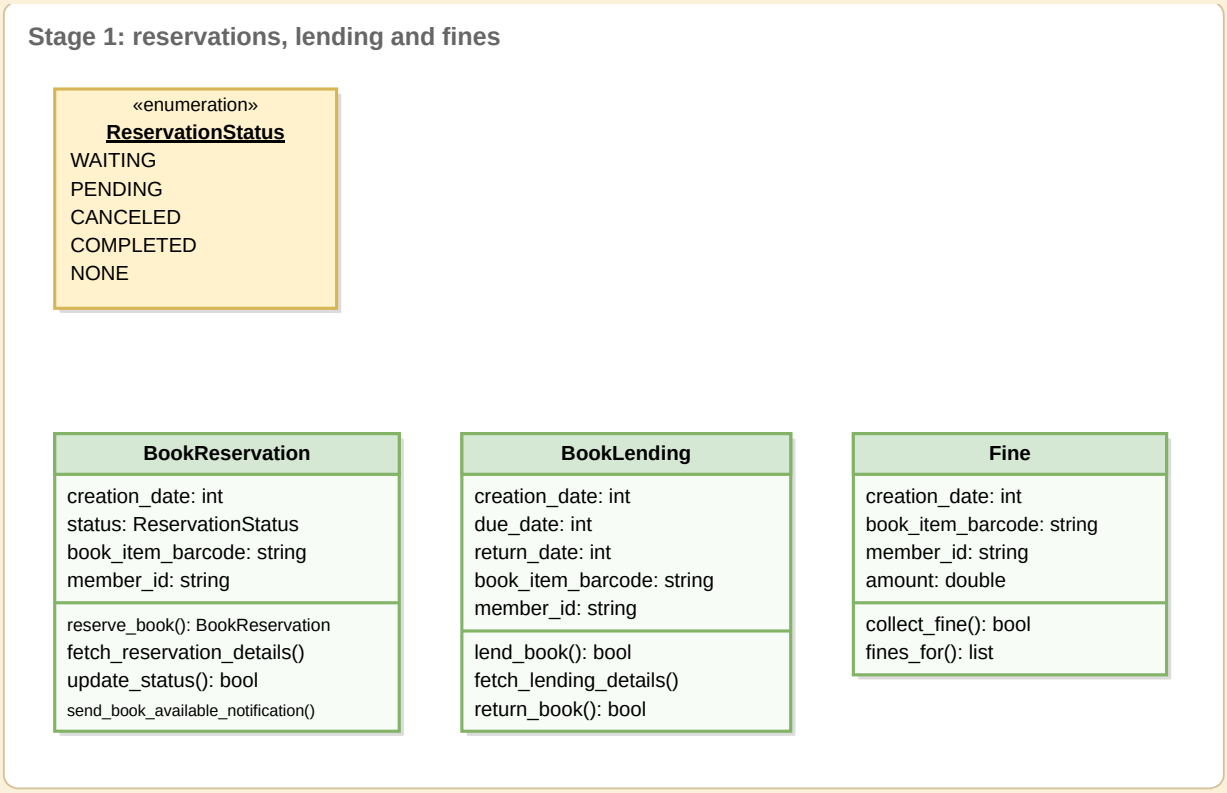

Figure — Stage 1: the three "what happened" records — `BookReservation`, `BookLending` and `Fine` — each keeping a copy's barcode and a member id (course diagram)

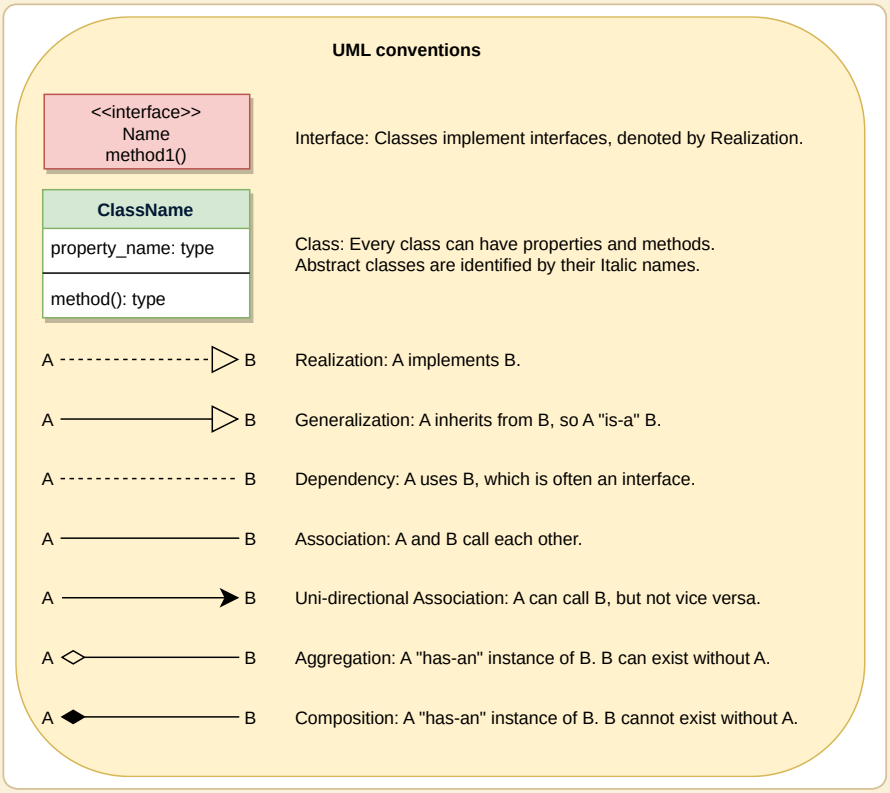

Figure — How to read a class box (name, `property: type`, `method(): type`) and the arrow styles used in these diagrams (course diagram)

Stage 1 answers requirements 4, 7 and 8, which are all about *remembering what happened*. Because each record stores the copy's barcode and the member's id, both halves of "who took this book / what does this member have" are answered by scanning these records.

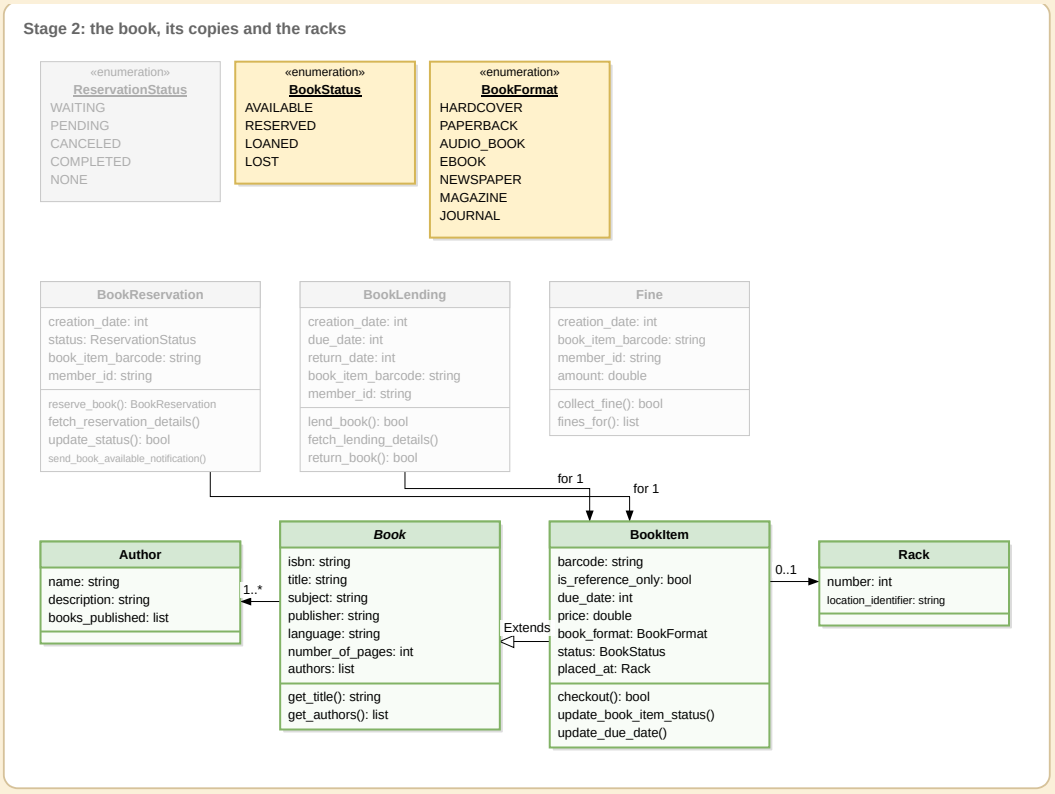

Figure — Stage 2: `Book` (the title) and `BookItem` (one copy with barcode, price and rack), plus `Author` and `Rack`; every reservation and every loan refers to one single copy (course diagram)

Stage 2 is the split that carries the whole design. In the course's diagram `BookItem` *inherits* from `Book`: the reading is that a copy carries all of the title's details and adds its own barcode, price and rack position. In our Java we use **`composition`** instead (`BookItem` *has a* `Book`) — see *Design decisions* for why.

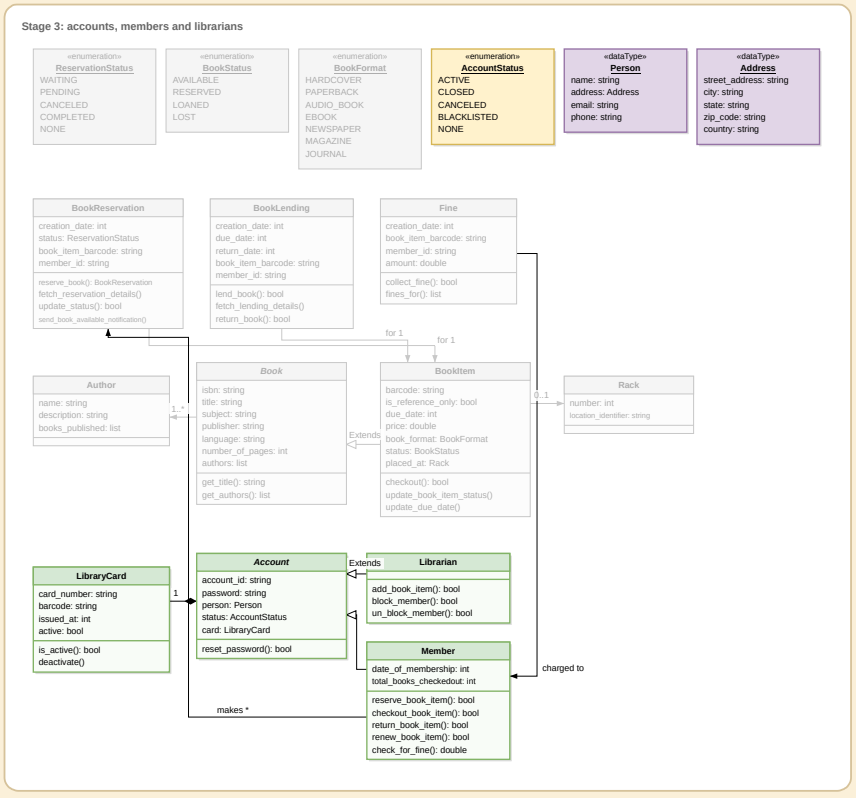

Figure — Stage 3: abstract `Account` with `Member` and `Librarian`; the account owns its `LibraryCard` (filled diamond = composition); a fine is charged to a member; a member makes reservations (course diagram)

Requirements 5 and 6 restrict *what one member may do*, so they belong to the people classes. `Account` is an **`abstract class`**: you can never create a plain `Account`, only a `Member` or a `Librarian`. The **`filled diamond`** is composition — the card has no life of its own, so closing the account destroys the card too.

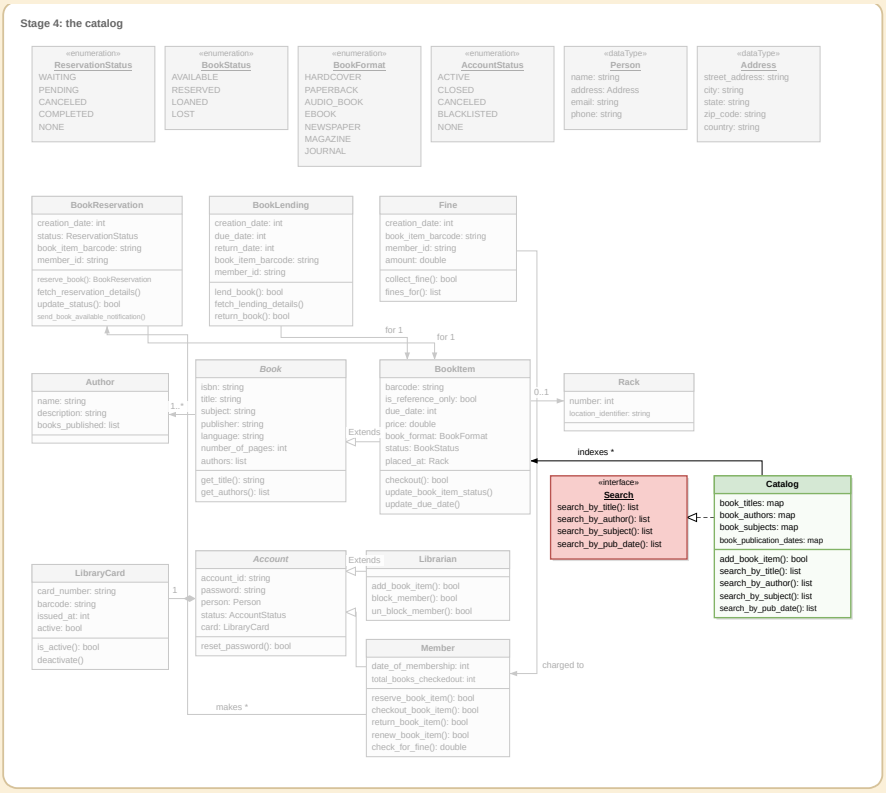

Figure — Stage 4: the `Search` interface (four methods) and `Catalog` implementing it (dashed line, hollow head), indexing book items without owning them (course diagram)

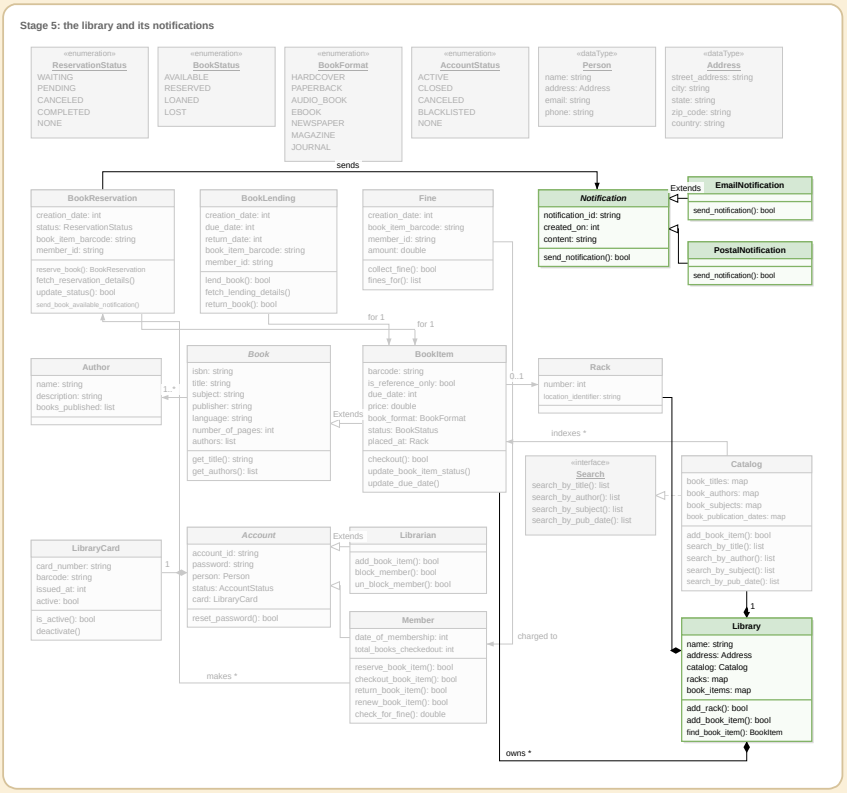

Figure — Stage 5: `Library` is the owner of the catalog, every rack and every book item; `Notification` is abstract with one subclass per delivery channel; a reservation triggers a notification when its copy comes back (course diagram)

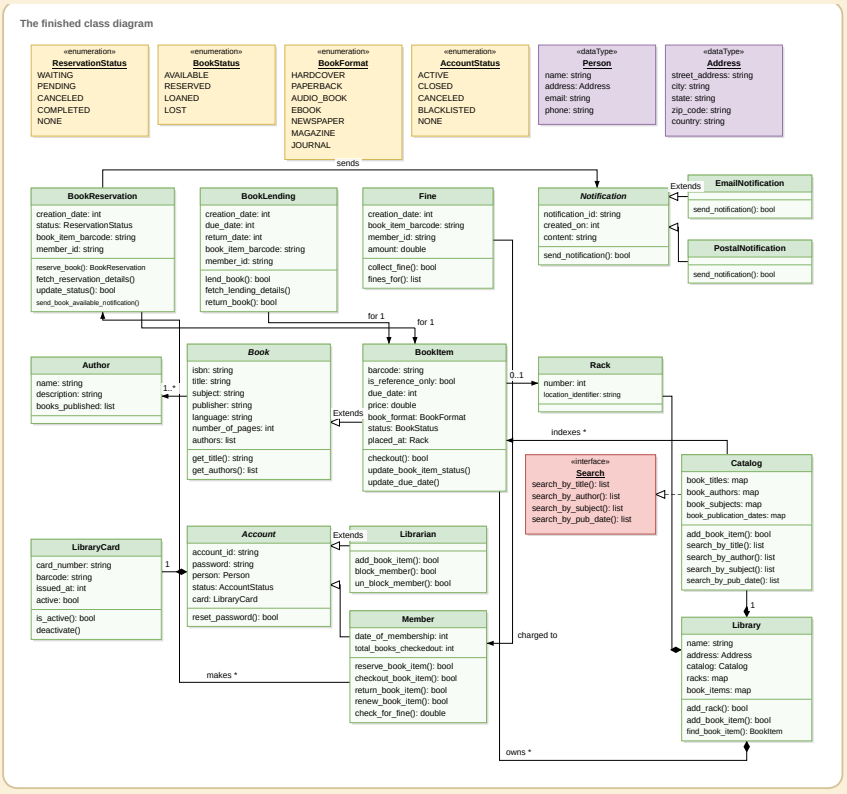

Figure — The finished library class diagram: every class from the five stages in full colour (course diagram)

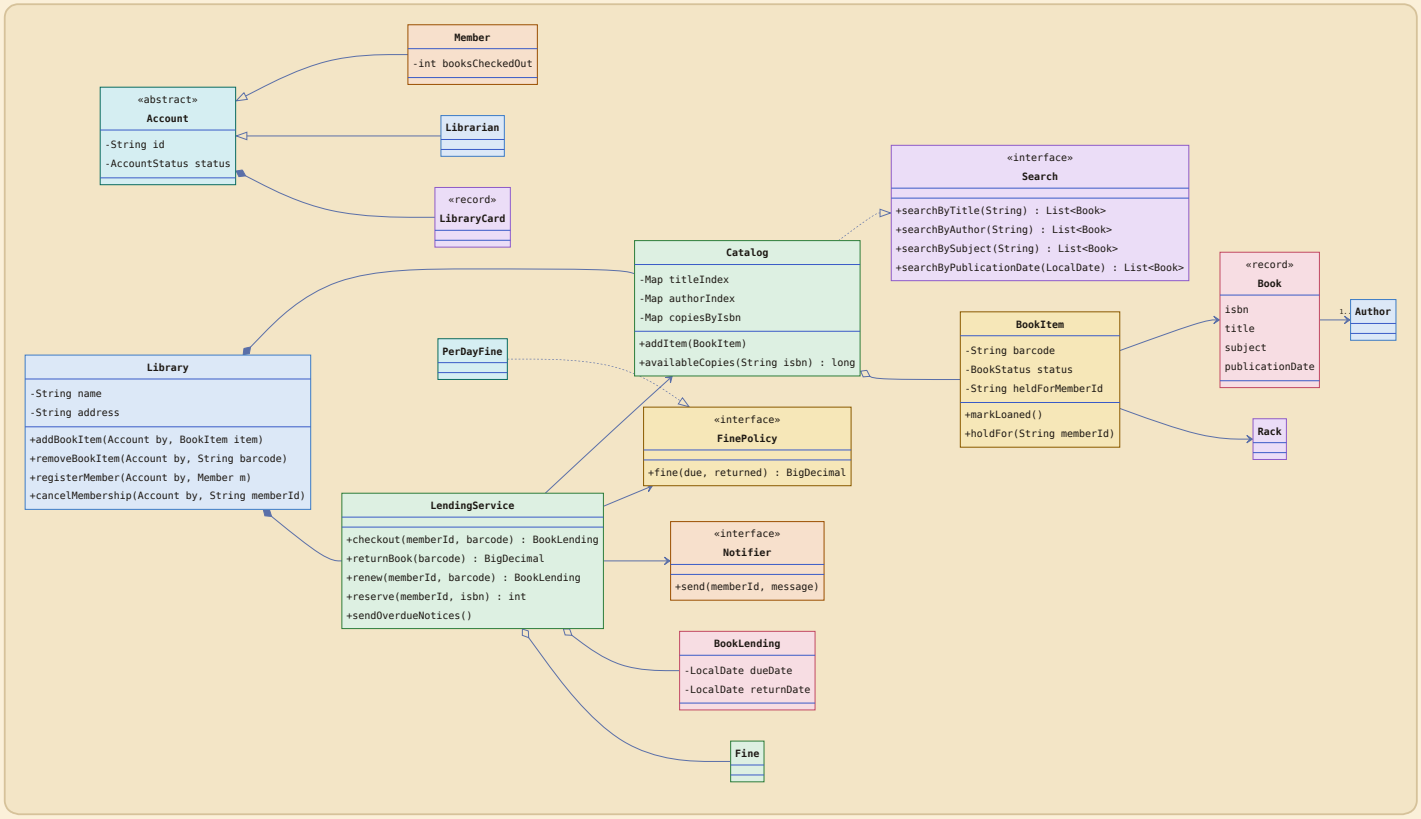
Here is the class diagram of **our Java code** (the one you would draw on the whiteboard):



Key flows

The course gives three activity diagrams — check out, return and renew.

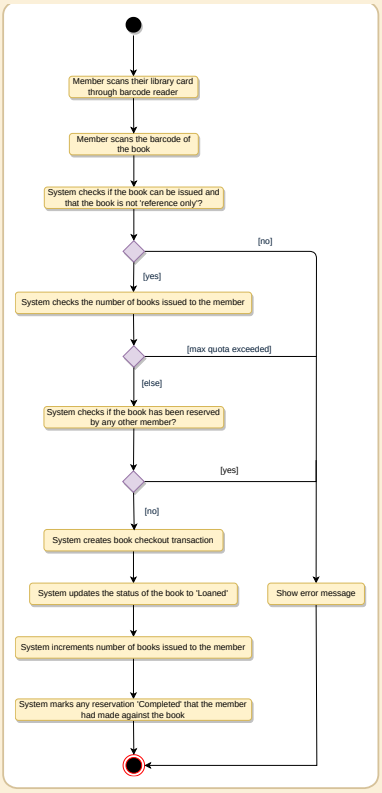


Figure — Check out: scan the book, check it can be issued (not reserved by someone else), check the member's quota, create the checkout transaction, mark the copy "Loaned", increment the member's count, complete any reservation this member had (course diagram)

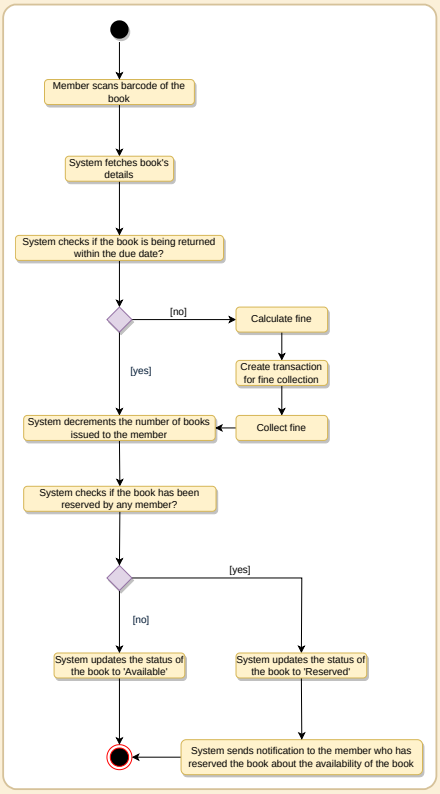

Figure — Return: scan the book, check whether it is late (if so, calculate and collect the fine), decrement the member's count, then check whether the book is reserved — if yes, notify the member who reserved it and mark it reserved, otherwise make it available (course diagram)

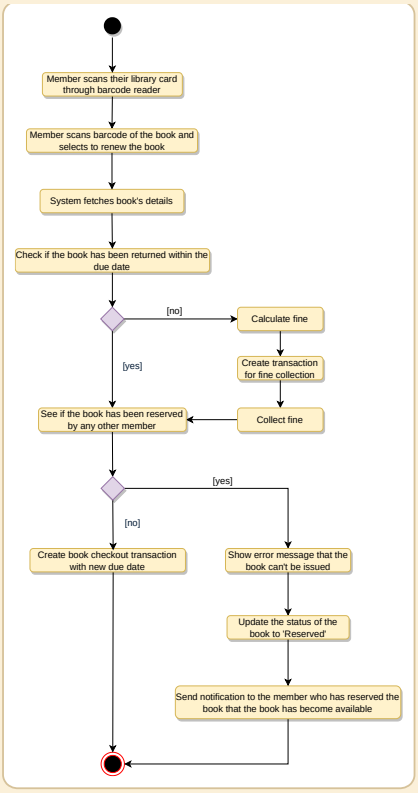

Figure — Renew: scan card and book, collect a fine if it is already late, check whether another member reserved it (if so, refuse and show an error), otherwise create a new checkout transaction with a new due date (course diagram)

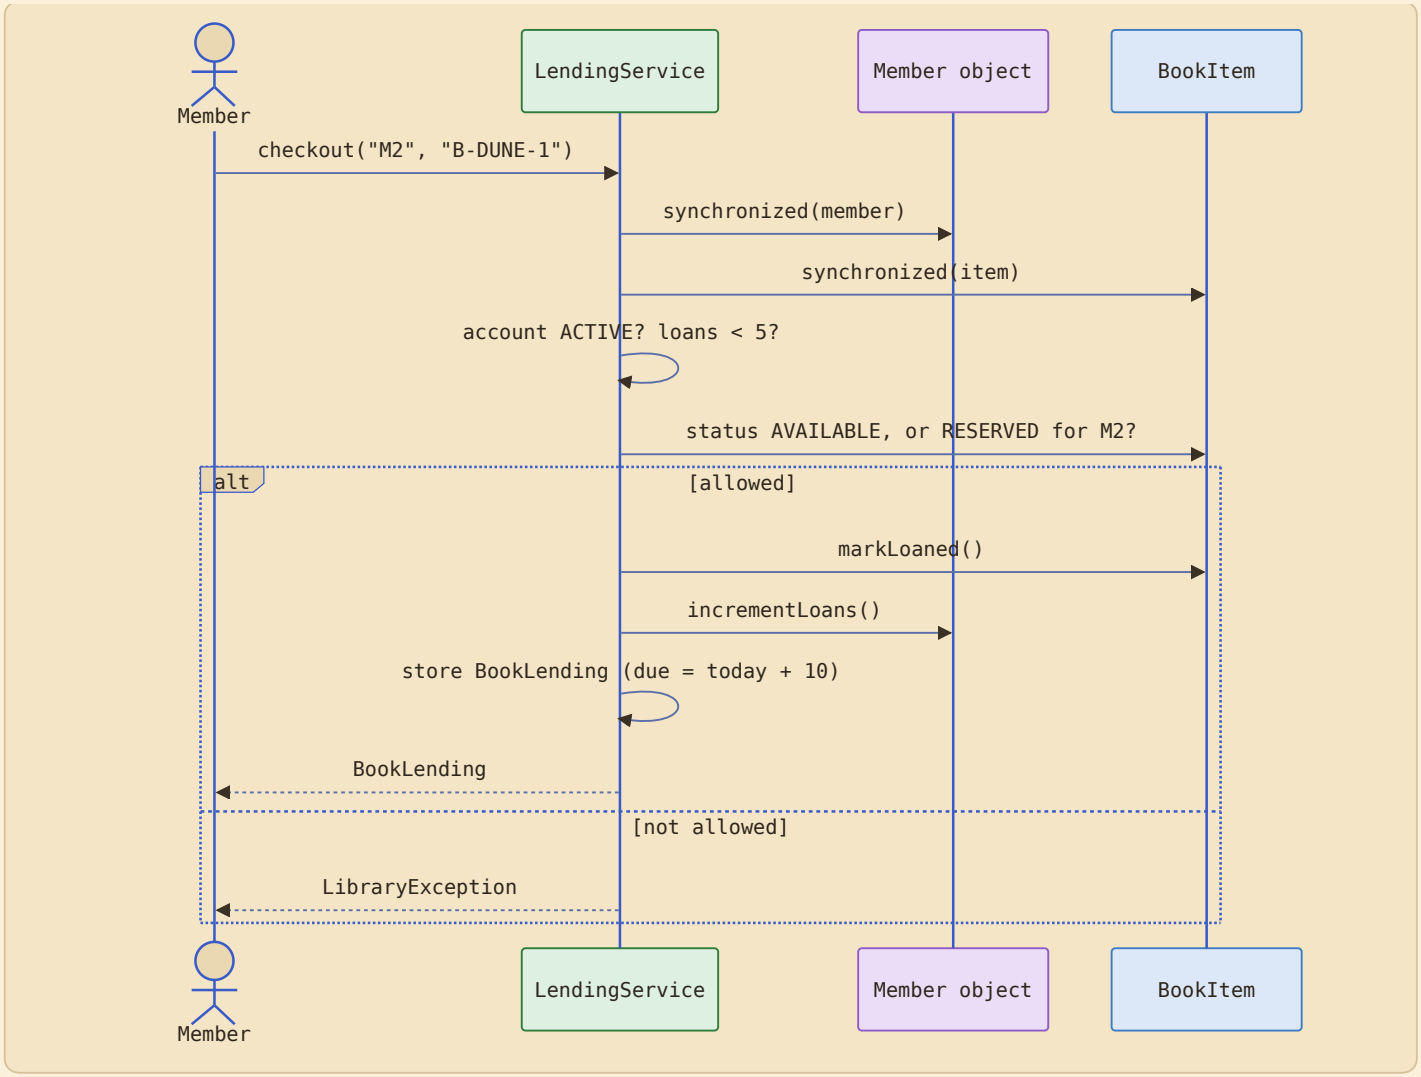
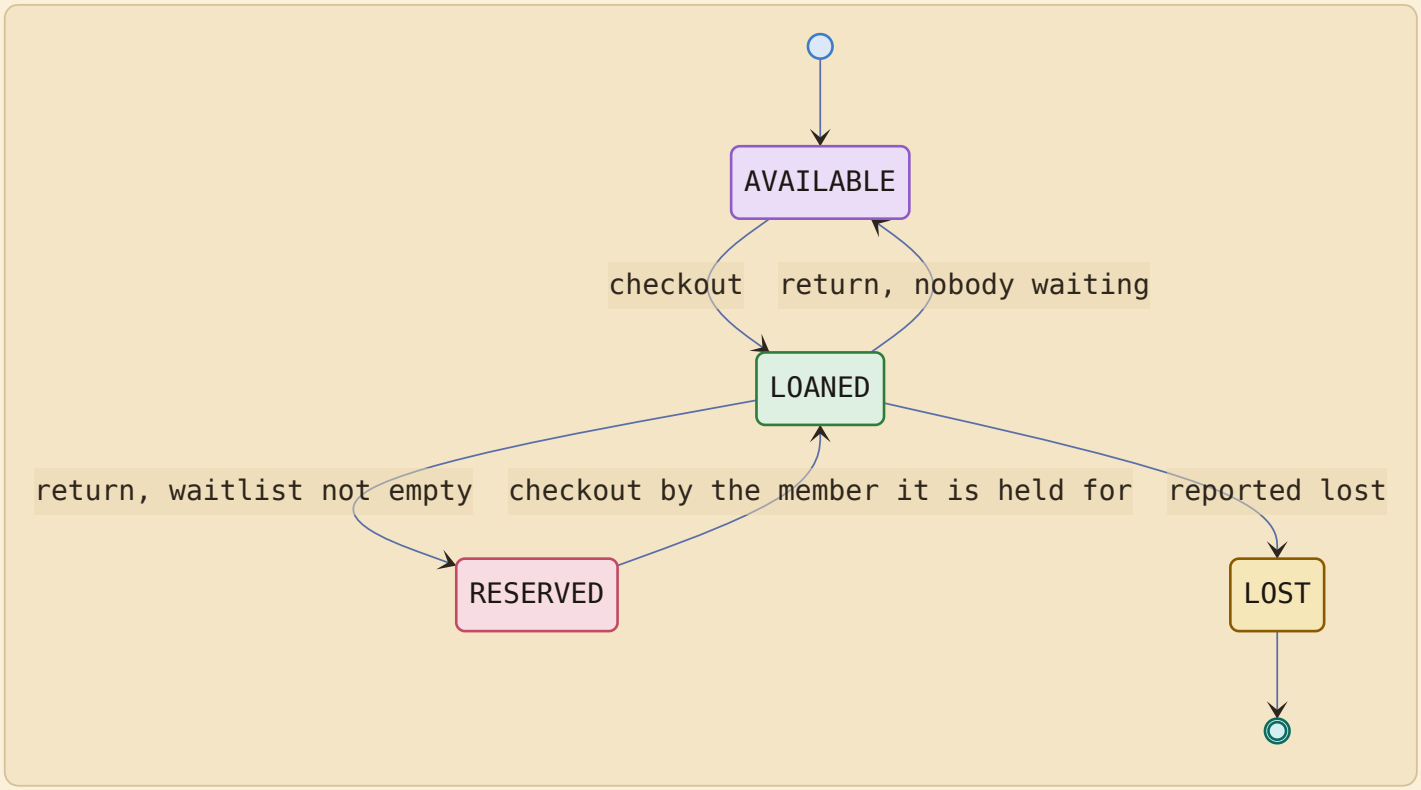
The same check-out flow as a sequence diagram (messages between objects in time order, top to bottom) of our code, including the locks:



A book copy's life is a small **state machine** (a fixed set of states plus the moves allowed between them):



Design decisions & patterns used

Decision	Why	Alternative rejected
`Book` vs `BookItem` split	A member borrows a *copy*; search works on *titles*. Every later class depends on this split, so say it early.	One `Book` class with a `copies` counter — cannot say *which* copy is late, on which rack, or who has it.
Composition (`BookItem` has a `Book`) instead of the course's inheritance	Many copies share one immutable title; with inheritance each copy would duplicate every title field, and changing a title's subject would mean editing every copy. "A copy *is a* title" also fails a strict substitution test (the Liskov Substitution Principle: a subclass must work wherever its parent is expected): a title has no barcode or status.	`BookItem extends Book` (the course diagram) — works for a small model, and is worth mentioning as the other valid reading.
Lending rules in `LendingService`, not on `Member`	The course itself flags that a `Member` doing checkout/return/renew has *two reasons to change* (a person, and the lending rules) — a Single Responsibility violation. Moving the flows to a service keeps `Member` a plain person.	Methods on `Member` (course version) — fine for a first sketch.
Reservation = FIFO (first in, first out) waitlist per *title*	A member wants "a copy of Dune", not "copy #3". When *any* copy is returned, the first person in line gets it.	Reservation per copy (course's `BookReservation` keyed by barcode) — a member could wait on copy #3 while copy #1 sits on the shelf.
Strategy for fines (`FinePolicy`)	Fine rules change (caps, student discounts, holidays). The service calls `fine(due, returned)` and does not care how.	`if/else` inside `returnBook`.
Observer-style `Notifier`	(Observer: the sender announces events to whoever subscribed.) Lending code announces events; delivery (email, SMS, push) is someone else's job. The course's abstract `Notification` with one subclass per channel is the same idea.	Sending email directly from `LendingService`.
Facade (`Library`)	Desk software calls one object; role checks (only librarians add stock) live there.	Exposing the catalog and service directly to the UI.
Catalog keeps one index per search	Every lookup is a map read. The course names the cost: each new way of searching adds another map, whereas a single index keyed by (field, value) would stay one structure.	Scanning all books per search.

Java implementation

Package `lld.ch15.library`. Files: `Model.java` (enums, records, entities), `Catalog.java`, `Support.java` (fine policy, notifier, clock, money formatting), `LendingService.java`, `Library.java`, `Main.java`.

```java
// File: lld/ch15/library/Model.java
package lld.ch15.library;

import java.math.BigDecimal;
import java.time.LocalDate;
import java.util.List;

enum BookFormat { HARDCOVER, PAPERBACK, AUDIO_BOOK, EBOOK, NEWSPAPER, MAGAZINE, JOURNAL }

enum BookStatus { AVAILABLE, RESERVED, LOANED, LOST }

enum AccountStatus { ACTIVE, CLOSED, CANCELED, BLACKLISTED }

  M1 took B-HOB-3, due 2026-03-11
  M1 took B-HOB-4, due 2026-03-11
  M1 took B-HOB-5, due 2026-03-11
  REFUSED: M1 already has 5 books
  M1 has [B-HOB-1, B-HOB-2, B-HOB-3, B-HOB-4, B-HOB-5]

== 3. 8 members race for the ONLY copy of Dune ==
  winners=1 losers=7 (exactly one copy was lent)
  holder = M9  (which member wins varies from run to run)

== 4. Reserve a title with no free copy (FIFO waitlist) ==
  M2 position 1
  M4 position 2
  M6 reserve Hobbit REFUSED: a copy is on the shelf, just check it out

== 5. Renew is blocked while someone waits ==
  REFUSED: cannot renew B-DUNE-1: another member reserved this title

== 6. 13 days later: overdue notices, late return, fine, hand-over ==
  [notify M9] 'Dune' (B-DUNE-1) was due 2026-03-11
  [notify M1] 'The Hobbit' (B-HOB-1) was due 2026-03-11
  [notify M1] 'The Hobbit' (B-HOB-2) was due 2026-03-11
  [notify M1] 'The Hobbit' (B-HOB-3) was due 2026-03-11
  [notify M1] 'The Hobbit' (B-HOB-4) was due 2026-03-11
  [notify M1] 'The Hobbit' (B-HOB-5) was due 2026-03-11
  [notify M9] fine of $1.50 for late B-DUNE-1
  [notify M2] 'Dune' copy B-DUNE-1 is held for you
  fine charged = $1.50 (3 days late x $0.50)
  M4 REFUSED: B-DUNE-1 is held for another member
  M2 checks out held copy, due 2026-03-24
  who has B-DUNE-1? M2

== 7. Renew on time with nobody waiting ==
  [notify M1] fine of $1.50 for late B-HOB-1
  M6 renewed B-HOB-1, new due 2026-03-28
  fines on record: 2

== 8. Librarian housekeeping: remove a copy, cancel a membership ==
  REFUSED: B-DUNE-1 is LOANED, cannot remove it now
  copies of LOTR left: 0
  REFUSED: M6 must return 1 book(s) first
  REFUSED: M8 account is CANCELED
```

What to notice in the output: section 2 refuses the sixth book (requirement 5); section 3 lets exactly one of eight concurrent members borrow the only copy; section 5 refuses a renewal because someone is waiting; section 6 sends overdue notices, charges 3 days × $0.50, and hands the returned copy to the first person in the waitlist — the second person is refused because the copy is *held* for the first; section 8 covers the librarian's "remove book item" and "cancel membership" use cases — a copy that is out on loan cannot be removed, a member with a book still out cannot be cancelled, and a cancelled member can no longer borrow.

Concurrency & edge cases

- **Two members, one last copy.** `checkout` locks the copy (`synchronized (item)`), so "is it available? → mark loaned" is one atomic step. The demo's 8-thread race always has exactly one winner.
- **Two librarians scanning for the same member.** The quota check and increment happen under `synchronized (member)`, so a member can never end up with 6 books.

- **Deadlock avoidance.** (A **deadlock** is two threads each holding a lock the other needs, so both wait forever.) Every method locks **member first, then item** — a fixed global lock order. Two threads can never each hold one lock while waiting for the other. (`returnBook` reads the loan first to find the member, then locks in the same order and re-checks the loan is still active.)
- **Renew vs reserve.** Renewal is refused if the title's waitlist is non-empty. The check happens *before* charging any late fine, so a refused renewal never fines the member twice.
- **A known small window.** `reserve` checks "no free copy" and then joins the queue as two steps. If a copy is returned in between, it goes to the shelf while the member sits first in the queue; the *next* return reaches them. We accept this rather than make `reserve` take the queue lock before the copies' locks, because returns take them in the opposite order (copy, then queue) — mixing the two orders is exactly how deadlocks are born.
- **Held copy.** A returned copy with a waitlist becomes `RESERVED` for one member only; everybody else is refused at checkout.
- **Edge cases handled:** unknown barcode or member, duplicate barcodes, inactive/blacklisted/cancelled accounts, removing a copy that is on loan or held, cancelling a membership while books are still out, reserving a title that has a free copy ("just check it out"), joining the same waitlist twice (keeps your place), returning a book that is not out.
- **Across several servers** the `synchronized` blocks are not enough — the same guarantee must come from the database: e.g. `UPDATE book_item SET status='LOANED' WHERE barcode=? AND status='AVAILABLE'` and check that exactly one row changed (a *conditional update*).

Extensions & follow-up questions

- **"Two members reserve the last copy at the same moment — what happens?"** The course calls this out as unguarded in its own design. In ours, `reserve` appends to a FIFO deque (double-ended queue) under a lock, so both are queued in a definite order and the first one gets the next copy.
- **"Where do you keep the number of available copies of a title?"** Don't store a counter that can drift; derive it: `Catalog.availableCopies(isbn)` counts copies with status `AVAILABLE`. If that becomes slow, cache it (keep a ready-made copy for fast reads) and update it in the same lock as the status change.
- **"What is a `BookLending` for?"** It is the loan record: it answers "who has this copy, since when, due when", drives overdue notices and fines, and is the history of the copy.
- **"How is the fine paid?"** Add a `FinePayment` / `PaymentService` and block checkouts while unpaid fines exceed a threshold — a one-line rule in `checkout`.
- **"Hold expiry?"** A held copy should not wait forever: add `heldUntil` to `BookItem` and a daily job that passes the copy to the next person (or shelves it) when the hold lapses — exactly the TTL idea of section 15.2.
- **"E-books?"** An e-book "copy" is a licence: `BookFormat.EBOOK` items with no rack, and many libraries buy a fixed number of concurrent licences — the same copy model works.

Real-world example

Open-source integrated library systems such as **Koha** and **Evergreen** implement exactly this model: bibliographic *records* (titles) with attached *items* (copies with barcodes and shelf locations), circulation (lending and return) rules per patron (library member) category (loan period, maximum items, fine per day), a holds queue per title, and overdue/hold-available notices by email or SMS. Digital lending apps such as **OverDrive's Libby** apply the same waitlist idea to e-books: a library owns a fixed number of licences, borrowers join a holds queue, and when a licence frees up the next person is notified and given a limited window to borrow before it passes on.

In the interview

30–45 minute plan. (1) 3 min — clarify: copies, limits (5 books, 10 days), fines, reservations, notifications. (2) 5 min — actors and use cases. (3) 10 min — entities, *starting with the `Book` / `BookItem` split*, then accounts, lending records, catalog. (4) 10 min — code `checkout` and `returnBook` with the locking; mention lock ordering. (5) 5 min — the reservation hand-over and fines (Strategy). (6) Remaining — follow-ups: concurrency across servers, fine payment, hold expiry.

> **30-second answer:** "The key split is `Book` (the title) vs `BookItem` (a physical copy with a barcode and rack). Members borrow copies; search works on titles through a `Catalog` with one index per search type. A `LendingService` enforces 5 books and 10 days, records `BookLending`s, charges fines via a `FinePolicy` strategy, and passes returned copies to a FIFO waitlist per title with a notification. Checkout locks member then copy so the last copy can't be double-lent."

Self-check

- **Q:** Why is `Book` separate from `BookItem`? **A:** Search and metadata are per title; status, rack, barcode and loans are per physical copy. One title has many copies.
- **Q:** What guarantees a member can't get a 6th book when two desks scan at once? **A:** The quota check and increment happen inside `synchronized (member)`.
- **Q:** Why a fixed lock order? **A:** Without it, thread A could hold member→wait item while B holds item→wait member: deadlock.
- **Q:** Which pattern lets the library change its fine rules without touching lending code? **A:** Strategy (`FinePolicy`).
- **Q:** When can't a book be renewed? **A:** When another member is waiting for that title.

TL;DR

Title vs copy. Limits on the member, state on the copy, history in `BookLending`. Rules in a `LendingService`; fines as a Strategy; notifications behind an interface. Lock member-then-copy so the last copy is never lent twice. Reservations are a FIFO queue per title.

15.2 Design a Movie Ticket Booking System (BookMyShow)

Figure — Cover image for the movie ticket booking case study (course diagram)

Problem & clarifying questions

An online movie ticket booking system (think **BookMyShow**, **Fandango**, **AMC's app**) lets customers see which movies are playing, pick a show, choose seats on a seat map, pay, and receive a ticket — from anywhere, at any time. It is *the* classic LLD booking question because it has a hierarchy of places (city → cinema → hall → seat), a time dimension (shows), and a genuine race (two people tapping the same seat).

Question	Answer we assume
One city or many?	Many cities with affiliate (partner) cinemas; the app lists cities.
Can a cinema have several halls? Several shows per hall?	Yes and yes — but a hall runs **one show at a time**.
What do customers search by?	Title, language, genre, release date, **city**.
Can a customer pick several seats in one booking?	Yes, from a seat map showing free vs booked seats.
How long is a seat kept while paying?	A few minutes (we use **5**). If payment does not finish, the seats go back.
Payment methods? Discounts?	Credit card or cash (cash at the front desk); optional **discount coupon**.
Refunds?	On cancellation, refund if within the allowed time (we use: up to 2 hours before the show).
Notifications?	New movie, booking made, booking cancelled.
Who else uses it?	Admins (add movies/shows, block customers), front-desk officers (book for walk-ins), guests (search only).

Requirements

Functional (the course's list, in order)

1. List the **cities** where affiliate cinemas are located.
2. Each cinema has many **halls**; each hall runs **one show at a time**.
3. Each movie has many **shows**.
4. **Search** movies by title, language, genre, release date and city.
5. After choosing a movie, show the **cinemas and shows** running it.
6. Pick a show and **book** tickets.
7. Show the **seating plan**; let the customer pick several seats.
8. Distinguish **available** seats from booked ones.
9. **Notify** on a new movie, and on booking or cancellation.
10. Pay by **credit card or cash**.
11. **No two customers can reserve the same seat.**
12. Apply a **discount coupon** to the payment.

Non-functional

- **Strong consistency on seats** (every reader sees the latest confirmed state; see System Design Fundamentals): double booking is the one bug that must never happen.
- **High read, bursty write** (writes arrive in sudden spikes): browsing dwarfs booking, but a blockbuster's first-day shows get many simultaneous seat grabs.
- **Hold expiry**: abandoned checkouts must not block seats (the course lists this as a gap in its own design; we implement it).
- **Failure-safe payments**: a customer must never pay for a seat they don't get.

Use cases

Five actors: **Admin** (add movies and shows, cancel a movie or show, block/unblock customers), **FrontDeskOfficer** (book and cancel tickets for walk-ins), **Customer** (view schedules, book, cancel), **Guest** (search only — must register to book), **System** (notifications).

Top use cases: search movies; create/modify/view booking; make payment; add a coupon to the payment; assign seats (seat map); refund payment on cancellation within the allowed time.

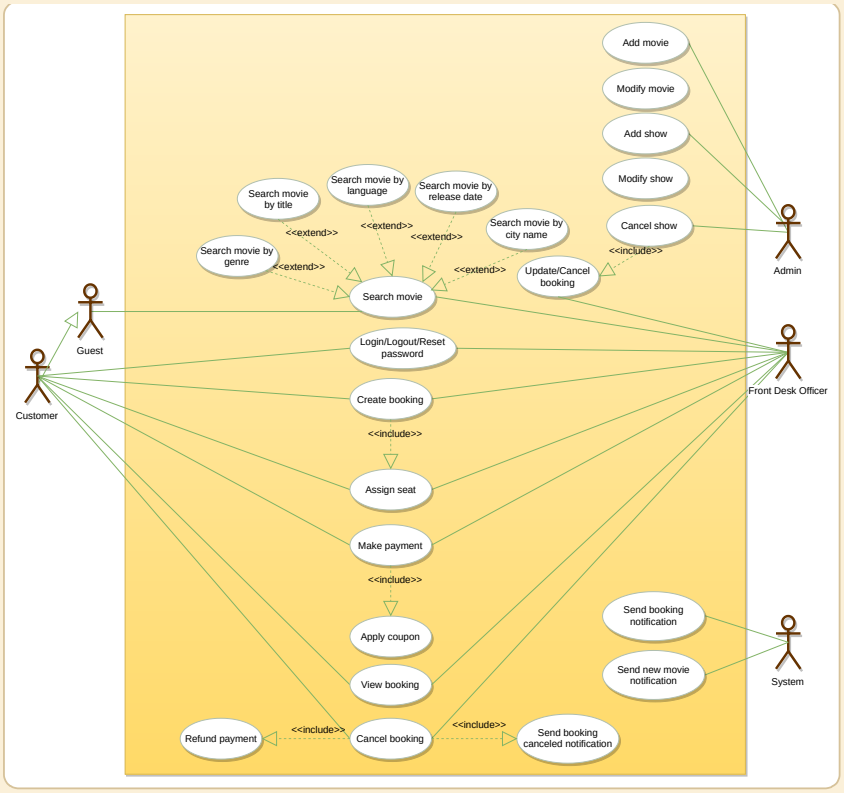

Figure — Movie booking use cases. The hollow arrow from Customer to Guest says a customer can do everything a guest can; the five "search by" use cases extend "Search movie"; "Create booking" includes "Assign seat"; "Make payment" includes "Apply coupon"; "Cancel booking" includes "Refund payment" and the cancellation notification; the admin's "Cancel show" includes updating/cancelling its bookings (course diagram)

Notice in the figure above that a **Customer is a specialised Guest**: everything a guest can do (search), a customer can do too, plus booking. That is the use-case version of the inheritance we enforce in code by giving `BookingService` a `Customer` parameter.

Core entities

Class	Responsibility
`City` (record)	Name and state. Cinemas point to it (association — the city exists without the cinema).
`Cinema`	Name, city; **owns** its halls.
`CinemaHall`	Name, physical seats; refuses an overlapping show.
`HallSeat` (record)	The seat bolted to the floor: id and `SeatType` (`REGULAR`, `PREMIUM`, `ACCESSIBLE`, `EMERGENCY_EXIT`, `OTHER`). **No booking state.**
`Movie` (record)	Title, language, genre, release date, duration.
`Show`	One screening of a movie in a hall at a time; **owns one `ShowSeat` per hall seat**.
`ShowSeat`	A seat *for this show*: price and `booked` flag. **This is what gets booked.**
`SeatLockProvider` / `InMemorySeatLockProvider`	Temporary, expiring **holds** on show seats; all-or-nothing lock, commit, release.
`Booking`	Customer, show, seat ids, status (`PENDING`, `CONFIRMED`, `CHECKED_IN`, `CANCELED`, `ABANDONED`), payment, coupon.
`BookingService`	hold → pay → commit (make final); cancel; seat map.
`Payment`, `PaymentMethod` (`CardPayment`, `CashPayment`), `PaymentGateway`	Money. The gateway (the external service, such as a card processor, that actually moves the money) is the boundary to the real provider.
`Coupon`	Percentage off, applied to the booking amount before payment.
`CancellationPolicy` / `CutoffRefundPolicy`	How much comes back on cancel (Strategy).
`MovieSearch` / `Catalog`	Five searches; "by city" is answered from shows.
`Customer`, `Guest`, `FrontDeskOfficer`, `Admin`	Actors; a `Guest` has no type that `BookingService` accepts.
`Notifier`	Messages to users: new movie (sent by `Catalog.addMovie`), booking confirmed, booking cancelled.

Class diagram

The course grows the model over **six stages**; after each one the system gains a capability it lacked:

Stage	Adds	What works afterwards
1	City, cinema, hall, physical seat	There is a building with seats in it
2	Movie, show, show seat	Every screening carries its own seat list and prices
3	Coupon, payment types, notification types	An amount can be reduced by a coupon and then paid
4	Booking and `BookingService`	One seat can never go to two customers
5	Search interface and catalog	A movie can be looked up in five different ways
6	People and accounts	Booking is restricted to registered customers

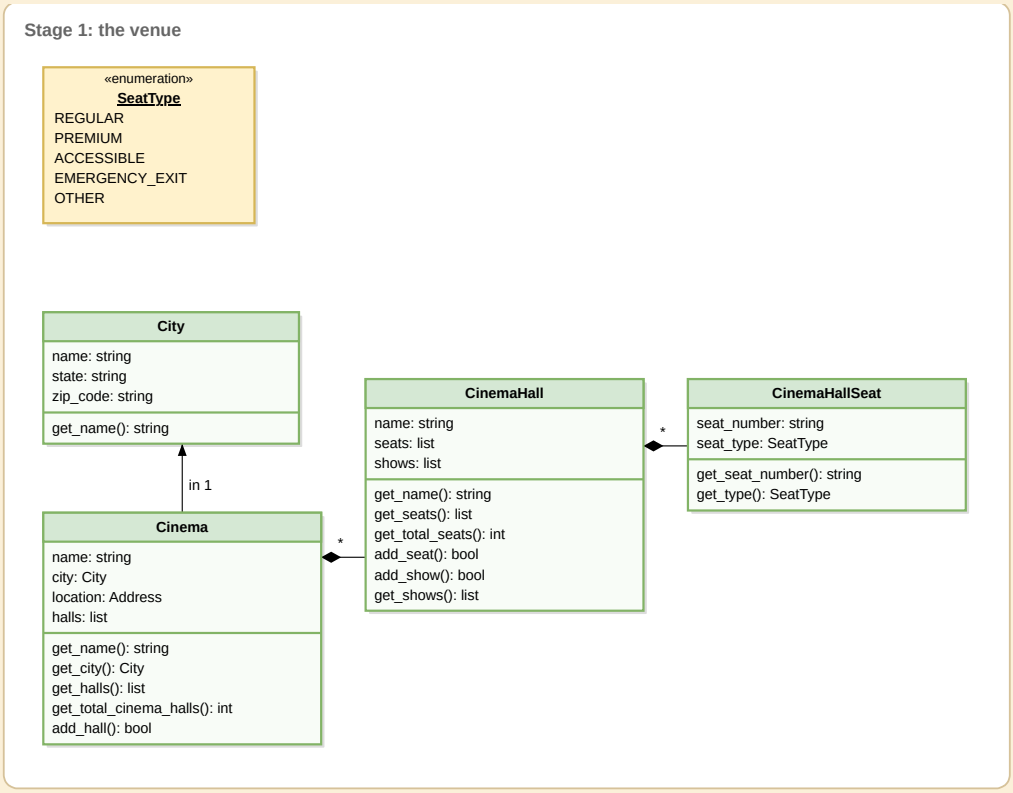

Figure — Stage 1: `City`, `Cinema`, `CinemaHall` and `CinemaHallSeat`; cinema→city is a plain association, cinema→hall and hall→seat are composition (course diagram)

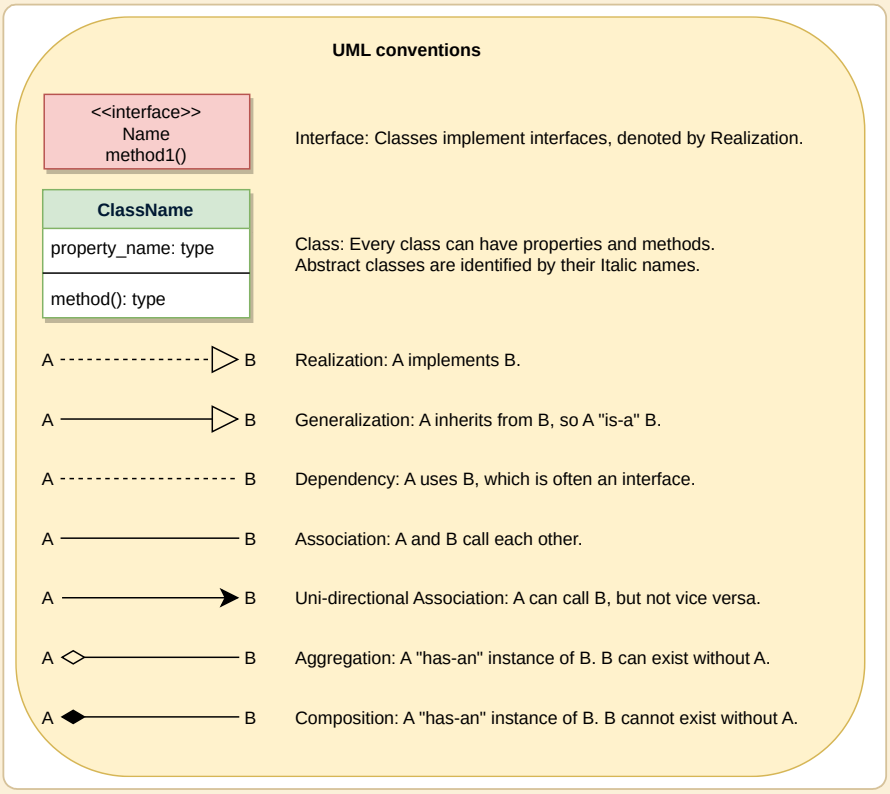

Figure — How to read a class box and the arrow styles used in these diagrams (course diagram)

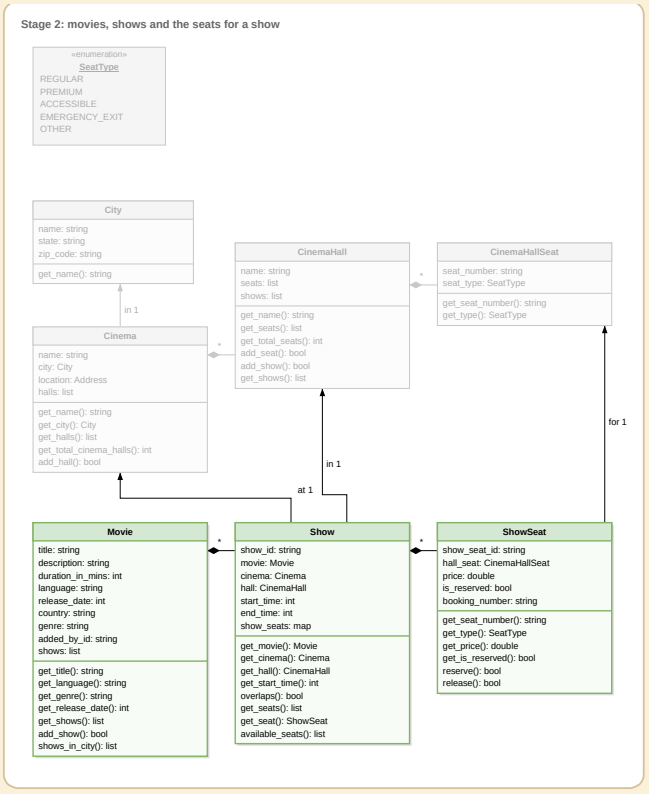

Figure — Stage 2: `Movie` owns its `Show`s; each `Show` owns one `ShowSeat` per physical seat, and each show seat points back at its `CinemaHallSeat` (course diagram)

Stage 2 is **where the design succeeds or fails**. One physical seat can be empty for the 3 pm screening and sold for the 9 pm one, so the thing you reserve cannot be the physical seat. You reserve a `ShowSeat` — one per seat per show — which also lets each show price its seats differently (a premium seat costs more).

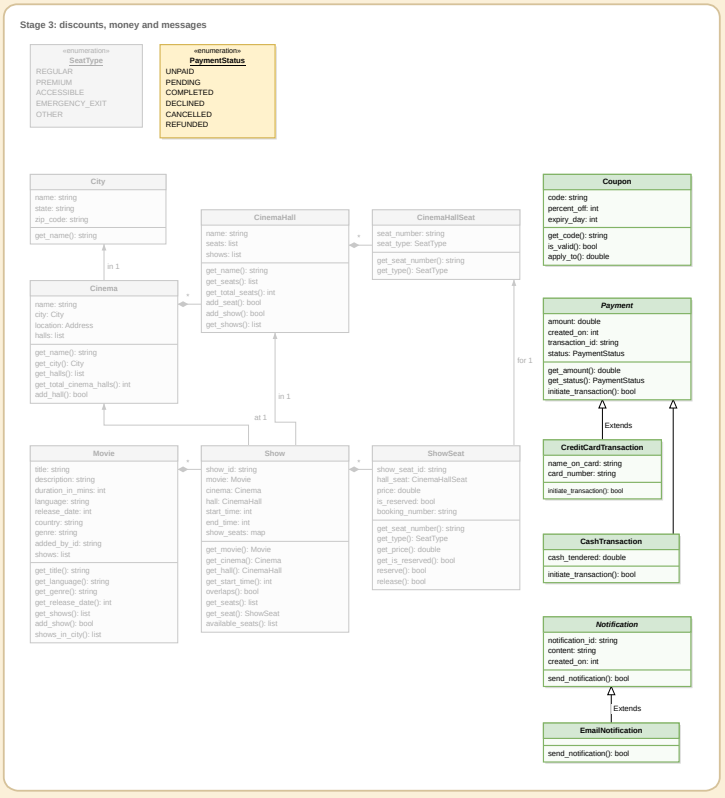

Figure — Stage 3: `Coupon`, abstract `Payment` (credit card and cash subclasses) and abstract `Notification` (one subclass per channel); none of them points at anything yet (course diagram)

The coupon reduces **the booking's amount, not the payment**: by the time any payment object is created the price is final, and no payment type needs its own discount logic.

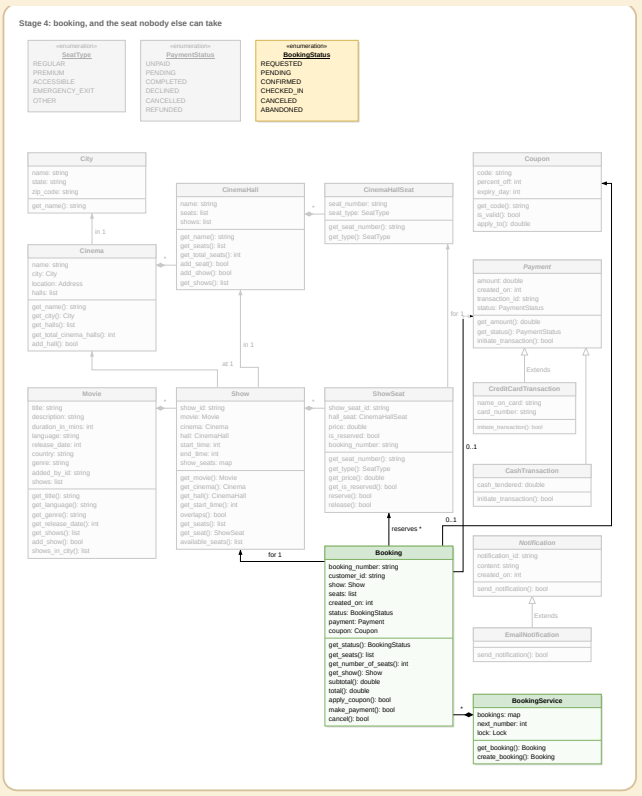

Figure — Stage 4: `Booking` points at the show, seats, payment and coupon without owning them; `BookingService` owns the bookings and is the only class holding a lock (course diagram)

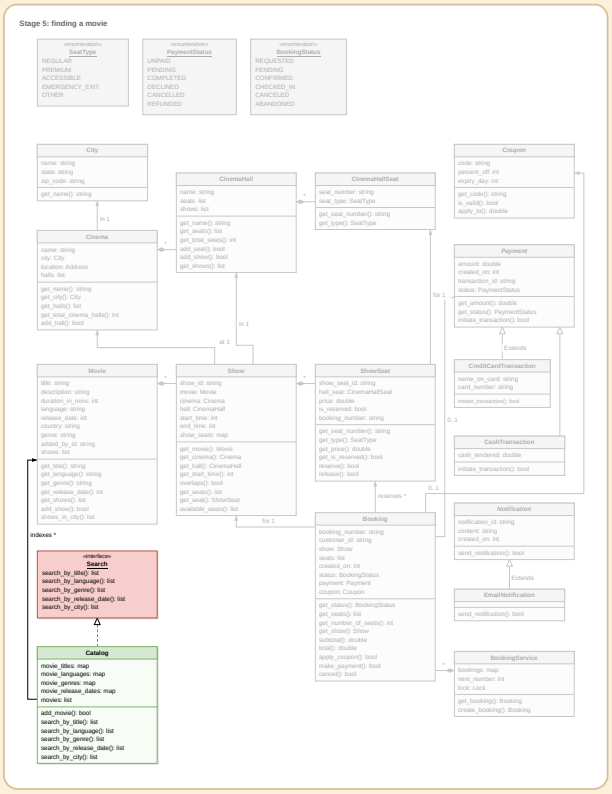

Figure — Stage 5: the `Search` interface with five methods, implemented by `Catalog`; four searches use indexes built when a movie is added, while city search is computed from the scheduled shows (course diagram)

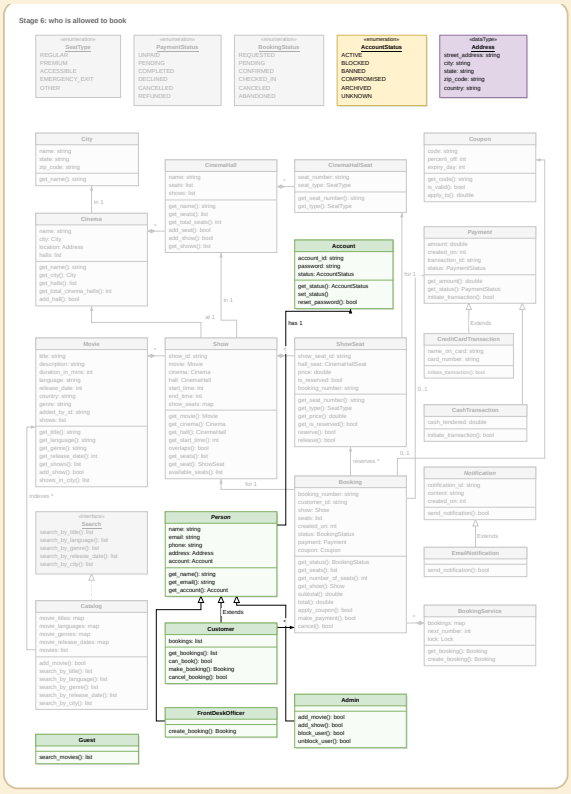

Figure — Stage 6: `Person` with `Customer`, `FrontDeskOfficer` and `Admin`; `Guest` sits outside that tree and has no booking method; a customer keeps the bookings it made (course diagram)

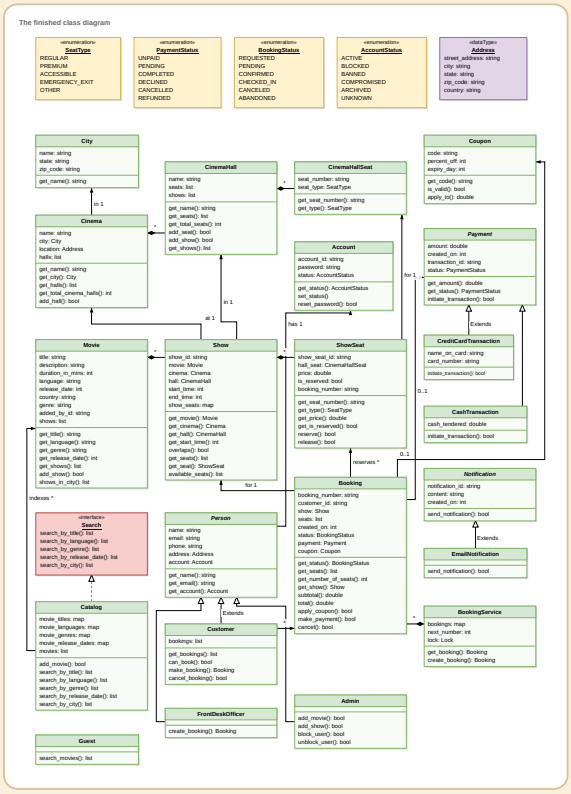

Figure — The finished movie booking class diagram (course diagram)

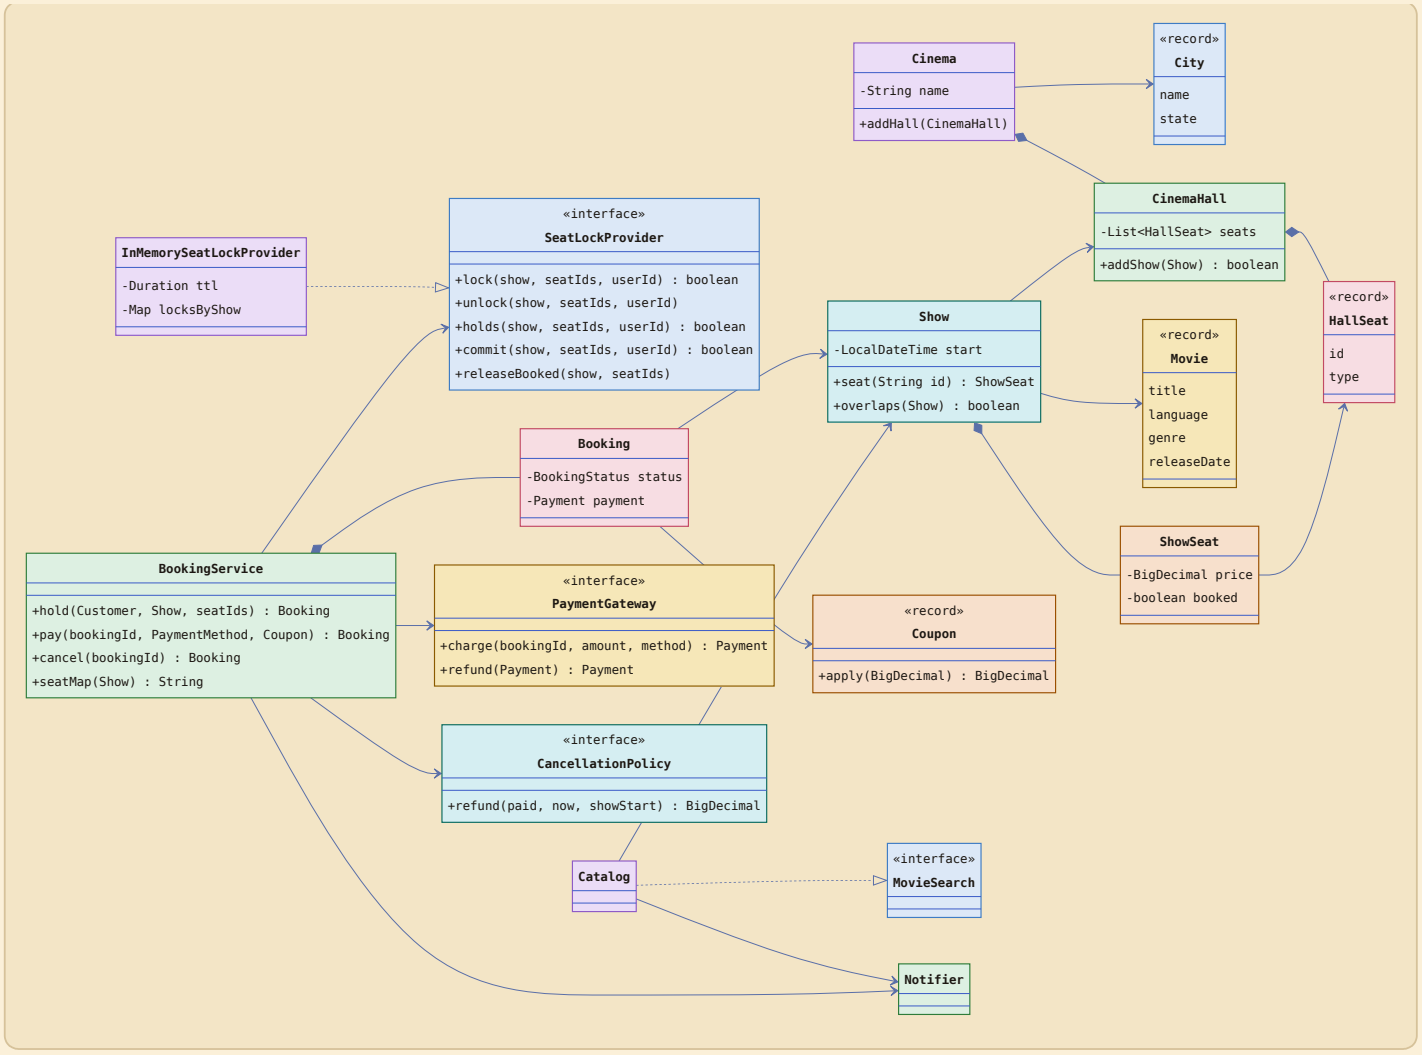
Our Java design (the main difference from the course: a separate `SeatLockProvider` with **TTL holds**, which the course names as its biggest omission):



Key flows

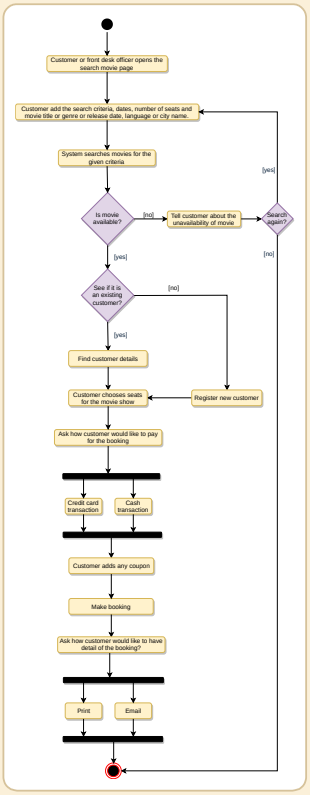


Figure — Make a booking: search movies; if available, find or register the customer, pick seats, ask how they will pay (credit card or cash), and choose how to receive the ticket (course diagram)

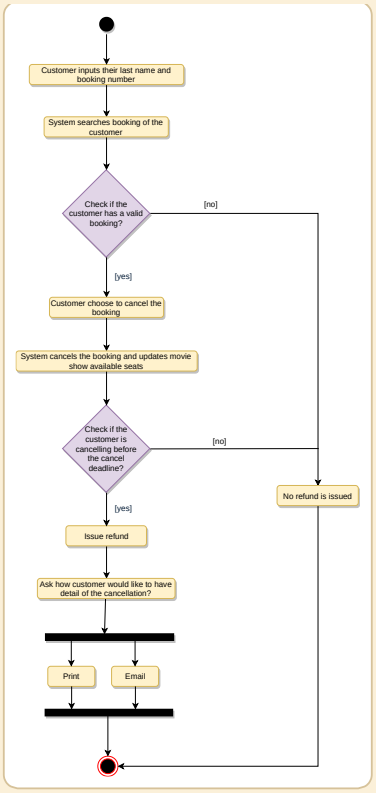

Figure — Cancel a booking: the customer gives last name and booking number; the system finds the booking, issues a refund if the cancellation is within the allowed time (otherwise no refund), cancels, updates the show's available seats, and prints or emails the details (course diagram)

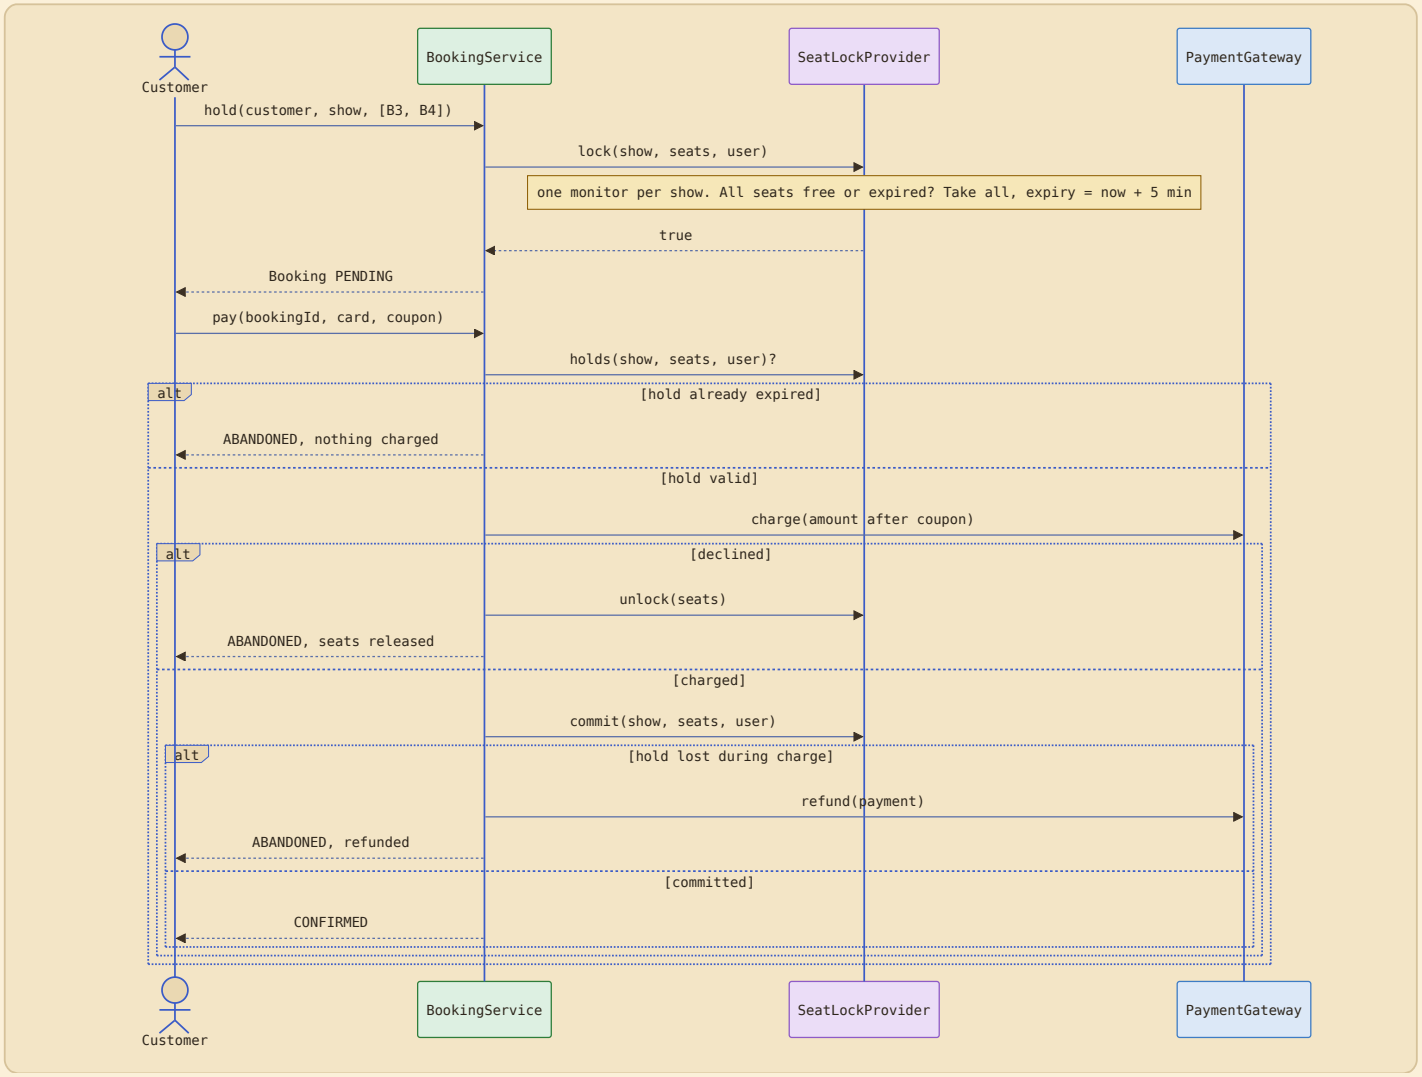
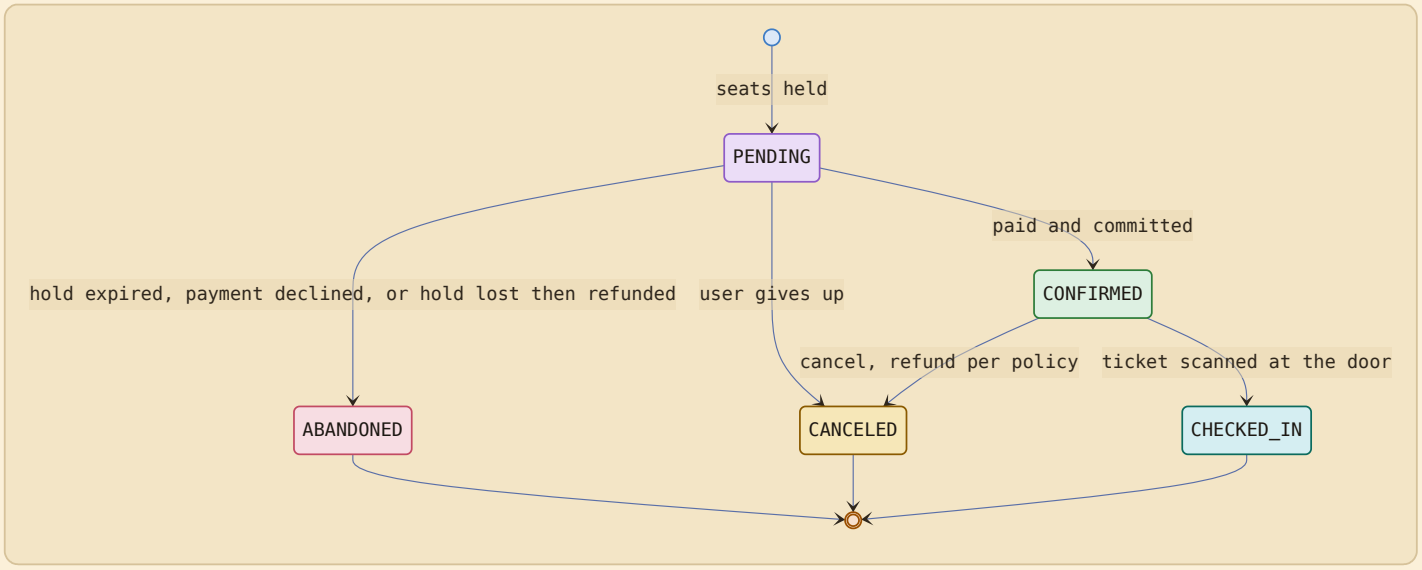
The heart of the design is a **three-step booking path**: *hold → pay → commit*.



Why `commit` must re-check inside the lock: the payment call can take seconds. If the hold expires during it and someone else grabs the seat, a naive "mark booked" would double-book. `commit` verifies "these seats are still held by me and not expired" **and** marks them booked in one atomic step. If that fails after money was taken, we run a **compensating action** — a refund — instead of a database-style rollback (undoing unfinished changes as if they never happened), because a card charge cannot be "un-happened". This is the essence of the **Saga** idea: each step has an undo.

Booking lifecycle:



A show seat, as the customer sees it on the map: **free** (`.`), **held** by someone paying (`L`), **booked** (`X`). "Held" is not stored on the seat — it lives in the lock provider and simply disappears when it expires.

Design decisions & patterns used

Decision	Why	Alternative rejected
`ShowSeat` per show (course's key point)	The same physical seat is free in one show and taken in another; prices differ per show.	Booking `HallSeat` directly — breaks the moment there are two shows a day.
`SeatLockProvider` interface with TTL holds	Seats are kept only while the customer pays; abandoned checkouts free themselves. The interface lets you swap the in-memory version for **Redis** (a fast in-memory key-value store, often used for locks and caches; `SET key value NX PX 300000` — set only if absent, expire in 300 000 ms) or a database table with an `expires_at` column.	Holding seats until the booking is cancelled (course's version; it names this as the gap).
All-or-nothing lock	A customer asking for 4 seats together must never be left with 2. Check every seat first, then take all.	Locking seats one by one without rollback.
One monitor per show	Shows never block each other; within a show, every decision is serialized (made one at a time). Fine-grained enough for a cinema.	One global lock (the course's single-process lock) — correct but serializes the whole country's bookings.
Commit re-validates + compensation	Closes the "lock expired during payment" gap; the customer never pays for a seat they don't get.	Trusting the earlier check.
Idempotent `pay` (safe to repeat: two calls have the effect of one)	A double-click or network retry must not charge twice: paying a non-PENDING booking returns it unchanged. Real systems add an **idempotency key** per request.	Charging on every call.
Strategy for cancellation refunds and **Strategy-like `PaymentMethod`**	Refund rules and payment types vary independently of booking logic.	`if (method == CARD)` chains.
Adapter boundary (a wrapper that turns a foreign interface into ours) `PaymentGateway`	Wraps the external provider (Stripe, Razorpay…) behind our own interface; tests use `FakeGateway`.	Calling the provider's SDK (software development kit: the provider's own client library) from `BookingService`.
Coupon applied to the booking	Amount is correct before payment; payment types stay simple.	Each payment type applying coupons.
Guest has no booking method	The rule "guests must register to book" is enforced by *types*, not just written down: `hold` takes a `Customer`.	A `Guest.book()` that throws.
"Search by city" from shows	A movie is in a city only once a show is scheduled there; the other four searches are indexed when a movie is added.	Storing a city on `Movie`.

Java implementation

Package `lld.ch15.moviebooking`. Files: `Venue.java` (city, cinema, hall, seats, movie, show), `SeatLockProvider.java` (interface + in-memory TTL implementation), `Payments.java` (payment types, gateway, coupon, cancellation policy, notifier, clock), `Catalog.java` (five searches), `BookingService.java` (actors, booking, the booking path), `Main.java`.

```java

    }

    private static List<String> titles(List<Movie> ms) { return ms.stream().map(Movie::title).toList(); }
}
```

Output:

```
== 1. Admin adds movies (subscribers told) and schedules shows; the hall refuses an overlap ==
  [notify subscribers] new movie: Inception (English, Sci-Fi)
  [notify subscribers] new movie: RRR (Telugu, Action)
  add SH1 Inception 18:00 -> true
  add SH2 RRR 19:00 same hall -> false

== 2. Search ==
  city Bengaluru -> [Inception]
  genre Action   -> [RRR] (no show yet, but indexed)
  Inception shows in Bengaluru -> [SH1@2026-05-01T18:00]

== 3. 10 customers click B3+B4 at the same instant ==
  holds granted = 1 (the other 9 saw 'not available')
  A . . . . .
  B . . L L .

== 4. The winner pays by card with a 10% coupon ==
  [notify U10] BK-1 CONFIRMED [B3, B4] for 'Inception' at 2026-05-01T18:00, paid Rs.630.00
  paying twice is harmless -> CONFIRMED
  A . . . . .
  B . . X X .

== 5. Hold expires (TTL 5 min) before paying ==
  Ravi re-held A1,A2 after Asha's hold expired -> BK-3
  [notify ASHA] BK-2 hold expired before payment, nothing charged
  [notify RAVI] BK-3 CONFIRMED [A1, A2] for 'Inception' at 2026-05-01T18:00, paid Rs.400.00

== 6. Hold expires WHILE the bank is charging -> refund (compensation) ==
  [notify MEENA] BK-4 hold expired during payment, Rs.200.00 refunded
  BK-4 [A5] ABANDONED REFUNDED Rs.200.00

== 7. Declined card releases the seats immediately ==
  [notify NEHA] BK-6 payment DECLINED, seats released
  B1 held by anyone now? false

== 8. Blocked customer, then cancellation with refund ==
  REFUSED: U10 is BLOCKED
  [notify U10] BK-1 canceled, refund Rs.630.00
  BK-1 [B3, B4] CANCELED REFUNDED Rs.630.00
  A X X . . L
  B . . . . .
```

What to notice: section 1 announces each new movie to subscribers (requirement 9) and refuses an overlapping show in the same hall (requirement 2); section 3 lets exactly 1 of 10 simultaneous customers hold B3+B4; section 4 applies the 10% coupon (Rs.700 → Rs.630) and a second `pay` is a no-op; section 5 shows an expired hold being re-sold and the slow customer *not* being charged; section 6 is the compensation path — Meena's card was charged, but her hold expired during the charge and Kiran took A5, so she is refunded; section 7 releases seats immediately on a decline; section 8 blocks a customer and cancels with a full refund.

Concurrency & edge cases

- **Check-then-act is atomic.** `lock`, `holds`, `commit`, `unlock` and `releaseBooked` for one show all run inside `synchronized` on that show's lock table. "Is the seat free? → take it" can't interleave.
- **Expired holds are lazy.** There is no background thread; an expired `SeatLock` is simply treated as absent the next time anyone looks. (In Redis, the key's TTL does the same.)
- **The payment-window race** (hold expires mid-payment) is handled by commit re-validation + refund, as shown in section 6.
- **Lock granularity** (how much data one lock covers). The booking's own monitor makes `pay`/`cancel` on the same booking serial (no double charge, no pay-while-cancel). The show monitor protects seats. The two are always taken in the order booking → show, never the reverse, so no deadlock.
- **Across many servers** (real BookMyShow), in-process locks are not enough. Options, from simplest:
  1. **Conditional update** (course): `UPDATE show_seat SET status='HELD', held_by=?, held_until=? WHERE show_id=? AND seat_id IN (...) AND (status='FREE' OR held_until < now())`, then check the row count equals the number of seats; if not, roll back.

2. **Pessimistic lock** (lock first, then work, assuming conflicts are likely): `SELECT ... FOR UPDATE` on the seat rows inside a transaction (a group of database statements that succeed or fail together).
3. **Serializable transaction** (course): the result is as if each transaction had run alone, in some order — easiest to reason about, but the slowest option when many buyers collide.
4. **Optimistic locking**: a `version` column; update `WHERE version = ?`; retry on conflict. Good when conflicts are rare.
5. **Unique constraint** (a database rule that rejects a second row with the same values) on `(show_id, seat_id)` in the confirmed-tickets table as the final safety net.
6. **Distributed lock / hold store** (a lock kept in a shared store, so all servers see it) in Redis with TTL for the *hold* phase, with the database as the source of truth (the one copy that wins when copies disagree) for *confirmed* seats. The course's point, in short: the in-process lock only makes the common case quick; once there are two servers, correctness comes from the database.

- **Edge cases:** empty seat list; duplicate seat ids in one request (de-duplicated); unknown seat; blocked customer; overlapping show in a hall; cancelling an abandoned booking (rejected); cancelling too late (no refund).

Extensions & follow-up questions

- **"Show the seat map live."** Push seat changes (held/booked/released) to open seat-map pages over WebSockets or server-sent events (two ways for a server to push updates to an open browser page); the lock provider publishes events (Observer).
- **"Extend the hold when the user reaches the payment page."** Add `extend(show, seats, user, extra)` that refreshes `expiresAt` only if the caller still holds the lock.
- **"Dynamic pricing / different prices per seat type and time."** Replace the price map with a `PricingStrategy` (base by `SeatType`, surcharge for weekends or premieres).
- **"Payment succeeded but our server crashed before commit."** Store the booking as `PENDING` with the gateway's transaction id before charging; a reconciliation job (a periodic task that compares our records with the gateway's and fixes mismatches) queries the gateway for pending bookings and either commits (if the seats are still held) or refunds. Payment providers' **webhooks** (HTTP calls the provider makes to your server when something happens) notify you of the final result.
- **"Cancel a whole show."** Admin cancels → every confirmed booking of the show is cancelled with a full refund and a notification (iterate bookings by show).
- **"Loyalty points, food & beverage add-ons."** Extra line items on the booking; points as another `PaymentMethod`.
- **"Seat gaps rule (no single empty seat left between bookings)."** A validation step in `hold` before locking — a `SeatSelectionRule` chain (Chain of Responsibility).

Real-world example

On **BookMyShow**, after you pick seats the app shows a **countdown timer** on the payment screen; if it runs out the seats are released and you must start again — that timer is the seat hold's TTL. If your bank debits you but the booking does not complete, the app tells you the amount will be **refunded automatically** — that is the compensation path. Big releases put the "one monitor per show" idea under real stress: first-day-first-show bookings for a blockbuster concentrate thousands of users on a handful of shows.

In the interview

30–45 minute plan. (1) 4 min — requirements; ask about hold time, payment, refunds. (2) 4 min — actors/use cases. (3) 8 min — entities: city → cinema → hall → seat; movie → show → **show seat** (say why). (4) 12 min — the booking path: `SeatLockProvider` (all-or-nothing, TTL), `BookingService.hold/pay/cancel`; write `lock` and `commit`. (5) 5 min — payment failure and the expired-during-payment refund. (6) Remaining — multi-server concurrency (conditional update / Redis TTL), follow-ups.

> **30-second answer:** "Venue hierarchy is City → Cinema → Hall → HallSeat. A Show owns a ShowSeat per hall seat, and that's what's booked. Booking is hold → pay → commit: a SeatLockProvider takes all requested seats atomically with a 5-minute TTL; payment goes through a gateway interface; commit re-checks the hold and marks seats booked atomically, and if the hold was lost we refund. In one process a per-show monitor guarantees no double booking; across servers the database's conditional update or a unique constraint is the real guarantee, with Redis TTL keys for holds."

Follow-ups with answers: *Why not lock the whole show table?* Fine for one cinema, but a global lock serializes all shows. *Why TTL?* Without it an abandoned checkout blocks seats forever. *Optimistic or pessimistic?* Pessimistic/conditional-update for hot shows (conflicts common); optimistic when conflicts are rare.

Self-check

- **Q:** Why is `ShowSeat` separate from `HallSeat`? **A:** Booking state and price are per show; the physical seat is shared by every show in the hall.
- **Q:** What does "all-or-nothing" mean in `lock`? **A:** Check every requested seat first; take them all only if all are free — never a partial set.
- **Q:** A payment succeeded but `commit` returned false. What now? **A:** Refund (compensation) and mark the booking abandoned.
- **Q:** How does an expired hold get cleaned up here? **A:** Lazily: any lock/holds check treats an expired lock as absent.
- **Q:** What makes `pay` safe to call twice? **A:** It runs under the booking's monitor and returns immediately unless the booking is `PENDING`.

TL;DR

Book `ShowSeat`s, not seats. Hold (all-or-nothing, TTL) → pay → commit (re-validate atomically) → refund if the hold was lost. Coupon on the booking, gateway behind an interface, refund rule as a Strategy. Per-show lock in one JVM (Java Virtual Machine — one running Java process); conditional updates, unique constraints and Redis TTL keys across servers.

15.3 Design a Concert Ticket Booking System

Problem & clarifying questions

A concert ticketing system (think **Ticketmaster**, **Live Nation**, **SeatGeek**, **BookMyShow Live**) sells tickets for a single, huge, one-off event. The *objects* look like section 15.2 — an event, a venue, seats, bookings, payments — so we reuse those ideas and do **not** repeat them. The *focus* is different: **extreme contention**. A movie show has a few hundred seats and demand spread over days; a stadium tour sells 50,000 tickets in minutes to a million people who all arrive at 10:00:00. That changes three things:

1. **Fairness** — who gets to try first? (a *virtual waiting room*)
2. **Throughput under contention** (throughput = requests completed per second; see System Design Fundamentals) — locks that serialize everyone become the bottleneck (the one point that limits overall speed) (so we use *lock-free* compare-and-set)
3. **Abuse** — scalpers (people who buy tickets to resell at a markup) and bots (automated scripts) (so *per-user limits*), and what happens to fans who miss out (a *waitlist*)

Question	Answer we assume
Seat types?	Tiers: **VIP** and **PREMIUM** are numbered seats; **GENERAL_ADMISSION** (GA) is a standing area — just a *count*.
Search?	By artist, venue, date and time (same catalog idea as 15.2 — not repeated).
How do we stop a stampede?	A **virtual waiting room**: everyone gets a queue number; people are admitted in batches, in order.
Limit per person?	**4 tickets** per user per concert.
Hold time?	**10 minutes** to pay.
Sold out?	Fans can join a **waitlist** per tier; released tickets are offered to the waitlist first.
Notifications?	Confirmation and "a ticket freed up for you" (email/SMS).

Requirements

Functional — show concerts with their seating layout and availability; search by artist, venue, date, time; choose seats (or a GA quantity) and buy; **prevent double booking under concurrent requests**; **fair access** for all users; secure payments; confirmation notifications; **waitlist** for sold-out events.

Non-functional — very high write contention for a few minutes; **no overselling** ever (GA count never below zero, a seat never sold twice); fairness (first-come-first-served into the sale); bounded per-user purchases; holds that expire on their own.

Use cases

Actors: **Fan** (join queue, hold, buy, cancel, join waitlist), **Organizer/Admin** (create concert, set tiers and prices, open the sale), **System** (admit batches from the queue, expire holds, offer released tickets to the waitlist, notify), **Payment provider** (external).

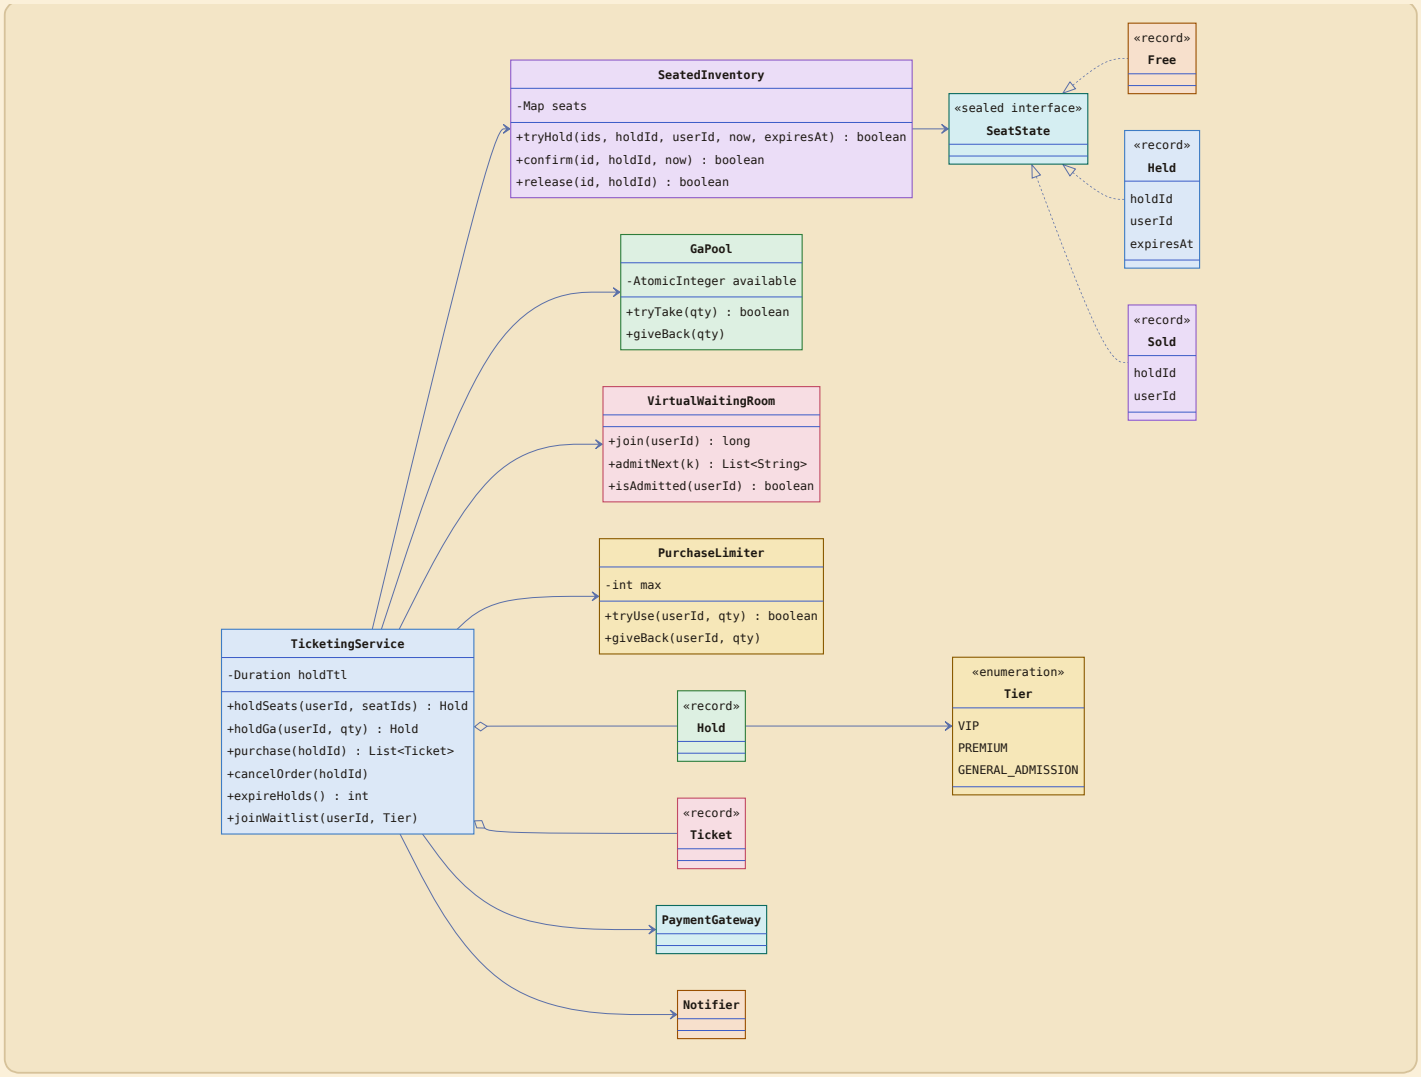
Main use cases: join the waiting room → get admitted → **hold** seats or a GA quantity → **purchase** → receive tickets; **cancel** an order (refund); **join waitlist**; system **reaps** expired holds.

Core entities

Class	Responsibility
`Concert` (record)	Artist, venue, date/time.
`Tier` (enum)	`VIP`, `PREMIUM` (seated) and `GENERAL_ADMISSION` (unseated), each with a price.
`SeatState` (sealed) → `Free`, `Held`, `Sold`	A seat's whole state as one immutable value.
`SeatedInventory`	One `AtomicReference<SeatState>` (a holder for one object reference that supports CAS) per numbered seat; claims by **CAS**.
`GaPool`	GA capacity as an `AtomicInteger` (an int with atomic updates); take/give back by CAS.
`Hold` (record)	A temporary claim: seats or a GA quantity, amount, expiry.
`Ticket` (record)	One admission: tier and seat id or "GA".
`VirtualWaitingRoom`	Queue numbers in arrival order; admits batches FIFO.
`PurchaseLimiter`	At most N tickets per user, checked and updated atomically.
`TicketingService`	hold → purchase → (cancel); reaper; waitlist offers.
`PaymentGateway`, `Notifier`	External boundaries (as in 15.2).

Class diagram

There is no course lesson for this problem; the problem statement comes from the *awesome-low-level-design* problem set. Our design:



SeatedInventory
-Map seats
+tryHold(ids, holdId, userId, now, expiresAt) : boolean
+confirm(id, holdId, now) : boolean
+release(id, holdId) : boolean
«sealed interface»
SeatState
«record»

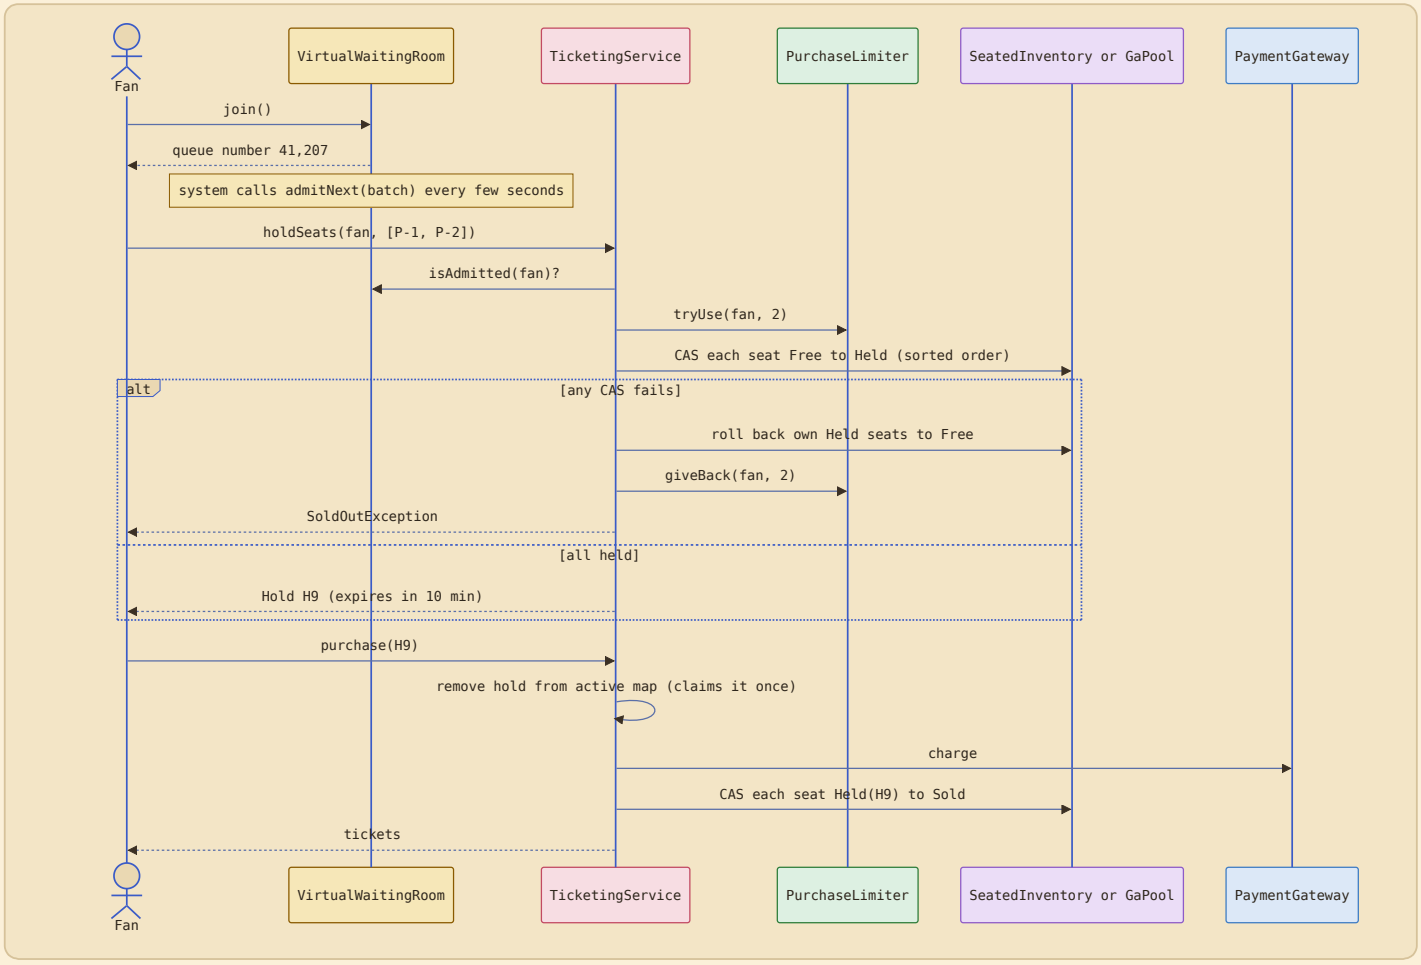
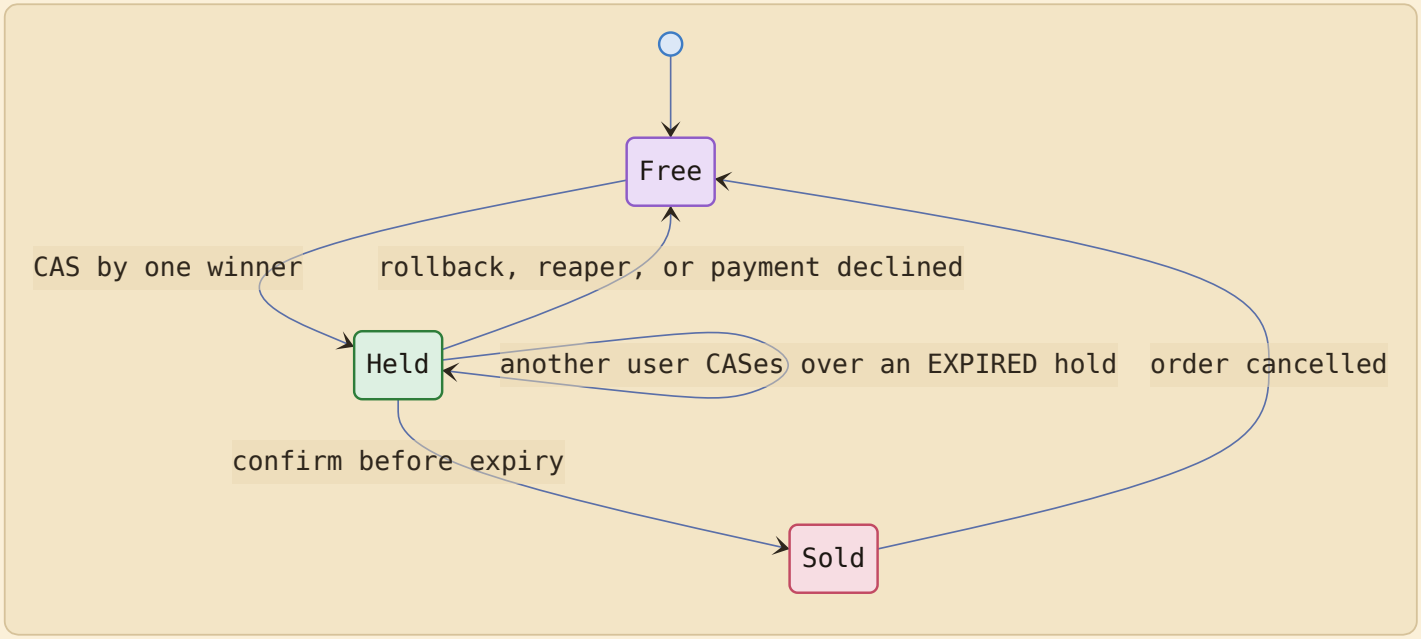
VIP
PREMIUM
GENERAL_ADMISSION
«record»
Ticket
PaymentGateway
Notifier

Key flows



A numbered seat's state machine — every arrow is a single `compareAndSet`:



When inventory is released (expired hold, cancellation), `TicketingService` **offers it to the tier's waitlist first**: the next waiting fan is admitted directly and given a fresh hold, plus a notification. If they do not pay in time, the reaper releases it again and the next fan gets it.

Design decisions & patterns used

Decision	Why	Alternative rejected
Lock-free CAS per seat (`AtomicReference<SeatState>`)	Buyers of *different* seats never wait for each other; on the *same* seat, exactly one `compareAndSet` wins and the losers learn instantly. No thread is ever blocked holding a lock, so there is no deadlock.	One monitor per concert (15.2's approach) — correct, but at 50,000 simultaneous buyers every request queues behind one lock.
Immutable sealed `SeatState`	CAS compares *references* (which object it is, not what it contains); making each state a fresh immutable record means "the state I read" is exactly "the state I replace". Pattern-matching `switch` / `instanceof` on a sealed type is exhaustive and readable.	Mutable fields (`status`, `heldBy`, `expiry`) updated separately — a reader could see a half-updated seat.
Multi-seat hold in sorted order + rollback	Each seat is claimed independently; on failure we release the ones *we* took (matching our hold id). Sorted order makes two buyers of overlapping sets contend on the same first seat, so one of them fails fast.	Holding several seats with nested locks — deadlock-prone without ordering.
GA as a counter	Standing places are interchangeable — there's nothing to name. A CAS loop on an `AtomicInteger` (`if cur < qty fail; else CAS(cur, cur-qty)`) never oversells.	A `Seat` object per standing place — 40,000 objects for no benefit.
Virtual waiting room	Fairness and load control: arrival order decides who gets to *try*, and admitting in batches caps the load on inventory. Bots gain nothing by hammering "buy". `join` is `synchronized` so number order and queue order can never disagree.	"Whoever's request lands first" — rewards bots and fast connections, and melts the backend (the servers behind the app).
Per-user limit via `ConcurrentHashMap.compute` (a thread-safe map; `compute` updates one key atomically)	`compute` runs the check-and-update for one key atomically, so two parallel requests from the same user can't both slip under the limit.	`get` then `put` — a classic race.
Holds with TTL + a reaper	Seat holds are also reclaimed lazily (a CAS can overwrite an expired `Held`); GA holds have no per-item state, so a periodic `expireHolds()` returns their count. `holds.remove(id, h)` ensures the reaper and `purchase` never both process one hold.	Holds that never expire.
Waitlist offers on release	Released tickets go to the longest-waiting fan (FIFO), not to whoever refreshes fastest.	Returning tickets silently to the pool.
Compensation on lost hold	Same as 15.2: if a seat could not be confirmed after payment, release and refund.	Assuming the hold is still valid.
Singleton?	The *awesome-lld* reference solution makes the booking system a Singleton. We pass collaborators through the constructor instead (dependency injection): it is easier to test and allows one service per concert.	A global Singleton.

Java implementation

Package `lld.ch15.concert`. Files: `Model.java` (tiers, seat states, hold, ticket, interfaces, clock), `Inventory.java` (CAS seat inventory, GA pool, purchase limiter, waiting room), `TicketingService.java`, `Main.java`. The demos use Java 21 **virtual threads** (lightweight threads managed by the JVM rather than the operating system) (`Executors.newVirtualThreadPerTaskExecutor()`), which make 1,000 concurrent buyers cheap.

```java
// File: lld/ch15/concert/Model.java
package lld.ch15.concert;

import java.math.BigDecimal;
import java.time.Clock;
import java.time.Duration;
import java.time.Instant;
import java.time.LocalDateTime;
import java.time.ZoneId;
import java.time.ZoneOffset;
import java.util.List;

/** Seated tiers have numbered seats; general admission (GA) is just a count of standing places. */
enum Tier {
    VIP(true, "5000.00"), PREMIUM(true, "2500.00"), GENERAL_ADMISSION(false, "800.00");
    final boolean seated;
    final BigDecimal price;                       // money: BigDecimal, never double
    Tier(boolean seated, String price) { this.seated = seated; this.price = new BigDecimal(price); }
    BigDecimal priceFor(int qty) { return price.multiply(BigDecimal.valueOf(qty)); }
}

record Concert(String id, String artist, String venue, LocalDateTime startsAt) {}

/** A seat's whole life in one immutable value, swapped atomically with compare-and-set (CAS). */
sealed interface SeatState permits Free, Held, Sold {}

        Hold forgotten = svc.holdSeats("dev", List.of("P-6"));
        clock.advance(Duration.ofMinutes(11));
        System.out.println("  expired holds reaped = " + svc.expireHolds() + " (VIP-1, cai's unpaid offer, dev's P-
6)");
        try { svc.purchase(forgotten.id()); } catch (IllegalStateException e) { System.out.println("  dev: " +
e.getMessage()); }
        System.out.println("  P-6 now " + seated.stateOf("P-6") + ", GA left " + svc.gaAvailable());
        System.out.println("  availability: " + svc.availability());
        System.out.println("  money collected = " + collected.get());
    }
}
```

Output:

```
== 1. Seating and availability, then the virtual waiting room ==
  availability: VIP free [VIP-1, VIP-2, VIP-3, VIP-4], PREMIUM free [P-1, P-2, P-3, P-4, P-5, P-6],
GENERAL_ADMISSION free 100
  ana got number 1
  ben got number 2
  cai got number 3
  dev got number 4
  eli got number 5
  ben joins again, keeps number 2
  admitted batch 1: [ana, ben, cai]
  REFUSED: eli is still in the waiting room

== 2. 40 admitted fans CAS for the same seat VIP-1 ==
  holds on VIP-1 = 1

== 3. Flash sale: 1,000 fans, 100 GA places (98 left after test buys) ==
  sold=98 soldOut=902 gaLeft=0 (never negative)

== 4. Per-user limit (4) stops a scalper ==
  ben holds [P-1, P-2, P-3] = 7500.00
  REFUSED: ben would exceed the per-user ticket limit
  ben bought [P-1, P-2, P-3]

== 5. Sold out -> waitlist -> a cancellation is offered to the waitlist ==
  cai: general admission sold out, joins waitlist
  [notify cai] a GA ticket freed up, held for you as H244 until 2026-06-01T09:10:00Z
  GA left after offers = 1

== 6. Unpaid holds expire; the reaper returns them ==
  admitted batch 2: [dev, eli]
  expired holds reaped = 3 (VIP-1, cai's unpaid offer, dev's P-6)
  dev: H245 unknown, expired or already used
  P-6 now Free[], GA left 2
  availability: VIP free [VIP-1, VIP-2, VIP-3, VIP-4], PREMIUM free [P-4, P-5, P-6], GENERAL_ADMISSION free 2
  money collected = 85900.00
```

What to notice: section 1 admits the first three in arrival order and refuses someone still in the queue; section 2 — 40 concurrent CAS attempts on one seat, exactly one hold; section 3 — 1,000 buyers for 98 remaining GA places sell exactly 98 and the counter stops at 0; section 4 — a fifth ticket is refused by the per-user limit; section 5 — a cancellation's released ticket goes straight to the waitlisted fan as a hold; section 6 — the reaper returns three expired holds (VIP-1, the unpaid waitlist offer, and dev's seat) and a late purchase is refused. The availability line at the end shows what is still for sale (three PREMIUM seats, four VIP seats, two GA places). Money collected is 85,900.00 = 98 × 800 + 3 × 2,500 (ana's 2 GA tickets were refunded).

Concurrency & edge cases

- **Why CAS is correct.** `compareAndSet(expected, new)` atomically replaces the value only if it is still the exact object we read. If another thread changed it in between, the CAS fails and we re-read and decide again. The loop in `tryHoldOne` only retries while the seat is still claimable; otherwise it returns `false`.
- **ABA problem?** ABA is when a value goes A → B → A and a CAS wrongly succeeds. Here every transition creates a *new* record object and `AtomicReference` compares references, so an "A" that came back is a different object and the CAS fails safely.
- **Hold claimed exactly once.** `purchase` starts with `holds.remove(holdId)`; the reaper uses `holds.remove(id, h)`. Only one of them can get the hold, so inventory is never released twice.
- **Per-user limit and failures.** Every failure path (sold out, declined, expired, lost seat) gives the limit back, so a user is never locked out by a failed attempt.
- **Lost hold after payment.** `confirm` fails if the hold expired and someone CASed over it; we release, give back the limit, and refund.
- **Fair queue scope.** The in-memory queue is fair *within one process*. At real scale the waiting room is a separate service (often at the CDN edge — a CDN, content delivery network, is a worldwide set of servers placed close to users; see System Design Fundamentals) that hands out signed, time-limited access tokens (short strings the server can verify it issued); inventory servers only check the token.

- **Across servers.** Seat CAS maps naturally to a database conditional update (`UPDATE seat SET state='HELD', hold_id=?, expires_at=? WHERE id=? AND (state='FREE' OR expires_at < now())`) or Redis `SET NX PX`. GA counts map to Redis `DECRBY` (decrement by an amount) guarded by a Lua script (a small script Redis runs as one atomic step), or to a database row updated with `WHERE available >= ?`.

Extensions & follow-up questions

- **"Best available seats."** Instead of the user choosing, a `SeatAllocator` strategy picks the best adjacent free seats in a tier, then calls the same CAS hold.
- **"Verified fans / presale codes."** Admission to the waiting room requires a token issued to pre-registered fans; the limiter keys on a verified identity, not an email.
- **"Dynamic pricing."** Prices per tier come from a `PricingStrategy` that looks at remaining inventory and time — decided when the hold is created and frozen in the `Hold`.
- **"Resale marketplace."** A sold ticket can be listed; a buyer's purchase transfers ownership and re-issues a new barcode (so the old one stops working).
- **"Waitlist for seated tiers."** Implemented the same way for each released seat (`offerSeat`).

Real-world example

Ticketmaster uses a virtual queue ("Smart Queue") for high-demand on-sales and a **Verified Fan** presale programme that registers fans in advance to filter out bots; purchase limits per account are standard on its events. The November 2022 presale for Taylor Swift's *Eras Tour* is the well-known stress case: demand far beyond what was planned for overwhelmed the system, many fans waited for hours or were dropped, and the general public sale was cancelled — a real lesson that fairness and admission control are as important as seat-locking correctness.

In the interview

30–45 minute plan. (1) Say up front: "the entities are like movie booking; the hard part is contention and fairness." (2) Tiers: seated vs GA, and why GA is a counter. (3) Holds with TTL; code the CAS seat claim and the GA CAS loop. (4) Fairness: waiting room with batches; per-user limit with atomic `compute`. (5) Waitlist on release; reaper. (6) Scale-out: tokens from the waiting room, conditional updates/Redis.

> **30-second answer:** "Seated tiers are an `AtomicReference<SeatState>` per seat, claimed by compare-and-set — one winner, no locks. GA is an `AtomicInteger` decremented by a CAS loop so it can't go negative. Everyone enters through a virtual waiting room that admits in arrival order, and a per-user limit is enforced atomically. Holds expire after 10 minutes; a reaper returns expired GA holds; released tickets go to a FIFO waitlist first. If a hold is lost during payment we refund."

Follow-ups with answers: *Lock-free vs locks?* Lock-free wins when contention is high and critical sections are tiny (one field swap); locks are simpler when an operation must update many things together. *What if the queue service fails?* Fail closed (on failure, deny rather than allow): pause admissions, don't open the floodgates. *How do you stop one person with 50 accounts?* Verified identity, payment-card fingerprinting (recognising the same card across accounts), and limits keyed on those.

Self-check

- **Q:** Why is GA modeled as a counter, not seats? **A:** Standing places are interchangeable; a counter with CAS is simpler and can't oversell.
- **Q:** What does `compareAndSet` guarantee? **A:** The update happens only if the value is still the one you read; otherwise it fails and you retry or give up.
- **Q:** Why must `join` be synchronized? **A:** So the number handed out and the position in the line are assigned together; otherwise two joiners could get numbers in one order and queue slots in the other.
- **Q:** How is a hold prevented from being purchased *and* reaped? **A:** Both paths remove it from the `holds` map first; only one removal succeeds.
- **Q:** What happens to a released ticket when fans are waitlisted? **A:** It becomes a fresh hold for the first fan in the waitlist, who is notified.

TL;DR

Same nouns as movie booking, different enemy: contention. CAS per seat, CAS counter for GA, a FIFO virtual waiting room for fairness, atomic per-user limits, TTL holds with a reaper, a waitlist that gets released tickets first, and refunds when a hold is lost.

15.4 Design a Hotel Management System

Figure — Cover image for the hotel management case study (course diagram)

Problem & clarifying questions

A **Hotel Management System** (often called a *property management system*, PMS) runs a hotel's operations in one place: it knows every room, takes bookings, checks guests in and out, issues key cards, records housekeeping and room service, and produces the bill. Management gets one portal to track available rooms, book them and generate invoices.

The inventory here is different from a cinema: a room is not sold once, it is sold **night by night**. That single fact shapes the whole design.

Question	Answer we assume
Several hotel locations?	Yes — a `Hotel` has many `HotelLocation`s, each with its own rooms.
Room types?	`STANDARD`, `DELUXE`, `FAMILY_SUITE`, `BUSINESS_SUITE`.
What does a guest search by?	Room type and **date range** (availability).
Cancellation policy?	**Full refund if cancelled more than 24 hours before check-in**; otherwise no refund (our assumption for the "otherwise" case).
Extra charges during the stay?	Room service, food (kitchen) and amenities are added to the bill.
How is the bill paid?	**Credit card, check or cash**.
Keys?	Electronic key cards with a barcode and key id; deactivated at check-out.
Housekeeping?	Every task is logged per room (a history, never overwritten).
One booking for several rooms?	No — one booking = one room (a known limitation; see follow-ups).

Requirements

Functional (course list)

1. Support booking different **room types**: standard, deluxe, family suite (and business suite).

2. Guests **search** room inventory and book any **available** room.
3. Retrieve **who booked a room** and **which rooms a customer booked**.
4. Customers can **cancel**; **full refund if more than 24 hours before check-in**.
5. **Notify** the guest shortly before check-in and shortly before check-out.
6. Keep a **housekeeping log** per room.
7. Customers can add **room services and food items**.
8. Customers can ask for **amenities**.
9. Pay bills by **credit card, check or cash**.

Non-functional — never double-book a room-night (even with concurrent bookings from the website and the front desk); the bill must always equal the sum of its lines; each actor may do only their own job; the refund rule must be changeable in one place.

Use cases

Actors (course): **Guest** (search, book), **Receptionist** (add/modify rooms, create bookings, check in/out), **System** (booking/cancellation/reminder notifications), **Manager** (adds new workers), **Housekeeper** (adds/modifies housekeeping records), **Server** (adds/modifies room-service records).

Top use cases: add/remove/edit room; search room (by type and availability); register or cancel an account; book room; **check in**; **check out** (end of booking, return of keys); add room charge; update housekeeping log.

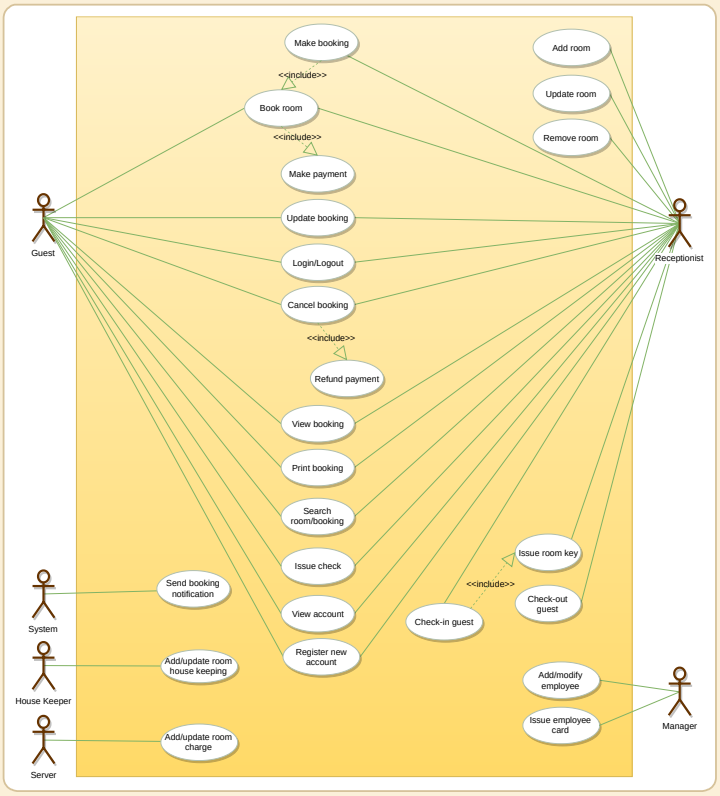

Figure — Hotel use cases: Guest and Receptionist share booking, update, cancel, view, print and search; "Make booking" includes "Book room", which includes "Make payment"; "Cancel booking" includes "Refund payment"; the receptionist's "Check-in guest" includes "Issue room key"; the System sends booking notifications; the House Keeper adds/updates housekeeping; a manager adds/modifies employees (course diagram)

Core entities

Class	Responsibility
`Hotel`	Owns its locations; searches each one in turn.
`HotelLocation` implements `Search`	Owns its rooms; answers "which rooms of this type are free for these dates?".
`Room`	Number, style, price per night; the **set of booked nights**; owns its `RoomKey`s and housekeeping log; current `RoomStatus`.
`RoomStyle`, `RoomStatus` (enums)	Type of room; what it is doing *now* (`AVAILABLE`, `RESERVED`, `OCCUPIED`, `NOT_AVAILABLE`, `BEING_SERVICED`, `OTHER`).
`RoomKey`	Key id, barcode, issue time, master flag, active flag.
`RoomHouseKeeping` (record)	One log line: when, who, what, how long.
`RoomBooking`	Reservation number, guest id, room, check-in/out dates, status, deposit; **owns its** `Invoice`; `refundDue()` holds the cancellation rule.
`BookingStatus` (enum)	`REQUESTED`, `PENDING`, `CONFIRMED`, `CHECKED_IN`, `CHECKED_OUT`, `CANCELLED`, `ABANDONED`.
`Invoice`, `InvoiceItem`	A list of lines; the total is computed from them.
`RoomCharge` (abstract) → `Amenity`, `RoomService`, `KitchenService`	A charge that knows how to write itself onto the invoice (Template Method: the parent fixes the steps, subclasses fill in one).
`Payment` (sealed, abstract) → `CreditCardTransaction`, `CheckTransaction`, `CashTransaction`	Three ways to pay with genuinely different behaviour.
`Person` (sealed) → `Guest`, `Receptionist`, `Server`, `Housekeeper`, `Manager`	Actors; service methods accept only the right actor type.
`FrontDesk`	Every flow of a stay: book, check in, add charge, check out, cancel, housekeeping, reminders, queries.
`Notifier`	Messages to guests.

Class diagram

The course's five stages:

Stage	Adds	What works afterwards
1	Invoice, payment types, notification types	A bill can be produced and settled by card, check or cash
2	Room, key card, housekeeping record	Each room can tell which of its nights are sold
3	Hotel, location, search interface	Free rooms can be listed for any date range
4	Booking and room charges	A stay can be followed from reservation to check-out
5	People and accounts	Every actor is limited to its own tasks

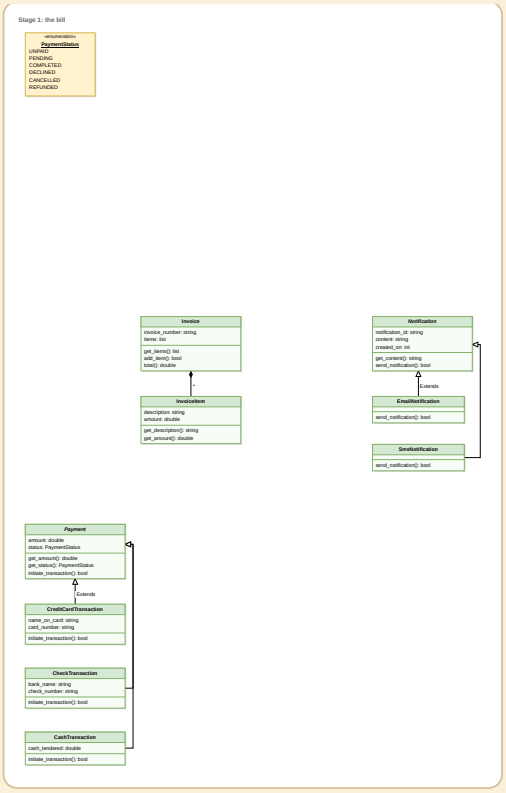

Figure — Stage 1: `Invoice` owns its `InvoiceItem`s (composition) and computes `total()`; abstract `Payment` with credit card, check and cash subclasses; abstract `Notification` with one subclass per channel (course diagram)

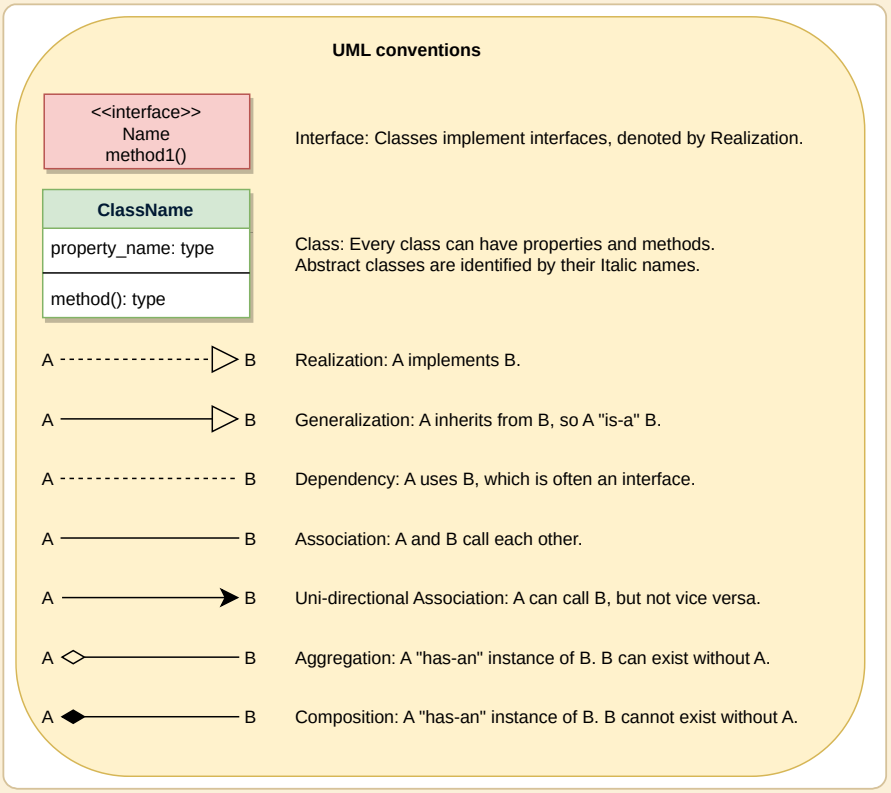

Figure — How to read a class box and the arrow styles used in these diagrams (course diagram)

Requirements 7 and 8 each put extra charges on a stay. That is why the invoice stores **individual lines** and computes its total on demand: a total that is always recomputed can never go out of step with the lines.

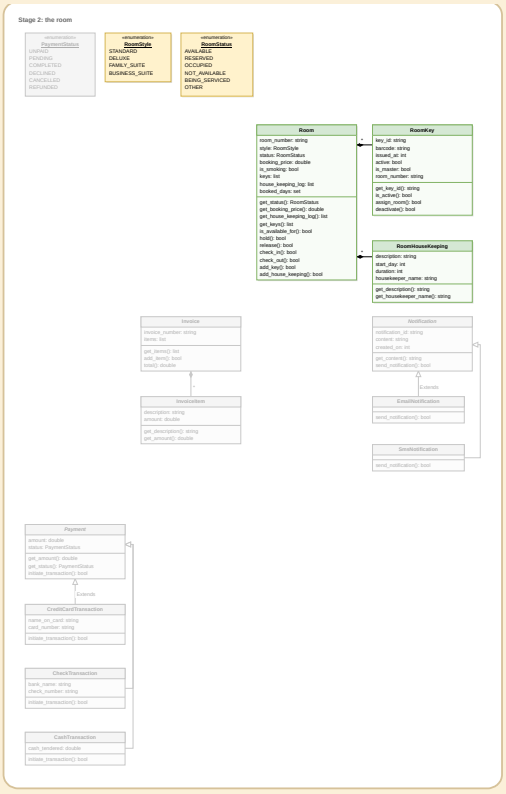

Figure — Stage 2: `Room` (number, style, status, price, and the set of nights it is committed to) owns its `RoomKey`s and its list of `RoomHouseKeeping` records (course diagram)

The key decision of the whole design sits here: **a status field is not availability.** `RoomStatus.OCCUPIED` describes the present moment only. A guest, however, asks about the future ("can I have it from the 10th to the 13th?"), and a single status value cannot answer that. So each room also stores the dates of the nights it has already sold.

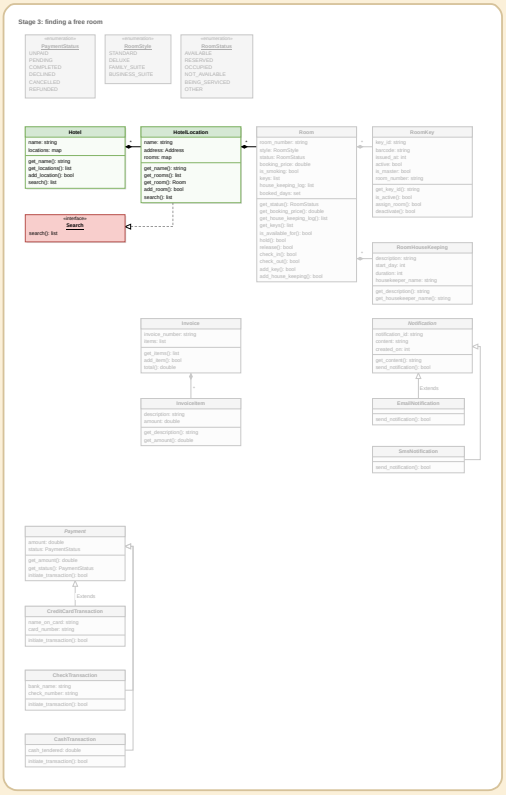

Figure — Stage 3: the `Search` interface implemented by `HotelLocation`, which owns its rooms; `Hotel` owns its locations (course diagram)

Search sits on the **location**, not on `Room`: one room has no knowledge of the other rooms, so it cannot list which of them are free. Putting `search` on `Room` is a frequent beginner mistake.

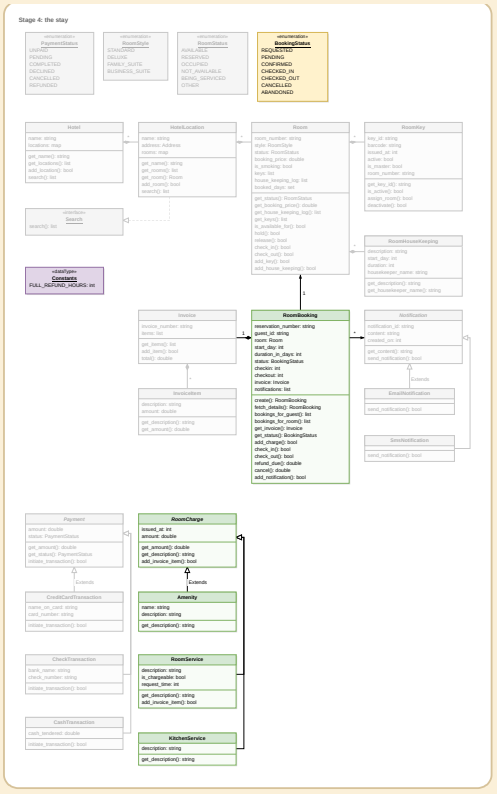

Figure — Stage 4: `RoomBooking` owns its invoice and points at its room (plain association); `RoomCharge` with `Amenity`, `RoomService` and `KitchenService` subclasses each writing an invoice line (course diagram)

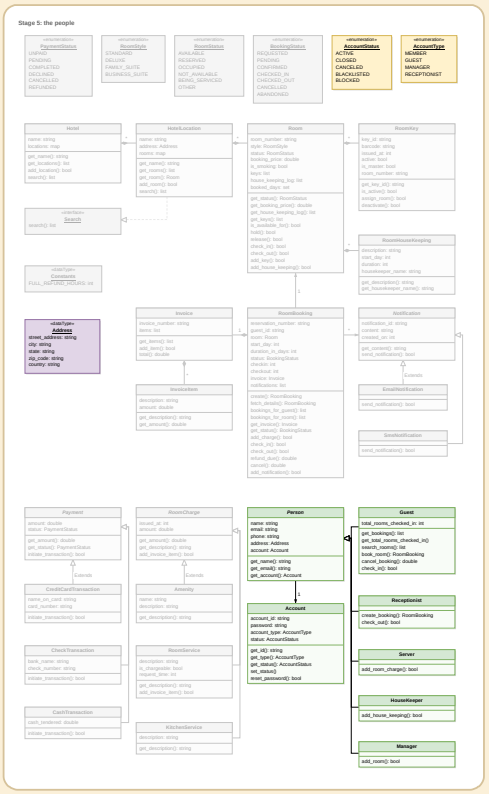

Figure — Stage 5: `Person` with `Guest`, `Receptionist`, `Server`, `HouseKeeper` and `Manager`, each with only its own methods; `Person` refers to its `Account`; there is deliberately no arrow from guest to booking (course diagram)

Notice what the figure does *not* have: an arrow between guest and booking. The booking stores only the guest's **id**, and queries filter bookings by that id — requirement 3 is met without either class holding a reference to the other.

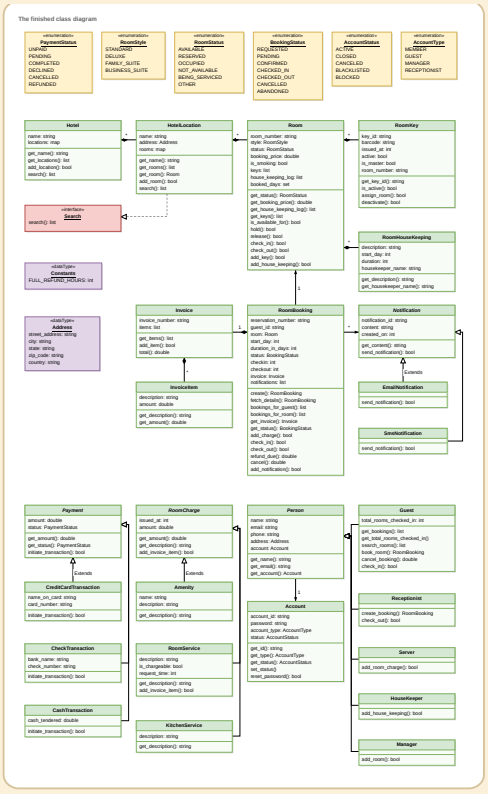

Figure — The finished hotel class diagram (course diagram)

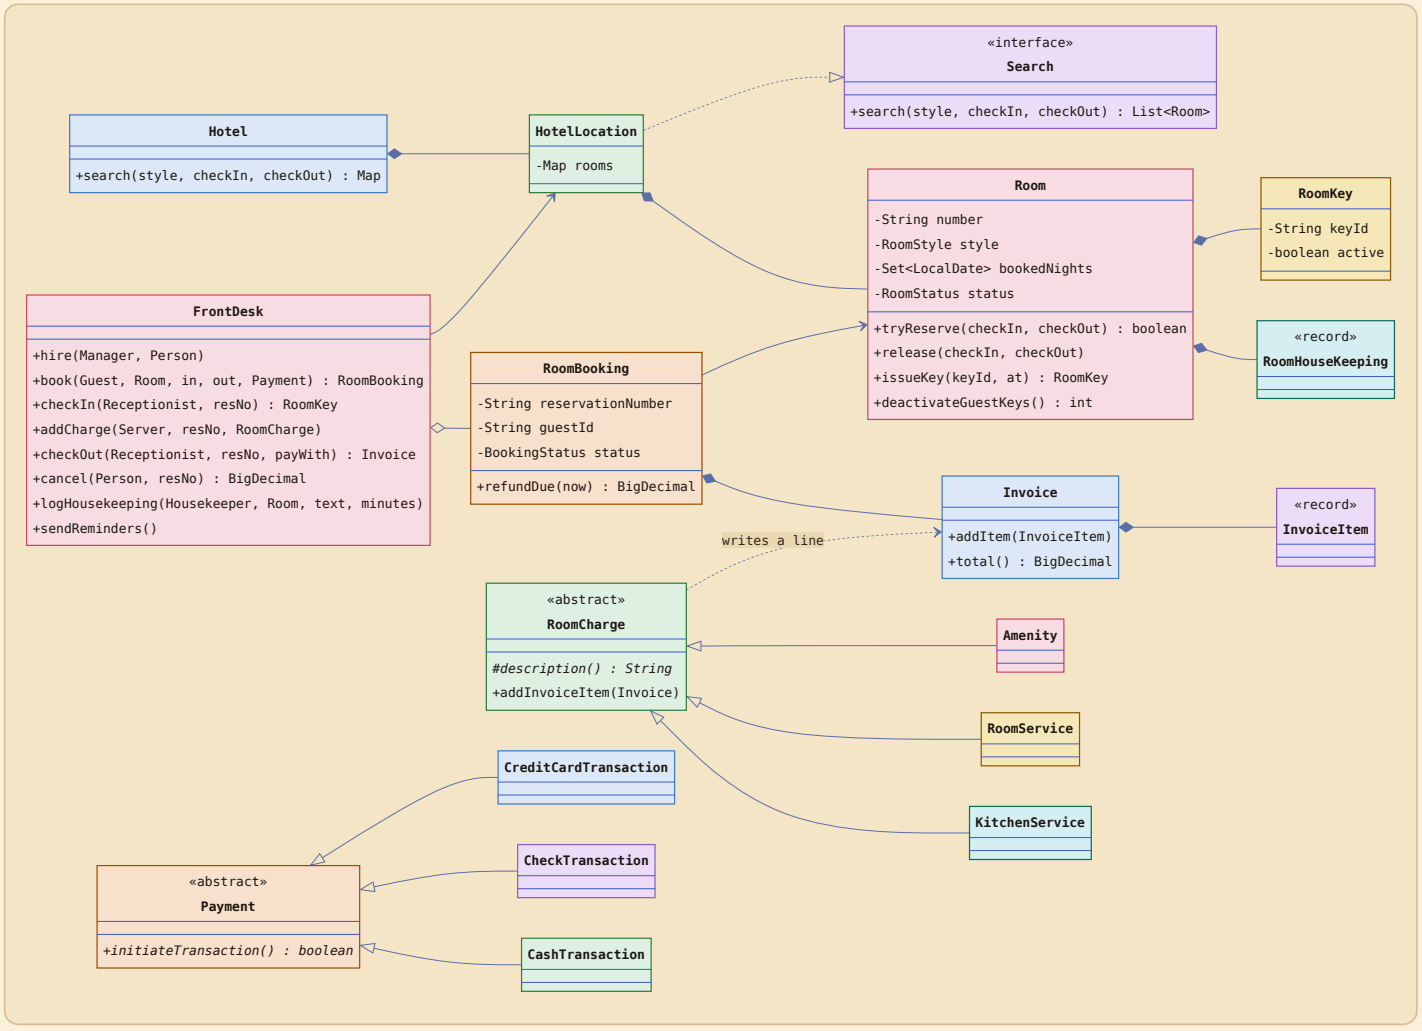
Our Java design:



Key flows

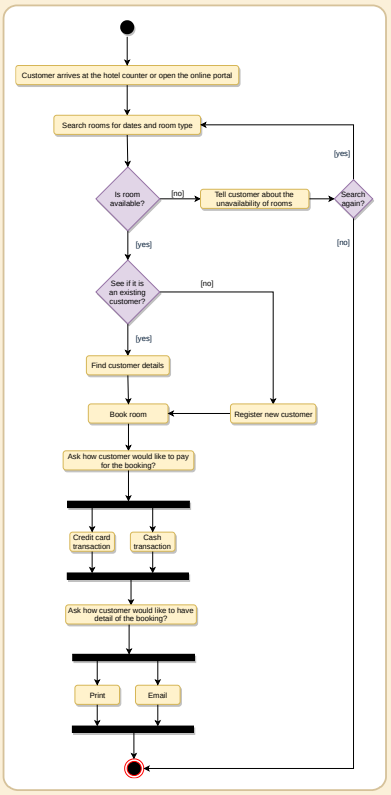


Figure — Make a room booking: search rooms for dates and room type; if none is available tell the customer; otherwise find or register the customer, book the room, ask how they will pay (credit card or cash), and how they want the booking details (course diagram)

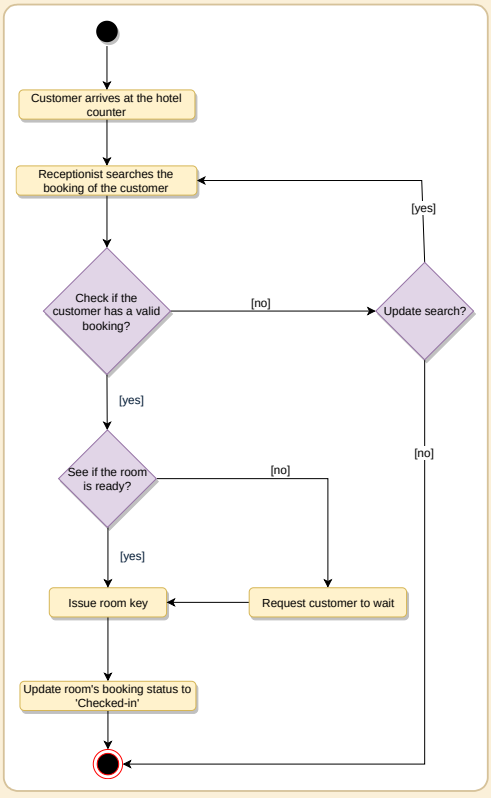

Figure — Check in: the customer arrives at the counter and the receptionist looks up the booking (searching again if it is not found); with a valid booking, check whether the room is ready — if not, the customer is asked to wait; if so, issue the room key and set the booking status to "Checked-in" (course diagram)

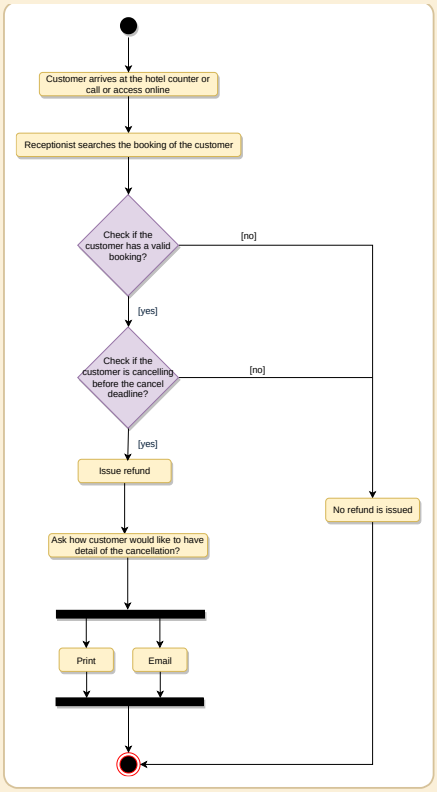

Figure — Cancel a booking: the customer comes to the counter, calls or goes online; the receptionist finds the booking and checks it is valid; if the customer is cancelling before the cancel deadline a refund is issued, otherwise no refund; the cancellation details are printed or emailed (course diagram)

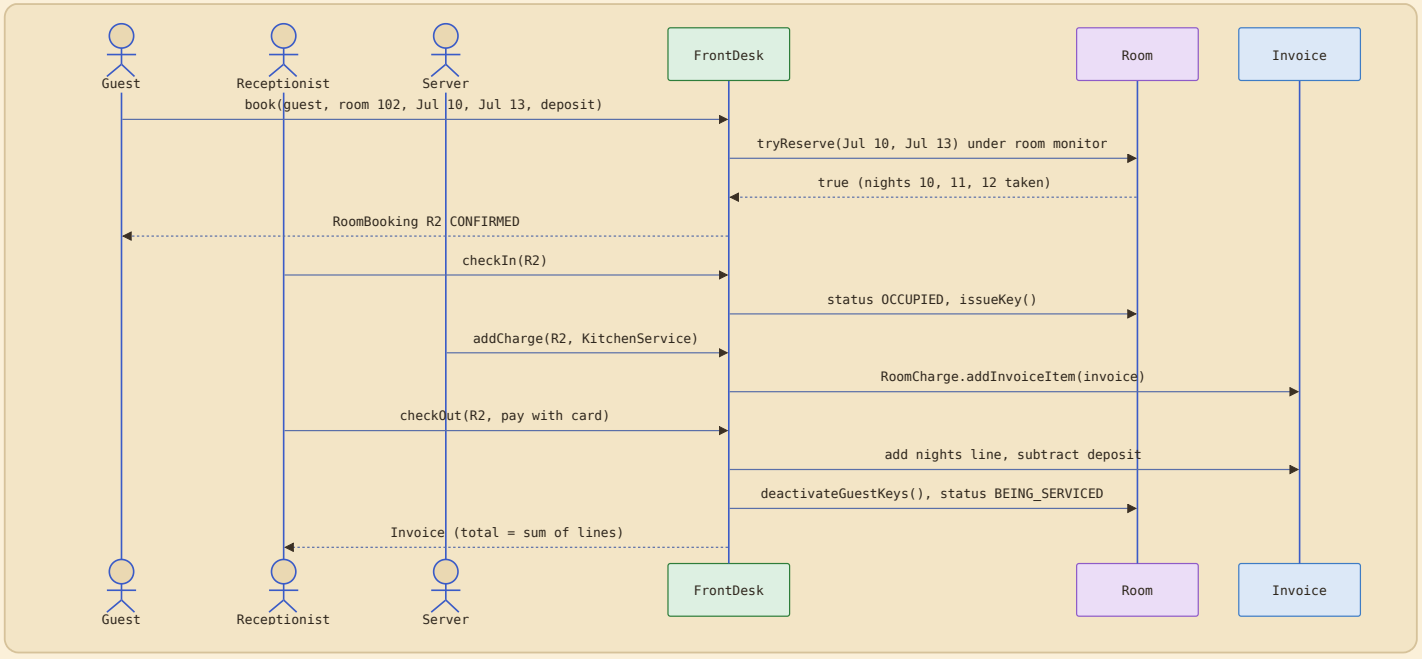
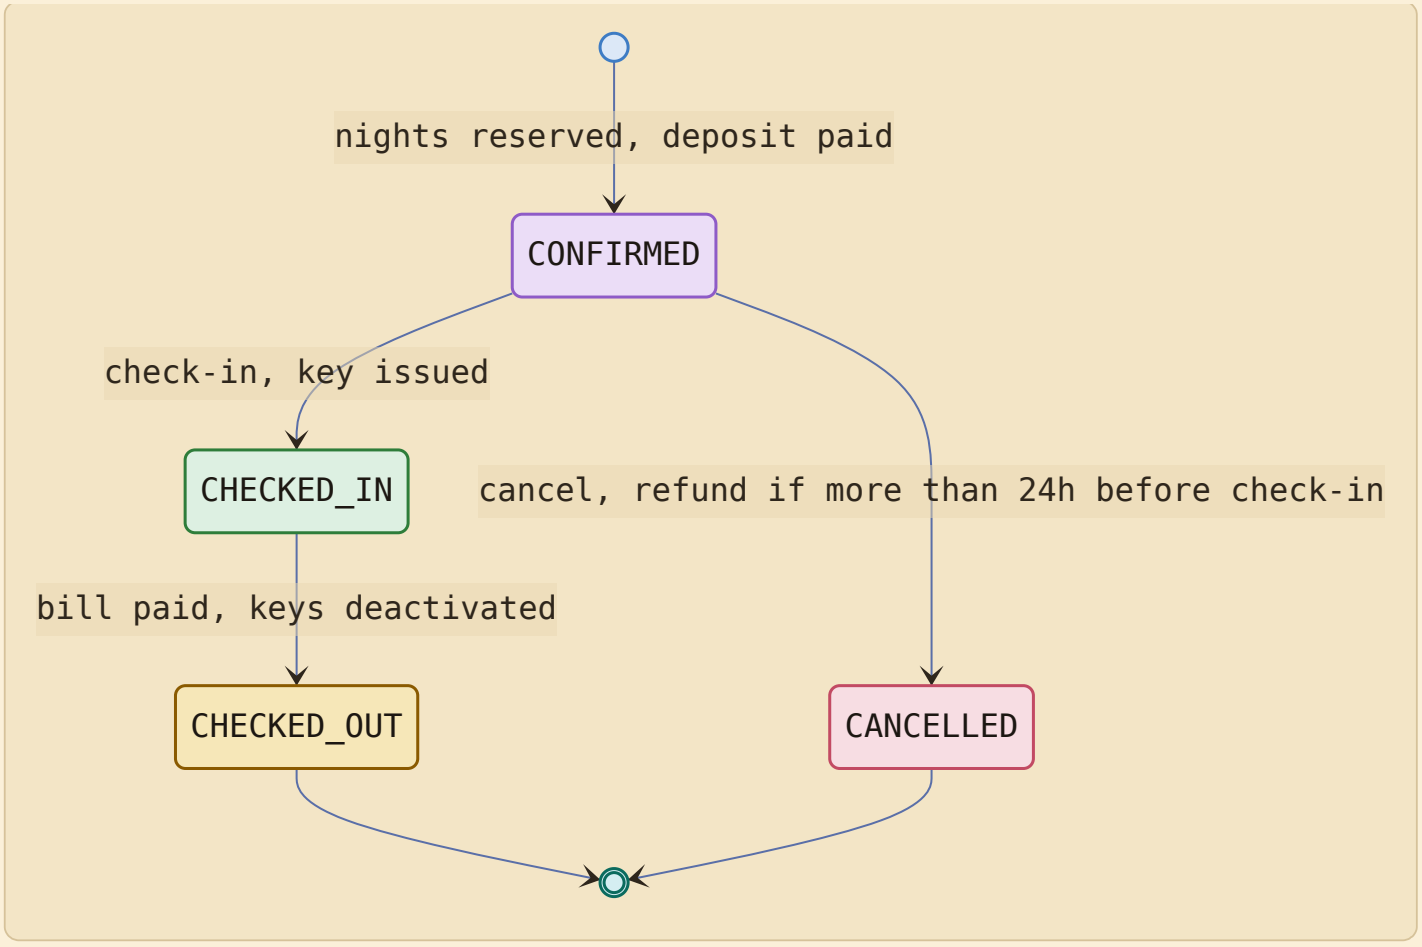
A whole stay as a sequence:



Booking lifecycle:



The room's *current* status cycles independently: `AVAILABLE` → `OCCUPIED` (check-in) → `BEING_SERVICED` (check-out) → `AVAILABLE` (housekeeping logged).

Design decisions & patterns used

Decision	Why	Alternative rejected
Availability = set of booked nights (course's key point)	Answers date-range questions; nights are half-open `[checkIn, checkOut)`, so a guest leaving on the 13th and one arriving on the 13th don't clash.	Using `RoomStatus` for availability — only knows *now*.
`tryReserve` is `synchronized` on the room	"Are all these nights free? → take them" is check-then-act; the room's monitor makes it atomic. Rooms don't block each other.	One hotel-wide lock.
Search on `HotelLocation`	A room can't answer "which rooms are free?".	`Room.search()`.
Invoice = list of lines, total computed	The total can never disagree with the lines (requirements 7 and 8).	A stored running total.
Template Method: `RoomCharge.addInvoiceItem`	The parent fixes the algorithm (describe → price → write a line) and is `final`; subclasses fill in only `description()`. A new kind of charge = a new subclass, no edit to `Invoice` (Open/Closed). The course calls this the clearest Template Method example in its catalogue. Compare with Strategy, where the *whole* method is swapped rather than one step.	A `switch` on charge type inside the invoice.
Three `Payment` subclasses	They really behave differently: a card completes immediately, a **check stays `PENDING`** until it clears, cash can be declined if the amount tendered is short. Each passes the substitution test (each can be asked to take money).	One `Payment` with a `type` field and `if`s.
Refund rule in one method (`refundDue`)	When the policy changes there is exactly one place to edit. To support several policies (non-refundable rates, partial refunds), promote it to a `CancellationPolicy` strategy as in 15.2.	Refund arithmetic scattered through cancel flows.
Actor types in service signatures	`addCharge(Server, …)`, `logHousekeeping(Housekeeper, …)`, `addRoom(Manager, …)` — the compiler enforces who can do what. The receptionist booking for a guest calls the *same* booking method — two actors, one behaviour, no duplication.	Every actor able to call everything.
Booking stores guest id, not a `Guest` reference	No two-way dependency; "which rooms did this guest book?" is a query.	Bidirectional links that must be kept in sync.
Nights released on failed deposit / cancel	Reserve-then-pay needs an undo: if the deposit fails the nights are given back immediately.	Leaving phantom reservations.

Java implementation

Package `lld.ch15.hotel`. Files: `Billing.java` (invoice, payments, room charges), `Rooms.java` (room, key, housekeeping, search, hotel, clock, money), `Stay.java` (booking, actors, front desk), `Main.java`.

```java
// File: lld/ch15/hotel/Billing.java
package lld.ch15.hotel;

import java.math.BigDecimal;
import java.util.ArrayList;
import java.util.List;

enum PaymentStatus { UNPAID, PENDING, COMPLETED, DECLINED, CANCELLED, REFUNDED }

record InvoiceItem(String description, BigDecimal amount) {}   // money: BigDecimal, never double

/** A bill is a list of lines; the total is always computed, so it can never disagree with the lines. */
final class Invoice {
    private final String number;

  room 102 is AVAILABLE
```

What to notice: section 0 — only a `Manager` can add rooms and hire staff (the course's "Manager adds new workers"); section 2 — six concurrent bookings of room 101 for overlapping dates produce exactly one booking (which guest wins varies per run); section 3 — Ben's stay starting the 13th fits right after Asha's ending the 13th (half-open ranges); section 4 — Carl cancels 19 hours before check-in and gets nothing, Asha cancels 8 days ahead and gets a full refund; section 5 — reminders fire within 24 hours of check-in/check-out, the key is issued at check-in and dead after check-out, a declined cash payment leaves the guest checked in and the invoice untouched (the retry by card does not duplicate any line), and the invoice lines add up (room service $5 + kitchen $24 + spa $30 + 3 nights $360 − $120 deposit = $299); section 6 — housekeeping is logged and the room becomes available.

Concurrency & edge cases

- **Double booking a room-night.** Prevented by `Room.tryReserve` being `synchronized`: the check and the add of every night are one atomic step. The demo's 6-thread race always has one winner.
- **Search is advisory.** `search` may show a room that is gone a millisecond later; the booking itself (`tryReserve`) is the real check — so always handle "no longer available" on book.
- **Booking-level transitions** (`checkIn`, `checkOut`, `cancel`) run under the booking's monitor, so a cancel can't interleave with a check-in. Lock order is always booking → room.
- **The 24-hour rule, exactly.** `refundDue` compares `Duration`s (`notice.compareTo(24h) > 0`). The tempting `Duration.toHours() > 24` is wrong: `toHours()` drops the minutes, so a cancellation 24 h 30 min ahead would count as "24, not more than 24" and lose its refund.

- **Checkout is retry-safe.** The nights and deposit lines are written to the invoice only after the payment succeeds, and `addCharge` takes the same booking monitor as `checkOut`, so no charge can be added between totalling the bill and closing it.
- **Edge cases:** check-out date not after check-in; checking in before the check-in date; adding charges when the guest is not in house; cancelling after check-in; cash tendered below the amount (declined); a check payment that stays `PENDING`.
- **Chain-wide inventory.** The course notes that storing nights on each room is simple but doesn't scale to a chain selling through many channels: real systems keep availability in one place (an **inventory table** keyed by `(room_type, date)` with a count, updated with a conditional `UPDATE ... SET sold = sold + 1 WHERE sold < capacity`), so two sites or two booking channels can't sell the same night.

Extensions & follow-up questions

- **"A family wants two rooms in one booking."** The course flags this: move the dates and the invoice *up one level* to a `Reservation` that holds several `RoomStay`s (each with its room and nights). Reserving several rooms then needs all-or-nothing across rooms — lock rooms in a fixed order (by room number) to avoid deadlock, or do it in one database transaction.
- **"Book by room type, assign the room at check-in."** Many hotels sell a *type* for a date range and pick the physical room later. Keep per-type-per-night counts for selling; assign a specific room at check-in (housekeeping status permitting).
- **"Seasonal rates."** A `RatePlan`/`PricingStrategy` gives the price per night (weekends, seasons, loyalty tiers); the nights line becomes one line per night.
- **"Overbooking."** Allow selling capacity × (1 + overbooking factor) of a type; the ones who can't be housed are "walked" to a partner hotel — a business policy, pluggable as a strategy on the availability check.
- **"Separate the booker from the occupants."** The course names this as missing: add `Occupant`s to the stay (names for fire safety/registration) distinct from the paying guest.
- **"Lost key."** Deactivate all active guest keys for that room and issue a new one — `deactivateGuestKeys()` + `issueKey()`.

Real-world example

Property management systems such as **Oracle Hospitality OPERA** run the front desk this way: reservations are made against room types and dates, a specific room is assigned by check-in, the folio (the guest's bill) collects charges from restaurants, minibar and spa as separate postings, and housekeeping status (dirty, clean, inspected) controls whether a room can be assigned. At check-in, the desk encodes an RFID (radio-frequency identification, a contactless chip) key card with an electronic lock system (for example ASSA ABLOY's VingCard or dormakaba) that is valid only until the check-out time. Online, **Booking.com** shows each rate's cancellation policy (for example "free cancellation until 24 hours before arrival") — exactly the one-method refund rule of this design, but chosen per rate plan.

In the interview

30–45 minute plan. (1) Clarify: room types, date-range search, 24-hour refund, charges, payment types, keys, housekeeping. (2) Actors and use cases. (3) Entities, stating early: **"a status field is not availability"** — rooms keep booked nights. (4) Code `tryReserve` (synchronized), `book`, `checkIn`, `checkOut` with the invoice. (5) Template Method for charges; payment subclasses; refund rule. (6) Follow-ups: two rooms per booking, chain-wide inventory, overbooking.

> **30-second answer:** "A `Hotel` has `HotelLocation`s which own `Room`s and implement search by type and date range. Each room keeps the set of nights it's committed to, and reserving nights is a synchronized check-then-act so two guests can't get the same night. A `RoomBooking` owns an `Invoice` made of lines; room service, kitchen and amenities are `RoomCharge` subclasses using Template Method to add a line. Payment is credit card, check or cash subclasses. Cancellation refunds in full if more than 24 hours before check-in — one method. Check-in issues a key card; check-out totals the invoice, takes payment, kills the keys and hands the room to housekeeping."

Self-check

- **Q:** Why isn't `RoomStatus` enough to know if a room can be booked? **A:** It only says what the room is doing now; a booking asks about a range of future nights.

- **Q:** Why are nights half-open `[checkIn, checkOut)`? **A:** The checkout day's night is not used, so the next guest can check in that day.
- **Q:** Which pattern lets a new charge type be added without touching `Invoice`? **A:** Template Method (`RoomCharge.addInvoiceItem` is fixed; subclasses supply `description()`).
- **Q:** Where does the refund rule live, and why? **A:** In `RoomBooking.refundDue` — one place to change when the policy changes.
- **Q:** How is it guaranteed only a server can add a room-service charge? **A:** `addCharge` takes a `Server` parameter; other actor types don't compile.

> **TL;DR**

Rooms are sold night by night: each room keeps its booked nights and reserves them atomically. Search lives on the location. The bill is a list of lines filled by `RoomCharge` Template Methods; three payment subclasses; one refund method (24 hours). Keys issued at check-in, killed at check-out; housekeeping is an append-only log (entries are only added, never changed or removed).

Chapter summary

Problem	Inventory unit	How a hold/booking is made safe	Payment failure handling	Cancellation
Library	`BookItem` (copy)	`synchronized` member → item (fixed order)	— (fines recorded)	Return → FIFO waitlist per title gets the copy
Movie tickets	`ShowSeat` (seat × show)	Per-show monitor; all-or-nothing lock with TTL; atomic commit	Declined → release; lost hold → refund (compensation)	Refund per `CancellationPolicy`; seats back on sale
Concert tickets	Numbered seat state / GA counter	Lock-free CAS; waiting room; per-user limit	Same compensation as movies	Released tickets offered to waitlist first
Hotel	Room × night	`synchronized` `Room.tryReserve` over a date range	Failed deposit → nights released	Full refund if > 24h before check-in

Five sentences to remember for any booking interview:

1. Name the *real* unit of inventory first (copy, show seat, room-night, GA count).
2. Every "if free then take" must be one atomic step — a monitor, a CAS, or a conditional `UPDATE`.
3. Temporary holds need an expiry, or abandoned checkouts block inventory forever.
4. Money can't be rolled back — failures after payment need a compensating refund.
5. In-process locks protect one server; with many servers, the database (constraints, conditional updates) or a TTL store like Redis is the real guarantee.

Chapter 16 — Case Studies: Booking & Inventory (Part 2)

> **Where this fits.** Chapter 15 covered the first group of booking problems. This chapter finishes the family with four more: a car rental company, a restaurant, an airline and a university's course registration. They look different on the surface, but they are the same problem underneath: **a limited resource, a calendar, and many people trying to claim it at once.** Once you see that shared skeleton, each new booking problem takes minutes to set up in an interview.

The shared skeleton of every booking problem

Idea	Car rental	Restaurant	Airline	Course registration
The thing being booked	a vehicle	a table	a seat on one flight instance	a seat in one section
The "calendar" it is booked on	days	hourly time slots	the flight instance (route + date)	the term
The check-then-claim step that must be atomic	`Vehicle.tryBook`	`Table.tryHold`	`FlightInstance.holdSeats`	`Section.enroll`
What happens when it is full	search another car	try the next table	pick another seat or flight	waitlist
Money	bill with lines + late fee	check split by seat + tax	fare per seat class, paid per itinerary	none (fees are an extension)

A **resource** is anything with a limited supply (a car, a table, a seat). A **race condition** is a bug where the result depends on which of two threads runs first — here, two people both "win" the same seat because both checked "free?" before either wrote "taken".

A **thread** is one independent line of execution inside a running program; a server handles many requests at once by running many threads side by side. A step is **atomic** when it happens as one indivisible unit: no other thread can see it half-done or slip in between its parts. **Concurrency** simply means several things are in progress at the same time.

How to run every example in this chapter

```
cd chapters/16-case-booking-2/code
javac --release 21 -d /tmp/lld_16 $(find . -name '*.java')
java -cp /tmp/lld_16 lld.ch16.carrental.Main          # or restaurant, airline, courseregistration
```

`javac` is the Java compiler (it turns `.java` source files into runnable `.class` files), `--release 21` targets Java version 21, and `-cp` (the **classpath**) tells `java` which folder to load compiled classes from. All four `Main` classes compile with Java 21 (standard library only — the classes that ship with Java itself, no extra downloads) and run. The output printed under each program is its real output. Where threads race, the *counts* are always the same, but *which* racer wins can differ from run to run.

> **Code-style note.** To keep each design readable, one file sometimes holds several small package-private types (visible only to other classes in the same package, i.e. the same folder of code) — for example `Types.java` holds the enums and records. An **enum** is a type with a fixed list of named values (`CAR`, `TRUCK` …); a **record** is a compact Java class that just holds a few fixed values and gets `equals`, `hashCode` and `toString` for free. That is legal Java. In production you would usually give each top-level type its own file.

> **Money.** All prices use `java.math.BigDecimal`, never `double`. A `double` is a binary floating-point number (it stores values in base 2 with limited precision); it cannot represent 0.1 exactly, so sums of prices drift by fractions of a cent. `BigDecimal` stores exact decimal digits.

Design a Car Rental System

Figure — A car rental company rents vehicles from many branches (course diagram)

Problem & clarifying questions

A **car rental system** is the software a rental company uses to rent vehicles for a short time — from a few hours to a few weeks. Companies usually have many branches, often near airports and city centres, and a customer may return a car to a different branch from the one they picked it up at.

Questions worth asking in the first two minutes, with the answers we assume:

Question	Assumed answer
Which vehicle kinds?	Cars, trucks, SUVs, vans and motorcycles.
One branch or many?	Many branches, each with its own vehicles.
Can the drop-off branch differ from the pick-up branch?	Yes, the reservation records both.
How is price worked out?	A daily rate per vehicle type, plus add-ons, plus a late fee per day late.
What can be added?	Insurance, equipment (navigation, child seat, ski rack), services (roadside assistance, wifi) and additional drivers.
How are vehicles identified?	Each has a unique barcode; a barcode reader scans it at pick-up and return.
Do we need history?	Yes: a vehicle log of every event (reserved, picked up, returned, fuelling, cleaning, damage).
Concurrency?	Many members book at once; two must never get the same car on overlapping days.

Requirements

Functional

1. Rent different vehicle types: car, truck, SUV, van, motorcycle.
2. Each vehicle is added with a unique barcode and details, including the parking stall number that tells staff where it is parked.
3. Answer "which member took this vehicle?" and "which vehicles has this member rented?".
4. Charge a late fee when a vehicle comes back after its due date.
5. Members search the inventory and reserve any available vehicle.
6. Send notifications when a pick-up date is near, when a vehicle is near its due date, and when it is overdue.
7. Read vehicle barcodes.
8. Members can cancel reservations.
9. Keep a vehicle log of all events on a vehicle.
10. Members can add rental insurance.
11. Members can rent extra equipment (navigation, child seat, ski rack).
12. Members can add services (roadside assistance, additional driver, wifi).

Non-functional

- **Correctness under concurrency:** no double booking of a vehicle for overlapping days.

- **Extensibility:** adding a new kind of add-on or a new pricing rule should not change the reservation code (the **Open/Closed Principle**: code should be open to extension by adding new classes, but closed to editing what already works).
- **Auditability:** every charge is a visible bill line, every vehicle event is a log entry.

Use cases

Four **actors** (people or systems that use the software):

- **Receptionist** — adds and edits vehicles and workers; can also reserve vehicles for a customer.
- **Member** — searches the catalogue, reserves, picks up and returns a vehicle.
- **Worker** — handles returned vehicles and updates the vehicle log (cleaning, refuelling, damage).
- **System** — sends notifications (pick-up reminders, overdue alerts, cancellations).

A **use case** is one goal an actor can achieve with the system, such as "reserve a vehicle". Top use cases: add/remove/edit vehicle; search catalogue by type and availability; register or cancel membership; reserve vehicle; check out (pick up) vehicle; return vehicle; add equipment or services; update the vehicle log.

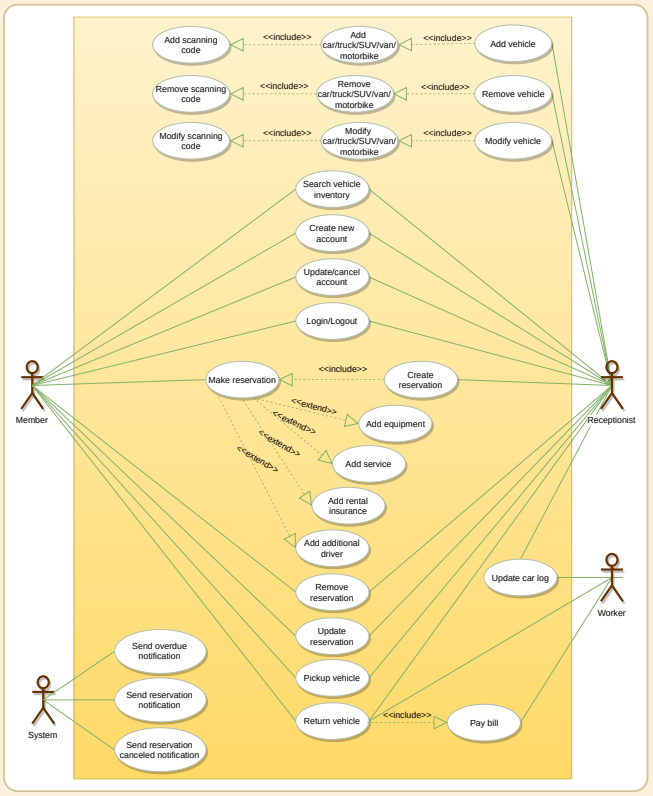

Figure — Use case diagram: receptionist, member, worker and system and the use cases each triggers (course diagram)

A **use case diagram** is a UML (Unified Modeling Language, a standard set of software diagrams) picture: stick figures are actors, ovals are use cases, and lines show who triggers what. In the figure above, notice that reserving is shared by the member and the receptionist, while updating the log belongs to the worker.

Core entities

Class	Responsibility
`CarRentalSystem`	Top-level object; owns the branches and the reservation service.
`CarRentalLocation`	One branch (name, code) with its own `VehicleInventory`.
`VehicleInventory`	Three indexes (lookup maps) over a branch's vehicles: by barcode, by type, by model. Answers "which SUVs are free on these days?".
`Vehicle`	Barcode, plate, make, model, type, seats, parking stall, mileage, **the set of booked days**, and its log.
`VehicleLogEntry`	One event on a vehicle (date, type, note).
`DateRange`	Half-open range of days `[start, end)` (includes `start`, excludes `end`); `end` is the due date.
`Reservation`	The rental: member, vehicle, dates, pick-up and return branch, add-ons, drivers, bill, status. Holds the business rules.
`ReservationAddOn` (+ `RentalInsurance`, `Equipment`, `Service`)	Anything that adds a charge to a rental.
`AdditionalDriver`	A named extra driver on the rental (no charge in our model).
`Bill`, `BillItem`	The one place that knows what a rental costs: a list of lines.
`PricingStrategy`, `LateFeePolicy`	Pluggable (swappable without code changes) rules for the base charge and the late fee.
`ReservationService`	Creates reservations atomically, answers the two "who rented what" questions, runs reminders.
`Notifier`, `PaymentMethod`	Ports (interfaces to outside systems) for sending messages and taking money.

Class diagram

A **class diagram** shows the classes, their fields and methods, and how they relate (owns, refers to, inherits from). The course builds its model in seven stages: money and messages, add-ons, vehicles, search, reservations, actors, and finally the system and its branches.

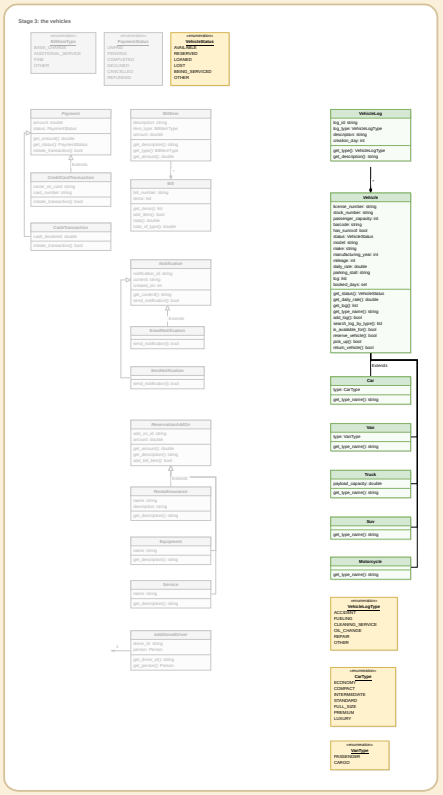

Figure — Vehicle, its log and the vehicle sub-types (course diagram)

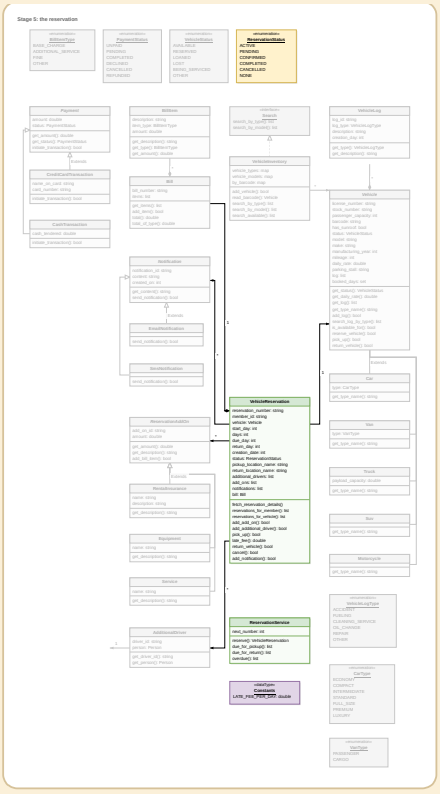

Figure — The reservation owns its bill and refers to the vehicle, add-ons, drivers and notifications (course diagram)

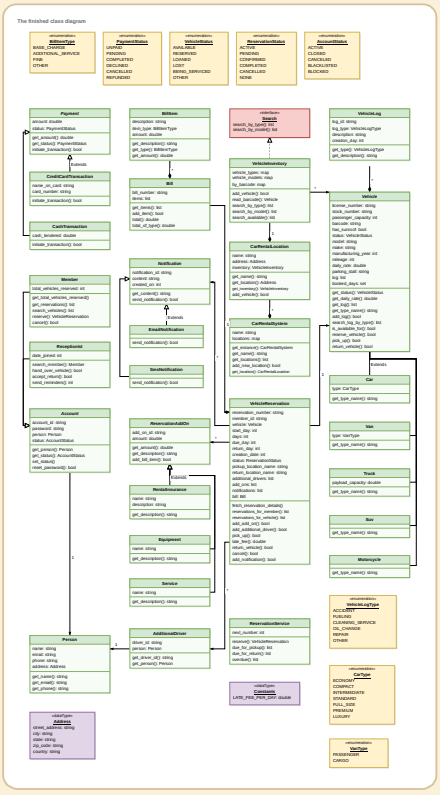

Figure — The finished class diagram of the car rental system (course diagram)

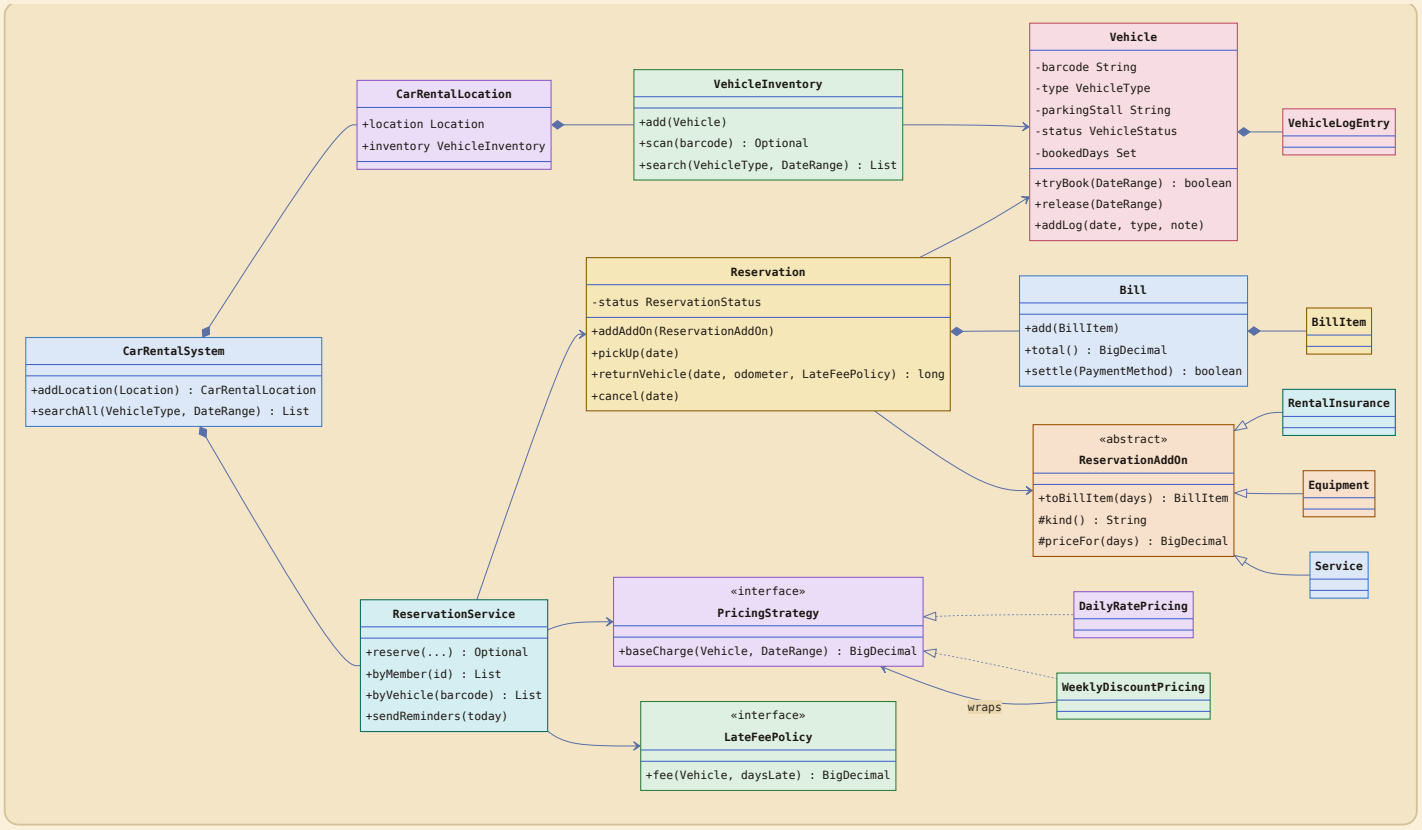
In the finished figure above, two ownership chains matter: the system owns its branches and each branch owns its inventory (filled diamonds, **composition** — the part dies with the whole), while the inventory only *refers to* vehicles (plain arrow, **association**). A reservation owns its bill but only refers to the vehicle.

Our Java design follows the same shape, with two deliberate differences: vehicle kinds are an enum (`VehicleType`) rather than five empty subclasses (classes that inherit from a parent class), because the subclasses add no behaviour; and pricing is a strategy object (an object you plug in to decide one varying rule) rather than a constant.



Key flows

The figures below are **activity diagrams** — flowcharts of one task, with diamonds for decisions. **Pick up a vehicle.** The receptionist scans the customer's licence (or searches by name), checks there is a valid reservation, scans the vehicle's barcode, and hands over the keys. If there is no reservation, the member can reserve a free vehicle on the spot.

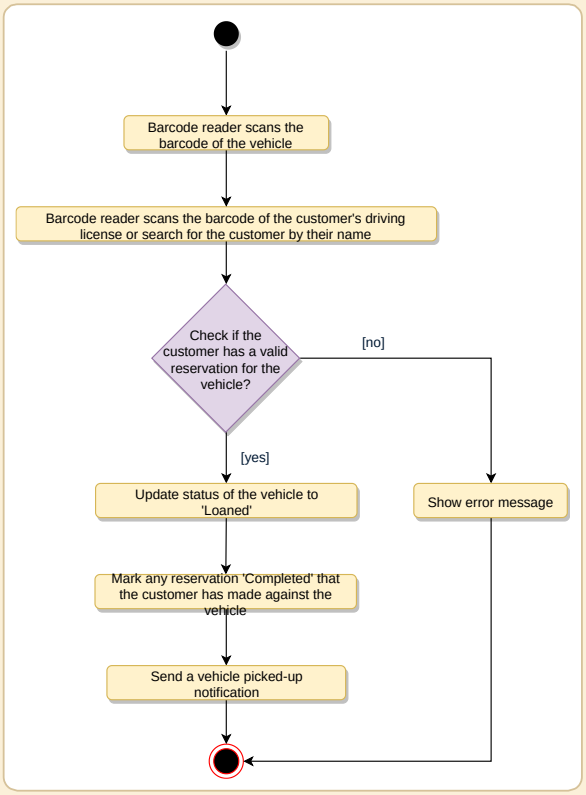


Figure — Activity diagram: picking up a vehicle (course diagram)

Return a vehicle. A worker scans the vehicle barcode; if it is past the due date, the system adds a late fee; the worker checks for damage and fuel; the bill is settled.

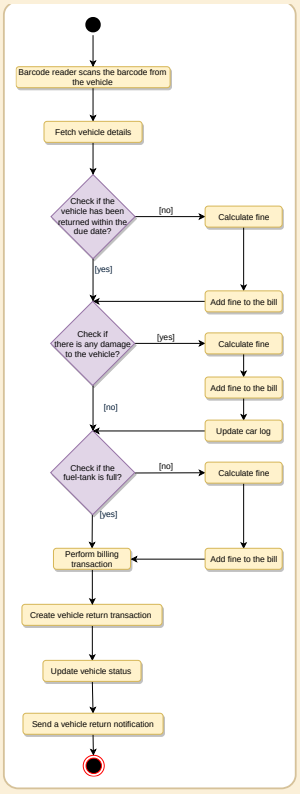

Figure — Activity diagram: returning a vehicle, with the late-fee branch (course diagram)

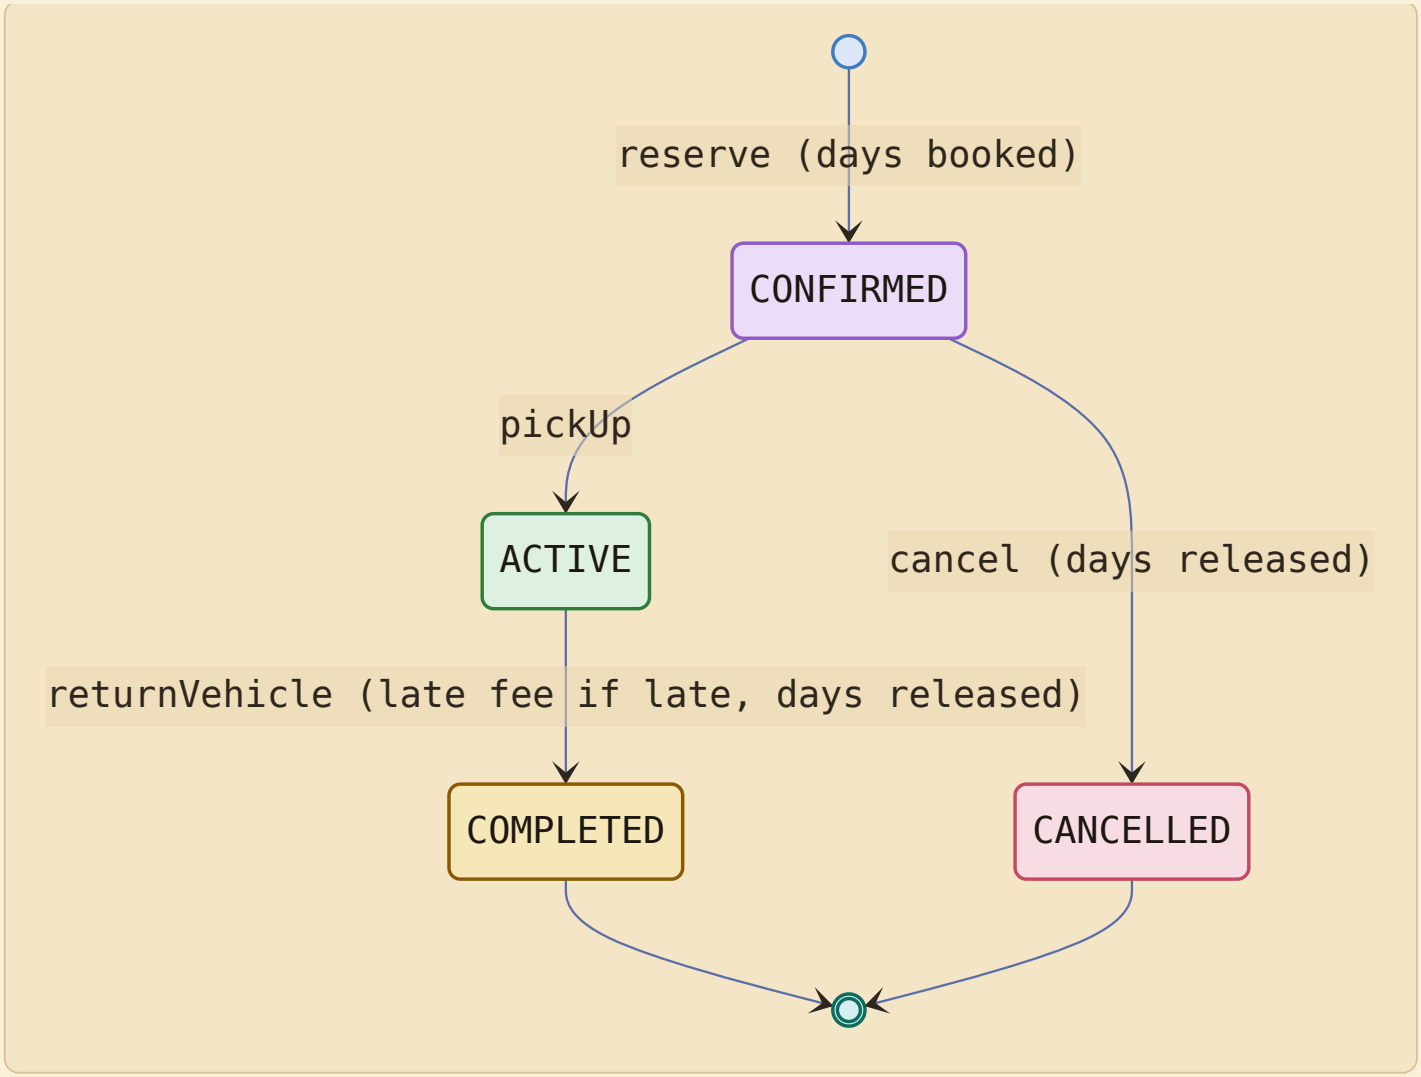
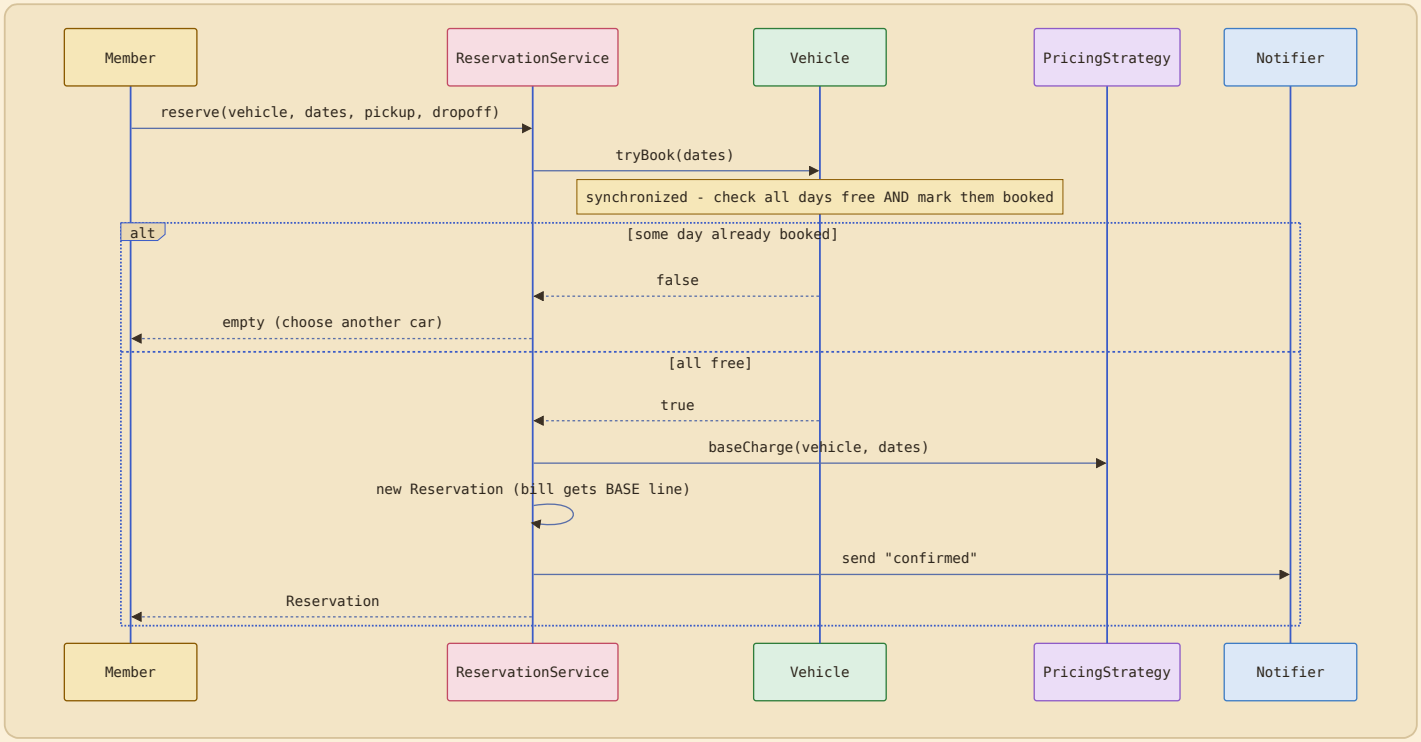
As the figure above shows, the late-fee decision is a branch on the return path — in our code it is one line inside `Reservation.returnVehicle`.

Reservation lifecycle (a **state machine** — a fixed set of states and the only moves allowed between them):



Reserve flow, including the race we must win (a **sequence diagram**: each column is an object, and arrows are calls in time order from top to bottom):



Design decisions & patterns used

Decision	Why	Alternative rejected
Availability comes from the days each vehicle has already sold, not from a status field	Members ask about future dates ("can I have it from the 10th to the 13th?"). A car that is out on loan right now may be back by then, and a car sitting on the lot today may already be promised to someone else next week.	A `RESERVED` status: cannot answer future-date questions, and a car can only hold one reservation.
Keep `VehicleStatus` too	Staff still need "where is the car right now" (on the lot, loaned, in service, lost).	Dropping status: loses the physical-location answer.
`Vehicle.tryBook` does check **and** book in one `synchronized` method (Java lets only one thread at a time run it on the same object)	Closes the check-then-act race (see below).	Separate `isFree()` then `book()` calls: two members can both see "free".
Template Method (a base class fixes the steps of an algorithm; subclasses fill in some steps) on `ReservationAddOn`	Billing is written once in the `final` (cannot be overridden) method `toBillItem`; subclasses only say what they are (`kind`) and may override the pricing hook (a step meant to be replaced) (`Service` is a flat fee). A fourth add-on is one new subclass.	A type enum with `switch` in the reservation: every new add-on edits the reservation.
Strategy (one interface, interchangeable implementations of a rule) for `PricingStrategy` and `LateFeePolicy`	Seasonal or length-based pricing changes one class, not the reservation.	Hard-coded rate constants.
Decorator (an object that wraps another of the same type and adds behaviour) `WeeklyDiscountPricing` wraps any `PricingStrategy`	Stacks a discount on top of whatever base rule is in place.	A subclass per combination (daily+weekly, seasonal+weekly …).
`Bill` is the only place charges live	Base, add-ons and late fees are lines on one bill; the total can never be computed in two places and disagree.	Each add-on keeping its own running total.
`ReservationService` separate from `Reservation`	Creating and indexing reservations is a different job from holding one reservation's rules (Single Responsibility: one class, one reason to change).	Static factory (a `static` method that builds objects) on `Reservation`.
Actors call the rules, they never compute them	The course's stage 6: a member calls the reservation service (search, reserve, cancel); a receptionist calls the reservation (hand over, take back, take payment, send reminders). An actor that starts working out fees is doing the reservation's job. In our code the actors are plain data (`Member`) and every rule sits in `Reservation` / `ReservationService`.	`Member.reserve()` / `Receptionist.computeLateFee()` methods.
`Bill` methods are `synchronized` and `settle` is idempotent (calling it twice has the same effect as once)	A late-fee line can never be added while the bill is being paid, and a double-clicked "pay" charges once.	Unsynchronized list + a second charge on retry.
The course makes `CarRentalSystem` a **Singleton** (a class allowed only one global instance); we pass it in instead	A singleton is easy to reach but hard to replace in tests. Constructing one and passing it (dependency injection: an object receives what it needs from outside instead of creating or looking it up itself) gives the same "one per app" without a global.	`static getInstance()`.

Java implementation

Package `lld.ch16.carrental`.

```java
// File: code/lld/ch16/carrental/Types.java
package lld.ch16.carrental;

import java.time.LocalDate;
import java.time.temporal.ChronoUnit;
import java.util.stream.Stream;

enum VehicleType { CAR, TRUCK, SUV, VAN, MOTORCYCLE }

/** Where the vehicle physically is RIGHT NOW. Future availability is answered by booked days, not by this. */
enum VehicleStatus { AVAILABLE, LOANED, BEING_SERVICED, LOST }

enum ReservationStatus { CONFIRMED, ACTIVE, COMPLETED, CANCELLED }

enum BillItemType { BASE_CHARGE, ADD_ON, LATE_FEE }

enum VehicleLogType { RESERVED, PICKED_UP, RETURNED, CANCELLED, FUELING, CLEANING, DAMAGE, REPAIR }

/** Half-open range [start, end): 10 Oct to 13 Oct is 3 rental days and the car is due back on 13 Oct. */
record DateRange(LocalDate start, LocalDate end) {
    DateRange {
        if (!end.isAfter(start)) throw new IllegalArgumentException("end must be after start");
    }
    long days() { return ChronoUnit.DAYS.between(start, end); }
    Stream<LocalDate> dates() { return start.datesUntil(end); }
    @Override public String toString() { return start + ".." + end; }
}

record Member(String id, String name, String email) {}

record Location(String code, String name) {}

Output:

```
1) Search SUVs at SFO for 2026-10-10..2026-10-13
   VH-001 Toyota RAV4 (SUV, 5 seats, plate 7ABC123) stall A-12
   VH-002 Honda CR-V (SUV, 5 seats, plate 7ABC124) stall A-13
2) Alice reserves VH-001 (pick up SFO, return Downtown) and adds extras
    [notify alice@example.com] Reservation R1001 confirmed: RAV4 2026-10-10..2026-10-13
3) 8 members race for VH-002 on the same dates
    [notify racer7@example.com] Reservation R1002 confirmed: CR-V 2026-10-11..2026-10-14
   successful reservations for VH-002: 1
   SUVs free for 2026-10-10..2026-10-13 now: 0
4) Daily reminder job on 2026-10-09
    [notify alice@example.com] Pick-up tomorrow for R1001 at SFO Airport
5) Pick up on 10 Oct, return at Downtown on 15 Oct (due 13 Oct)
   VH-001 status while out: LOANED
    [notify alice@example.com] OVERDUE: R1001 was due 2026-10-13
    [notify alice@example.com] Returned 2 day(s) late, late fee added to R1001
6) Alice's bill
   Base: RAV4 x 3 days                      BASE_CHARGE   240.00
   Insurance: Collision damage waiver       ADD_ON        45.00
   Equipment: Child seat                    ADD_ON        24.00
   Service: Roadside assistance             ADD_ON        25.00
   Late fee: 2 day(s)                       LATE_FEE      80.00
   TOTAL 414.00
    charged 414.00 to card token tok_alice_visa
   paid: true, settle again (double click) -> true, no second charge
7) Who rented VH-001? What has Alice rented?
   R1001 -> Alice 2026-10-10..2026-10-13 COMPLETED
   Alice: R1001 RAV4
8) Vehicle log for VH-001
   2026-10-01 RESERVED R1001 for 2026-10-10..2026-10-13
   2026-10-10 PICKED_UP R1001 by Alice at SFO
   2026-10-15 RETURNED R1001 at DTN, odometer 20640
   2026-10-15 CLEANING interior clean by worker W7
9) The VH-002 winner cancels; the days come back
    [notify racer7@example.com] Reservation R1002 cancelled
   SUVs free for 2026-10-10..2026-10-13: 2
10) A 7-day Civic rental gets the weekly discount
    [notify alice@example.com] Reservation R1003 confirmed: Civic 2026-11-01..2026-11-08
   base charge 315.00 (7 x 50 = 350, minus 10%)
11) Rules are enforced
   rejected: cannot add an add-on to reservation R1001 in state COMPLETED
   rejected: end must be after start
```

What to notice in the output: step 3 has eight threads racing for one car and exactly one wins (which racer wins varies per run); step 5 shows the overdue reminder and the 2-day late fee (2 × 40.00); step 6 shows that settling an already-paid bill does not charge again; step 9 shows cancellation giving the days back.

Concurrency & edge cases

> **Key term — lock:** A **lock** (also called a mutex) is a token only one thread can hold at a time; any other thread that wants it waits until it is released. In Java, a `synchronized` method uses the object itself as the lock. A *global lock* guards everything with one token (simple, but everyone queues), while a *per-object lock* (one per vehicle here) lets work on different objects run in parallel.

- **Double booking.** The course lists this as an open gap in its own design (checking the days and booking them are two separate steps there). Two members call `reserve` for the same car at the same moment. Because `tryBook` is `synchronized` on the vehicle, the check "are all days free?" and the write "mark them booked" happen as one step, so the second caller sees the first caller's days. Locking per vehicle (not one global lock) lets different cars be booked in parallel. In a database-backed system the same idea becomes a unique constraint on `(vehicle_id, day)` (the database refuses a second row with the same pair) or a `SELECT … FOR UPDATE` (a read that also locks the rows it returns) in one transaction (a group of database changes that succeed or fail together).
- **Search is advisory.** `search` may say a car is free and then `reserve` fails because someone else won. That is correct: the client (the app or web page the member is using) simply shows "no longer available". Never

reserve based on a stale (out-of-date) search result without re-checking.

- **Late return collides with the next rental.** If Alice returns two days late and Bob booked the car from the 14th, Bob's car is not on the lot. Real systems keep a buffer (for example a cleaning day) between bookings and, when a car is overdue, reassign the next reservation to another car of the same type.
- **Early return.** We release the whole booked range; the unused days become bookable. Whether the member is refunded is a policy question.
- **Cancelling after pick-up** is rejected by the state machine (`CONFIRMED` only).
- **Add-ons after the rental ends** are rejected (see step 11 of the output).
- **Invalid ranges** (end not after start) are rejected in the `DateRange` constructor.
- **Odometer going backwards** is rejected in `Vehicle.setMileage`.
- **Different return branch.** The reservation records the return branch, but the vehicle stays in the pick-up branch's inventory. The course calls this out as a known gap: moving a car between branches is a *transfer* the design does not model yet (see Extensions).

Extensions & follow-up questions

- **"How do you handle one-way rentals?"** — On return at a different branch, remove the vehicle from the old `VehicleInventory` and add it to the new one inside `returnVehicle`, and log a `TRANSFER` event. Add a one-way fee as another `BillItem`.
- **"Seasonal or dynamic pricing?"** — Add a `SeasonalPricing` strategy (rate per date) or wrap with another decorator (`SurgePricing`). The reservation does not change.
- **"Deposits and card holds?"** — A card *hold* reserves money on the card without taking it yet. A `PaymentMethod.authorize(amount)` at pick-up and `capture(amount)` at return; the difference is released.
- **"Mileage limits, fuel level, damage claims?"** — Record odometer and fuel at pick-up and return; add `BillItem`s of type `FINE` for extra miles, missing fuel or damage (the course's enum has a `FINE` bill item type for exactly this kind of charge).
- **"How do reminders run?"** — A scheduler (for example a `ScheduledExecutorService`, Java's built-in timer for repeating tasks, or a cron job, an operating-system entry that runs a command on a fixed timetable) calls `sendReminders(today)` once a day.
- **"How would you scale this?"** — Partition vehicles by branch (split the data so each branch's vehicles live on their own database or server); the booked-days table becomes `(vehicle_id, day)` with a unique key; searches go to a read replica (a read-only copy of the database kept in sync with the main one) or a search index (a separate store built for fast lookups, such as Elasticsearch); reservations are written with a transaction. These scaling ideas are explained in System Design Fundamentals.
- **"How do workers update the log?"** — `Vehicle.addLog(date, CLEANING, note)` as in step 5; restrict who can call it by role in the service layer (the classes, like `ReservationService`, that sit between callers and the domain objects and enforce who may do what).

In the interview

30-second pitch: "Branches own inventories, inventories index vehicles by barcode, type and model. The key decision: availability is a question about *dates*, so each vehicle keeps its booked days, and `tryBook` checks and books them atomically. A reservation owns a bill; every charge — base, insurance, equipment, services, late fee — is a line on it. Add-ons share a template-method base class; pricing and late fees are strategies."

Suggested 40-minute plan:

Minutes	Do
0–5	Clarify vehicle types, branches, one-way, add-ons, late fees.
5–10	Actors and use cases; list the entities.
10–20	Class diagram. Say "availability is dates, not status" early.
20–35	Code `Vehicle.tryBook`, `Reservation` (state machine + bill + late fee), `ReservationService.reserve`.
35–40	Concurrency, late-return collision, one-way transfers.

Likely follow-ups: "Can I book it for next month while it is loaned now?" (yes — dates, not status). "Two people click reserve together?" (atomic `tryBook`). "Add a new add-on?" (one subclass).

Self-check

1. **Q:** Why is a `RESERVED` status not enough to answer "is this car free next week?" **A:** Status describes *now*. A car can be loaned today and free next week, or on the lot today but promised next week. Only per-day bookings answer date questions.
2. **Q:** What pattern does `ReservationAddOn.toBillItem` use and what is the "hook"? **A:** Template Method; `toBillItem` is the fixed algorithm and `priceFor` is the overridable hook (`Service` overrides it to a flat fee).
3. **Q:** Why is `tryBook` one method rather than `isFree` + `book`? **A:** To make check-then-act atomic under the vehicle's lock, so two threads cannot both see "free".
4. **Q:** How is the late fee computed? **A:** Days between the due date (`period.end`) and the actual return date, times the per-day fee from `LateFeePolicy`, added as a `LATE_FEE` bill line.
5. **Q:** Which class answers "who rented VH-001"? **A:** `ReservationService.byVehicle`, from the one list of reservations.

TL;DR

- Availability = booked **days** per vehicle; status = where it is now.
- `tryBook` makes check-and-book atomic per vehicle.
- A reservation owns one bill; every charge is a line. Late fee = days late × rate.
- Template Method for add-ons, Strategy (+ Decorator) for pricing.
- Known gaps to mention: branch transfers, buffer between rentals.

Real-world example. Rental companies such as Hertz and Enterprise let you book a *car class* ("intermediate SUV or similar") rather than a specific plate; the exact vehicle is assigned at the counter. That is the same design one level up: availability is counted per type per day, and a specific `Vehicle` is bound at pick-up. Their counters and return lanes scan the car and compute extra-day and fuel charges on the spot — the "return" activity above.

Design a Restaurant Management System

Figure — A restaurant with branches, tables, waiters and a kitchen (course diagram)

Problem & clarifying questions

A **restaurant management system** runs the day-to-day of a restaurant from one place: which tables are free, table reservations, taking orders, sending them to the kitchen, and producing and settling the bill.

Question	Assumed answer
One restaurant or a chain?	A restaurant with several branches; each branch has its own menu, tables and staff.
Menu structure?	Menu → sections (Starters, Mains …) → items with prices.
How are orders taken?	A waiter creates an order for a table and adds meals **per seat**; each meal has meal items, each pointing at a menu item.
Reservations?	Receptionist searches tables by date/time and party size and reserves one; customers can cancel; the system reminds them before the time.
Walk-ins?	Yes: show tables free right now.
Seating layouts?	A branch can have several seating arrangements (for example "Weekday" and "Banquet").
Payment?	Credit card, cheque or cash.
Kitchen?	Orders go to a chef queue; chefs cook them in order and the waiter is told when food is ready.

Requirements

Functional

1. The restaurant has several branches.
2. Each branch has a menu.
3. A menu has sections; sections have menu items.
4. A waiter creates an order for a table and adds meals for each seat.
5. Each meal has meal items; each meal item corresponds to a menu item.
6. Show which tables are free now for walk-in customers.
7. Support table reservations.
8. The receptionist searches free tables by date and time and reserves one.
9. Customers can cancel a reservation.
10. Send a notification when the reservation time is approaching.
11. Customers pay by credit card, cheque or cash.
12. A branch can have several seating arrangements of tables.
13. (Added) Orders go to a kitchen queue; chefs take them one at a time and the waiter is notified when an order is ready.

Non-functional

- No two parties may be given the same table for overlapping time.
- Prices live in one place (the menu item) so an order and the menu can never disagree.
- Easy to add a new payment type or a new chef-assignment rule.

Use cases

Actors:

- **Receptionist** — adds and edits tables and layouts; creates and cancels reservations; checks guests in.
- **Waiter** — takes and changes orders.
- **Manager** — hires staff and edits the menu.
- **Chef** — views and cooks orders.
- **Cashier** — produces the check (bill) and takes payment.
- **System** — sends reservation reminders and cancellations.

Top use cases: add/modify tables; search tables; place order; update order; create reservation; cancel reservation; check in; make payment.

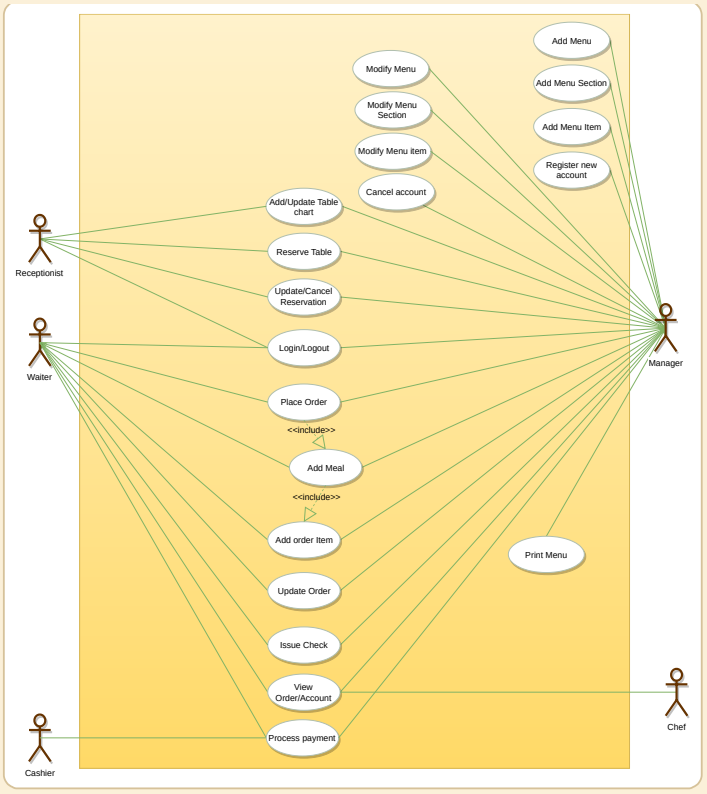

Figure — Use case diagram: receptionist, waiter, manager, chef, cashier and system (course diagram)

In the figure above, each role has a small, separate set of use cases. That is a hint for the code: each role class gets only its own methods.

Core entities

Class	Responsibility
`Restaurant`	Owns its branches. In the course the restaurant also registers its employees: closing (deactivating) the restaurant deactivates every employee account with it.
`Branch`	Owns its menu, kitchen, seating charts and reservation service; employs staff.
`Menu`, `MenuSection`, `MenuItem`	The menu tree. The **price lives only on** `MenuItem`.
`Table`, `TableSeat`	A table with a capacity and numbered seats. Keeps both its **current status** and the **time slots it is promised to**.
`TableChart`	A named seating arrangement; refers to tables (a table can appear in several charts).
`Reservation`	Customer, party size, time, table, status. `updatePeopleCount` refuses a party bigger than the reserved table seats (otherwise the booking would say six while the table holds four).
`ReservationService`	Searches tables (best fit), reserves atomically, cancels, checks in, sends reminders, lists walk-in tables.
`Order`	One per table visit: meals keyed by seat, status with allowed transitions, listeners.
`Meal`, `MealItem`	One meal per seat; a meal item = menu item × quantity.
`Kitchen`, `Chef`	Kitchen hands each order to a chef by a pluggable rule; each chef cooks from a FIFO (first in, first out) queue.
`Employee` and roles (`Receptionist`, `Waiter`, `Manager`, `Chef`, `Cashier`)	Each role's own operations.
`Check`	The bill: computed from the order (subtotal, tax, total), never stored separately.
`Payment` (`CardPayment`, `CashPayment`, `CheckPayment`)	Three ways to pay with three different behaviours.

Class diagram

The course grows the model in seven stages: payments and notifications, the menu, tables, reservations, orders, staff, and finally the branch that ties it together.

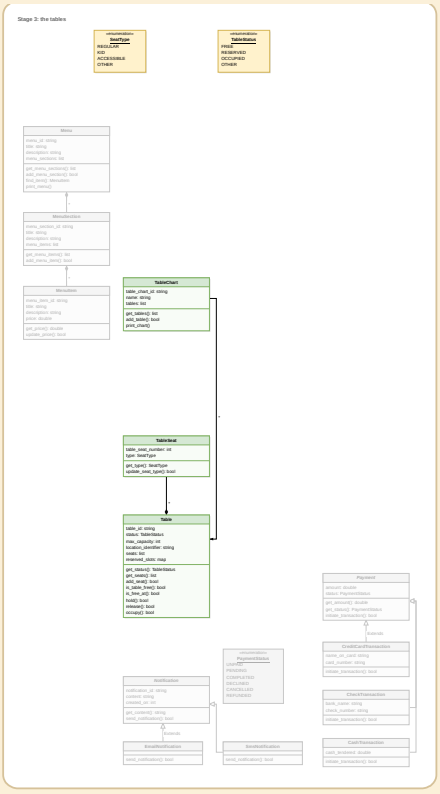

Figure — Table, TableSeat and TableChart: a table owns its seats; a chart only refers to tables (course diagram)

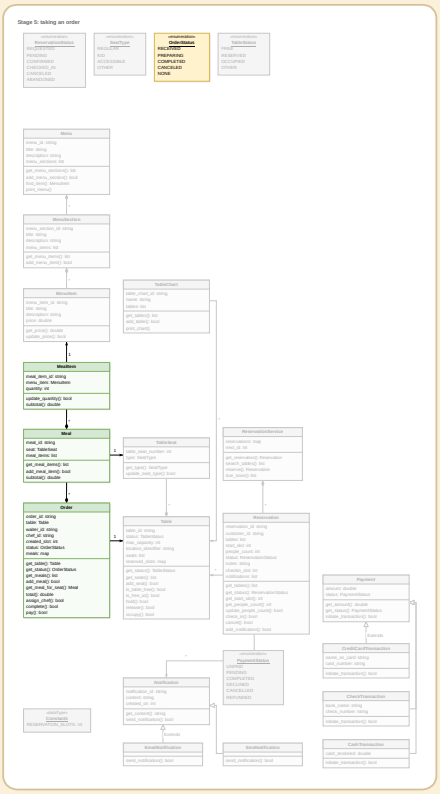

Figure — Order, Meal and MealItem: one order per table, one meal per seat (course diagram)

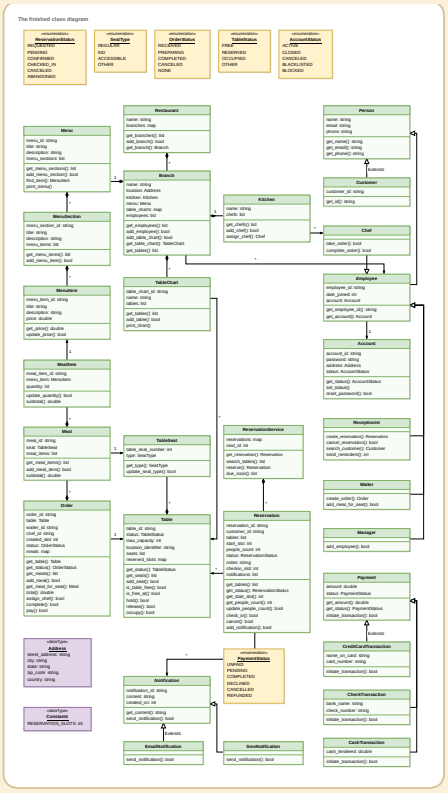

Figure — The finished class diagram of the restaurant management system (course diagram)

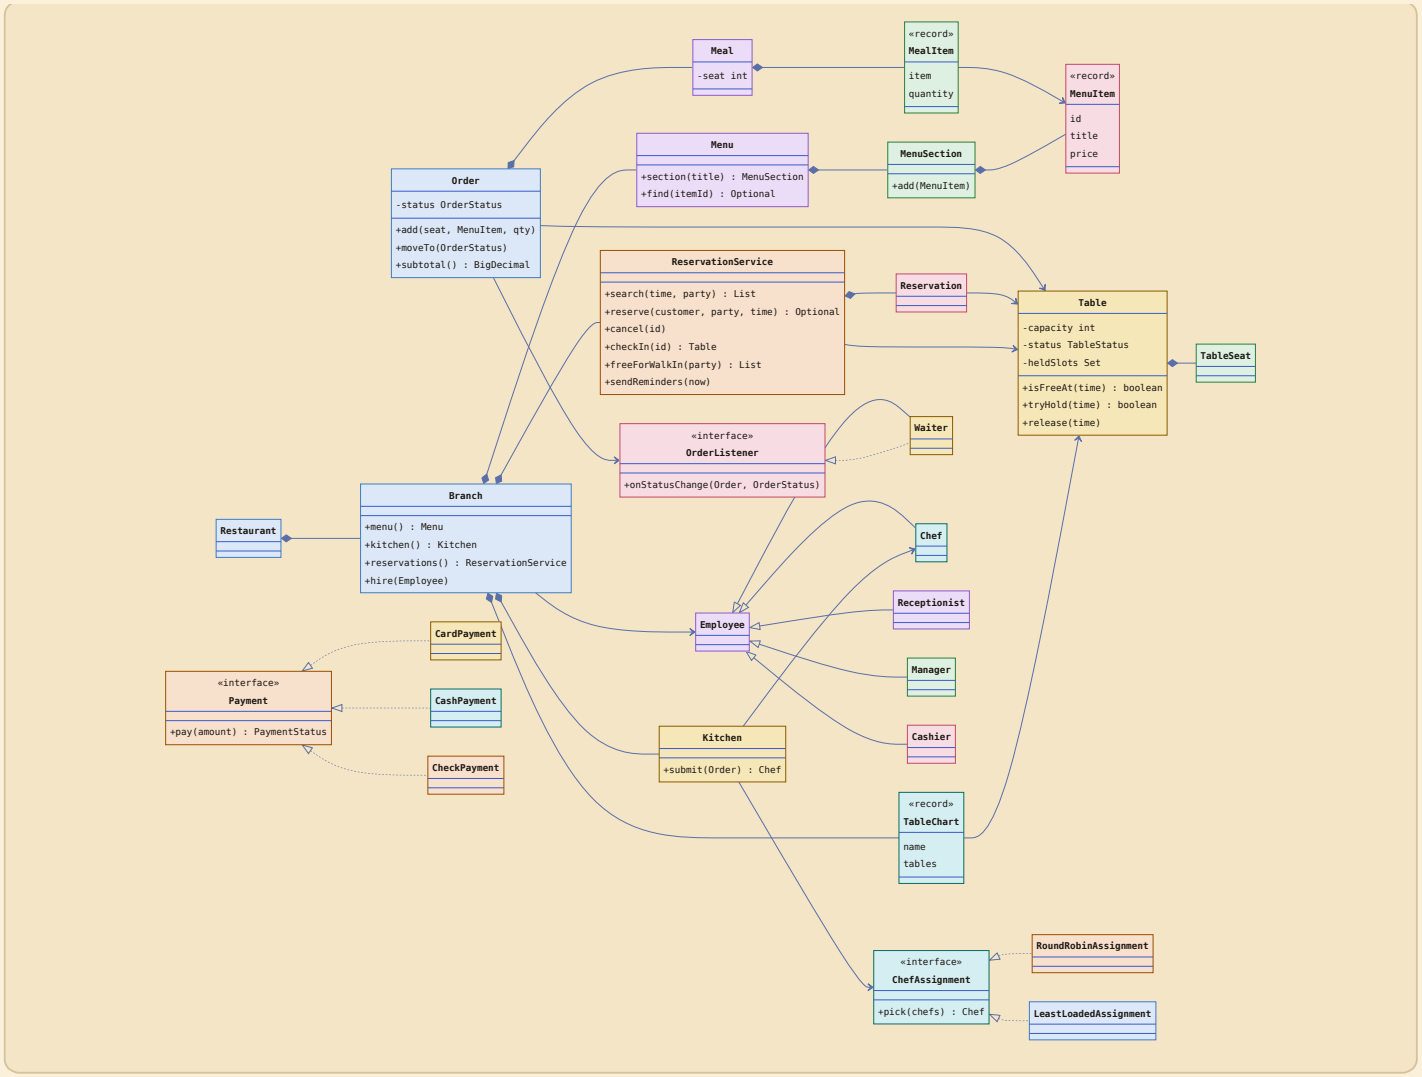
In the finished figure above, the branch is the hub: its menu, kitchen and seating charts are composition (they do not exist without the branch), while staff are only associated, because staff can move between branches. Note also what is *not* there: no separate `Bill` class that stores a total. The course's argument is that the order already holds every priced line, so storing the total again would create a second copy that could disagree. Our `Check` follows that rule — it is computed from the order on demand.



Key flows

Place an order. The waiter opens an order for the table, then for each seat adds a meal with its items, and sends the order to the kitchen.

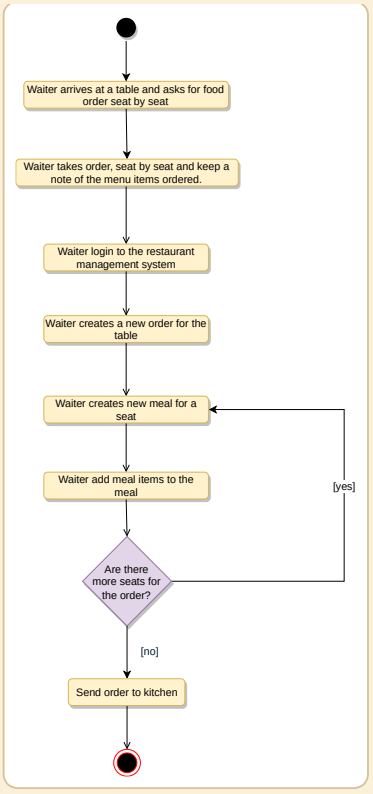


Figure — Activity diagram: placing an order seat by seat and sending it to the kitchen (course diagram)

Make a reservation. The customer calls or arrives; the receptionist searches tables for the time and party size; if one is free it is reserved and a confirmation is sent, otherwise the customer is told none is available.

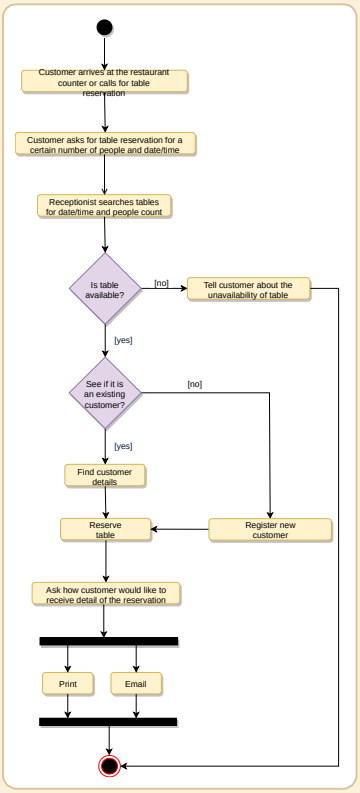

Figure — Activity diagram: making a table reservation (course diagram)

Cancel a reservation. The receptionist looks up the booking; if it is valid, it is cancelled, the table is released and the customer is notified.

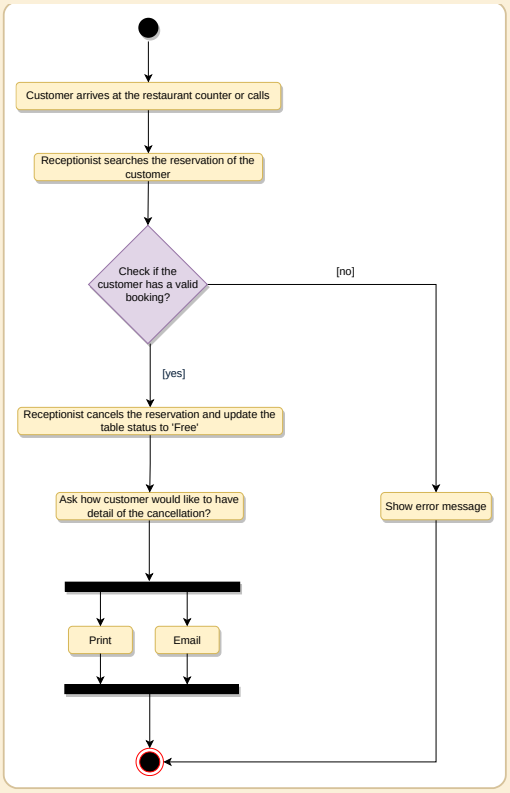

Figure — Activity diagram: cancelling a reservation (course diagram)

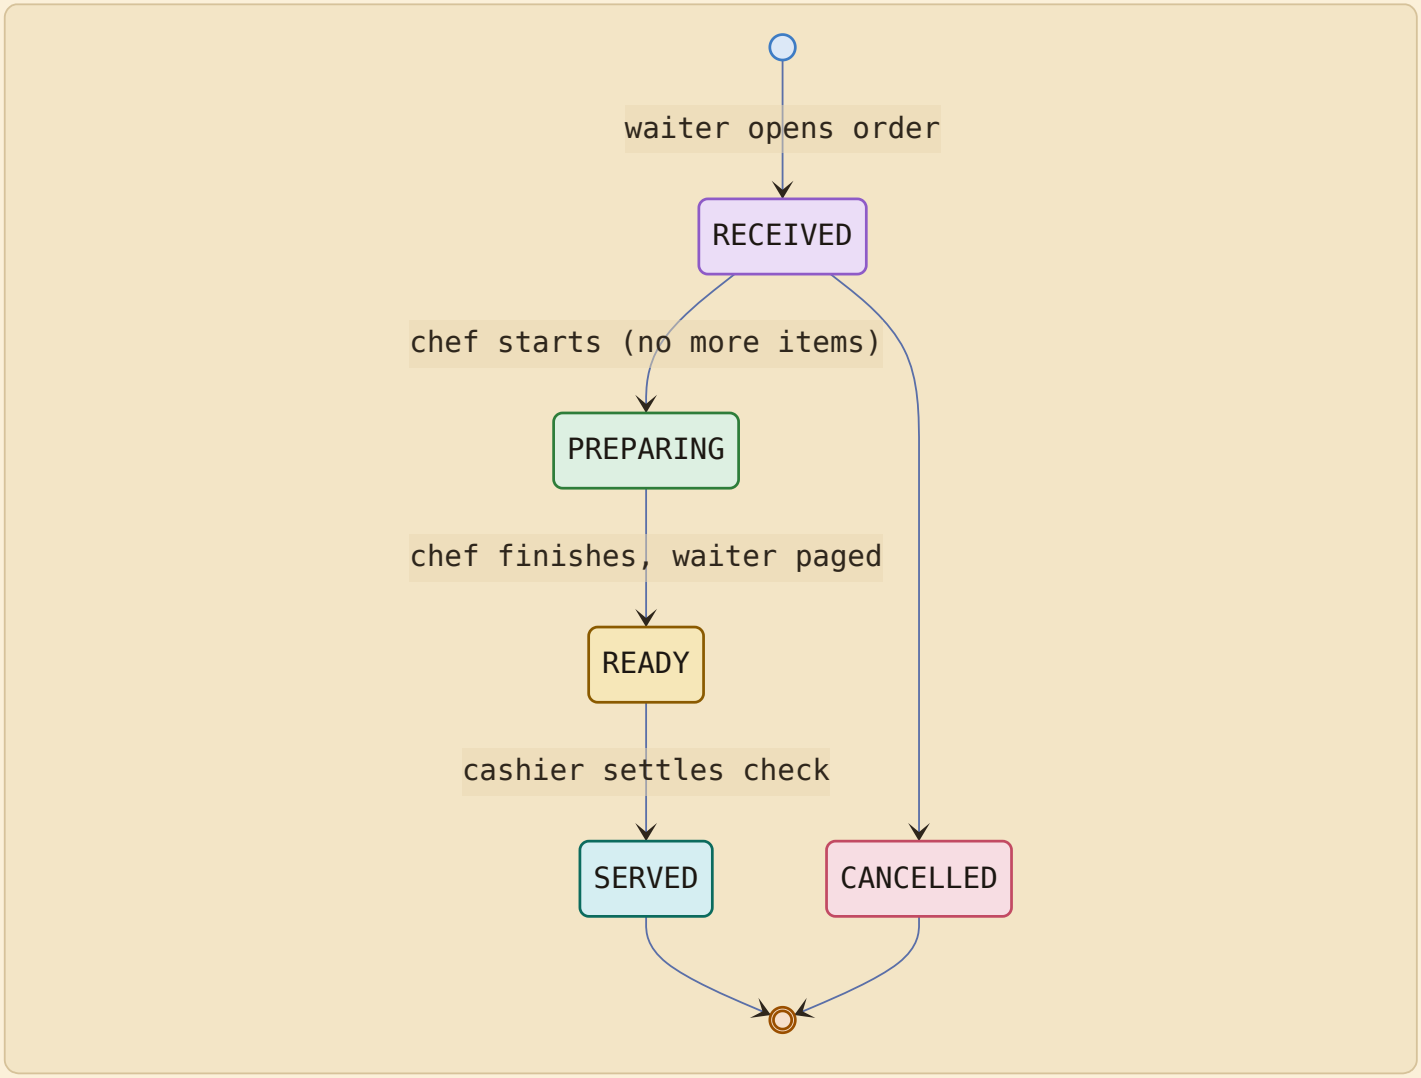
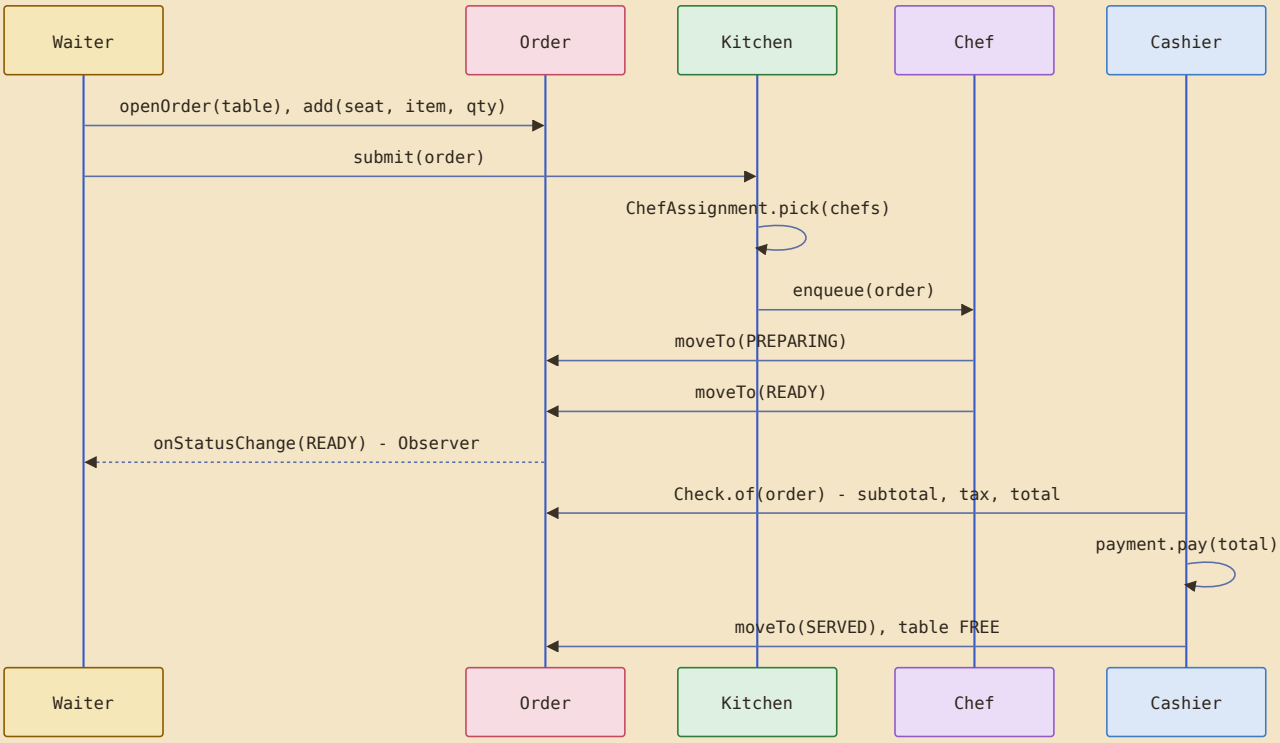
Order lifecycle — the transitions `Order.moveTo` allows:



From order to payment:



Waiter
Order
Kitchen
Chef
Cashier
openOrder(table), add(seat, item, qty)
submit(order)
ChefAssignment.pick(chefs)
enqueue(order)
moveTo(PREPARING)
moveTo(READY)
onStatusChange(READY) - Observer
Check.of(order) - subtotal, tax, total
payment.pay(total)
moveTo(SERVED), table FREE
Waiter
Order
Kitchen
Chef
Cashier

Design decisions & patterns used

Decision	Why	Alternative rejected
One meal per seat (`Map<seat, Meal>`)	Requirement 4 asks for it; it tells the kitchen which plate goes to which guest and makes split bills trivial.	A flat list of dishes per order.
Table keeps held time slots as well as status	Status answers "now" (walk-ins); slots answer "is it free at 19:00 on Friday" (reservations). A booking holds two hourly slots.	Status only: cannot take future bookings.
Search lives on `ReservationService`, not on `Table`	One table only knows about itself; "which tables are free at seven" needs all of them. The course notes an older version had a static search on `Table` that could not work.	Static `Table.search`.
Best fit when choosing a table	Smallest table that seats the party keeps large tables free for large parties.	First free table.
Observer (`OrderListener`; listeners register with a subject and are told when it changes)	The kitchen does not need to know who cares about "ready" — the waiter, a display screen, a delivery app can all subscribe.	Chef calling the waiter directly (tight coupling: classes that know too much about each other to change separately).
Strategy (`ChefAssignment`)	The course's kitchen rotates chefs; that is fair but not load-aware (it ignores how busy each chef already is). Swapping to `LeastLoadedAssignment` is one class, not a rewrite — the course's own point about keeping the rule in one place.	Round-robin (taking turns in a fixed rotation) hard-coded in `Kitchen`.
State machine in `Order.moveTo`	Illegal moves (adding food after cooking starts, serving before ready) fail loudly.	Free `setStatus`.
Three `Payment` classes behind a `sealed` interface (only the listed classes may implement it)	Card completes at once, cash may be short (declined) and returns change, a cheque must clear (pending). Different behaviour → different classes (Strategy).	One `Payment` class with a `type` field and `if`s.
Check computed, not stored	Prices live on menu items; the check is derived, so it cannot disagree with the order.	A stored `Bill` total.
Role classes extend `Employee`; `Customer` is not an employee	Only staff have employee ids and accounts; this keeps an account off the customer.	One `Person` class with a role flag.

Java implementation

Package `lld.ch16.restaurant`.

```java
// File: code/lld/ch16/restaurant/Types.java
package lld.ch16.restaurant;

import java.math.BigDecimal;

enum TableStatus { FREE, RESERVED, OCCUPIED }
enum SeatType { REGULAR, KID, ACCESSIBLE }
enum ReservationStatus { CONFIRMED, CHECKED_IN, CANCELLED, NO_SHOW }
enum OrderStatus { RECEIVED, PREPARING, READY, SERVED, CANCELLED }
enum PaymentStatus { COMPLETED, PENDING, DECLINED }

record MenuItem(String id, String title, BigDecimal price) {}
record Customer(String name, String phone) {}
record TableSeat(int number, SeatType type) {}
```

        System.out.println("   table statuses: " + tables.stream().map(t -> t.id() + "=" + t.status()).toList());
    }
}
```

Output:

```
1) Manager builds the menu
   Starters: [Tomato soup, Garlic bread]
   Mains: [Margherita pizza, Pasta arrabbiata]
   Drinks: [Lemonade]
   charts: [Default, Banquet]
2) Ravi searches tables for 4 at 19:00: [T2, T3, T4]
    [sms 555-0101] Table T2 booked for 4 at 2026-10-09T19:00
    [sms 555-0102] Table T3 booked for 4 at 2026-10-09T20:00
   Asha -> T2, Ben -> T3 (T2 is held 19:00-21:00)
   party of 8 at 19:00: no single table fits
   Asha's party grows to 6: rejected, table T2 seats 4, not 6
    [sms 555-0102] Reservation RES-2 cancelled
   after Ben cancels, free for 4 at 20:00: [T3, T4]
3) Reminder job at 18:15
    [sms 555-0101] Reminder: your table T2 at 19:00
4) Asha checks in; a couple walks in
   Asha seated at T2, walk-in couple seated at T1
5) Wendy takes two orders, one meal per seat
   O1 -> chef Chen, O2 -> chef Maria
6) Kitchen works the queues
   rejected: order O1 is already PREPARING
    [Wendy's pager] order O1 for table T2 is READY
    [Wendy's pager] order O2 for table T1 is READY
7) Check for O1 (split by seat)
   seat 1: [1x Tomato soup, 1x Margherita pizza] = 18.50
   seat 2: [1x Pasta arrabbiata, 2x Lemonade] = 20.50
   seat 3: [1x Garlic bread] = 4.00
   subtotal 43.00, tax 3.44, total 46.44
    change due: 13.56
   paid cash: COMPLETED
   O2 total 25.92 paid by check: PENDING
   table statuses: [T1=FREE, T2=FREE, T3=FREE, T4=FREE]
```

Step 2 shows best fit and slot holding (Ben cannot get T2 at 20:00 because Asha's 19:00 booking holds 19:00 and 20:00). Step 6 shows the state machine rejecting a late addition and the Observer paging the waiter. Step 7 shows the per-seat split and the three payment behaviours.

Concurrency & edge cases

- **Two receptionists book the same table.** `search` is only advisory; `reserve` calls `Table.tryHold`, which is `synchronized` and checks-and-holds both slots in one step. If it fails (someone else won) the loop tries the next table in best-fit order.
- **Notifying outside the lock.** `Order.moveTo` changes state inside `synchronized` but calls listeners *after* leaving it. Calling unknown code while holding a lock is a classic way to cause deadlocks or long waits. A **deadlock** is when two threads each hold a lock the other needs, so both wait forever.
- **Reminder spam.** The reminder job may run every few minutes; `markReminded` makes it send once per reservation.
- **Party larger than any table.** Returns "no single table fits". Combining tables is out of scope (see Extensions). The course notes the design already allows it, since a reservation can hold a list of tables.
- **No-shows.** `NO_SHOW` exists as a status; a job can release tables for bookings not checked in 15 minutes after start.
- **Party grows after booking.** `updatePeopleCount(6)` on a four-seat table is rejected (step 2 of the output); the receptionist must re-book.
- **Paying for food that is not ready.** `Cashier.settle` checks the order is `READY` *before* calling the payment, so a refused state change can never happen after the guest's money has been taken.
- **Unknown reservation id** on cancel or check-in fails with a clear `IllegalArgumentException` (Java's standard "you passed a bad value" error), not a `NullPointerException` (the confusing crash you get when code uses a missing object).
- **Seat number out of range** on an order is rejected.
- **Cash short** → `DECLINED`, the order stays `READY` and the table stays occupied.
- **Cheque** → `PENDING`: the meal is served, but the money is not yet confirmed.

Extensions & follow-up questions

- **"Large party needs two tables?"** — Let a reservation hold `List<Table>`; search for combinations of adjacent tables (tag tables with a zone); hold all of them atomically by locking tables in a fixed order (for example by id) to avoid deadlock.
- **"Split the bill?"** — Already easy: `Meal.subtotal()` per seat; create one `Check` per seat group.
- **"Tips and service charge?"** — Add lines to `Check` (percentage or amount chosen at payment).
- **"Waiting list for walk-ins?"** — A FIFO queue per party size; when a table frees, notify the head.
- **"Kitchen stock?"** — An `Inventory` of ingredients; each `MenuItem` has a recipe; placing an order reserves ingredients and marks items "86'd" (unavailable) when stock runs out.
- **"Real concurrency in the kitchen?"** — Each chef becomes a worker thread (a thread that loops, picking up jobs) taking from a `BlockingQueue<Order>` (a thread-safe queue whose `take()` waits when it is empty); `take()` blocks until an order arrives.
- **"Shift schedules?"** — A `Shift` entity (employee, branch, start, end); `Kitchen` only picks chefs on shift.

In the interview

30-second pitch: "Branch owns a menu tree, a kitchen, seating charts and a reservation service. Tables keep both current status for walk-ins and held time slots for bookings; the service searches best-fit and holds slots atomically. Orders have one meal per seat, move through a strict state machine, and notify the waiter through an observer. The kitchen assigns chefs by a strategy. The check is computed from the order, and payment is a strategy with card, cash and cheque."

Minutes	Do
0–5	Clarify branches, seating layouts, per-seat meals, payment types.
5–10	Actors (six) and use cases.
10–20	Class diagram — say "meal per seat" and "status vs time slots" out loud.
20–35	Code `Table.tryHold`, `ReservationService.reserve`, `Order` state machine, `Kitchen.submit`.
35–40	Races, large parties, kitchen load balancing.

Self-check

1. **Q:** Why does a table need both a status and held slots? **A:** Status answers "what is it doing now" (walk-ins); slots answer "is it free at a future time" (reservations).
2. **Q:** Why is search on the service, not the table? **A:** A single table only knows about itself; finding all free tables needs the collection.
3. **Q:** Which pattern tells the waiter the food is ready, and why notify outside the lock? **A:** Observer; calling foreign code while locked risks deadlock and slows other threads.
4. **Q:** Why is there no stored bill total? **A:** The order's lines already hold every price; a second stored total could disagree.
5. **Q:** Why is a cheque payment `PENDING`? **A:** A cheque has to clear at the bank, so it is not money yet.

TL;DR

- Menu → section → item; price only on the item.
- Table = status (now) + held slots (later); service searches best-fit and holds atomically.
- Order → meal per seat → meal item; strict state machine; Observer for "ready".
- Kitchen assigns chefs by Strategy (round-robin or least-loaded).
- Check is computed; card/cash/cheque are three payment strategies.

Real-world example. Restaurant point-of-sale (POS — the till software where orders are entered and paid) systems such as Toast send each order to a kitchen display screen as a "ticket", show it by station and in order, and let the front of house see when it is done — the Observer and FIFO queue above. Reservation platforms such as OpenTable model table inventory by time slot and party size, exactly like `Table.heldSlots`.

Design an Airline Management System

Figure — An airline flies passengers between airports with owned or leased aircraft (course diagram)

Problem & clarifying questions

An **airline management system** runs an airline's operations: scheduling flights, reserving tickets, cancelling flights, supporting customers and managing staff, plus daily flight updates.

Question	Assumed answer
What does a customer search by?	Date, source airport and destination airport.
One flight or a trip of several?	A customer can build an **itinerary** (the full planned trip) of several flights.
Several passengers per booking?	Yes — a reservation seats several passengers (who need not have accounts).
Seat classes?	Economy, economy plus, preferred economy, business, first; seat types regular, accessible, emergency exit, extra legroom.
Who manages flights?	Only the admin adds aircraft, flights and schedules, and cancels flights; everyone affected is notified.
Crew?	Pilots and crew are assigned to flights and can view their schedule.
Payment?	Paid per itinerary.
Notifications?	When a reservation is made or changed and when a flight's status changes.

Requirements

Functional

1. Search flights by date and by source and destination airport.
2. Reserve a ticket on any scheduled flight; build an itinerary of several flights.
3. View flight schedules: departure, arrival, available seats and other details.
4. Reserve seats for several passengers under one itinerary.
5. Only the admin adds aircraft, flights and schedules; the admin can cancel a scheduled flight and everyone affected is notified.
6. Customers can cancel a reservation or a whole itinerary.
7. Assign pilots and crew to flights.
8. Take payment for reservations.
9. Send the customer a message whenever a booking is created or modified, and whenever the status of one of their flights changes.

Non-functional

- A seat on a flight instance is sold at most once, even under heavy concurrent booking.
- Several passengers in one booking get all their seats or none (**atomic**).
- Fare rules (class multiplier, last-minute surcharge) change without touching booking code.

Use cases

Five actors:

- **Admin** — adds flights and schedules, cancels flights, manages staff and crew.
- **Front desk officer** — reserves and cancels tickets for walk-in customers.
- **Customer** — views schedules, reserves and cancels.
- **Pilot / Crew** — views assigned flights.
- **System** — sends itinerary and flight-status notifications.

Top use cases: search flights; create/modify/view reservation; assign seats to passengers; pay for a reservation; update the flight schedule; assign pilots and crew.

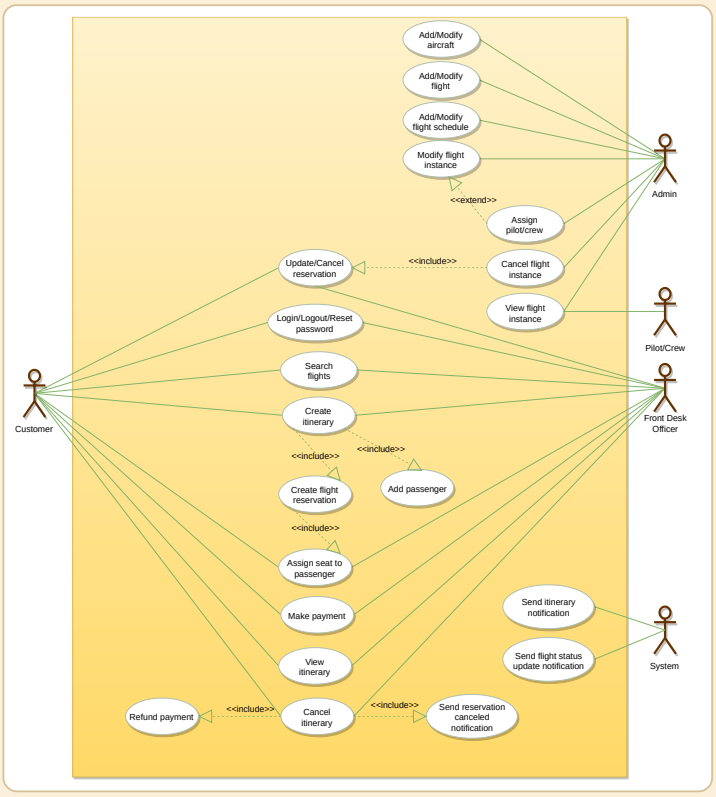

Figure — Use case diagram: admin, front desk officer, customer, crew and system (course diagram)

In the figure above, the front desk officer and the customer share the booking use cases: when an officer books for someone at the counter, it is the very same operation, just triggered by another actor.

Core entities

The one distinction that makes this design work is **four different "seat-ish" and "flight-ish" ideas**:

Idea	Class	Example
The route	`Flight`	GA212 London → Tokyo, 14 h, base fare 500
The route on one date	`FlightInstance`	GA212 on 8 Oct 2026 at 10:00
The physical seat on the aircraft	`Seat`	12A, extra legroom, economy plus
That seat on that one instance	`FlightSeat`	12A on GA212 8 Oct — booked by PNR147 (PNR = booking reference)

Class	Responsibility
`Airport`	Code and city.
`Aircraft`	Registration, model and its physical seats.
`Seat`	Number, type, class — nothing about bookings.
`Flight`	Route, duration, aircraft, base fare, weekly schedules; generates instances.
`WeeklySchedule`	"Every Tuesday at 10:00".
`FlightInstance`	Departure time, status, its `FlightSeat`s and assigned crew; holds seats atomically.
`FlightSeat`	One seat on one instance and which reservation holds it.
`Passenger`	A name on a ticket — deliberately **not** an account holder.
`Customer`	The account holder who books and pays.
`Admin`, `FrontDeskOfficer`	Staff actors. Admin-only methods on `Airline` require an `Admin` argument; the front desk books through `bookFor`.
`CrewMember`	Pilot, co-pilot or cabin crew.
`FlightReservation`	One leg: one instance, map passenger → seat, amount, status.
`Itinerary`	A trip of legs; owns the connection rule; the unit that is paid.
`FareStrategy`	Pluggable pricing: class multiplier, decorated with a last-minute surcharge.
`Airline`	Facade (one simple front object that hides many classes behind it) for admin and customer operations; keeps the index instance → reservations.

Class diagram

The course builds six stages: money and messages, people, what the airline owns, flights and the seats on one flight, reservations and itineraries, and the actors.

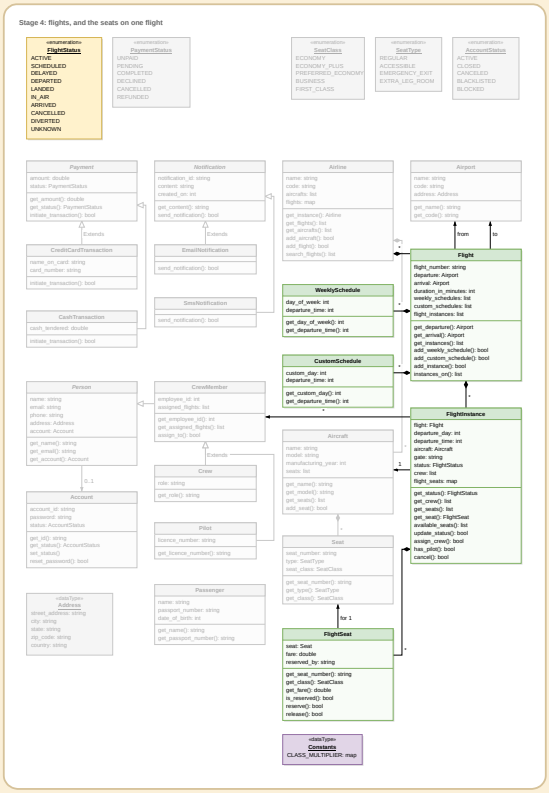

Figure — Flight, FlightInstance and FlightSeat: the route, the route on a day, and a seat on that day (course diagram)

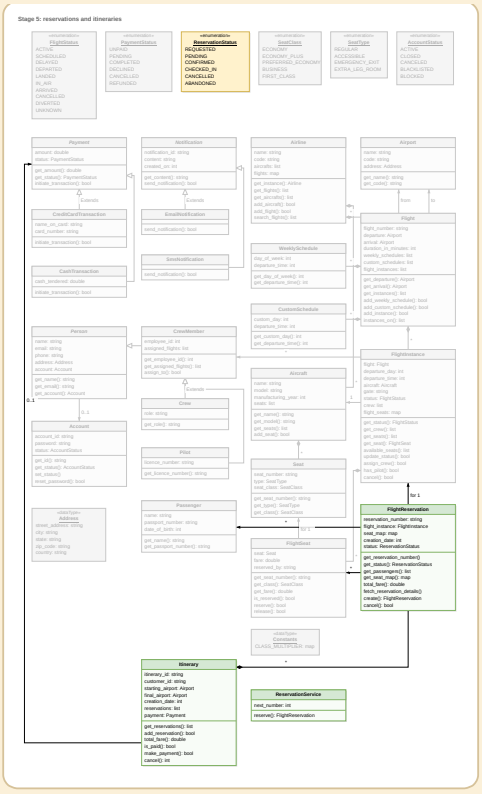

Figure — FlightReservation maps passengers to flight seats; an Itinerary owns its reservations (course diagram)

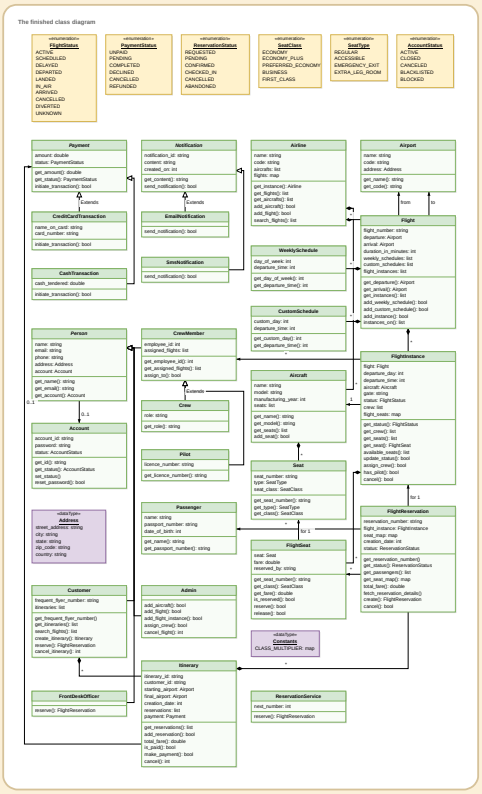

Figure — The finished class diagram of the airline management system (course diagram)

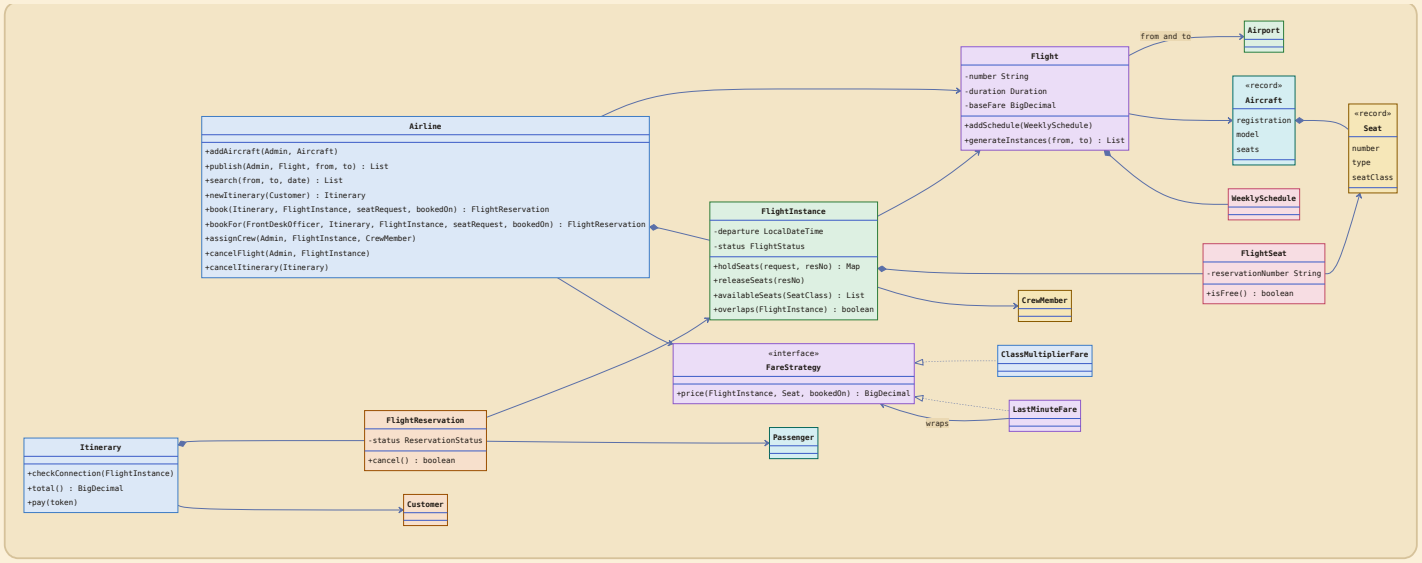
In the first figure above, all the ownership (filled-diamond) arrows run in one direction: schedules and instances belong to their flight, and flight seats belong to their instance. Airports, the aircraft and the crew are only referred to — cancelling a flight does not destroy an airport. Notice also in the finished diagram that `Passenger` sits outside the `Person`/account tree: the course's reason is that a passenger may never log in, and a customer can book for other people.



Key flows

Reserve a ticket. The customer (or front desk officer) searches; if a flight is available they choose seats and passengers, pay, and receive a confirmation; otherwise they search again.

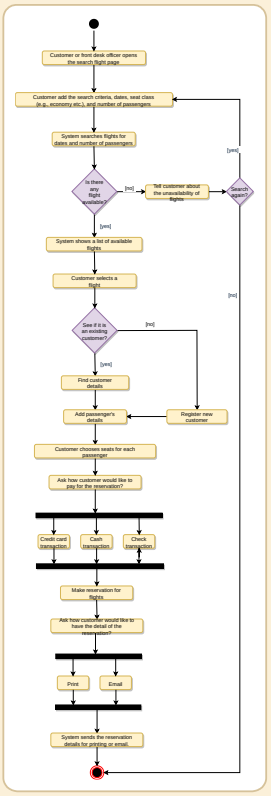


Figure — Activity diagram: reserving a ticket (course diagram)

Cancel a reservation. The system checks that the customer has a valid reservation; if so it cancels it, releases the seats and notifies the customer; if not, it reports the error.

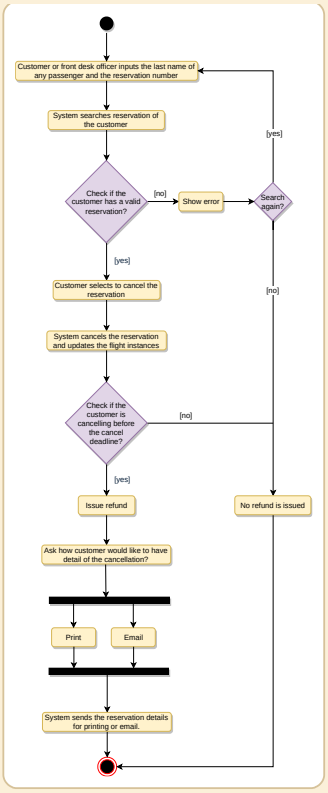

Figure — Activity diagram: cancelling a reservation (course diagram)

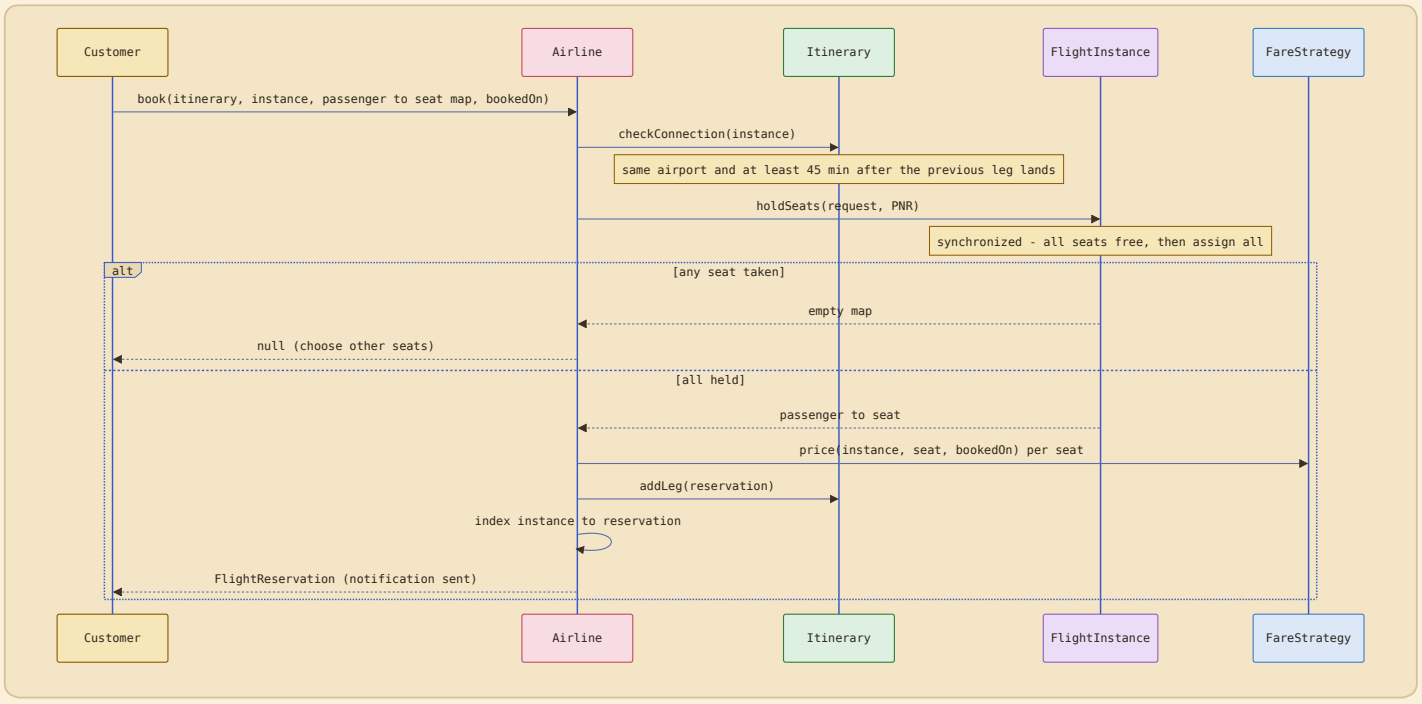
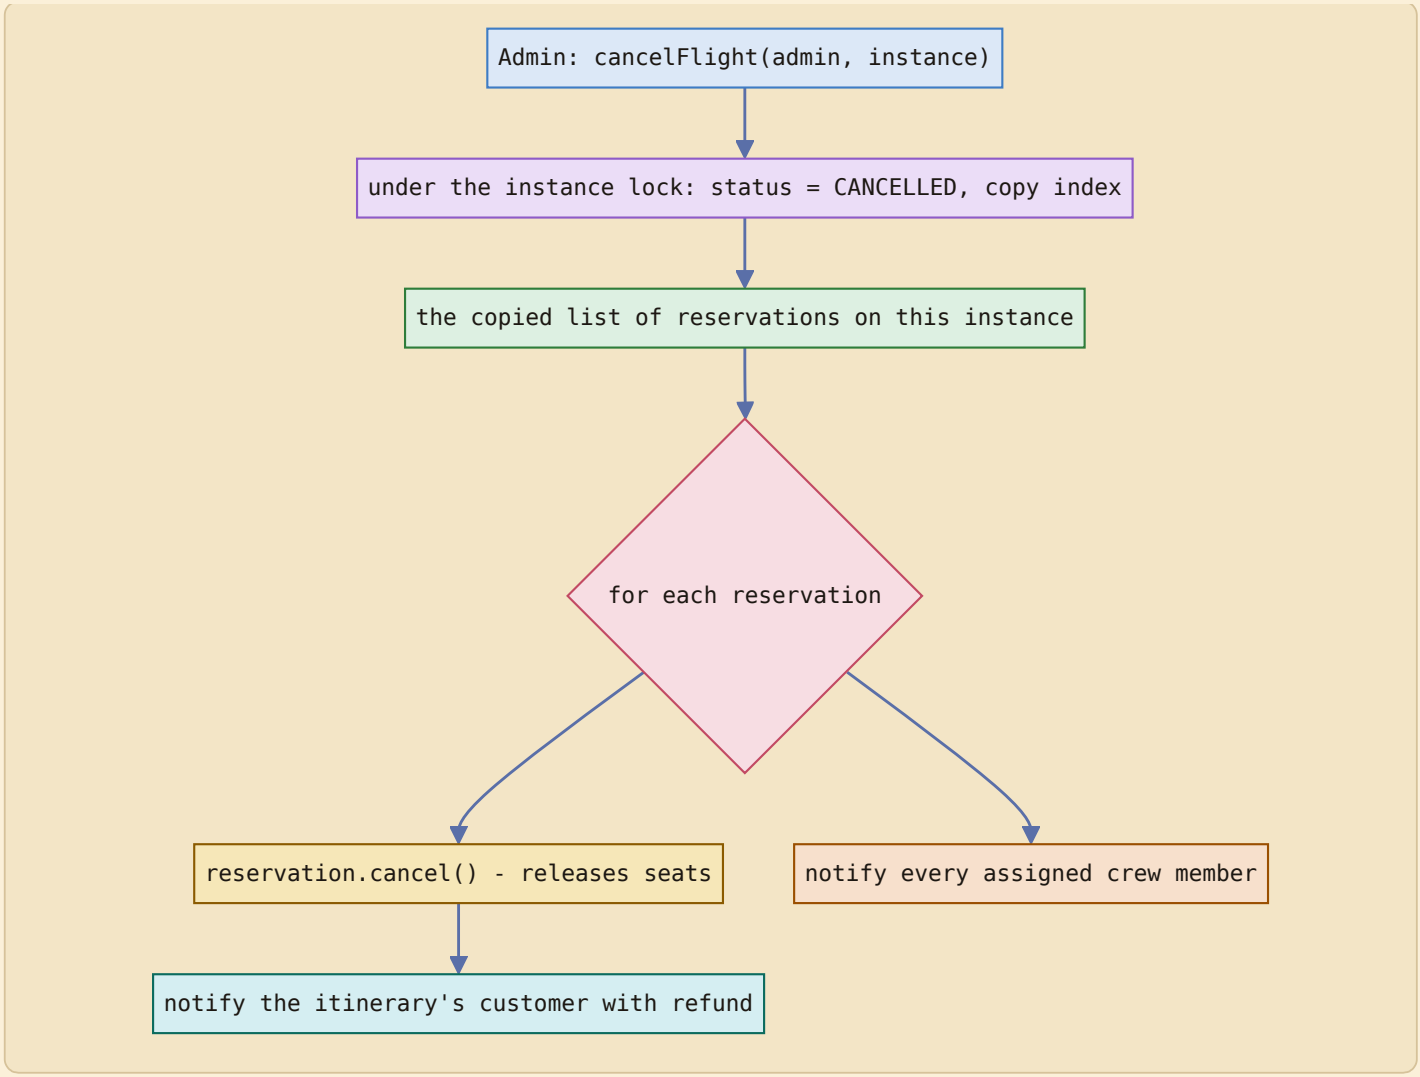
Booking one leg of an itinerary:



Admin cancels a flight instance:



Admin: cancelFlight(admin, instance)
under the instance lock: status = CANCELLED, copy index
the copied list of reservations on this instance
for each reservation
reservation.cancel() - releases seats
notify every assigned crew member
notify the itinerary's customer with refund

Design decisions & patterns used

Decision	Why	Alternative rejected
Flight vs FlightInstance vs Seat vs FlightSeat	12A is free on Tuesday and taken on Thursday, so "booked" and the fare belong to the seat *on an instance*. The course says an older version of its code had drifted from its diagram here — the code is what runs.	A `booked` flag on `Seat`: one booking would block the seat forever.
`holdSeats` is **all-or-nothing** and `synchronized` per instance	A family must get all seats or none; per-instance locks let different flights sell in parallel.	Holding seats one by one (half-booked families), or one global lock (no parallelism).
`Passenger` is not an account	A passenger is a name on a ticket; a customer books for others.	`Passenger extends Person` would force an account on a child.
Itinerary is paid, not the leg	A customer pays for the trip.	Paying per reservation.
Connection rule on `Itinerary`	The course names "no connecting-time check" as a gap; the rule belongs to the thing that holds the legs. We check same airport and a 45-minute minimum.	No check (impossible trips).
Index instance → reservations	The course's other named gap: cancelling a flight told the crew but not passengers, because there was no path from instance to its reservations. The index fixes it.	Scanning every itinerary.
Strategy + Decorator for fares	The course suggests Strategy for fares (base, seasonal, last minute). `ClassMultiplierFare` uses the course's multipliers (1.0, 1.3, 1.5, 2.5, 4.0); `LastMinuteFare` wraps any fare and adds 25% within 3 days.	Price field on the seat.
Crew overlap check	A pilot cannot be on two instances whose times overlap.	Trusting the admin.
Facade (`Airline`)	One entry point for admin and customer operations. Admin-only operations (`addAircraft`, `publish`, `assignCrew`, `cancelFlight`) take an `Admin` parameter, so "only the admin" is enforced by the compiler; `bookFor(FrontDeskOfficer, …)` is the same call as `book` made by a different actor, exactly as in the course's stage 6.	Actors holding the rules.
The course makes `Airline` a Singleton	We construct it once and pass it in, to stay testable.	Global `getInstance()`.

Java implementation

Package `lld.ch16.airline`.

```java

        m.put(a, sa);
        m.put(b, sb);
        return m;
    }
}
```

Output:

```
1) Admin adds flights (routes) and weekly schedules, then publishes instances
   GA212 instances: [GA212@2026-10-06, GA212@2026-10-08, GA212@2026-10-13, GA212@2026-10-15]
2) Search JFK->LHR on 7 Oct and LHR->NRT on 8 Oct
   GA100@2026-10-07 dep 2026-10-07T20:00 arr 2026-10-08T03:00, free seats 6
   GA212@2026-10-08 dep 2026-10-08T10:00 arr 2026-10-09T00:00, free seats 6
3) Priya books a two-leg itinerary for herself and her son
    [email priya@example.com] Booked GA100@2026-10-07 seats [10A, 10B] (PNR102, 800.00)
    [email priya@example.com] Booked GA212@2026-10-08 seats [1A, 1B] (PNR103, 2500.00)
   itinerary total 3300.00 (2 x 400 economy + 2 x 1250 business)
    charged 3300.00 to tok_priya_card for itinerary IT-101
4) Bad connection is rejected
    [email priya@example.com] Booked GA100@2026-10-07 seats [12A] (PNR105, 520.00)
   rejected: connection too short: GA212@2026-10-06 leaves before GA100@2026-10-07 lands + 45 min
    [email priya@example.com] Itinerary IT-104 cancelled
5) 20 customers race for seat 10C on GA212@2026-10-08
    [email racer7@example.com] Booked GA212@2026-10-08 seats [10C] (PNR115, 500.00)
   successful bookings of 10C: 1, free seats left: 3
6) Walk-in at the front desk, last-minute (booked 7 Oct for 8 Oct): pays +25%
    [email leo@example.com] Booked GA212@2026-10-08 seats [12A] (PNR147, 812.50)
   economy-plus fare 500 x 1.3 = 650.00, charged 812.50
7) Admin assigns crew
   rejected: Capt. Kim already flies GA212@2026-10-08 at that time
   Kim's schedule: [GA212@2026-10-08]
8) Admin cancels GA212@2026-10-08: every passenger and crew member is told
    [email priya@example.com] GA212@2026-10-08 is cancelled. Reservation PNR103 refunded 2500.00. Itinerary IT-101
now totals 800.00
    [email racer7@example.com] GA212@2026-10-08 is cancelled. Reservation PNR115 refunded 500.00. Itinerary IT-107
now totals 0.00
    [email leo@example.com] GA212@2026-10-08 is cancelled. Reservation PNR147 refunded 812.50. Itinerary IT-146 now
totals 0.00
    [email K1@crew] Stand down: GA212@2026-10-08 cancelled
    [email L1@crew] Stand down: GA212@2026-10-08 cancelled
    [email A1@crew] Stand down: GA212@2026-10-08 cancelled
   search LHR->NRT on 8 Oct now returns 0 flights
9) Priya cancels the rest of her trip; seats on GA100@2026-10-07 come back
    [email priya@example.com] Itinerary IT-101 cancelled
   free economy seats on GA100@2026-10-07: [10A, 10B, 10C]
```

Step 3 prices 2 × 400 economy + 2 × (500 × 2.5) business = 3300, and the second `pay` call charges nothing. Step 5 has 20 threads racing for seat 10C and exactly one wins (which racer wins, and therefore the PNR and itinerary numbers printed for them in steps 5 and 8, changes from run to run). Step 6 is 500 × 1.3 = 650, plus 25% last-minute = 812.50. Step 8 reaches every passenger through the index — the gap the course points out.

Concurrency & edge cases

- **Selling one seat twice.** `holdSeats` is `synchronized` on the instance: it checks every requested seat and only then assigns them all. No other thread can slip in between.
- **Booking while the admin cancels the flight.** `book` holds the seats *and* adds the reservation to the instance → reservations index inside one `synchronized (fi)` block, and `cancelFlight` sets `CANCELLED` and copies that index under the same lock. So every reservation is either in the copy (and gets cancelled and notified) or is refused by `holdSeats` because the flight is already `CANCELLED` — none can slip through un-notified.
- **Double payment.** `Itinerary.pay` returns at once if the itinerary is already paid (step 3 calls it twice and charges once).
- **Duplicate seat in one request** (two passengers asking for 12A) is rejected.
- **Booking a cancelled or departed flight** throws.
- **Idempotent cancel.** `FlightReservation.cancel()` returns `false` if already cancelled, so a customer cancelling while the admin cancels the flight does not double-refund.
- **Crew double-booking** across overlapping instances is rejected (`assignCrew` is `synchronized` over the scan and the add).
- **Time zones.** Our example keeps all times in one reference zone. Real systems store departures as `ZonedDateTime` (a date-time plus its time zone) or `Instant` (an exact moment on the global UTC timeline) with each airport's zone, because London and Tokyo are 8–9 hours apart.

- **Seat holds during payment.** Real booking flows put a seat on a short *hold* (for example 10–15 minutes) while the customer pays, and release it automatically if payment fails. Add a `heldUntil` timestamp on `FlightSeat` and a sweeper (a background job that regularly frees expired holds).

Extensions & follow-up questions

- **"Overbooking on purpose?"** — Airlines sell a few more seats than exist because some passengers do not show up. Model a per-class `overbookLimit` and assign physical seats at check-in.
- **"Check-in and boarding passes?"** — Add `CHECKED_IN` per passenger, a `BoardingPass` (seat, gate, group), and a check-in window.
- **"Baggage?"** — `Baggage(passenger, weight, tag)` on the reservation; fees as extra lines.
- **"Change fees and fare rules?"** — Fare class with rules (refundable, change fee); cancellation refund = fare − fee.
- **"Codeshares?"** — A codeshare is one physical flight sold under several airlines' flight numbers. A `MarketingFlight` (partner's number) pointing at the operating `FlightInstance`.
- **"Delays?"** — `FlightInstance.setStatus(DELAYED)` plus a new departure; notify via the same index; re-check itinerary connections and rebook broken ones.
- **"Scale?"** — Seat inventory per instance is a hot row (one database row that very many requests try to change at once); use one row per seat with a conditional update (`UPDATE … WHERE reservation IS NULL` — it only changes the row if the condition still holds, so exactly one buyer wins) or optimistic locking (no lock is taken; each row carries a version number and a write fails if the version changed since you read it, so you retry), and a cache (a fast in-memory copy of data that is read often) for search.

In the interview

30-second pitch: "Four separate ideas carry the design. `Flight` is the published route; `FlightInstance` is one departure of it on a particular day; `Seat` is the chair fixed in the aircraft; `FlightSeat` is that chair on that one departure, and it is where the fare and the booking live. Reservations map passengers to flight seats and are held atomically per instance. An itinerary groups legs, checks connections and is what gets paid. Fares are a strategy with a last-minute decorator. An index from instance to reservations lets a cancelled flight notify every passenger."

Minutes	Do
0–5	Clarify search, itineraries, multiple passengers, crew, cancellation.
5–10	Actors and use cases.
10–20	The four-way distinction, then the class diagram.
20–35	Code `FlightInstance.holdSeats`, `Airline.book`, `Itinerary.checkConnection`, `cancelFlight`.
35–40	Seat holds during payment, overbooking, time zones.

Expected follow-up: "A flight is cancelled — how do its passengers find out?" — "Through an index from instance to reservations; without it you can only reach the crew."

Self-check

1. **Q:** Where does the "booked" flag live and why? **A:** On `FlightSeat` — a seat's booking is per instance (per date), not per aircraft.
2. **Q:** Why is `Passenger` not a subclass of `Person`/account? **A:** A passenger may never log in; a customer books for other people.
3. **Q:** How do you guarantee a family gets all seats or none? **A:** `holdSeats` checks all requested seats and assigns them in one synchronized block.
4. **Q:** What does `LastMinuteFare` add and which pattern is it? **A:** +25% within 3 days of departure; a Decorator over any `FareStrategy`.
5. **Q:** What two gaps did the course admit and how did we close them? **A:** No passenger notification on flight cancel (fixed by the instance → reservations index) and no connection-time check (fixed in `Itinerary.checkConnection`).

TL;DR

- Flight (route) ≠ FlightInstance (route on a date); Seat (physical) ≠ FlightSeat (seat on that date).
- Hold seats all-or-nothing under the instance's lock.
- Itinerary = legs + connection rule + payment.
- Fares: Strategy + Decorator. Keep an instance → reservations index for cancellations.

Real-world example. Airline systems separate a *flight number* (a published schedule) from a *flight leg on a date*; inventory is controlled per leg and per booking class, and the booking record (a PNR, passenger name record) groups passengers and segments — the same shape as `FlightReservation` and `Itinerary` here. When an airline cancels a flight, its systems find every PNR on that leg and rebook or notify passengers, which is exactly why the index matters.

Design a Course Registration System

Problem & clarifying questions

A **course registration system** lets university students sign up for classes each term. It looks simple, but it is one of the harshest concurrency problems in this chapter: at 09:00 on registration day, thousands of students click "register" for the same few popular sections within seconds.

Terms first:

- A **course** is a catalogue entry (CS201 Data Structures, 4 credits).
- A **section** is one offering of a course with its own instructor, meeting time and capacity (CS201-A, Mon/Wed 10:00–11:30, 30 seats). Students register for **sections**, not courses — this is the same split as Flight vs FlightInstance.
- A **prerequisite** is a course you must have completed first.
- A **waitlist** is a first-come-first-served queue of students who want a seat in a full section.
- A **registration window** is the period when a student may register; universities often open it earlier for seniors (priority registration).

Question	Assumed answer
Register for courses or sections?	Sections.
Prerequisites?	Must be completed (not just in progress).
Capacity?	Per section; when full, join a bounded waitlist.
Waitlist promotion?	Automatic when someone drops, in FIFO order, after re-checking the student's timetable.
Limits?	A per-student credit limit; no two sections that meet at the same time; no two sections of the same course.
Windows?	Opens by class year (seniors first); closes for everyone at one time.
Search?	By course code or title.
Concurrency?	Many students at once; a section must never exceed its capacity; one student must not double-register from two tabs.

Requirements

Functional

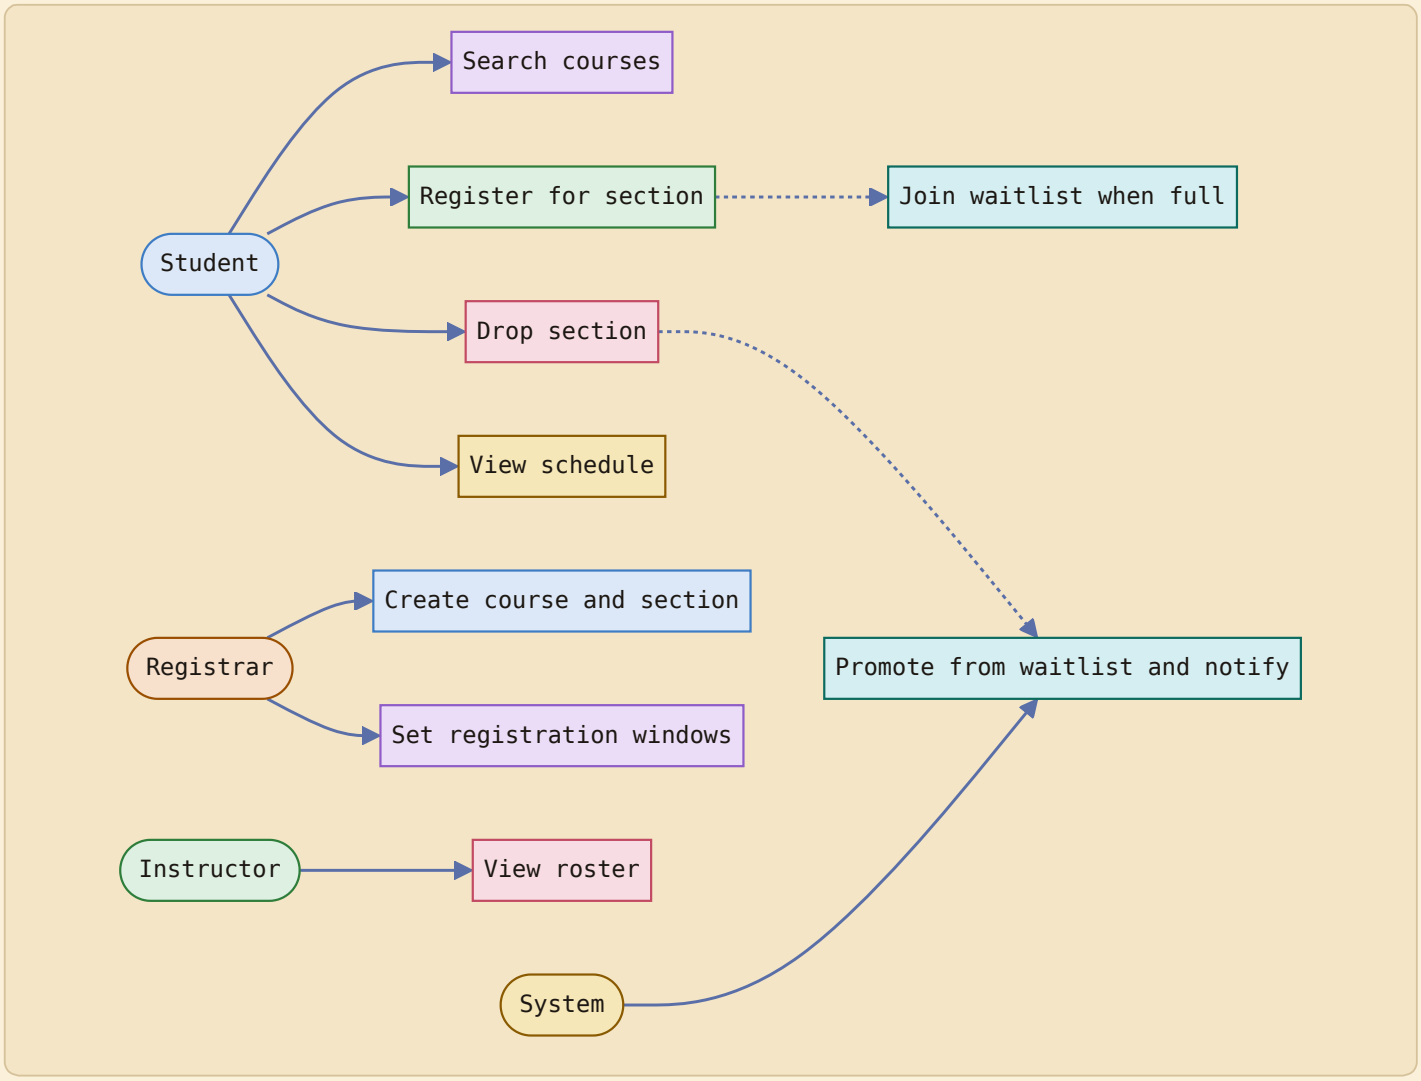
1. Students register for sections and view their registered sections.
2. Each course has a code, name and credits; each section has an instructor, time slot and enrolment limit.
3. Search courses by code or name.
4. Never enrol beyond a section's capacity; when full, put the student on the waitlist (if it has room).
5. Enforce prerequisites, credit limit, time conflicts, one section per course, and the registration window.
6. On drop, promote the first student on the waitlist automatically and notify them.

Non-functional

- Handle concurrent registrations safely: no race conditions, consistent data.
- Rules must be easy to add or remove (for example "department majors only").
- Extensible for future features (fees, holds, cross-listed courses).

Use cases

- **Student** — searches courses, registers, drops, views schedule, joins a waitlist.
- **Registrar / Admin** — creates courses and sections, sets capacity and windows.
- **Instructor** — views the roster.
- **System** — enforces rules, promotes from the waitlist, sends notifications.

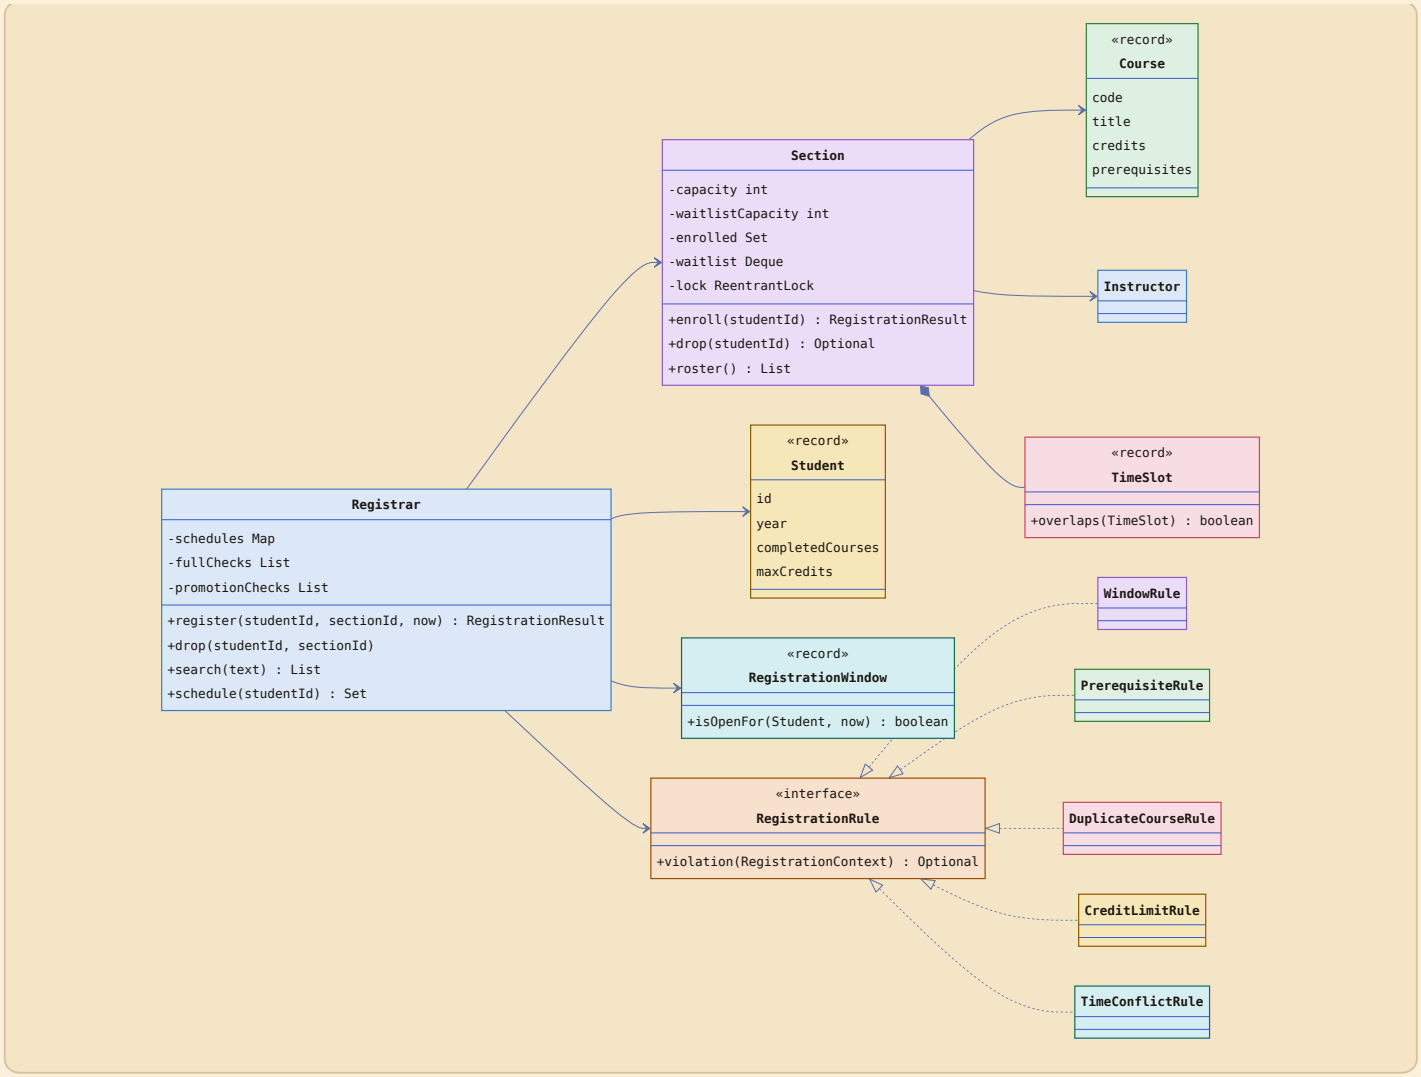


Core entities

Class	Responsibility
`Course`	Code, title, credits, prerequisite codes.
`Section`	One offering: instructor, time slot, capacity, enrolled set, waitlist. **The only place a seat is taken**, under its own lock.
`TimeSlot`	Days + start/end; knows whether it overlaps another slot.
`Instructor`	Who teaches.
`Student`	Year, completed courses, credit limit.
`RegistrationWindow`	Opening time per class year and a common closing time.
`RegistrationRule` (+ `WindowRule`, `PrerequisiteRule`, `DuplicateCourseRule`, `CreditLimitRule`, `TimeConflictRule`)	One rule each; returns the reason for a violation.
`RegistrationContext`	Everything a rule may look at.
`RegistrationResult`, `Outcome`	`ENROLLED`, `WAITLISTED` or `REJECTED` + message.
`Registrar`	The service: runs the rule chain, takes the seat, drops and promotes, keeps each student's schedule, and defines the lock order.

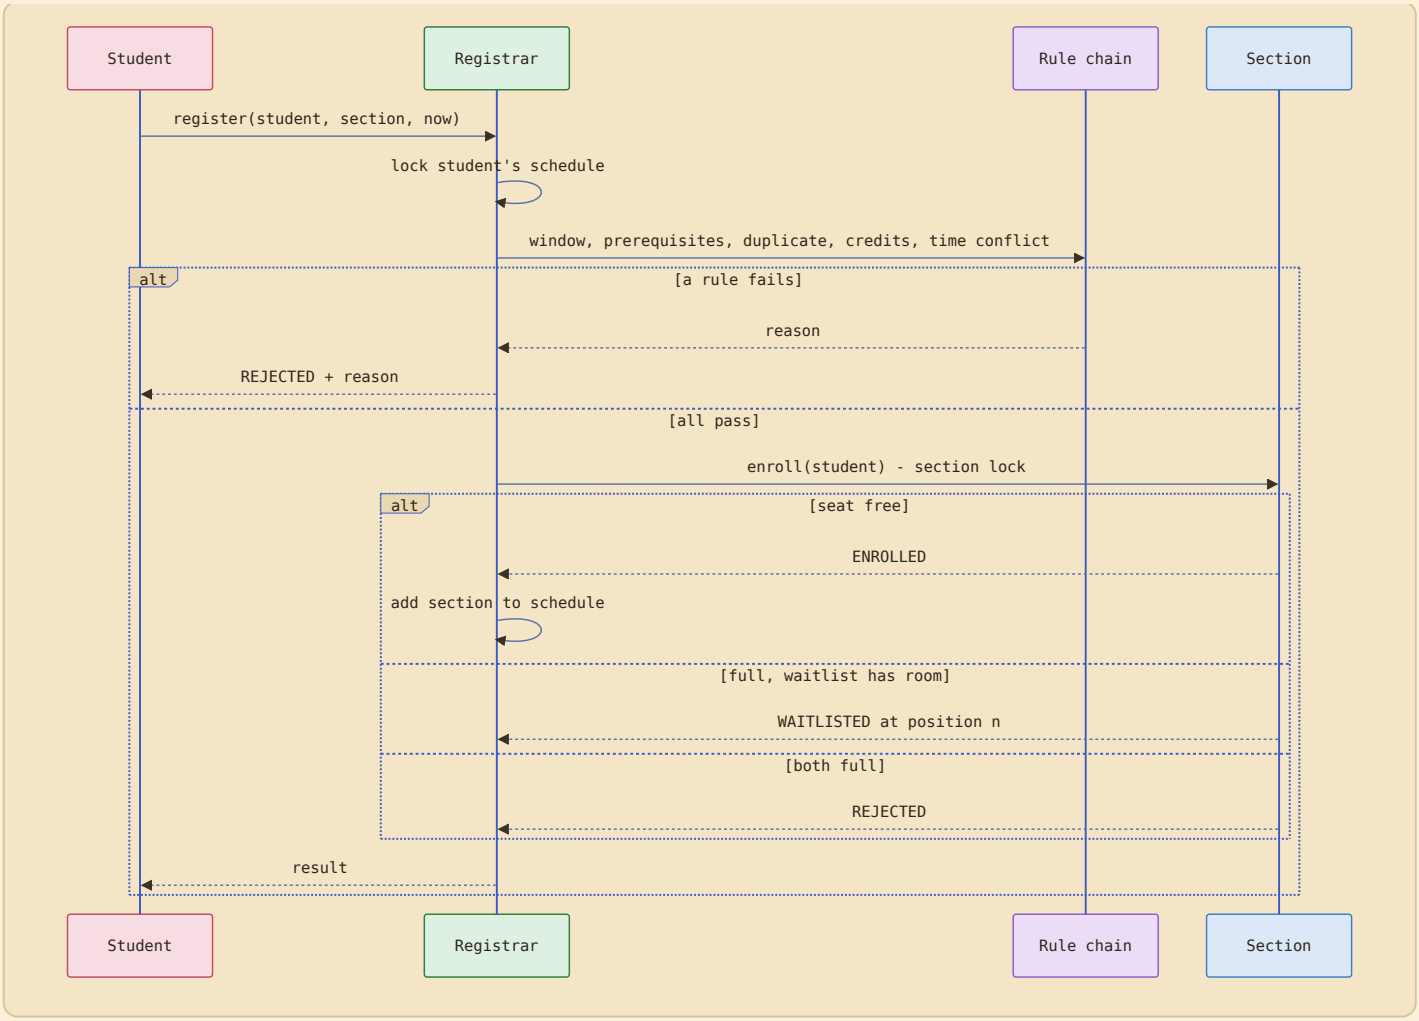
Class diagram

There is no course lesson for this problem. The problem statement comes from the *awesome-low-level-design* problem set: students register for courses and view their enrolments; a course has a code, name, instructor and maximum capacity; search by code or name; no enrolment past capacity; many students registering at once without race conditions; room to extend. Every one of those is covered above (the instructor and capacity sit on the `Section`). Here is the diagram of our Java design.

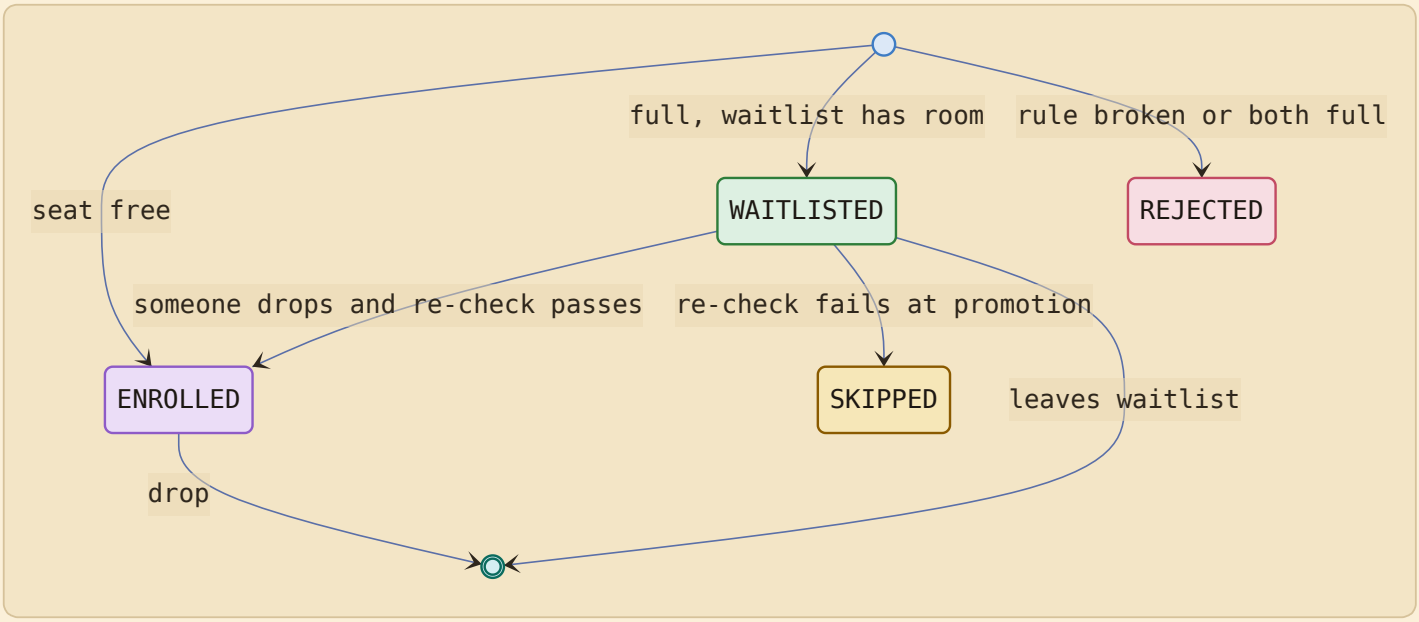


Key flows

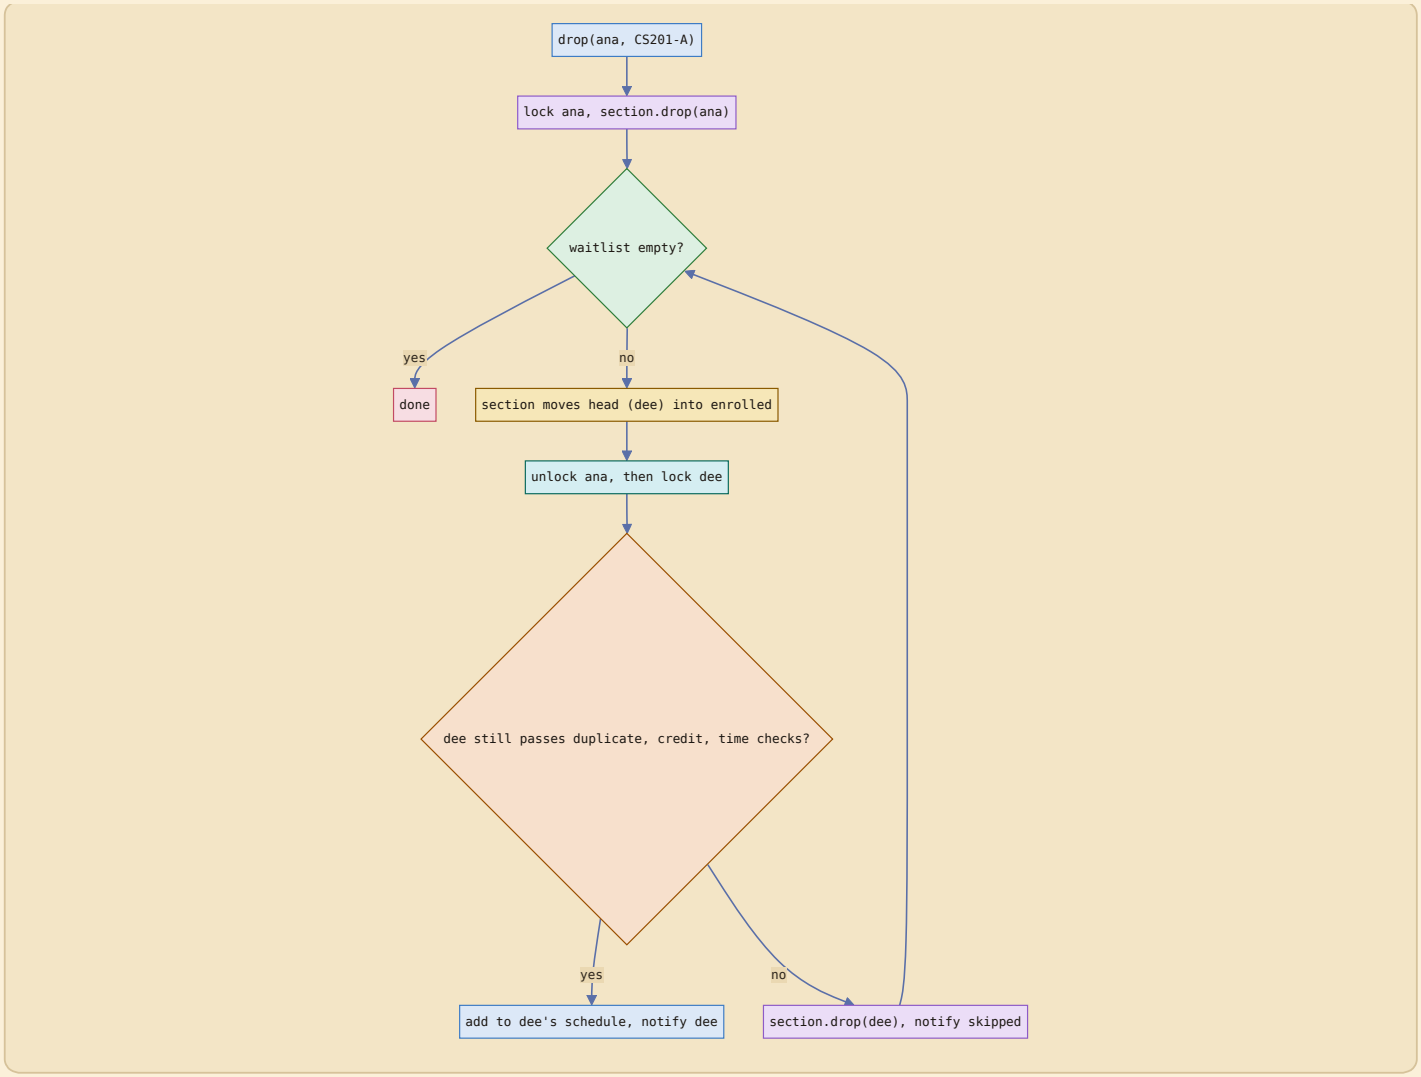
Register:



A student's status in one section:



Drop and promote:



drop(ana, CS201-A)
lock ana, section.drop(ana)
waitlist empty?
yes
no
done
section moves head (dee) into enrolled
unlock ana, then lock dee
dee still passes duplicate, credit, time checks?
yes
no
add to dee's schedule, notify dee
section.drop(dee), notify skipped

Design decisions & patterns used

Decision	Why	Alternative rejected
Course vs Section	Capacity, time and instructor belong to an offering, not the catalogue entry.	Capacity on `Course` (cannot have two sections).
Seat taken only inside `Section.enroll`, under a `ReentrantLock` (Java's explicit lock object, which the same thread may re-acquire) per section	Check-capacity-then-add is atomic; different sections do not block each other.	`synchronized` on the whole registrar (every student in the university waits in one line).
Per-student lock around rules + enroll	Credit limit and time-conflict checks read the schedule; two tabs registering the same student would both pass without it (step 6 of the output).	Lock only the section (a student could exceed credits via two sections in parallel).
Fixed lock order: student, then section	Deadlock needs two threads taking the same two locks in opposite orders. Always taking student before section rules it out. Promotion takes the next student's lock only *after* releasing the dropper's, so two student locks are never held together.	Promoting while still holding the dropper's lock (student → section → student: deadlock risk).
Rules as objects (Specification / Chain of Responsibility style: each check is its own object, and a request passes along the chain until one rejects it)	Each rule is one small class; the registrar runs them in order and stops at the first failure. A new rule ("majors only") is a new class plus one list entry — Open/Closed. The promotion path reuses a *subset* of the same rules.	One long `register` method with nested `if`s.
Waitlist is a FIFO `Deque`, bounded (a double-ended queue with a maximum size)	Fair (first come, first served) and prevents unbounded queues.	Unbounded list; priority by year (a valid extension).
Re-check on promotion	A student may have registered for a clashing section while waiting.	Promote blindly (broken timetables).
Time passed in (`now`)	Makes window logic testable without waiting for real dates.	Calling `LocalDateTime.now()` inside rules.
Singleton? The GitHub problem uses a singleton `CourseRegistrationSystem`.	We construct one `Registrar` and pass it in: one instance, still testable.	Global `getInstance()`.

Java implementation

Package `lld.ch16.courseregistration`.

```java
// File: code/lld/ch16/courseregistration/Types.java
package lld.ch16.courseregistration;

import java.time.DayOfWeek;
import java.time.LocalDateTime;
import java.time.LocalTime;

Output:

```
1) Search 'cs2': [CS201-A [MONDAY, WEDNESDAY] 10:00-11:30, CS201-B [TUESDAY, THURSDAY] 14:00-15:30]
2) Rules
   ben  CS201-A on Nov 2  -> REJECTED: registration window is closed for year 3 at 2026-11-02T10:00
   ana  CS201-A on Nov 2  -> ENROLLED: enrolled in CS201-A (1/2)
   ana  MATH201-A         -> REJECTED: time conflict with CS201-A [MONDAY, WEDNESDAY] 10:00-11:30
   ana  CS201-B           -> REJECTED: already registered for CS201 in section CS201-A
   ana  CS301-A           -> REJECTED: missing prerequisites [CS201, MATH201]
   cy   CS201-B on Nov 4  -> REJECTED: missing prerequisites [CS101]
   ana  after close       -> REJECTED: registration window is closed for year 4 at 2026-11-21T09:00
3) Capacity 2 + waitlist 2 on CS201-A (juniors open Nov 3)
   ben  CS201-A           -> ENROLLED: enrolled in CS201-A (2/2)
   dee  CS201-A           -> WAITLISTED: waitlisted for CS201-A at position 1
   eve  CS201-A           -> WAITLISTED: waitlisted for CS201-A at position 2
   fay  CS201-A           -> REJECTED: CS201-A and its waitlist are full
   ben  MATH201-A         -> REJECTED: credit limit 4 exceeded (7)
4) Ana drops CS201-A: the head of the waitlist is promoted
    [notify] ana dropped CS201-A
    [notify] dee promoted from waitlist into CS201-A
   roster [ben, dee], waitlist [eve]
5) 50 first-years grab 30 seats (+10 waitlist) in CS101-A at 09:00 sharp
   ENROLLED=30 WAITLISTED=10 REJECTED=10, roster size 30
6) One student double-clicks: two threads, same request
   {ENROLLED=1, REJECTED=1}, gus schedule [CS201-B]
```

Step 2 shows each rule firing with a clear reason. Step 3 fills two seats and two waitlist places. Step 4 promotes Dee automatically. Step 5 is the "09:00 rush": 50 threads, 30 seats, 10 waitlist places — the counts are exact every run. Step 6 is the double-click: two threads for the same student and section, exactly one succeeds.

Concurrency & edge cases

- **Overselling a section** — prevented by the section lock around "size < capacity → add".
- **Double-click / two tabs** — prevented by the per-student lock; the second request sees the first enrolment and is rejected by `DuplicateCourseRule` (or by the section's "already enrolled" check).
- **Deadlock** — avoided by the fixed lock order (student → section) and by never holding two student locks at once.
- **Waitlisted in one section, enrolled in another section of the same course** — possible while waiting, because waitlist entries are not in the schedule; the promotion re-check (`DuplicateCourseRule`) catches it and skips to the next student.
- **Registration closes while on the waitlist** — promotion does not re-check the window (it is the drop that triggers it). Many universities stop automatic promotion after a deadline; add `WindowRule` to `promotionChecks` if that is the policy.
- **Dropping a section you are not in** → `IllegalArgumentException`.
- **Rules with time** — the window uses half-open time (`opens ≤ now < closes`).
- **Scaling beyond one JVM** (Java Virtual Machine — the running program that executes Java code) — the in-memory locks work for one process (one running copy of the program). With several app servers (copies of the application on different machines, usually behind a load balancer that spreads requests among them), the seat count moves to the database: `UPDATE section SET enrolled = enrolled + 1 WHERE id = ? AND enrolled < capacity` succeeds for exactly `capacity` requests (an atomic conditional update), or use optimistic locking with a version column. A queue in front of hot sections smooths the 09:00 spike. (Load balancers, queues and databases at scale are covered in System Design Fundamentals.)

Extensions & follow-up questions

- **"Co-requisites or 'prerequisite OR instructor permission'?"** — Model prerequisites as a small expression tree (a tree whose inner nodes are operators like `And` / `Or` and whose leaves are simple checks: `And`, `Or`, `CourseCompleted`, `Permission`) — the Composite pattern, where a group of objects is treated exactly like a single one — and evaluate it in `PrerequisiteRule`.
- **"Holds (unpaid fees, advising)?"** — A `HoldRule` that rejects if the student has an active hold.
- **"Priority waitlists (seniors first)?"** — Replace the `Deque` with a `PriorityQueue` (a queue that always hands out the smallest item by some ordering, not the oldest) ordered by (year, time joined).

- **"Seat reservations for majors?"** — Split capacity into buckets (majors 20, others 10) and check the bucket in `Section.enroll`.
- **"Linked sections (lecture + lab)?"** — Register both atomically: lock both sections in a fixed order (by id), check both, enrol both.
- **"Notify by email/SMS?"** — The registrar takes a `Consumer<String>` notifier (Java's built-in "function that takes a value and returns nothing"); swap for an email service or publish an event to a message queue (a service such as Kafka or RabbitMQ that stores messages until another program reads them).
- **"Course fees and billing?"** — Add a `Bill` per student per term, a line per enrolled section, recomputed on drop.

In the interview

30-second pitch: "Students register for sections, not courses. A section owns capacity and a bounded FIFO waitlist, and takes seats only inside its own lock. The registrar runs a chain of rule objects — window, prerequisites, duplicate course, credit limit, time conflict — while holding the student's lock, then asks the section for a seat. Lock order is always student then section, so no deadlocks. On drop the head of the waitlist is promoted after a re-check."

Minutes	Do
0–5	Clarify course vs section, rules, waitlist, windows, concurrency.
5–12	Entities and class diagram.
12–30	Code `Section.enroll/drop`, the rule interface and two rules, `Registrar.register`.
30–40	Concurrency: run the 50-threads demo in your head; lock order; DB conditional update for scale.

Self-check

1. **Q:** Why do students register for sections, not courses? **A:** Capacity, time and instructor belong to each offering; a course can have many sections.
2. **Q:** Which two locks does `register` take and in what order? **A:** The student's schedule lock, then the section's lock — always in that order.
3. **Q:** Why not simply make `register` `synchronized` on the registrar? **A:** It would be correct but serialise (force to run strictly one at a time) every student in the university; per-section and per-student locks let unrelated requests run in parallel.
4. **Q:** Why re-check rules on promotion? **A:** The student's timetable may have changed while waiting (a clash or the same course in another section).
5. **Q:** How do you enforce capacity with many servers? **A:** An atomic conditional update in the database (`… WHERE enrolled < capacity`) or optimistic locking.

TL;DR

- Course (catalogue) vs Section (offering with capacity, slot, waitlist).
- Rules are small objects run as a chain; add a rule without touching the registrar's logic.
- Seats are taken only inside `Section.enroll` under the section's lock; student lock first, section lock second.
- Drop → promote waitlist head → re-check → notify.
- At scale: conditional update in the database.

Real-world example. University student-information systems (for example Ellucian Banner, used by many US universities) run priority registration windows by class standing, check prerequisites and time conflicts, and keep section waitlists that notify a student when a seat opens (some schools enrol the student automatically; others give a time-limited window to claim the seat). Registration-day slowdowns at such schools are the 09:00 "thundering herd" (a huge crowd of requests all arriving at the same instant) this design addresses with per-section locking and, at scale, database conditional updates.

Chapter summary

Problem	Key insight	Atomic claim	Patterns
Car rental	Availability is a question about **dates**, not a status field	`Vehicle.tryBook(range)`	Template Method (add-ons), Strategy + Decorator (pricing), state machine
Restaurant	**Meal per seat**; table = status (now) + slots (later)	`Table.tryHold(time)`	Observer (order ready), Strategy (chef assignment, payment), state machine
Airline	**Flight ≠ FlightInstance, Seat ≠ FlightSeat**	`FlightInstance.holdSeats(map)` (all or nothing)	Strategy + Decorator (fares), Facade, index for cancellation
Course registration	**Course ≠ Section**; rules as objects	`Section.enroll` under a section lock, inside a student lock	Specification / Chain of rules, lock ordering

The four problems share one lesson: **find the calendar, find the atomic check-then-claim, and put the rules on the object that owns the data.**

Chapter 17 — Case Studies: Games & Rules

> **Where this fits.** Chapters 14–16 designed things that model the real world (an ATM, a parking lot, booking systems). Games are different: the "world" is a set of **rules**, and the rules are exact. That makes games a favourite interview topic. There is nowhere to hide a vague class, because every rule must live *somewhere*, and the interviewer will ask where.

An **LLD** (low-level design) interview asks you to design the classes, their responsibilities and some of the code for one system — as opposed to high-level design, which is about servers, databases and networks.

What games test in an LLD interview

Skill	What it means	Where you see it in this chapter
Rule encapsulation (hiding a rule inside the class that owns it)	Each rule lives in one obvious class, not spread across `if` statements everywhere.	Blackjack scoring in `BlackjackScoring`; chess legality in `Rules`; 2048 merging in `LineMerger`.
Turn management	Whose turn is it, what may they do now, and what happens when the turn ends?	A turn index (tic-tac-toe), a queue of players (snake and ladder), `turn` colour (chess), rounds (blackjack).
Polymorphic pieces	Different kinds of objects answer the same question in their own way (*polymorphism* = "many shapes": one method call, many behaviours).	Chess `Piece.targets(...)` overridden by King, Knight, Pawn and the sliding pieces.
Pluggable strategies	Behaviour that varies (how a bot plays, how dice roll, when the game ends) sits behind an interface (a list of methods with no fixed implementation; the **Strategy** pattern, Chapter 10).	`PlayerStrategy`, `DealerPolicy`, `MoveStrategy`, `Dice`, `OverflowRule`, `WinStrategy`, `TileSpawner`.
Deterministic testing (same input, same result every time)	Randomness is *injected* (handed in from outside). Pass `new Random(seed)` and the "random" sequence is the same on every run, so tests and demos repeat exactly. Or pass a scripted source (stacked shoe, loaded dice).	Every `Main` in this chapter prints the same output every time.
State and status	A game moves through states (in progress, won, draw, over). Illegal actions in the wrong state are rejected.	`GameStatus`, `GameState` enums (types with a fixed list of named values) in every game.

> **Key idea: seeded randomness.** `java.util.Random` is a *pseudo-random* generator: it computes its numbers from a starting value called the **seed**. The same seed always produces the same sequence (the algorithm is fixed by the Java specification). `Collections.shuffle(list, rnd)` is also deterministic for a given `Random`. So the rule for game code is: **never call `new Random()` or `Math.random()` inside the game. Accept a `Random` (or a `Dice` / `Spawner` interface) from outside.** Production passes an unseeded (or `SecureRandom` — a slower generator whose output cannot be predicted, used for security) source; tests pass a seed. This is plain Dependency Injection (Chapter 5): an object receives what it needs from its caller instead of creating it itself.

Problems in this chapter

#	Problem	Main ideas
17.1	Blackjack and a Deck of Cards	generic deck, shoe, soft/hard hand values, dealer rule, betting, split, double, insurance
17.2	Chess	board, polymorphic pieces, legal moves, check/checkmate/stalemate, castling, en passant, promotion, undo
17.3	Tic-Tac-Toe	N×N board, O(1) win detection with counters, pluggable players
17.4	Snake and Ladder	board config and validation, seeded dice, rules engine, pluggable win rules
17.5	2048	slide/merge logic, seeded tile spawns, game-over detection

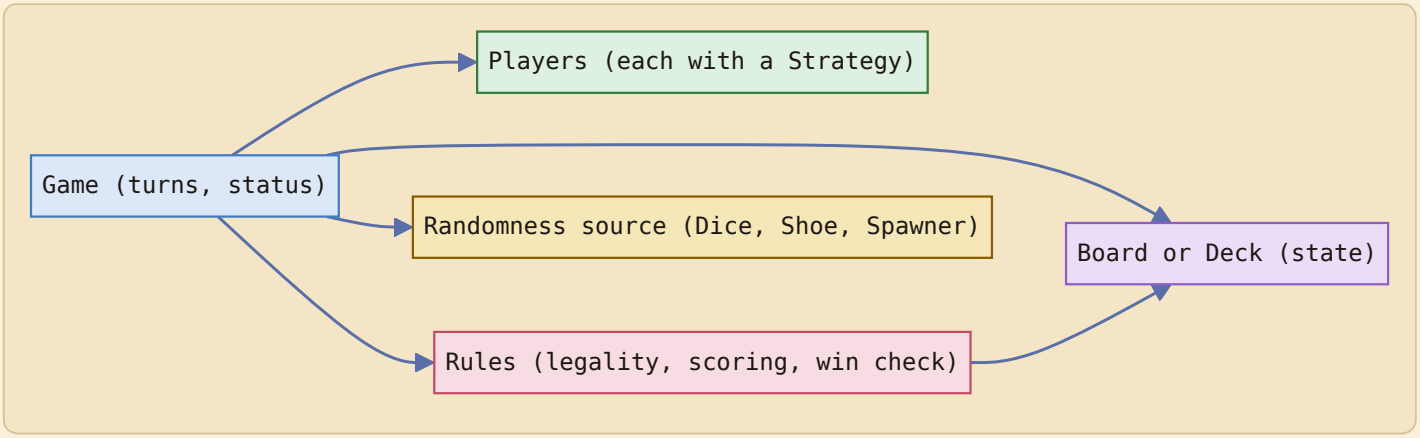
> **Key term — Big-O notation:** Expressions like O(1), O(n) and O(N²) describe how an algorithm's work grows as the input grows. **O(1)** ("constant time") means the work stays the same no matter how big the input is; **O(n)** means it grows in step with the input size n; **O(N²)** means doubling N makes the work about four times bigger. Interviewers use it to compare approaches without timing them.

How to run every example in this chapter

```
cd chapters/17-case-games/code
javac --release 21 -d /tmp/lld_17 $(find . -name '*.java')
java -cp /tmp/lld_17 lld.ch17.blackjack.Main    # or chess, tictactoe, snakeladder, game2048
```

`javac` is the Java compiler and `-cp` (the classpath) tells `java` where the compiled classes are. All five `Main` classes compile with Java 21 (standard library only — just the classes that ship with Java) and run. All randomness is seeded or scripted, so the output shown under each program is exactly what you will see.

A reusable skeleton for any board/card game. Almost every game design in an interview has the same five parts. Name them early and the rest of the interview becomes filling in details.



Part	Question it answers	Typical class names
State	What does the table look like right now?	`Board`, `Deck`, `Shoe`, `Hand`, `Cell`
Actors	Who acts, and how do they decide?	`Player` + `PlayerStrategy` / `MoveStrategy`
Rules	Is this action allowed? What does it do? Who won?	`Rules`, `DealerPolicy`, `OverflowRule`, `WinStrategy`
Controller	Whose turn? What state is the game in?	`Game`, `GameStatus`
Randomness	Where does chance come from?	`Dice`, `Shoe`, `TileSpawner` — always injected

Design Blackjack and a Deck of Cards

Figure — A blackjack table: players each compete against the dealer (course diagram)

Problem & clarifying questions

Blackjack is the casino card game played more than any other. Nobody plays against the other people at the table: every player's cards are measured only against the cards of the **dealer** (the dealer is the casino employee who deals and plays for the house). Everybody tries to get as close to **21 points** as possible without going over. Going over 21 is called **busting** and loses at once.

The interviewer often phrases it as "Design a deck of cards, then use it to build blackjack". The first half checks that you keep the deck **generic**; the second half checks rule placement.

Questions worth asking (with the answers this design assumes):

Question	Assumed answer
One deck or several?	A **shoe** holding several standard 52-card decks (casinos use 6–8). One deck is just a shoe of 1.
How many players?	One or more players, each against the dealer.
Which player options?	Hit, stand, double down, split (once), insurance. Surrender and side bets are out of scope.
Dealer rule?	Hit on 16 or less, stand on 17 or more. Some casinos also hit a "soft 17" — make it pluggable.
Payouts?	Win 1:1, blackjack 3:2, tie ("push") returns the bet, insurance 2:1 (odds like 3:2 mean you win 3 chips for every 2 bet).
Money?	Bets are counted in whole **chips** (an `int`, a whole-number type), and the ante (the starting bet) must be even. Never use `double` (an inexact binary floating-point number) for money.
Real UI (user interface — the screens), network, accounts?	Out of scope. The course model has `Account`/`Person` for sign-in; we keep `Player` minimal and say where it would attach.

Requirements

Background rules

- A standard deck has **13 ranks** (A, 2–10, J, Q, K) in **4 suits** (clubs, diamonds, hearts, spades). Blackjack uses one or more such decks.
- At the start, each player and the dealer receive **two cards**. Both player cards are face up. The dealer has one card face up (the **up card**) and one face down (the **hole card**), so players decide with incomplete information.
- **Card points:** 2–10 are worth their number. J, Q, K are worth 10. An **ace is worth 1 or 11**, whichever helps.
- **Soft vs hard total:** when an ace is counted as 11 the total is **soft** (it can still "soften" to 1 later, so one more card can never bust it). When every ace counts as 1 the total is **hard**. Example: A+5 is "soft 16" (or hard 6).
- **Blackjack** (also called a *natural*): exactly two cards totalling 21, i.e. an ace plus a 10-point card.
- **Dealer rule:** the dealer has no choices. Hit (take a card) while the hand is 16 or less; stand at 17 or more.

Functional requirements

1. A player must place an initial bet (the **ante**) to play a round.
2. Deal two cards to each player and to the dealer (one up, one hole).
3. If the dealer's up card is an **ace**, offer **insurance**: a side bet of half the ante that pays **2:1** if the dealer has blackjack. After that, the dealer checks ("peeks at") the hole card. If it is blackjack, the round ends at once: insurance wins, main bets lose, except a player blackjack, which ties.
4. A player whose hand is below 21 chooses:
   - **Hit** — take one more card, and choose again.
   - **Stand** ("stand pat") — take no more cards.
   - **Double down** — double the bet (the extra must equal the ante), take exactly **one** more card, and stop.
   - **Split** — only when the first two cards have the same rank: pay a second bet equal to the ante, split the pair into two hands, deal one card to each, and play each hand separately. No re-splitting.
5. A hand over 21 is **resolved immediately as a loss**.
6. The dealer then plays by the fixed rule.
7. **Resolution:** if the dealer busts, every non-bust hand wins. Otherwise the higher total wins; equal totals are a **push** (bet returned). A winning blackjack pays **3:2**; every other win pays **1:1**.
8. **Even money** (course requirement): if a player holds blackjack and the dealer shows an ace, the player may accept an immediate 1:1 payout instead of risking a push. (It is mathematically identical to buying insurance with a blackjack, so we explain it rather than build it — see Extensions.)

Non-functional requirements

- **Generic deck:** the `Card` / `Deck` classes must work for any card game, not just blackjack.
- **Deterministic tests:** shuffling uses an injected `Random`; a *stacked* shoe (fixed card order) makes exact scenarios reproducible.
- **Extensible rules:** dealer rule and player decision-making are pluggable.
- **Correct money:** bets and balances are whole chips held in an `int`, never a `double`. This is the one place in the handbook where money is not a `BigDecimal`, and it is deliberate: a table only accepts whole chips, and requiring an **even ante** makes every payout a whole number of chips (3:2 on 10 is 15; insurance is exactly half the ante, 5, and pays 2:1 = 10). If the table ever had to pay fractions (a 3:2 payout on an odd ante, or converting chips to currency at the cashier), switch the amounts to `BigDecimal` (Java's exact decimal number type) with an explicit `RoundingMode` (the rule for what to do with a leftover fraction, such as "round half up").

Use cases

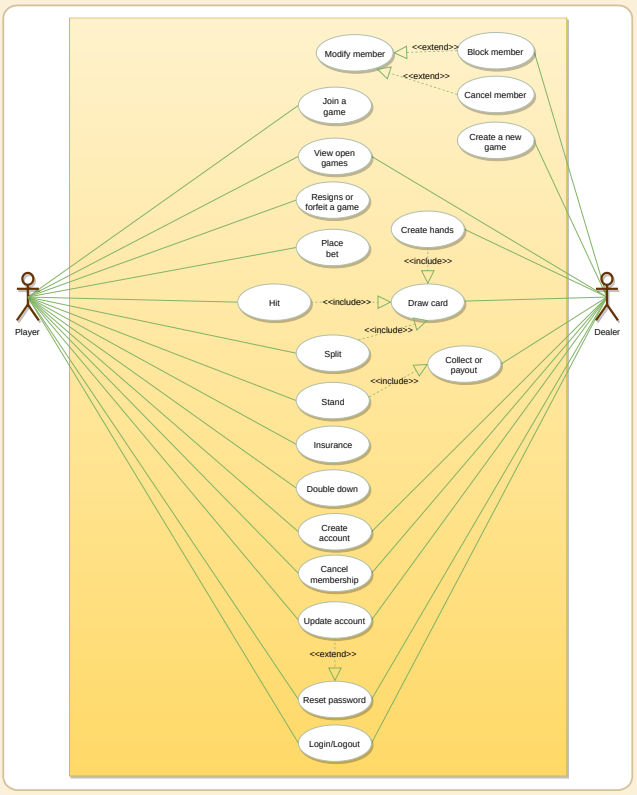


Figure — Blackjack use cases for the Player and the Dealer, including account management (course diagram)

The figure above is a **use case diagram** (UML — Unified Modeling Language — notation: stick figures are *actors*, the people or systems using the software; ovals are *use cases*, the goals they can achieve). In the figure above there are two actors:

- **Player** — places the initial bet; accepts or declines extra bets (insurance, split, double); accepts or declines an offered resolution such as even money; chooses hit, double or stand. The player also has account-level use cases (create account, log in, join or view games), which belong to a lobby service (the separate part of the app where players sign in and pick a table), not the game engine (the code that enforces the game's rules).
- **Dealer** — deals cards, plays the house hand by the fixed rule, collects losing bets and pays winners.

The main use cases (note the `<<include>>` arrows in the figure — an include arrow means one use case always runs another as part of itself: dealing and payout are part of every round):

Use case	What happens
Create hands	Deal two cards each; dealer shows one card.
Place bet	The ante; required before cards are dealt.
Player plays the hand	Hit (repeat), double (one card, done), or stand. A hand over 21 is resolved as a bust.
Dealer plays the hand	Draw while 16 or less, stop at 17 or more. A dealer bust pays every live hand.
Insurance / even money / examine hole card	Only when the up card is an ace. The hole card is checked; a 10-value hole card means dealer blackjack, insurance wins and the round ends; otherwise insurance loses and the hole card stays hidden.
Split	Pair of equal rank: second bet, two hands, one extra card each, no further splitting.
Game resolution	Compare totals; tie returns the bet; blackjack 3:2; other wins 1:1.

Activity: hit or stand

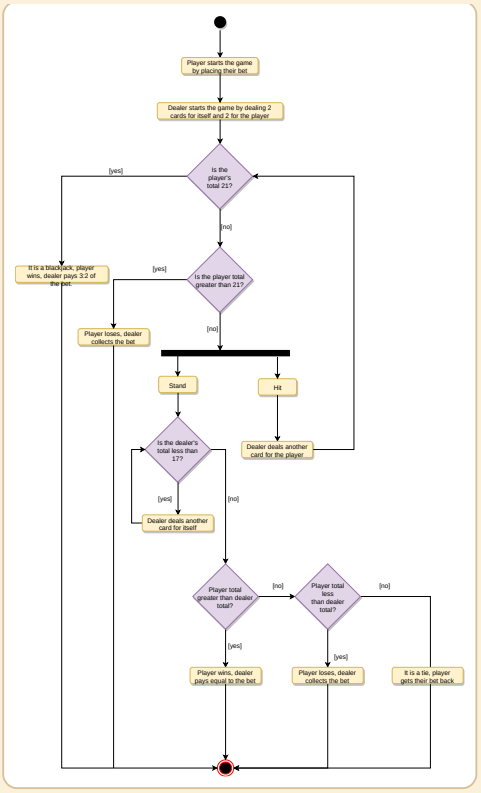

Figure — Activity diagram for one player's hit-or-stand round against the dealer (course diagram)

An **activity diagram** is a flowchart of one task, with diamonds for decisions. The figure above walks through one round: bet, deal, check for 21 (blackjack pays 3:2), check for bust, hit or stand, then the dealer draws while below 17, and finally the three outcomes — player wins 1:1, player loses, or a tie returns the bet.

Core entities

Class	Responsibility
`Suit`, `Rank` (enums)	The fixed values of a French deck (the standard 52-card deck with four suits). `Rank` stores the *face value* 1–13 (ace = 1, J = 11, Q = 12, K = 13).
`Card` (record — a compact class that just holds fixed values)	Rank + suit. Knows **nothing** about blackjack. Immutable (cannot change after creation).
`Deck<T>`	A generic (works for any type `T` you plug in), shuffleable stack of any card type `T`; `standard52()` factory (a method that builds objects) builds a French deck.
`Shoe`	Several decks shuffled together; deals one card at a time; reshuffles at the **cut card** (a marker card placed near the end of the shoe). `Shoe.stacked(...)` gives a fixed order for tests.
`BlackjackScoring`	The blackjack value of a rank (K = 10, ace = 1 hard). The *game* rule, kept off `Card`.
`Hand`	Cards + bet; computes hard/soft/best totals, bust, blackjack, can-split; splits and doubles.
`Action` (enum)	HIT, STAND, DOUBLE, SPLIT.
`PlayerStrategy` (interface)	How a player decides. `BasicStrategy` and `MimicDealerStrategy` are two bots (computer-controlled players); a UI-backed human would be a third.
`DealerPolicy` (interface)	When the dealer hits. `standOnAll17()` and `hitSoft17()`.
`Player`	Name, chip balance, strategy.
The dealer	Not a class of its own here: during a round the dealer is a `Hand` inside `BlackjackGame` plus the `DealerPolicy` that decides when it draws. (The course has a `Dealer` class next to `Player`, both under `BasePlayer`.)
`BlackjackGame`	Runs a round: bets, deal, insurance + peek, player turns, dealer turn, settlement.

Class diagram

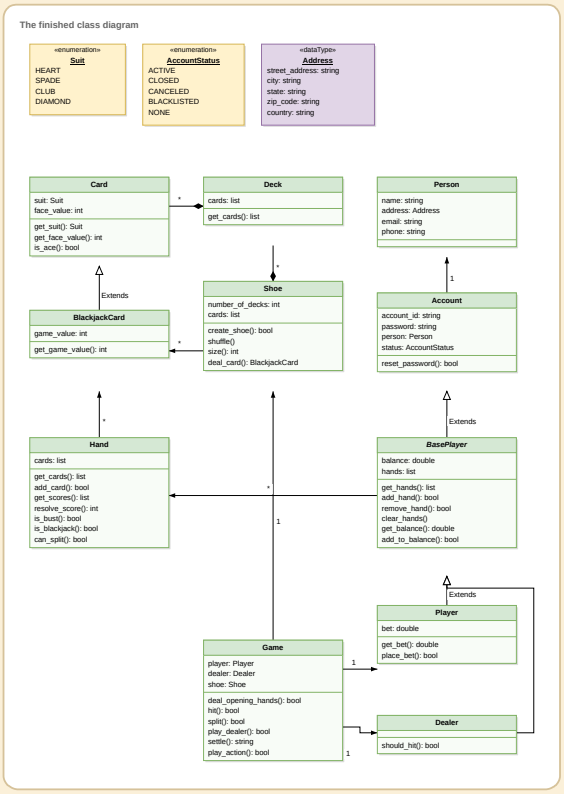

Figure — Course class diagram: Card, BlackjackCard, Deck, Shoe, Hand, BasePlayer, Player, Dealer, Game, Account (course diagram)

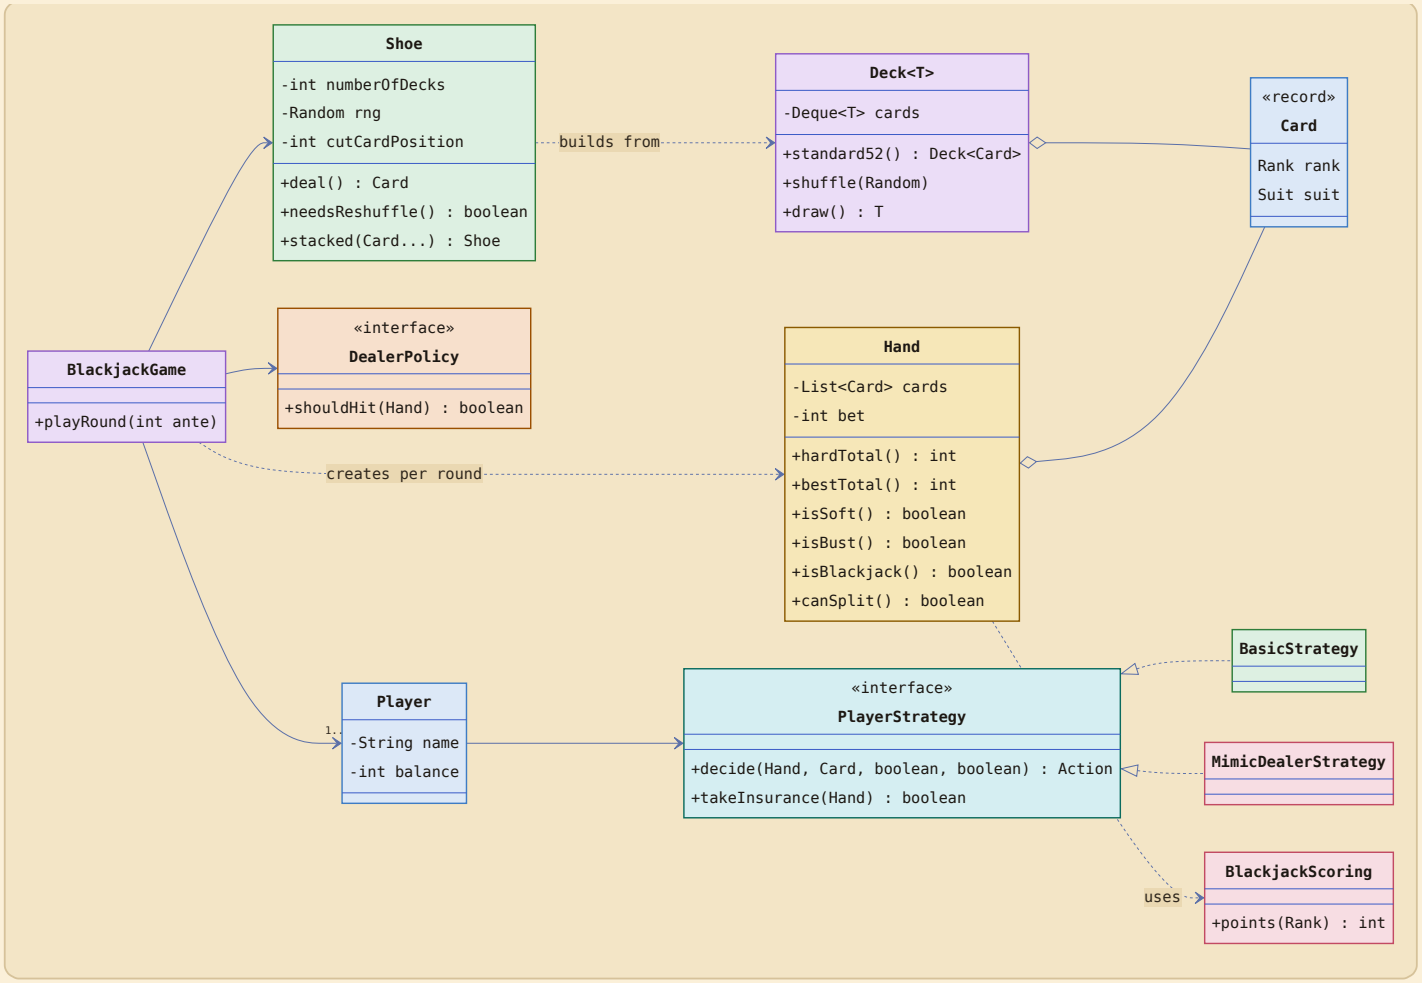
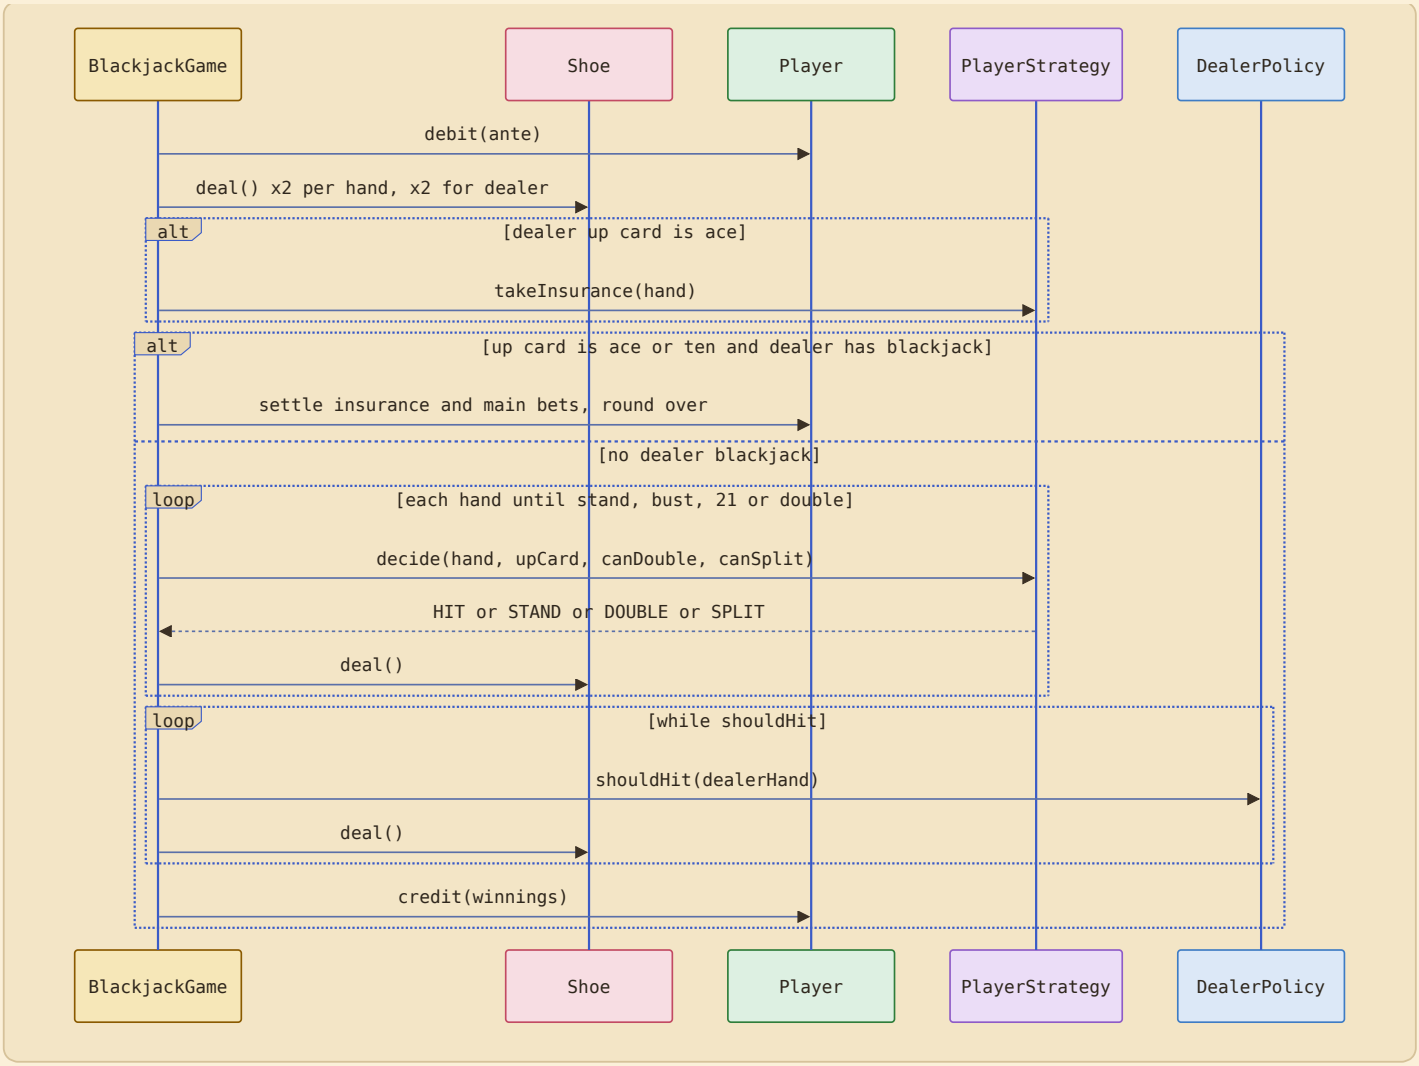
In the course model (figure above), `Card` holds a suit and a face value, and a subclass `BlackjackCard` adds the *game value* — because a king has face value 13 but is worth 10 in blackjack. A `Shoe` is composed of several `Deck`s (filled diamonds = composition: the parts belong to the whole). A plain arrow is an *association* (one class merely refers to another), and an open triangle is *inheritance* (a subclass extends a parent class). `Hand` scores itself. `Player` and `Dealer` share a `BasePlayer` (balance, hands), which extends `Account`. `Player` adds the bet; `Dealer` adds the "should I hit?" rule. `Game` points at a player, a dealer and a shoe and holds the order of play. Note the `*` from `BasePlayer` to `Hand`: splitting gives one player several hands.

Our Java design keeps the same core idea — **the game value must not live on the generic card** — but implements it with a separate scoring function instead of a subclass, and turns the two things that vary (player decisions, dealer rule) into strategies:

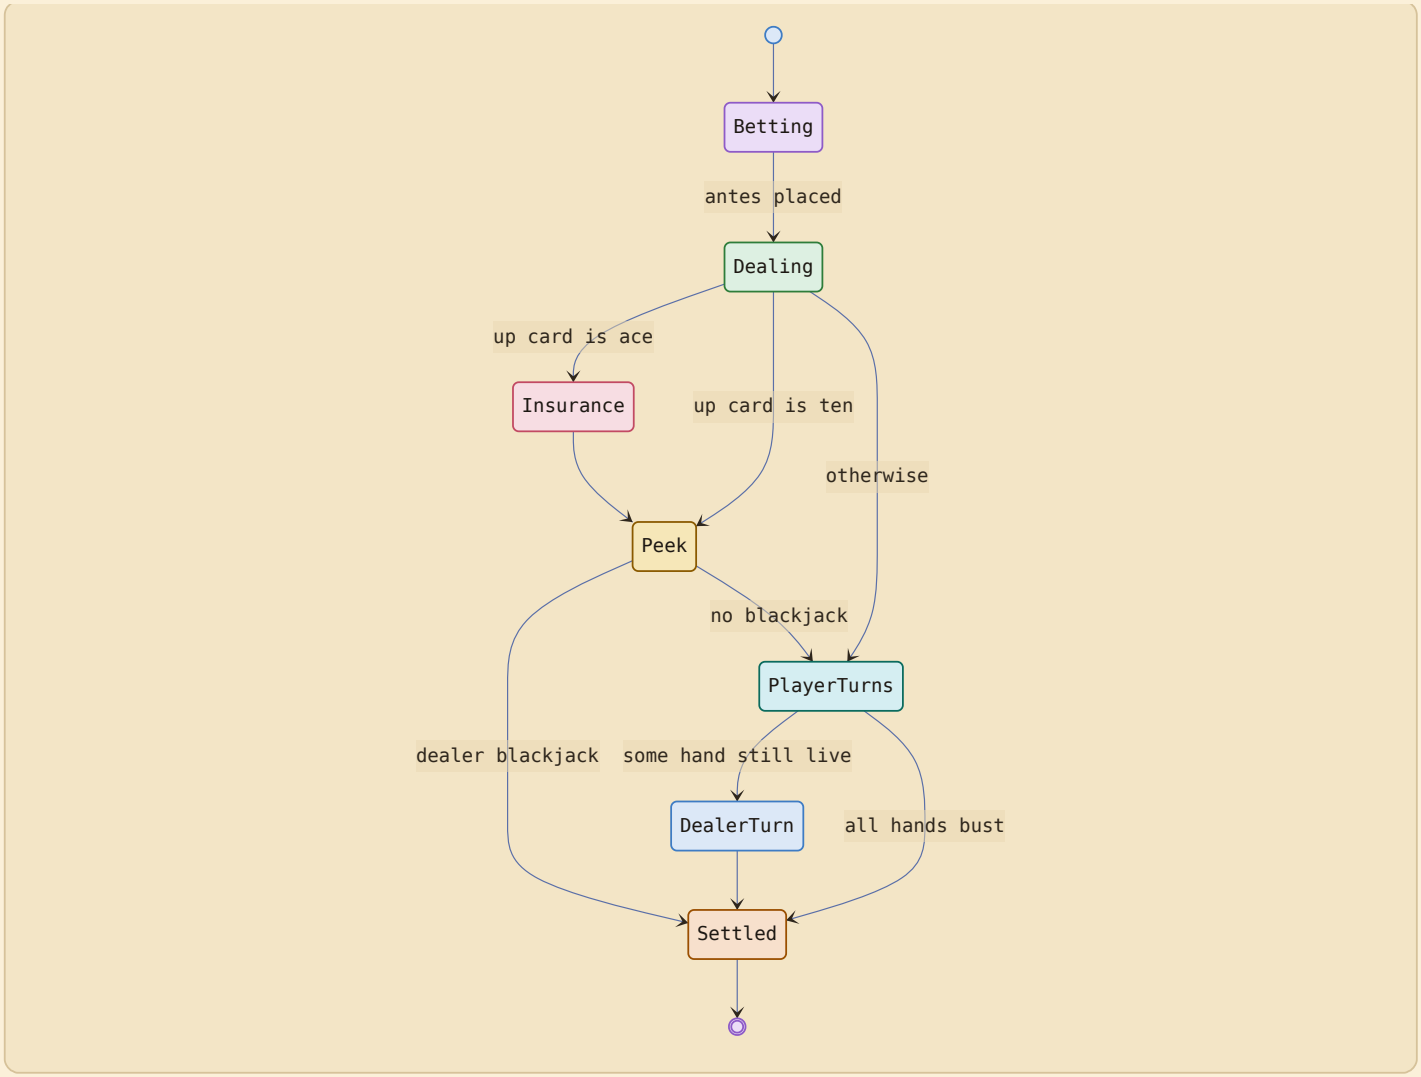


Key flows

One round (sequence)



States of one round



Scoring a hand (the ace problem). The trick is that **at most one ace can ever count as 11** (two elevens would be 22, a bust). So:

1. Add up every card with the ace as 1. This is the **hard total**.
2. If the hand has at least one ace and `hard + 10 ≤ 21`, one ace can be 11: the hand is **soft** and the best total is `hard + 10`.
3. Otherwise the best total is the hard total.

This is O(n) in the number of cards, needs no search over combinations, and gives the soft/hard flag for free (the dealer's "hit soft 17" rule needs it).

Design decisions & patterns used

Decision	Why	Alternative rejected
`Card` is a game-agnostic **record** (rank + suit).	A deck of cards is reused by poker, bridge, solitaire. A king's blackjack value (10) is a *rule of this game*, not a fact about the card.	Putting `getValue()` returning 10 for K on `Card` — breaks every other game.
Blackjack value in `BlackjackScoring`, not a `BlackjackCard` subclass.	Records cannot be extended, and the value depends only on the rank. A function is simpler and keeps one card type in the shoe.	The course's `BlackjackCard extends Card` — also valid, and also keeps `Card` clean. Say both in the interview; the important point is the same.
`Deck<T>` is **generic**.	"Design a deck of cards" follow-up: Uno or tarot cards reuse the same shuffle/draw code.	A deck hard-wired to `Card`.
Strategy for players (`PlayerStrategy`) and dealer (`DealerPolicy`).	Human UI, bots and test scripts plug in; casino variants (S17 vs H17: dealer stands on soft 17 vs hits soft 17) are one line. Open/Closed principle (add new behaviour with new classes, without editing working code).	`if (isHuman) ... else ...` and `if (casino == X)` branches inside the game.
Factory methods `Deck.standard52()`, `Shoe.stacked(...)`, `DealerPolicy.standOnAll17()`.	Named constructors make intent obvious.	Big constructors with flags.
Randomness injected (`Random` passed into `Shoe`).	Seeded shuffles make demos and tests exact.	`Collections.shuffle(list)` with a hidden random source.
`Hand` answers with `hardTotal()`, `bestTotal()` and `isSoft()`.	The course's `Hand` returns *every* possible total (A+6 is both 7 and 17) and lets the caller choose. Because at most one ace can ever count as 11, the hard total plus the soft flag already carries all of that information, and most callers just want `bestTotal()`.	Returning a list of totals that each caller must filter.
Hand stores its **own bet**.	Split and double change the bet *per hand*, not per player.	One bet per player — breaks as soon as a player splits.
The game **validates** a strategy's choice (`canDouble`, `canSplit` passed in, and re-checked).	A buggy or malicious client (the program sending the player's choices) cannot double without money.	Trusting the client.

Honest weaknesses (and what a longer design would do). `BlackjackGame.playRound` owns the whole sequence of play *and* the payout rules. Each new option (surrender, side bets) adds another branch. A larger design would model the round as a **State** machine (a fixed set of states plus the allowed moves between them; the State pattern gives each state its own class — one class per state in the diagram above, like the vending machine in Chapter 14) and move payouts into a `PayoutTable`. Say this out loud; interviewers reward knowing where your design will strain.

Java implementation

Package `lld.ch17.blackjack`.

```java
// File: code/lld/ch17/blackjack/Suit.java
package lld.ch17.blackjack;

/** The four suits. A suit never affects a blackjack score, but a generic deck needs it. */
public enum Suit {
    CLUBS('C'), DIAMONDS('D'), HEARTS('H'), SPADES('S');

    private final char letter;

    Suit(char letter) { this.letter = letter; }

    public char letter() { return letter; }
}
```

```java
// File: code/lld/ch17/blackjack/Rank.java
package lld.ch17.blackjack;

/** Thirteen ranks with their face value (ace = 1, jack = 11, queen = 12, king = 13). */
public enum Rank {
    ACE("A", 1), TWO("2", 2), THREE("3", 3), FOUR("4", 4), FIVE("5", 5), SIX("6", 6),
    SEVEN("7", 7), EIGHT("8", 8), NINE("9", 9), TEN("10", 10),
    JACK("J", 11), QUEEN("Q", 12), KING("K", 13);

    private final String symbol;
    private final int faceValue;

    Rank(String symbol, int faceValue) { this.symbol = symbol; this.faceValue = faceValue; }

    public String symbol() { return symbol; }
    public int faceValue() { return faceValue; }
}
```

```java
// File: code/lld/ch17/blackjack/Card.java
package lld.ch17.blackjack;

/** A game-agnostic playing card: just a rank and a suit. Immutable, so it is safe to share. */
public record Card(Rank rank, Suit suit) {
    @Override public String toString() { return rank.symbol() + suit.letter(); }
}
```

```java
// File: code/lld/ch17/blackjack/Deck.java
package lld.ch17.blackjack;

  Balances: Carol=105 Dave=90
```

Reading the output. Part 1 shows the scoring: A+6 is soft 17, adding a 10 makes it a *hard* 17 (the ace dropped to 1), A+A+9 is soft 21. Part 2 uses a stacked shoe to force an exact scenario: Alice splits eights against a dealer 6, doubles both hands, and the dealer busts — she staked 40 chips and won 40. Part 3 shows insurance working as a hedge: Bob loses his main bet of 10 but the 5-chip insurance pays 10, so he breaks even. Part 4 is a seeded six-deck game: run it again and you get the same cards.

Concurrency & edge cases

- **One table = one thread.** A **thread** is one independent line of execution in a program; a server runs many side by side. A round is a strict sequence, so the simplest safe design runs each table's rounds on a single thread (or an actor/event loop — a single worker that processes incoming messages one at a time from its own queue) and funnels player commands into it. Many tables run in parallel; they share nothing except the wallet service.
- **Balances are shared across tables** in a real casino app. Move `debit`/`credit` into a wallet service with atomic operations — ones that happen as a single indivisible step no other thread can interrupt (a database transaction, i.e. a group of changes that all succeed or all fail, or `AtomicLong`/`synchronized` in memory; `synchronized` lets only one thread at a time run that code) and debit *before* dealing.
- **Odd antes and 3:2.** 3:2 on 5 chips is 7.5. We require even antes. Real casinos either round down or use smaller chip units — decide and state it.
- **Split aces.** Many casinos deal only one card to each split ace, and 21 after a split is *not* a blackjack (our `isBlackjack()` checks `fromSplit`).
- **Shoe exhaustion.** The cut card triggers a reshuffle *between* rounds; the shoe also refills if emptied mid-round. A stacked test shoe throws instead, so a wrong test fails loudly.
- **Player cannot afford a double/split.** The game passes `canDouble=false` and rejects the action if chosen anyway.
- **Dealer peek only on ace or ten.** If the up card is anything else the dealer cannot have blackjack, so there is no peek.

Extensions & follow-up questions

- **"Where would even money go?"** — It is the same as insurance for a player holding blackjack: insurance of half the ante plus a blackjack always nets exactly +1× the ante whatever the dealer has. Add `PlayerStrategy.takeEvenMoney(hand)` and, if accepted, settle that hand at 1:1 before the peek.
- **"Add surrender."** — New `Action.SURRENDER`, allowed only as the first decision; refund half the bet and end the hand.
- **"Several players at the table?"** — Already supported: the game iterates players in seat order, then the dealer plays once.
- **"Card counting detection / security?"** — Card counting is tracking which cards have gone to guess what is left. Shoe penetration (how deep into the shoe the cut card sits) already limits counting. Log every dealt card for audit (a later independent check of what happened); never send the hole card to clients until it is revealed.
- **"How would you test the dealer rule?"** — Stacked shoe + `DealerPolicy.hitSoft17()`: deal the dealer A+6 and assert it draws; with `standOnAll17()` assert it stands.
- **"Make the deck work for Uno."** — `Deck<UnoCard>` with its own factory; nothing else changes.

- **"Replace the round logic with a state machine."** — One class per state (Betting, Dealing, PlayerTurns, DealerTurn, Settled), each handling only the commands valid in that state; invalid commands are rejected by the current state.

Real-world example

Online casino tables (for example live-dealer blackjack products) separate exactly these concerns: a **shuffle/RNG service** that is certified and audited (gambling regulators, for example the UK Gambling Commission, require the random number generator to be independently tested), a **game engine** that enforces the table rules (number of decks, S17 or H17, payout 3:2 or 6:5 — printed on the physical table felt), and a **wallet** service that debits bets atomically. The rule variants are configuration (settings chosen at deploy time, not code), which is exactly why `DealerPolicy` is a strategy.

In the interview

30-second answer: "A generic `Card` (rank, suit) and a generic `Deck<T>`. A `Shoe` combines several decks and deals with an injected `Random`, plus a stacked constructor for tests. The blackjack value of a card lives in the game's scoring, not on `Card`. `Hand` scores itself: hard total with aces as 1, and it's soft if one ace can be 11 without busting. Player decisions and the dealer's hit rule are strategies. `BlackjackGame` runs the round: bets, deal, insurance and peek, player turns with hit/stand/double/split, dealer turn, settle 3:2, 1:1 or push."

How to spend 30–45 minutes: 5 min questions and rules → 5 min entities → 10 min class diagram (defend `Card` vs game value, hand-owned bet) → 15 min code `Hand` scoring and `playRound` → 5 min edge cases (split aces, insurance, money) and extensions.

Likely follow-ups with answers

- *"Why not an `int value` on `Card`?"* — Because value is game-specific; poker ranks aces high, bridge uses suits, blackjack makes K = 10.
- *"How do you compute the best hand value?"* — Hard total, then add 10 if there is an ace and it fits. At most one ace can be 11.
- *"How do you make the game testable?"* — Inject the randomness: seeded `Random` for repeatability, stacked shoe for exact scenarios.

Self-check

1. **Q:** Why does the `Hand` store the bet instead of the `Player`? **A:** After a split, one player has two hands with separate bets; after a double, only that hand's bet changes.
2. **Q:** A+A+9 — soft or hard, and what total? **A:** Hard 11 with aces as 1; one ace can be 11 → soft 21.
3. **Q:** When does the dealer peek? **A:** Only when the up card is an ace or a 10-value card — otherwise blackjack is impossible.
4. **Q:** What does insurance pay, and how much is it? **A:** 2:1. In this design (and the course) it is exactly half the ante; real casinos let you buy *up to* half.
5. **Q:** Is 21 after splitting a blackjack? **A:** No, a blackjack must be the original two-card hand.

TL;DR

- Keep `Card` / `Deck` generic; the game's value rule lives in the game (`BlackjackScoring`, or a `BlackjackCard` subclass in the course version).
- Hand value: hard total + 10 if an ace fits → soft. Blackjack = original two cards totalling 21.
- Strategies for player decisions and dealer rule; inject randomness; stacked shoe for tests.
- Round = bet → deal → (insurance + peek) → player turns → dealer turn → settle (3:2, 1:1, push).

Design Chess

Figure — A chess board in play (course diagram)

Problem & clarifying questions

Chess is a two-player strategy game on an 8×8 board of 64 squares. Each side starts with 16 pieces: **8 pawns, 2 rooks, 2 knights, 2 bishops, 1 queen, 1 king**. The goal is **checkmate**: attack the enemy king so that it has no legal escape. We design an **online** two-player chess game.

Question	Assumed answer
Full international rules?	Yes: every piece's moves, captures, check, checkmate, stalemate, castling, en passant, promotion.
How are sides chosen?	Randomly assigned white or black (`Game.withRandomSides`, with an injected `Random`); **white moves first**; players alternate.
Can players take moves back?	Not in a rated game (one that counts toward the players' official ratings; course requirement). We still support `undo()` for analysis mode and tests.
How can a game end?	Checkmate, stalemate (a draw), resignation, or forfeit.
Move log?	Yes — every move by both players is recorded.
Timers, rating, spectators, draw by repetition?	Out of scope; discussed in Extensions.
AI opponent?	Out of scope; a bot would be a `MoveStrategy` that picks from `legalMoves()`.

Requirements

Functional

1. Two players play one game; each is assigned a colour, white moves first, turns alternate.
2. A player moves one of **their own** pieces; the system rejects moves out of turn, moves a piece cannot make, and moves that would leave the mover's own king in check.
3. All international rules, including the special moves:
    - **Castling** — the king moves two squares toward a rook and the rook jumps over to the square the king crossed. Allowed only if neither piece has moved, the squares between are empty, the king is not in check, and the king does not pass through or land on an attacked square.

    - **En passant** ("in passing") — if a pawn advances two squares and lands beside an enemy pawn, that enemy pawn may capture it *as if it had moved only one square*, but only on the very next move.
    - **Promotion** — a pawn reaching the last rank becomes a queen, rook, bishop or knight (the player's choice).
4. Detect **check** (the king is attacked), **checkmate** (in check and no legal move — the attacker wins) and **stalemate** (not in check but no legal move — a draw).
5. Support **resignation** (the player gives up) and **forfeit** (the player loses without choosing to, for example by leaving or timing out); record the result.
6. Keep a **log** of every move.

Non-functional

- Adding a new piece type (for a chess variant) should not touch existing pieces (Open/Closed).
- Legality checks must be correct first; speed is a secondary concern for a two-human game.
- Online play: the game object must be safe when two player connections call it concurrently (at the same time, from different threads).

Use cases

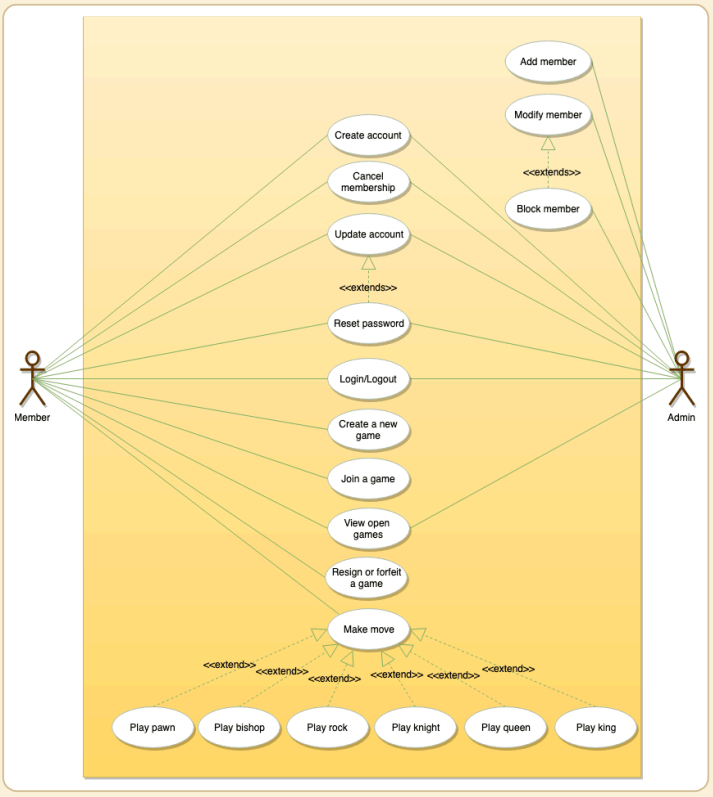

Figure — Chess use cases for Member (player) and Admin, with "Make move" extended by each piece type (course diagram)

In the figure above there are two actors:

- **Player** (a registered member) — creates or joins a game, views open games, **makes moves**, resigns or forfeits, and manages their account.
- **Admin** — adds, modifies, or blocks (bans) members.

The key use cases are **Player moves a piece** (extended per piece type — "Play pawn", "Play knight"... — which is exactly the polymorphism in our `Piece` hierarchy), **Resign or forfeit**, **Register/cancel membership**, and **Update game log** (every move is appended).

Activity: make a move

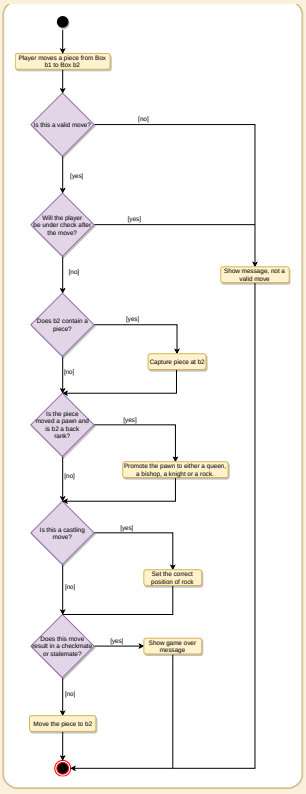

Figure — Activity diagram for making a move: validate, check self-check, capture, promotion, castling, and checkmate/stalemate (course diagram)

The figure above shows the full decision chain for one move. We follow the same order in `Game.move` and `Game.play`:

1. Is the move valid for that piece? If not, show "not a valid move".
2. Would the mover's king be in check afterwards? If yes, reject.
3. Does the destination hold a piece? Capture it.
4. Is it a pawn reaching the back rank? Promote it.
5. Is it castling? Move the rook as well.
6. Does the move produce checkmate or stalemate? Then the game is over.

Core entities

Class	Responsibility
`Color` (enum)	WHITE/BLACK and `opposite()`.
`Position` (record)	A square (file a–h, rank 1–8). Validates bounds; parses "e4". The course calls this a *Box*.
`Piece` (abstract — cannot be created directly, only through subclasses; sealed — only listed subclasses allowed)	Colour + `targets(board, from)`: where it can move by its own rules. `attacks(...)` for check detection.
`King`, `Knight`, `Pawn`	Step pieces and the pawn's special forward/diagonal rule.
`SlidingPiece` → `Rook`, `Bishop`, `Queen`	Share one "slide until blocked" loop; each subclass only lists its directions.
`Board`	8×8 grid of pieces; `copy()`, `kingOf(color)`, `isAttacked(square, byColor)`, `render()`. No turn or history knowledge.
`Move` (record) + `MoveType` (enum)	A move as data: from, to, type (NORMAL, CASTLE_KINGSIDE, CASTLE_QUEENSIDE, EN_PASSANT, PROMOTION), promotion piece.
`CastlingRights` (record)	The four castling permissions; how they change after a move.
`Rules`	Stateless (keeps no data between calls) rules engine: pseudo-legal moves (allowed by piece movement, before the king-safety check), legal moves (king-safety filter), special moves, `apply(board, move)`, `isInCheck`.
`Game`	Turn, status, winner, en passant square, castling rights, move log, undo (Command + Memento — patterns explained below), resign, forfeit, random side assignment. Thread-safe (correct even when several threads call it at once).
`Player` (record), `GameStatus` (enum), `IllegalMoveException`	Supporting types.

Class diagram

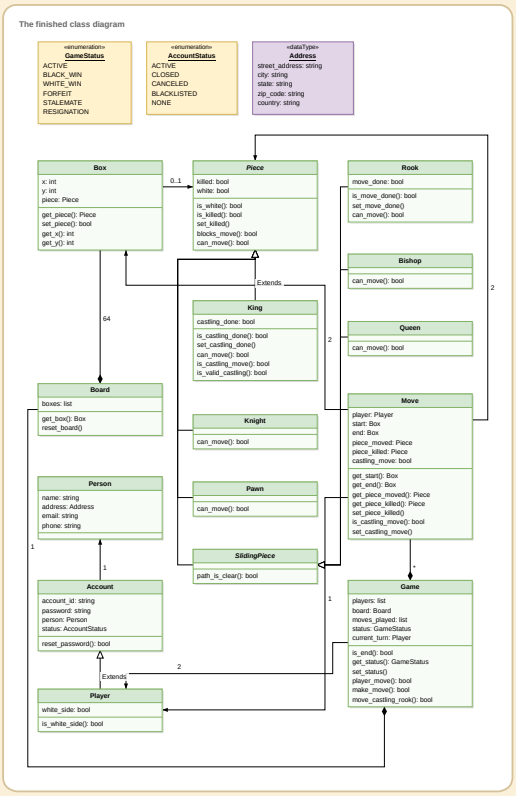

Figure — Course class diagram: Box, Board, Piece hierarchy with SlidingPiece, Move, Player, Account, Game, GameStatus (course diagram)

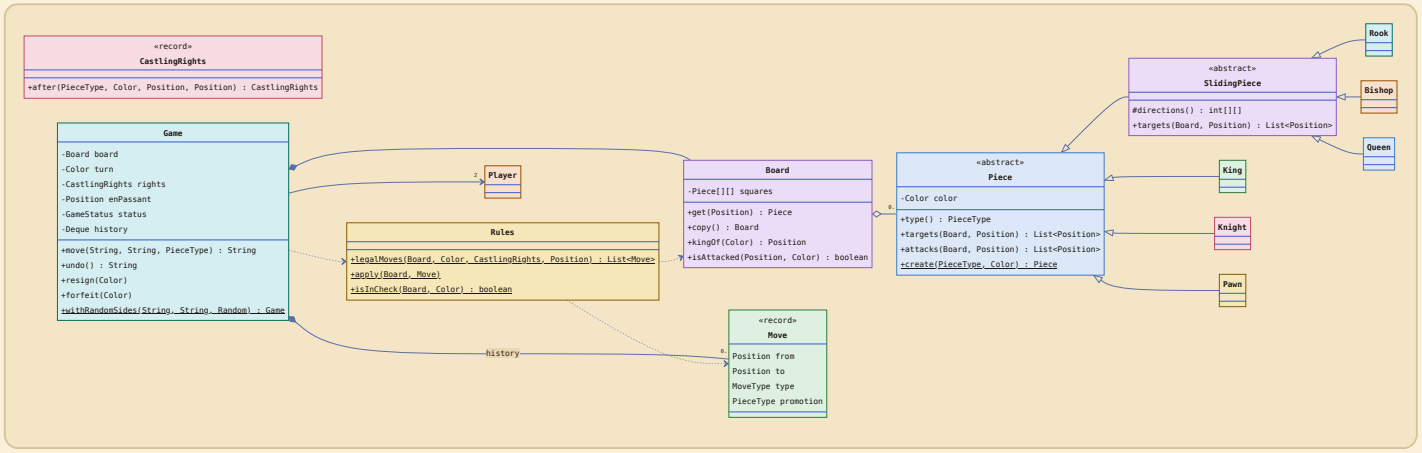
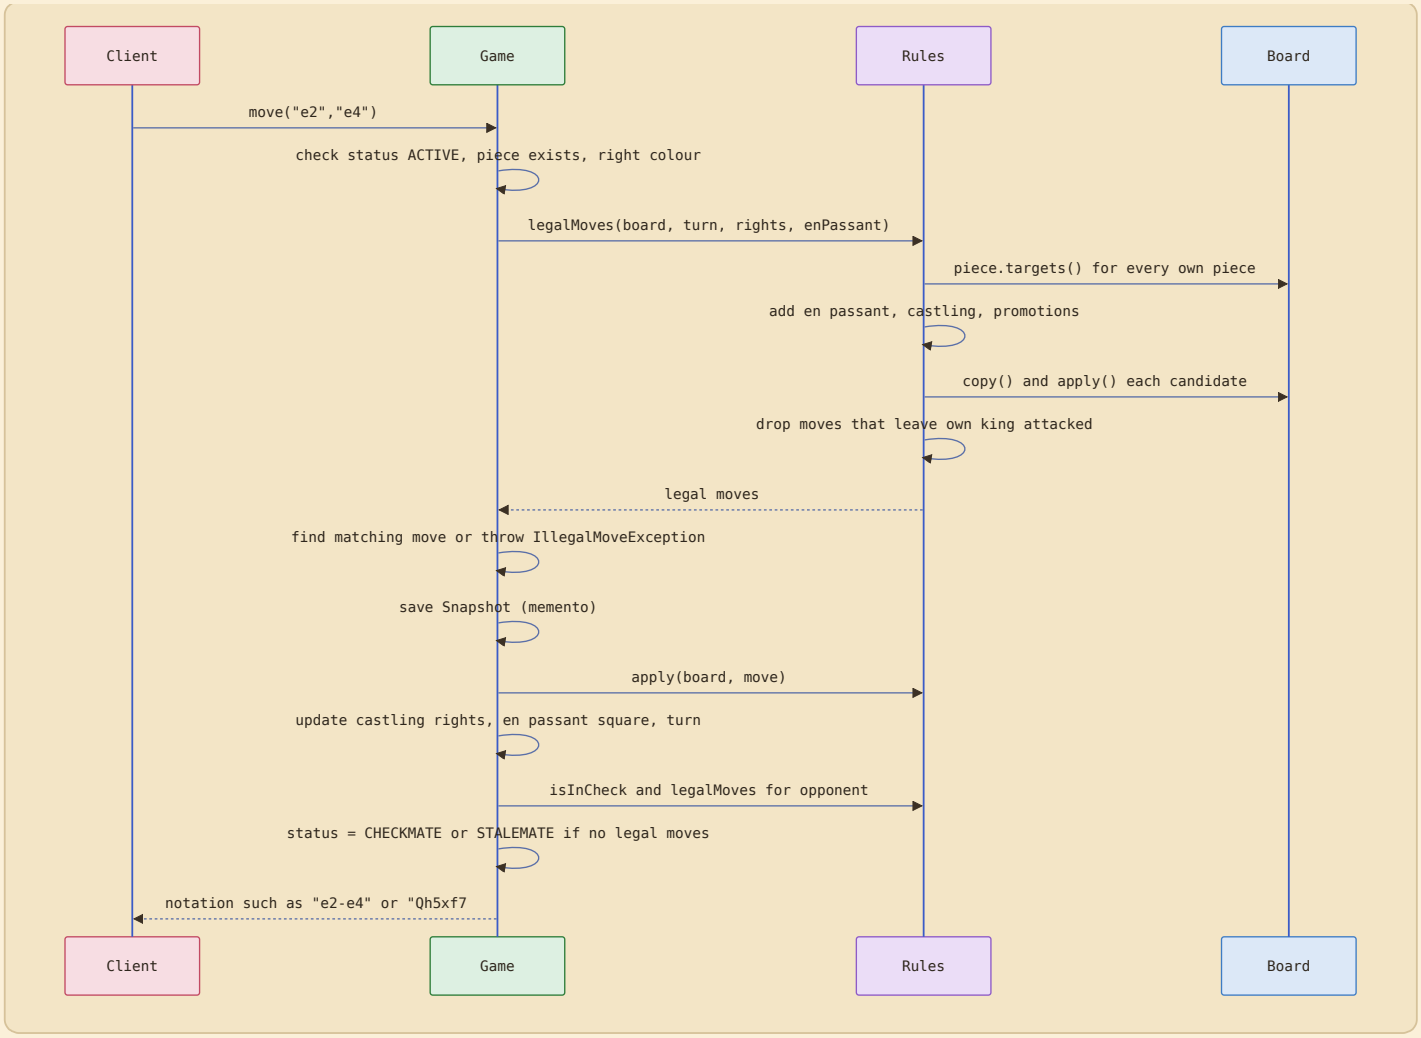
In the course model (figure above), a `Board` is **composed** of 64 `Box`es; a `Box` refers to at most one `Piece` with a *plain association* (not composition), because capturing a piece takes it off the board without destroying it — which is what makes a move log replayable. `Piece` is abstract with `can_move(board, start, end)`; `SlidingPiece` sits between `Piece` and rook/bishop/queen so the "path is clear" check is written once, while knight and king extend `Piece` directly. A `Move` is a *record* of what happened (player, start and end box, piece moved, piece captured, castling flag). `Game` owns the board and the list of moves and refers to the two players (they exist before and after the game). The course's `GameStatus` has ACTIVE, BLACK_WIN, WHITE_WIN, FORFEIT, STALEMATE, RESIGNATION.

Our Java design keeps that shape and fixes the two limits the course itself points out: (1) its pieces decide legality from the board alone, so history-based rules (castling rights, en passant) have nowhere to live, and (2) checkmate/stalemate are not detected. We add `Rules` (which sees history through `CastlingRights` and the en passant square) and make `Move` carry a `MoveType`, so a single move can move two pieces (castling) or remove a piece that is not on the target square (en passant).

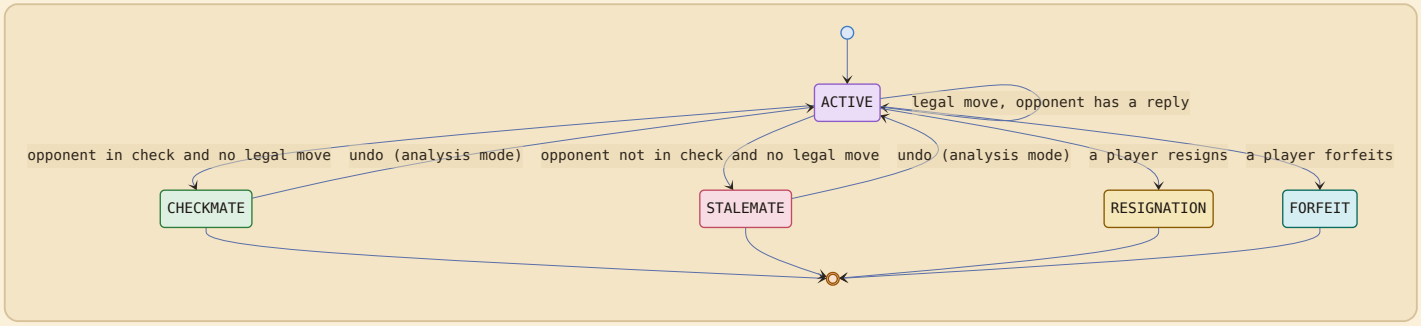


Key flows

Making a move



Game status



How check, checkmate and stalemate are detected (the "reasonable depth" answer)

1. **Pseudo-legal moves** — every move allowed by the pieces' movement rules, plus castling, en passant and promotions.
2. **Legal moves** — for each pseudo-legal move, apply it to a *copy* of the board and keep it only if the mover's king is **not attacked** afterwards. This one filter handles pins, moving into check, and ignoring a check, with no special cases.
3. **Is the king attacked?** Ask every enemy piece for the squares it attacks (`attacks(...)`); pawns attack diagonally even onto empty squares, which is why `Pawn` overrides `attacks`.
4. After a move, look at the **opponent**: if it has **zero legal moves**, it is **checkmate** when its king is in check, otherwise **stalemate**.

This is a one-ply (one move deep) search, which is all the *rules* need. Searching deeper is what a chess *engine* does to choose good moves — not required for enforcing rules.

Cost: at most ~200 pseudo-legal moves, each checked with an attack scan over ≤16 pieces — trivial for a human game. A production engine would use bitboards (each piece type's squares packed into one 64-bit number, so set

operations become fast bit tricks) and incremental attack maps (attacked squares updated per move instead of recomputed); mention it only if asked.

Design decisions & patterns used

Decision	Why	Alternative rejected
Polymorphic pieces (`targets` overridden per piece), **Template-like** `SlidingPiece`.	Each piece's rule lives in its own class; the blocked-path loop is written once for three pieces.	One giant `switch (pieceType)` in the board.
Sealed hierarchy (`sealed ... permits`).	The set of chess pieces is closed; the compiler knows all subclasses, so `switch` on type can be exhaustive (the compiler checks every case is handled).	Open hierarchy — fine too for variants; say so.
Pieces are **immutable**; `Board.copy()` copies references (pointers to the same piece objects) only.	Trial moves and snapshots are cheap and safe.	Mutable pieces with `hasMoved` flags — then undo must restore every flag.
History-based rules in `Rules` / `Game`, not in pieces.	Castling rights and en passant depend on earlier moves. The course notes that a piece seeing only the board cannot know this.	Letting `King` look up history — couples a piece to the game log.
`Move` carries a `MoveType`.	One move can move two pieces (castling) or capture off-square (en passant).	Special-casing in `Game` (the course's `move_castling_rook`), which breaks "rules live in one place".
Command + Memento for undo. `Move` is the command (an action stored as an object); `Snapshot` is the memento (a saved copy of an object's state that can be restored later) of the state before it.	Restoring a snapshot is always correct, even for promotion/castling/en passant, with no inverse logic.	Pure Command with `undo()` per move type — works, but every special move needs a hand-written inverse, a common bug source.
Factory method `Piece.create(type, color)`.	Used by board set-up and promotion.	`new` calls scattered around.
`Game` methods are `synchronized`.	Two player connections may call `move` / `resign` at the same time.	No locking — race (result depends on which thread runs first) between a move and a resignation.

Memento vs incremental undo — trade-off. A snapshot of an 8×8 reference array is 64 references (~0.5 KB): nothing for a human game (a few hundred moves). An engine searching millions of positions would instead store only what the move changed (captured piece, old castling rights, old en passant square) and reverse it. Know both.

Java implementation

Package `lld.ch17.chess`.

```java
// File: code/lld/ch17/chess/Color.java
package lld.ch17.chess;

public enum Color {
    WHITE, BLACK;

    public Color opposite() { return this == WHITE ? BLACK : WHITE; }
}
```

```java
// File: code/lld/ch17/chess/PieceType.java
package lld.ch17.chess;

public enum PieceType {
    KING('K'), QUEEN('Q'), ROOK('R'), BISHOP('B'), KNIGHT('N'), PAWN('P');

    private final char letter;

    PieceType(char letter) { this.letter = letter; }

    public char letter() { return letter; }
}
```

```java
// File: code/lld/ch17/chess/Position.java
package lld.ch17.chess;

/** A square. file 0..7 = a..h, rank 0..7 = 1..8. Immutable value object. */
public record Position(int file, int rank) {
    public Position {
        if (!onBoard(file, rank)) throw new IllegalArgumentException("off board: " + file + "," + rank);
    }

    public static boolean onBoard(int file, int rank) { return file >= 0 && file < 8 && rank >= 0 && rank < 8; }

    /** Parses algebraic notation such as "e4". */
    public static Position of(String sq) {
        if (sq == null || sq.length() != 2) throw new IllegalArgumentException("bad square: " + sq);
        return new Position(sq.charAt(0) - 'a', sq.charAt(1) - '1');
    }

    @Override public String toString() { return "" + (char) ('a' + file) + (rank + 1); }
}
```

```java
// File: code/lld/ch17/chess/Piece.java
package lld.ch17.chess;

import java.util.List;

/**
 * Every piece answers "which squares can I reach from here on this board?" in its own way
 * (polymorphism). Pieces are immutable: moving a piece moves the reference, so a board copy is cheap
 * and undo can simply restore an old board. Rules that need history (castling rights, en passant)
 * live in Rules/Game, not here.
 */
public abstract sealed class Piece permits King, Knight, Pawn, SlidingPiece {
    private final Color color;

    protected Piece(Color color) { this.color = color; }

    public Color color() { return color; }

  Status: FORFEIT, winner WHITE
```

Reading the output. Part 1 shows validation (out of turn, illegal king jump, blocked rook), then Scholar's mate (`Qh5xf7#`), and `undo()` returning the game to ACTIVE with white to move. Part 2 plays en passant (`e5xd6 e.p.` removes the black pawn from d5), kingside castling (`O-O`), and a capturing promotion that gives check

(`c7xd8=Q+`); black's attempt to ignore the check is rejected, and the king captures the new queen. Part 3 is the famous 10-move stalemate composed by Sam Loyd: black is not in check but has no legal move, so the game is a draw. Part 4 shows the castling guards: white may not castle through f1 while the a6 bishop attacks it, black may not castle out of check, and once the check is blocked both sides castle. Part 5 assigns sides at random (seeded) and shows resignation and forfeit.

Concurrency & edge cases

- **Two players, one game.** `Game`'s public methods are `synchronized`, so a move and a resignation cannot interleave (have their steps mixed together). For a server with thousands of games, each game gets its own lock (the object's monitor — the built-in lock every Java object carries, which `synchronized` uses) — games do not block each other.
- **Moving out of turn / game over / empty square** — rejected with a clear message before any rule work.
- **Pins and discovered checks** (a *pin* is a piece that cannot move because it shields its king; a *discovered check* is a check revealed when a blocking piece moves away) — handled automatically by the "apply to a copy and test the king" filter.
- **Castling through check** — explicitly tested for the squares the king crosses and lands on; the rook's crossing square on the queenside (b1/b8) may be attacked — that is legal. Section 4 of the output shows both refusals with their reason (`Rules.whyCannotCastle`): passing through an attacked f1, and castling while in check; once the check is blocked the same castle is accepted.
- **Castling rights** are lost when the king moves, when that rook moves, or when that rook is **captured** on its corner (we check both `from` and `to`).
- **En passant expires** after one move: the square is reset on every move unless a pawn just advanced two.
- **Promotion without a choice** defaults to a queen; underpromotion (knight, rook, bishop) is supported.
- **Not implemented, but should be named:** draw by threefold repetition (the same position occurs three times), the 50-move rule (50 moves each with no capture or pawn move), insufficient material (e.g. king vs king), clocks/timeouts, draw offers.

Extensions & follow-up questions

- **"Add threefold repetition."** — Keep a `Map<PositionKey, Integer>` where the key is (board, side to move, castling rights, en passant square). Production engines hash this (turn it into one compact number for quick comparison) with Zobrist hashing, which combines a random number per piece-and-square. Three occurrences → draw.
- **"Add a 50-move rule."** — A half-move (one player's move) clock reset on every pawn move or capture; at 100 half-moves either player may claim a draw.
- **"Add chess clocks."** — A `Clock` per player; the server stamps time on each move; a flag-fall (a player's time running out) ends the game (Observer — listeners register once and are told about every change — notifies both clients).
- **"Add an AI player."** — A `MoveStrategy` that picks from `legalMoves()`; a real one runs minimax (search ahead, assuming you pick your best move and the opponent picks the move worst for you) with alpha-beta pruning (skipping branches that provably cannot change the answer).
- **"Support Chess960 (a variant with a shuffled back row) or a new piece."** — New `Piece` subclass (e.g. an Archbishop = bishop + knight) and a different starting-position factory; existing pieces are untouched.
- **"Spectators and UI updates."** — Observer: `GameListener.onMove(notation)`. The course mentions a `GameController` (takes input, calls `Game`) and a `GameView` (redraws) — that is the MVC (Model–View–Controller: data, display and input handling kept in separate classes) split from Chapter 11.
- **"Why is `Position` a record?"** — It is a value: two `e4`s are equal. Records give `equals`/`hashCode` (the methods Java uses to decide if two objects are equal and to place them in hash tables) for free, which `List.contains` relies on.

Real-world example

Online chess sites such as Lichess and Chess.com treat the **server** as the source of truth (the one copy whose data wins whenever copies disagree): the board in your browser is only a view, and a move counts only after the server has accepted it as legal. Games are exported in PGN (Portable Game Notation — a move log like ours) and positions in FEN (Forsyth–Edwards Notation — one line describing the board, side to move, castling rights and en passant square, i.e. exactly the fields of our `Snapshot`). "Takeback" is offered only when the opponent agrees, and then the server undoes the move — the same `undo()` our `Game` exposes.

In the interview

30-second answer: "`Board` is an 8×8 grid of immutable `Piece`s. `Piece` is abstract with `targets(board, from)`; each piece overrides it, and rook/bishop/queen share a `SlidingPiece` loop. A stateless `Rules` class generates pseudo-legal moves, adds castling, en passant and promotion using history kept in `Game` (castling rights, en passant square), and filters out moves that leave your king attacked. After each move, if the opponent has no legal move, it's checkmate if they're in check, otherwise stalemate. `Game` handles turns, status, a move log, and undo via Command plus Memento."

How to spend 30–45 minutes: 5 min requirements → 5 min entities → 10 min class diagram (piece hierarchy, why history lives outside pieces) → 15 min code `Piece`/`SlidingPiece`/`Pawn` and the legal-move filter → 5–10 min checkmate/stalemate, special moves, concurrency.

Likely follow-ups with answers

- *"How do you detect checkmate?"* — No legal moves and in check. Legal = pseudo-legal filtered by "king not attacked after the move".
- *"Where does castling live?"* — In `Rules`, because it moves two pieces and depends on history; `MoveType.CASTLE_*` tells `apply` to move the rook too.
- *"Why is `Box -> Piece` not composition?"* — Removing a piece from a square doesn't destroy the piece; it goes to the captured list or the log.
- *"How is undo safe with promotion?"* — The memento stores the whole prior board, so undo simply puts the old pawn back.

Self-check

1. **Q:** Why does `Pawn` override `attacks()`? **A:** A pawn moves straight but attacks diagonally, even onto empty squares; check detection needs the attack squares.
2. **Q:** What is the difference between checkmate and stalemate? **A:** Both mean no legal move; checkmate is while in check (loss), stalemate is while not in check (draw).
3. **Q:** When is en passant allowed? **A:** Only on the move immediately after an enemy pawn advanced two squares past your pawn's attack square.
4. **Q:** Name three conditions for castling. **A:** King and that rook have not moved; squares between empty; king not in check, not passing through or landing on an attacked square.
5. **Q:** Why are pieces immutable in this design? **A:** Board copies for trial moves and undo snapshots can share pieces safely.

TL;DR

- Polymorphic `Piece.targets()`; `SlidingPiece` shares the path loop; pawn overrides `attacks()`.
- `Rules`: pseudo-legal → add castling / en passant / promotion → drop moves leaving own king attacked.
- No legal moves: in check = checkmate, else stalemate.
- History-dependent rules live in `Game`/`Rules`, not in pieces. Undo = Command + Memento. `synchronized` game for online play.

Design Tic-Tac-Toe

Problem & clarifying questions

Tic-tac-toe is played on a grid. Players take turns placing their mark (X or O). The first to fill a whole **row, column or diagonal** wins; if the board fills with no winner, it is a **draw**. The classic game is 3×3 with two players; interviewers love to generalise it to **N×N** and ask for **fast win detection**.

Question	Assumed answer
Board size?	Any N ≥ 3 (classic N = 3).
Win condition?	A full line of N marks: any row, column, or one of the two main diagonals.
Players?	Two by default; the design allows more (each with its own mark).
Human or computer?	Both: each player has a pluggable **move strategy** (human input, random bot, rule-based bot, scripted test).
Invalid moves?	Rejected (occupied or off-board); the same player tries again.
UI?	Console rendering only; the engine exposes state for any UI.

Requirements

Functional

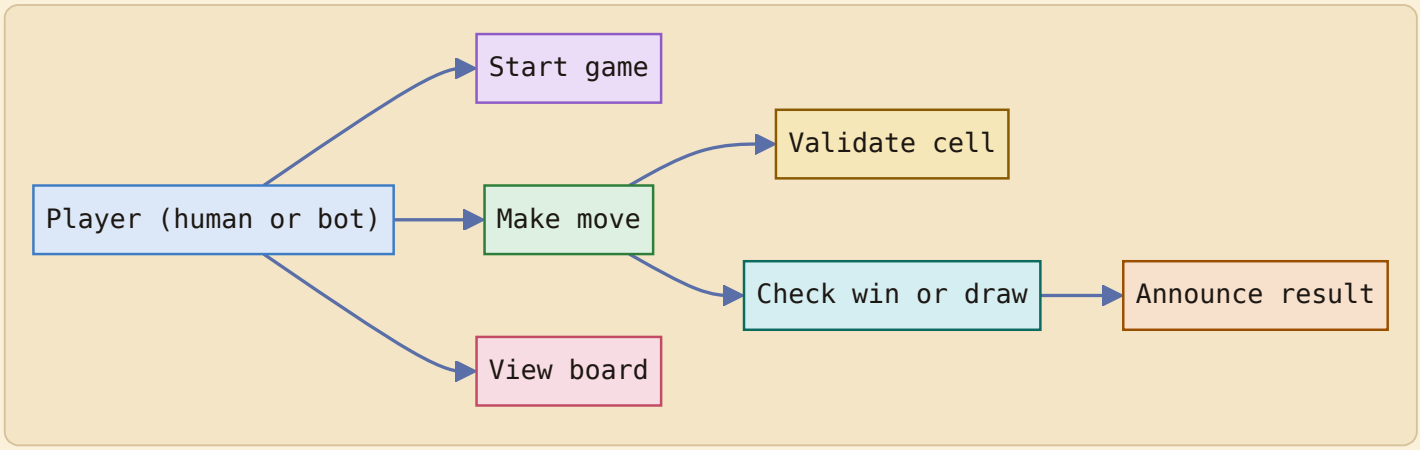
1. Create an N×N board and a game with two (or more) players, each with a unique mark.
2. Players take turns; the current player chooses an empty cell.
3. Validate moves: inside the board and empty.
4. After each move, detect a **win** (the mover completed a line) or a **draw** (board full).
5. Announce the result and show the board.

Non-functional

- Win check in **O(1)** per move (not a full $O(N^2)$ board scan).
- New player types (AI levels, network player) without touching `Game` (Open/Closed).
- Deterministic tests: random bots take a seeded `Random`; scripted players replay fixed moves.
- Separate games must not share state (many games can run at once on a server).

Use cases

Actors: **Player** (human or bot). Use cases: *start game* (choose N and players), *make move*, *view board*, *see result*. A system actor (the `Game`) validates moves, switches turns and declares the result.

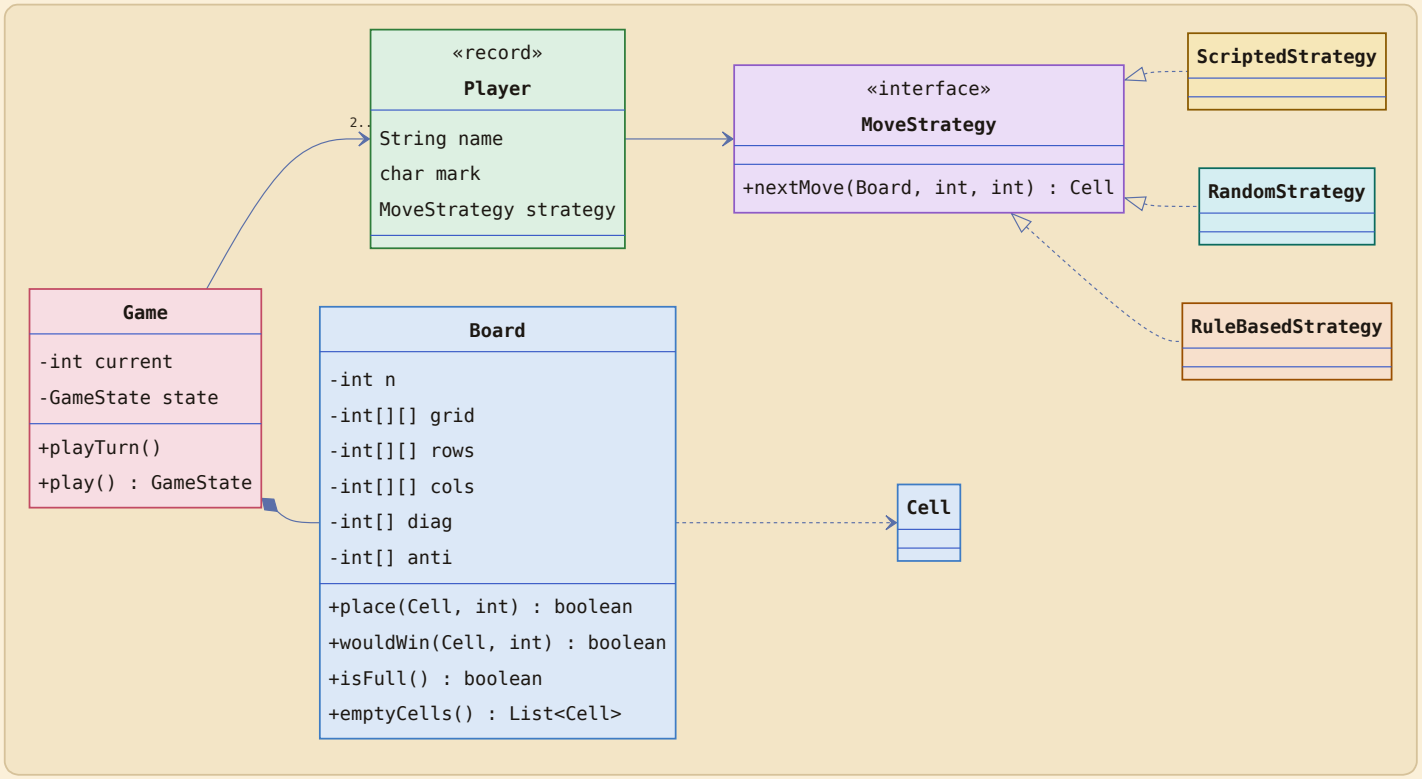


Core entities

Class	Responsibility
`Cell` (record)	Row + column of a square.
`Board`	The grid plus **per-player line counters**; `place` returns "did this win?" in O(1); `wouldWin` for bots; `isFull`, `emptyCells`, `render`.
`MoveStrategy` (interface)	Chooses the next cell. Implementations: `ScriptedStrategy`, `RandomStrategy`, `RuleBasedStrategy`.
`Player` (record)	Name, mark, strategy.
`GameState` (enum)	IN_PROGRESS, WON, DRAW.
`Game`	Turn order, move validation, state, winner, result.

Class diagram

There is no course lesson for this problem; it comes from the *awesome-low-level-design* problem set. That statement asks for: a 3×3 grid; two players taking turns with X and O; three in a row, column or diagonal wins; a full board with no winner is a draw; a way to display the grid and take moves; turn handling and move validation; announcing the winner or the draw. All of these are covered (the board size is generalised to N×N).



Key flows

O(1) win detection — how it works

A naive win check scans every row, column and diagonal after each move: O(N²). But a move at `(r, c)` can only complete **row r, column c, and (maybe) the two diagonals**. So we keep counters:

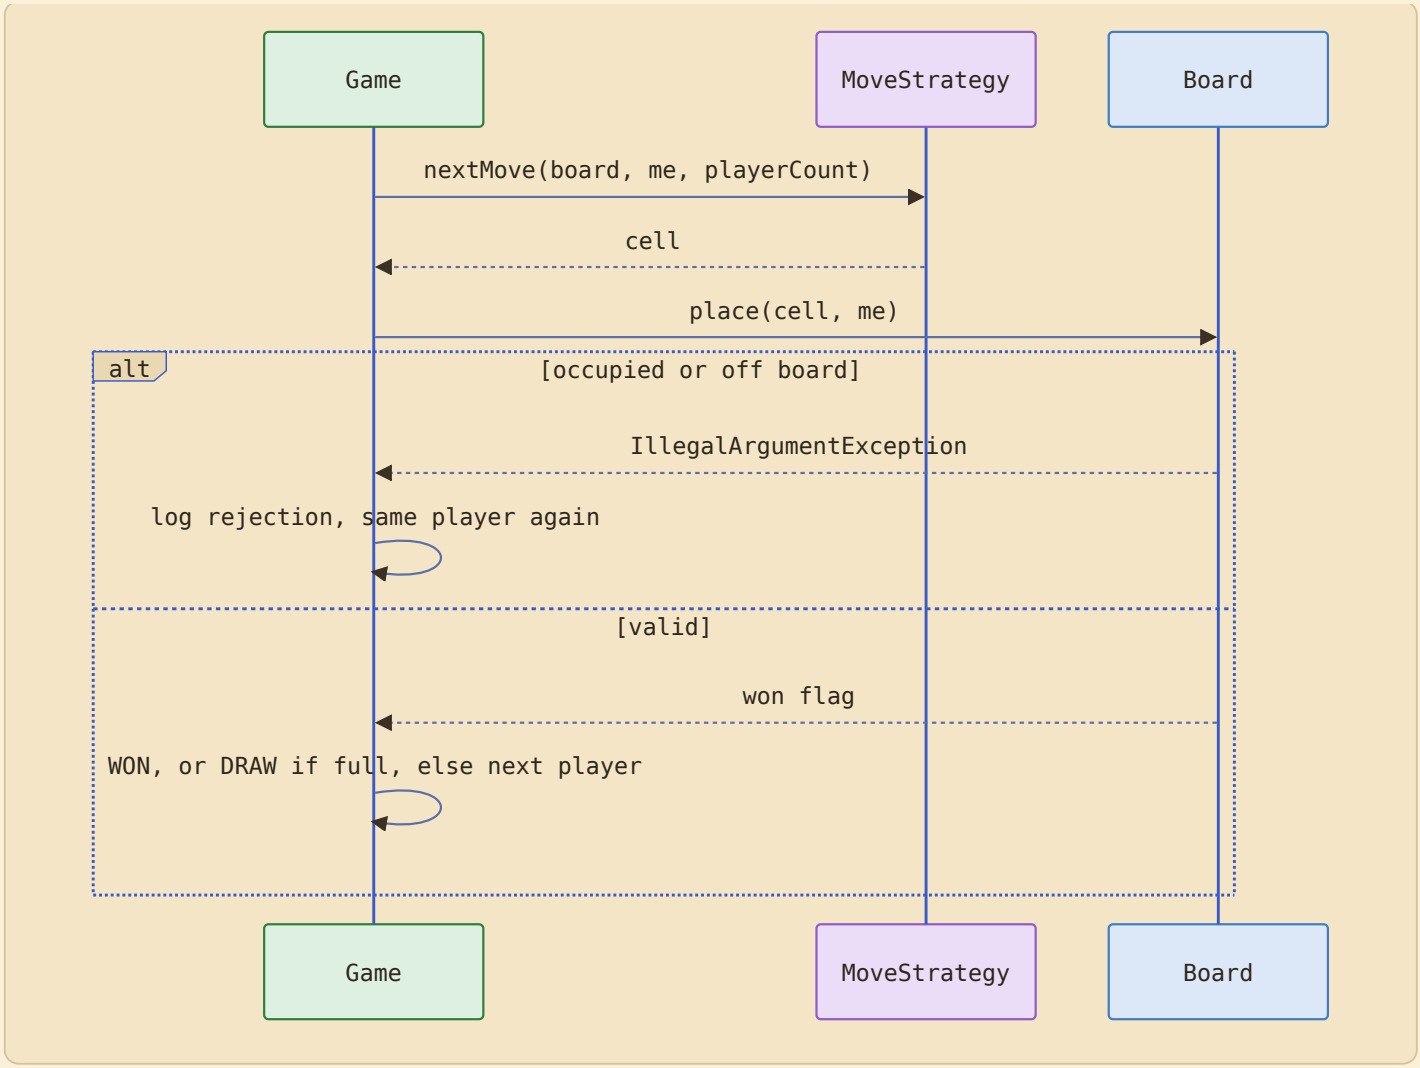
1. `rows[p][r]` = how many marks player `p` has in row `r`; `cols[p][c]` likewise.
2. `diag[p]` counts marks on the main diagonal (`r == c`); `anti[p]` on the anti-diagonal (`r + c == N-1`).
3. When player `p` places at `(r, c)`, increment the counters that cell belongs to.
4. If any of them reaches **N**, player `p` owns the whole line — a win. Because only `p`'s marks increment `p`'s counters, no check for opponents' marks is needed.

Four increments and four comparisons: **O(1) time**, **O(P·N) memory** for P players.

> **The 2-player trick you may see online:** one shared counter per line, +1 for X and −1 for O; `|count| == N` means a win. It uses half the memory but only works for exactly two players. Our per-player counters work for any number of players.

The same counters give a free **"would this move win?"** check: an empty cell wins for `p` if any of its lines already has `N-1` of `p`'s marks. The rule-based bot uses it to *win* if possible and *block* the opponent otherwise.

One turn



Game
MoveStrategy
Board
nextMove(board, me, playerCount)
cell
place(cell, me)
alt

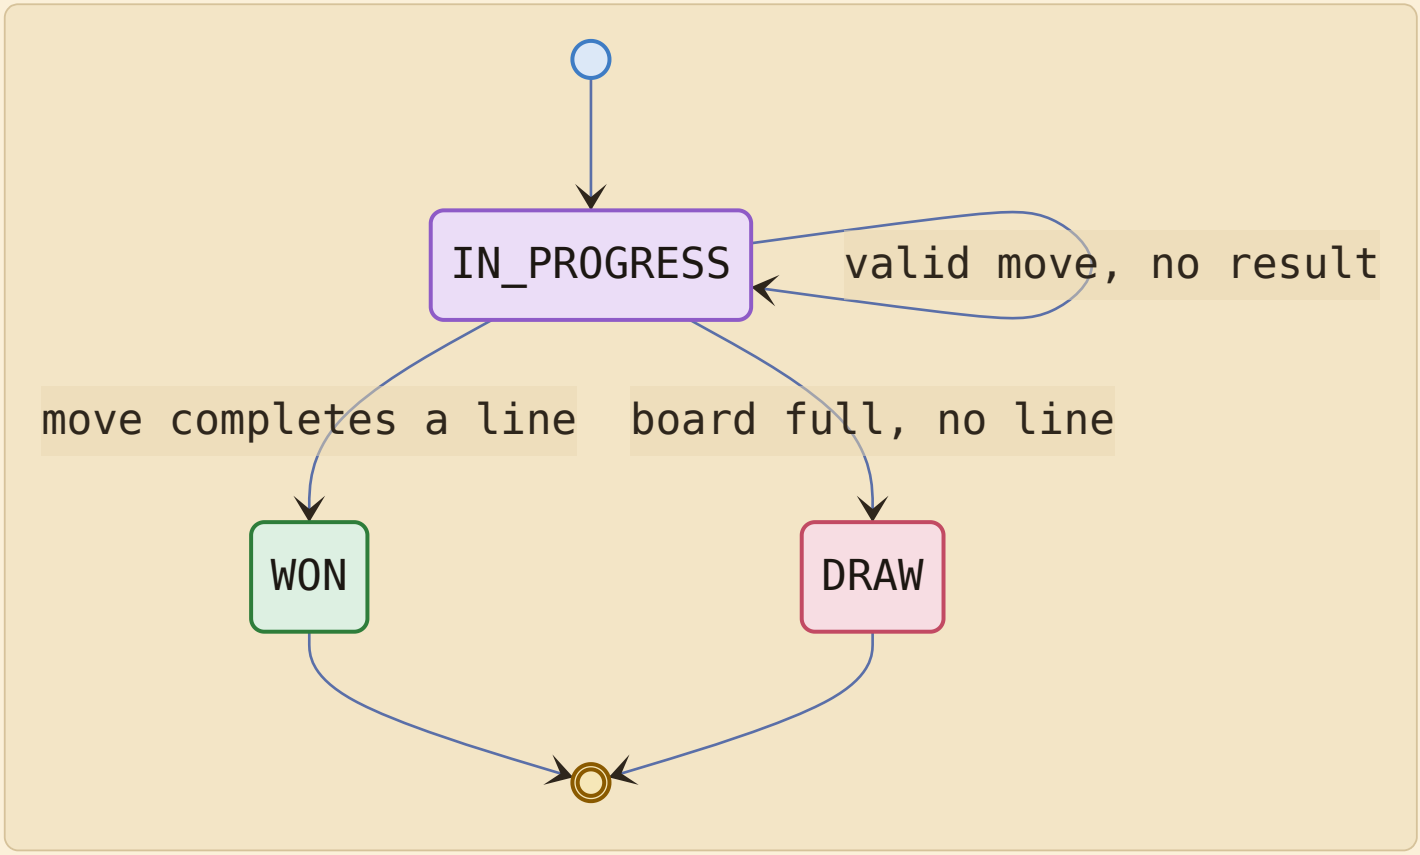
IllegalArgumentException
log rejection, same player again
[valid]
won flag
WON, or DRAW if full, else next player
Game
MoveStrategy
Board



IN_PROGRESS
valid move, no result
move completes a line
board full, no line
WON
DRAW

Design decisions & patterns used

Decision	Why	Alternative rejected
Strategy for player moves.	Human, random, rule-based, network or minimax players plug in; `Game` never changes.	`if (player.isComputer())` branches in `Game`.
Counters inside `Board` (not a separate "WinChecker" that scans).	O(1) check, kept next to the data it summarises.	Scanning all lines each move — O(N²) and duplicated for "would win".
Board returns "won?" from `place`.	The only moment a win can appear is right after a move.	Separate `checkWinner()` that the caller might forget to call.
Invalid move → exception from `Board`, caught by `Game`.	The board protects its invariant (a fact that must always stay true, e.g. one mark per cell); the game decides the policy (retry).	Silently ignoring a bad move.
Seeded `Random` injected into `RandomStrategy`.	Repeatable demos/tests.	`Math.random()` inside the bot.
Players as a list + index `current = (current+1) % size` (`%` is remainder, so the index wraps back to 0).	Works for any number of players.	Hard-coded X/O toggling.

Java implementation

Package `lld.ch17.tictactoe`.

```java
// File: code/lld/ch17/tictactoe/Cell.java
package lld.ch17.tictactoe;

public record Cell(int row, int col) {
    @Override public String toString() { return "(" + row + "," + col + ")"; }
}
```

```java
// File: code/lld/ch17/tictactoe/Board.java
package lld.ch17.tictactoe;

import java.util.ArrayList;
import java.util.List;

/**
 * N x N grid plus per-player line counters, so "did that move win?" is O(1) instead of O(N^2).
 * rows[p][r] = how many marks player p has in row r. Same idea for columns and the two diagonals.
 * A line is won when one player's count reaches N (other players' marks make that impossible).
 */

package lld.ch17.tictactoe;

import java.util.List;
import java.util.Random;

public final class Main {
    public static void main(String[] args) {
        System.out.println("== 1. 3x3 scripted game (with one invalid move) ==");
        Player x = new Player("Xena", 'X', new ScriptedStrategy(List.of(
                new Cell(0, 0), new Cell(1, 1), new Cell(2, 2))));
        Player o = new Player("Omar", 'O', new ScriptedStrategy(List.of(
                new Cell(0, 0), new Cell(0, 1), new Cell(0, 2))));   // first one is already taken
        new Game(3, List.of(x, o), System.out::println).play();

        System.out.println("\n== 2. 3x3 rule-based bot vs seeded random bot (seed 7) ==");
        new Game(3, List.of(new Player("Bot", 'X', new RuleBasedStrategy()),
                new Player("Rand", 'O', new RandomStrategy(new Random(7)))), System.out::println).play();

        System.out.println("\n== 3. 4x4 rule-based vs rule-based ==");
        new Game(4, List.of(new Player("A", 'X', new RuleBasedStrategy()),
                new Player("B", 'O', new RuleBasedStrategy())), line -> { if (!line.startsWith("  A") &&
!line.startsWith("  B")) System.out.println(line); }).play();

        System.out.println("\n== 4. 5x5 with three players (two random, seeds 1 and 2; one rule-based) ==");
        new Game(5, List.of(new Player("P1", 'X', new RandomStrategy(new Random(1))),
                new Player("P2", 'O', new RandomStrategy(new Random(2))),
                new Player("P3", 'Z', new RuleBasedStrategy())), line -> { if (!line.startsWith("  P"))
System.out.println(line); }).play();
    }
}
```

Output:

```
== 1. 3x3 scripted game (with one invalid move) ==
  Xena (X) -> (0,0)
  Omar tried (0,0): rejected (cell (0,0) is already taken), try again
  Omar (O) -> (0,1)
  Xena (X) -> (1,1)
  Omar (O) -> (0,2)
  Xena (X) -> (2,2)
    X O O
    . X .
    . . X
  Result: Xena wins

== 2. 3x3 rule-based bot vs seeded random bot (seed 7) ==
  Bot (X) -> (1,1)
  Rand (O) -> (2,0)
  Bot (X) -> (0,0)
  Rand (O) -> (1,0)
  Bot (X) -> (2,2)
    X . .
    O X .
    O . X
  Result: Bot wins

== 3. 4x4 rule-based vs rule-based ==
    O O X X
    O O X X
    X X X O
    O O O X
  Result: draw

== 4. 5x5 with three players (two random, seeds 1 and 2; one rule-based) ==
    Z Z Z O O
    X O X Z X
    X X Z O O
    Z O O X O
    Z X X X Z
  Result: draw
```

Reading the output. Game 1 shows the retry after an invalid move and a diagonal win found by the O(1) counters. Game 2: the rule-based bot takes the centre, then a corner, and completes the diagonal against a seeded random bot (no block was needed: the random bot's two O's in column 0 were already blocked by the X in the corner). Game 3: two rule-based bots on 4×4 draw (the move lines are filtered out of the log for brevity). Game 4 runs the same counters with three players on 5×5 (a draw).

Concurrency & edge cases

- **Many games on one server:** each `Game` owns its own `Board`, so games share nothing. Keep them in a `ConcurrentHashMap<gameId, Game>` (a hash map that many threads can read and write safely at once) and process each game's moves one at a time (per-game lock or single-threaded actor).
- **Two clicks at once from the same game:** make `playTurn`/a `makeMove(player, cell)` method `synchronized` and check that the caller is the current player.
- **Edge cases:** move after game over (rejected with `IllegalStateException`, Java's standard "not allowed right now" error); off-board or occupied cell (rejected, same player retries); a scripted strategy running out of moves (returns `null` → fail fast, i.e. stop with a clear error at once, in tests); N = 3 minimum.
- **A cell on both diagonals** (the centre of an odd board) updates both diagonal counters — handled by two independent `if`s.

Extensions & follow-up questions

- **"Win with K in a row on an N×N board (Gomoku, K = 5)?"** — Counters no longer work because lines are shorter than the board. After each move, walk out from the new cell in the 4 directions (horizontal, vertical, two diagonals) and count consecutive own marks: O(K) per move.
- **"Unbeatable AI?"** — Minimax over the game tree (every possible sequence of moves drawn as a branching tree; tic-tac-toe 3×3 has at most 9! = 362,880 move orders, easily searched); add alpha-beta pruning or memoisation

(caching the result for each position already evaluated) for larger boards. Plug it in as another `MoveStrategy`.

- **"Undo?"** — Store moves in a stack (last in, first out); undo = clear the cell and **decrement** the counters (counters are reversible, unlike a boolean "won" flag).
- **"Online multiplayer?"** — Server holds the `Game`; clients send `makeMove(gameId, playerId, cell)`; the server broadcasts the new state (Observer).
- **"Replay a game?"** — The move list plus `ScriptedStrategy` replays it exactly.

Real-world example

Google Search has a built-in tic-tac-toe game (search "tic tac toe") with difficulty levels — different computer players behind the same game rules, which is the Strategy split in this design. Tic-tac-toe is also the classic first example for the minimax algorithm in AI courses, because the full game tree is small enough to search completely.

In the interview

> **30-second answer:** "`Board` is N×N plus per-player counters for each row, column and the two diagonals. Placing a mark bumps at most four counters; if one hits N, that player wins — O(1) per move. `Game` holds a list of players and a turn index, validates moves, and ends on a win or a full board. Each `Player` has a `MoveStrategy` — human, random with a seeded `Random`, or rule-based that wins if it can and blocks otherwise."

Time plan: 5 min requirements and N×N/players → 5 min entities → 10 min the counter idea (draw it!) → 15 min code → 5 min extensions (K-in-a-row, minimax, undo).

Self-check

1. **Q:** Why does a move only need to check four lines? **A:** A cell belongs to exactly one row, one column, and at most the two diagonals.
2. **Q:** How do you know a cell is on the anti-diagonal? **A:** `row + col == N - 1`.
3. **Q:** Why per-player counters instead of +1/−1? **A:** They work for more than two players and give "would win" for any player.
4. **Q:** How is a draw detected? **A:** No win and the number of filled cells equals N^2.
5. **Q:** How do you test a bot that plays randomly? **A:** Inject `new Random(seed)`; the game is then identical every run.

TL;DR

- Per-player row/column/diagonal counters → O(1) win check; `N-1` → O(1) "would win".
- `Game` = players list + turn index + state enum; invalid moves rejected, same player retries.
- Players via `MoveStrategy` (human, random-seeded, rule-based, minimax later).
- K-in-a-row needs a directional walk from the last move instead.

Design Snake and Ladder

Problem & clarifying questions

Snake and Ladder is a race on a numbered board (usually 1–100). Players take turns rolling a die and move forward by the number rolled. Landing on the **foot of a ladder** takes you up to its top; landing on the **head of a snake** sends you down to its tail. The first to reach the last square wins. There are no decisions — everything is dice and rules — so the design is about a **clean rules engine**, **turn management** and **testable randomness**.

Question	Assumed answer
Board size and snakes/ladders?	Configurable (default 100 squares, a given list of snakes and ladders). Validate the config.
How many dice?	Configurable: count and faces (default one six-sided die).
How many players?	Two or more; all start off the board (square 0).
Overshooting the last square?	Configurable: **exact finish** (stay put) or **bounce back**.
Rolling a six?	Common house rule (an optional rule some players add): roll again; three sixes in a row cancels the whole turn. Configurable on/off.
When does the game end?	Configurable: **first to finish** wins, or keep playing to **rank everyone**.
Several games at once?	Yes, independent sessions (e.g. many groups online).

Requirements

Functional

1. A board of numbered cells (typically 100) with a predefined set of snakes and ladders connecting cells.
2. Multiple players, each with one token, starting off the board.
3. Players take turns rolling the dice and move forward by the total.
4. Landing on a snake head slides the token down to its tail; landing on a ladder foot climbs to its top.
5. Handle overshooting the final square (exact-finish or bounce-back rule).
6. Optional bonus roll on a six, with the three-sixes penalty.
7. The game continues until the win strategy says it is over (first to finish, or everyone ranked).
8. Support many independent game sessions at once.

Non-functional

- **Deterministic** dice for tests (seeded or loaded).
- Rules are **pluggable** without editing the game loop.
- Invalid boards are rejected **at construction**, not discovered mid-game.

Use cases

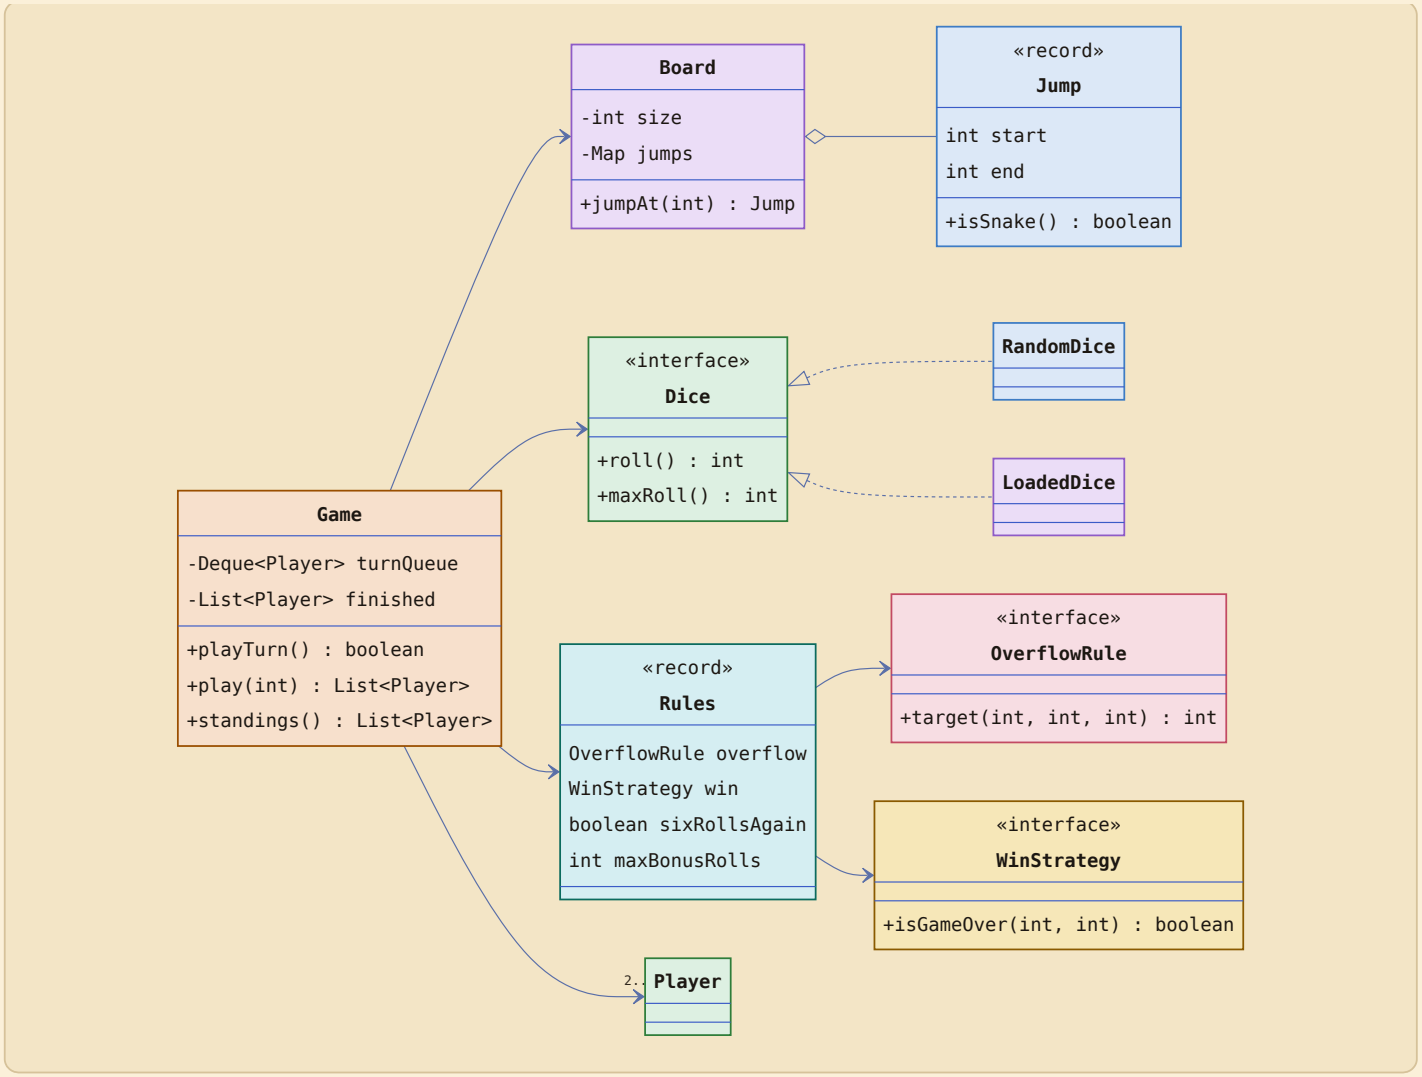
Actors: **Player** (rolls the dice — or the system rolls for them), **Game admin/host** (configures board, dice and rules, starts a game). Use cases: *configure board*, *add players*, *start game*, *take turn* (roll → move → apply snake/ladder → maybe bonus roll), *declare winner / standings*.

Core entities

Class	Responsibility
`Jump` (record)	A snake or a ladder: `start → end`. One class, because the behaviour is identical ("land on start, move to end"); `isSnake()` is just `end < start`.
`Board`	Size + `Map<start, Jump>` for O(1) lookup; validates configuration.
`Dice` (interface)	`roll()`, `maxRoll()`. `RandomDice` (count, faces, seeded `Random`), `LoadedDice` (scripted rolls for tests).
`OverflowRule` (functional interface — exactly one method, so a lambda, a short unnamed function like `x -> x + 1`, can implement it)	Where a roll past the end lands: `exactFinish()` or `bounceBack()`.
`WinStrategy` (functional interface)	When the game ends: `firstToFinish()` or `rankAll()`.
`Rules` (record)	Bundles a variant: overflow rule, win strategy, six-rolls-again flag, max bonus rolls.
`Player`	Name and position.
`Game`	Turn queue, `playTurn()`, `play(maxTurns)`, standings, event log.

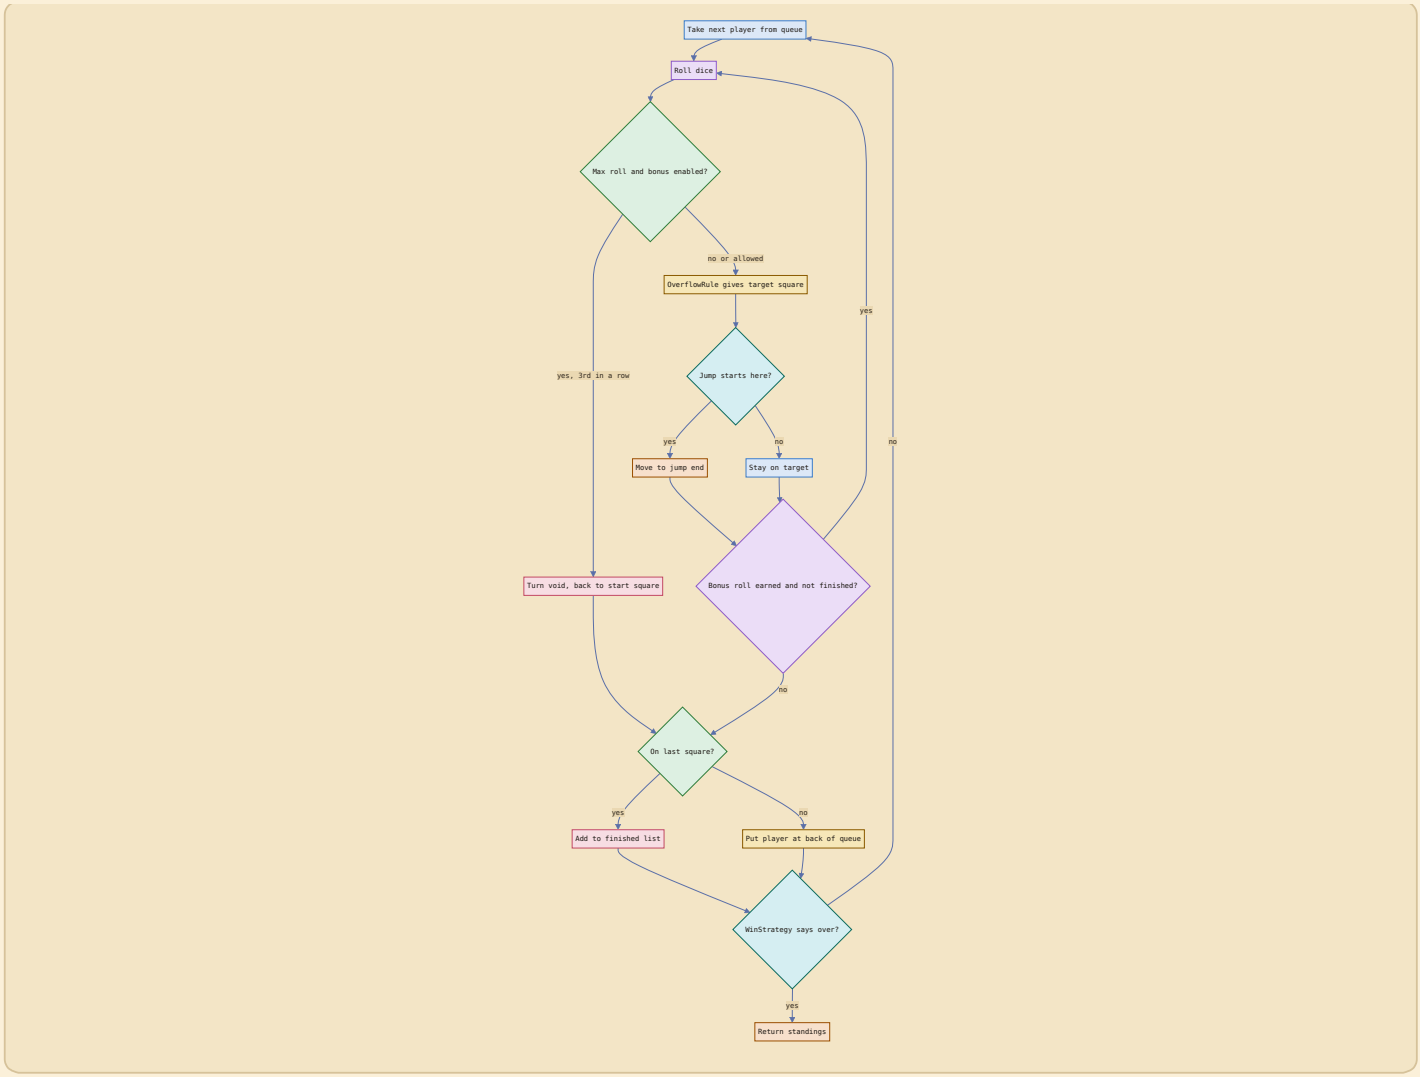
Class diagram

There is no course lesson for this problem; it comes from the *awesome-low-level-design* problem set. That statement asks for: a board of numbered cells (usually 100); predefined snakes and ladders; several players, each with a token; turn-based dice rolls; sliding down a snake's head to its tail and climbing a ladder's foot to its top; a win on reaching the last cell; and many independent game sessions running at once (its reference solution uses a singleton — a class with only one global instance — `GameManager` with one thread per session). All of these are covered; part 6 of the output runs eight sessions in parallel.



Key flows

One turn



Board validation (done once, in the constructor)

1. A jump must not start and end on the same square.
2. No jump starts on square 1 or the last square (you could never win if the last square were a snake).
3. No two jumps share a start square.
4. A jump may not end on another jump's start. This forbids chains, and therefore also forbids infinite loops (snake A → ladder B → snake A...).

Design decisions & patterns used

Decision	Why	Alternative rejected
One `Jump` type for snakes and ladders.	Identical behaviour; the direction is data.	`Snake` and `Ladder` classes with duplicate code — only worth it if they behave differently.
`Map<Integer, Jump>` lookup.	O(1) per move instead of scanning a list.	Array of size 101 — also fine; a map scales to sparse or huge boards.
Strategy for `Dice`, `OverflowRule`, `WinStrategy`.	House rules vary a lot; each is swappable. Lambdas keep them tiny.	Flags and `if`s in the game loop.
`Rules` record groups a variant.	One object = one rule set ("classic", "kids", "tournament"); easy to pass around.	Many constructor parameters on `Game`.
Queue of players.	Natural turn order; finished players simply are not re-queued.	Index arithmetic that must skip finished players.
Event log via `Consumer<String>` (a built-in "takes a value, returns nothing" function type).	The engine does not print; the caller decides (console, UI, nothing). A full design would use **Observer** (`GameListener.onMove/onSnake/onLadder/onWin`).	`System.out.println` inside the engine.
Validation in the `Board` constructor (fail fast).	The loop can trust the board.	Detecting a loop mid-game.
`play(maxTurns)` guard.	A misconfigured rule set can never hang (loop forever and never finish) a server thread.	An unbounded `while (true)`.

Java implementation

Package `lld.ch17.snakeladder`.

```java
// File: code/lld/ch17/snakeladder/Jump.java
package lld.ch17.snakeladder;

/** A snake (goes down) or a ladder (goes up). Both are just "land on start -> move to end". */
public record Jump(int start, int end) {
    public boolean isSnake() { return end < start; }
    public String kind() { return isSnake() ? "snake" : "ladder"; }
}
```

```java
// File: code/lld/ch17/snakeladder/Board.java
package lld.ch17.snakeladder;

import java.util.Collection;
import java.util.HashMap;
import java.util.Map;

/**
 * Board configuration: size plus a map start -> Jump for O(1) lookup.
 * Validates the config once, up front, so the game loop can trust it.
 */
public final class Board {
    private final int size;
    private final Map<Integer, Jump> jumps = new HashMap<>();

    public Board(int size, Collection<Jump> all) {
        if (size < 10) throw new IllegalArgumentException("board too small");
        this.size = size;
        for (Jump j : all) {
            if (j.start() == j.end()) throw new IllegalArgumentException("jump to itself: " + j);
            if (j.start() <= 1 || j.start() >= size) throw new IllegalArgumentException("jump cannot start on
first/last square: " + j);
            if (j.end() < 1 || j.end() > size) throw new IllegalArgumentException("jump ends off board: " + j);
            if (jumps.putIfAbsent(j.start(), j) != null) throw new IllegalArgumentException("two jumps start at " +
j.start());
        }
        for (Jump j : jumps.values()) {   // no chains: an end square may not be another jump's start (also rules
out loops)
            if (jumps.containsKey(j.end())) throw new IllegalArgumentException("jump " + j + " ends on another
jump's start");
        }
    }

  Cid @99: rolls 1 -> 100
  *** Cid finishes in place 1 ***
  Winner: Cid

== 5. Same seed, rank-everyone rule, bounce-back overflow (log hidden) ==
  Standings: Cid > Ann > Bob

== 6. Eight independent sessions on eight threads at once ==
  winners by seed: {1=Ann, 2=Bob, 3=Cid, 4=Bob, 5=Cid, 6=Cid, 7=Ann, 8=Bob}
  same as running each session alone? yes
```

Reading the output. Part 1 uses loaded dice to force every rule: Ann climbs 4→14, Bob rolls a 6 and gets a bonus roll that lands on the 9→31 ladder, Ann hits the 17→7 snake, and Bob's three sixes void his turn (he goes back to 31). Part 2 compares overflow rules from square 97 with a roll of 5: exact-finish stays, bounce-back goes to 100 and back 2 to 98. Part 3 shows bad boards rejected. Part 4 is a full seeded game; Part 5 replays with different rules and ranks every player. Part 6 runs eight games with different seeds on eight threads at the same time and checks that each winner is exactly what the same seed gives when that game runs alone — proof that sessions share no mutable state (data that can be changed after creation).

Concurrency & edge cases

- **Many sessions:** each `Game` owns its players, queue and dice. Give **each game its own** `Random` (sharing one `java.util.Random` across threads is thread-safe but becomes a contention point — many threads waiting on the same shared object — and breaks per-game reproducibility). Keep games in a `ConcurrentHashMap` and run each game's turns on one thread at a time.
- **Rolling after the game ends** → `IllegalStateException`.
- **A player on the last square** is removed from the queue, so they are never asked to roll again.
- **Bonus roll that finishes the game** stops immediately — no roll after reaching 100.
- **Three sixes** → the turn is voided, and the token returns to where the turn started (even if a ladder was climbed during the turn).
- **Bounce-back landing on a snake** (e.g. bouncing to 98 on the standard board) is applied — the rule output goes through the same jump lookup.
- **Endless games** are impossible with a valid board and fair dice (probability of never finishing is 0), but `maxTurns` guards against bad custom rules.

Extensions & follow-up questions

- **"Add special cells (skip a turn, extra move, teleport)."** — Generalise `Jump` into a `CellEffect` interface (`apply(player, game)`); snakes and ladders become two implementations.
- **"Two dice, or a 1–12 die?"** — `new RandomDice(2, 6, rng)`; `maxRoll()` is 12, so the bonus rule triggers on double-max. Note that 2d6 (two six-sided dice added together) is not uniform — not every total is equally likely (7 is the most likely), which changes game balance.
- **"Players must roll a 6 to enter the board."** — A new rule strategy: `EntryRule` checked when position is 0.
- **"Pause and resume."** — Serialize (turn into bytes or text that can be saved and loaded back) the game state (positions, queue order, and the dice's state — or a seed plus number of rolls so far).
- **"Real-time UI / spectators?"** — Observer: publish `PlayerMoved`, `SnakeBitten`, `LadderClimbed`, `PlayerFinished` events.
- **"Random board generation?"** — A `BoardGenerator` with a seed, calling the same validating constructor.

Real-world example

Online multiplayer board-game apps (for example Ludo King, which also offers a Snakes & Ladders mode) have to solve the same problems as this design: every match is an isolated session with its own state, the dice must be rolled somewhere the players cannot tamper with (in a sound design, on the server, not in the client app), and each move is pushed to all players as an event. That is the "one game = isolated state + injected dice + event stream" split used here.

In the interview

> **30-second answer:** "`Board` holds size and a map from square to `Jump` (snake or ladder — same behaviour, just direction), validated on construction. `Dice` is a strategy: seeded random for play, loaded for tests. `Rules` bundles pluggable policies: overflow (exact or bounce), win strategy (first finish or rank all), and the bonus-six rule. `Game` keeps a queue of players; each turn rolls, applies the overflow rule, then any jump, and re-queues the player unless they finished."

Time plan: 5 min rules questions (overshoot, sixes, win) → 5 min entities → 10 min diagram + validation rules → 15 min code turn loop → 5 min extensions and concurrency.

Self-check

1. **Q:** Why is one `Jump` class enough for snakes and ladders? **A:** Both mean "land on start, go to end"; only the direction differs, which is data.

2. **Q:** How do you guarantee there is no infinite snake/ladder loop? **A:** Forbid any jump from ending on another jump's start.
3. **Q:** How do you test "three sixes voids the turn"? **A:** `LoadedDice(6, 6, 6)` and assert the position is unchanged.
4. **Q:** What changes to support "bounce back"? **A:** Pass `OverflowRule.bounceBack()` — no game-loop edits.
5. **Q:** Why a queue for turns? **A:** Players who finish simply are not put back; turn order stays correct.

TL;DR

- Board = size + `Map<start, Jump>`; validate once (no jump on last square, no chains/loops).
- Dice, overflow, win condition, bonus rule are all strategies; seeded or loaded dice for tests.
- Queue-based turn loop with a `maxTurns` guard; events go to a listener, not `System.out`.

Design 2048

Problem & clarifying questions

2048 is a single-player sliding puzzle on a 4×4 grid. Each move (left, right, up, down) slides every tile as far as possible in that direction. Two tiles with the **same value** that collide **merge** into one tile with double the value, and the merged value is added to the **score**. After every move that changes the board, a new tile (a 2 most of the time, sometimes a 4) appears in a random empty cell. You "win" by making a 2048 tile; the game is **over** when no move can change the board.

There is no course lesson for this problem. The problem statement is the common machine-coding (an interview round where you write working code for a small system in 1–2 hours) version (the "2048" exercise found in LLD practice lists such as Tharun's and on machine-coding sites): start with **two tiles numbered 2** at random positions; after every move insert a random tile in a random empty cell; tiles slide until stopped by another tile or the edge; two equal tiles that collide merge into their sum; if **three** equal tiles line up, the pair **nearest the wall you move toward** merges; if **four** are equal, the first two and the last two merge; win at 2048; lose when there is no empty cell and no two equal neighbours; read moves from the command line as **0 = left, 1 = right, 2 = up, 3 = down**. Every one of those rules is in the design below.

Question	Assumed answer
Board size?	Configurable N (default 4).
New tile?	One per successful move: value 2 with probability 0.9, else 4, in a uniformly random empty cell. The game starts with two 2s.
Merge rule?	Each tile merges **at most once per move**; merges happen from the wall you move toward.
Move that changes nothing?	Not a turn: no new tile, no score.
Win?	Reaching the target tile (2048, configurable). The player may continue afterwards.
Game over?	No empty cell **and** no two equal neighbours (horizontally or vertically).
Undo, high scores, animations?	Out of scope; see Extensions.

Requirements

Functional

1. Start an N×N board with two tiles numbered 2 at random positions.
2. Move in four directions: slide, merge equal neighbours once, add merged values to the score.
3. If the move changed the board, spawn one tile (2 or 4) in a random empty cell.
4. Detect reaching the target (WON, then allow continuing).
5. Detect game over (LOST) when no move is possible.
6. Accept the command-line codes 0/1/2/3 for left/right/up/down (`Direction.fromKey`).

Non-functional

- **Deterministic** spawns via an injected, seeded `Random` for tests.
- The merge logic must be written **once**, not four times (one per direction).
- The spawning rule is pluggable (e.g. an "evil" spawner for testing hard cases).

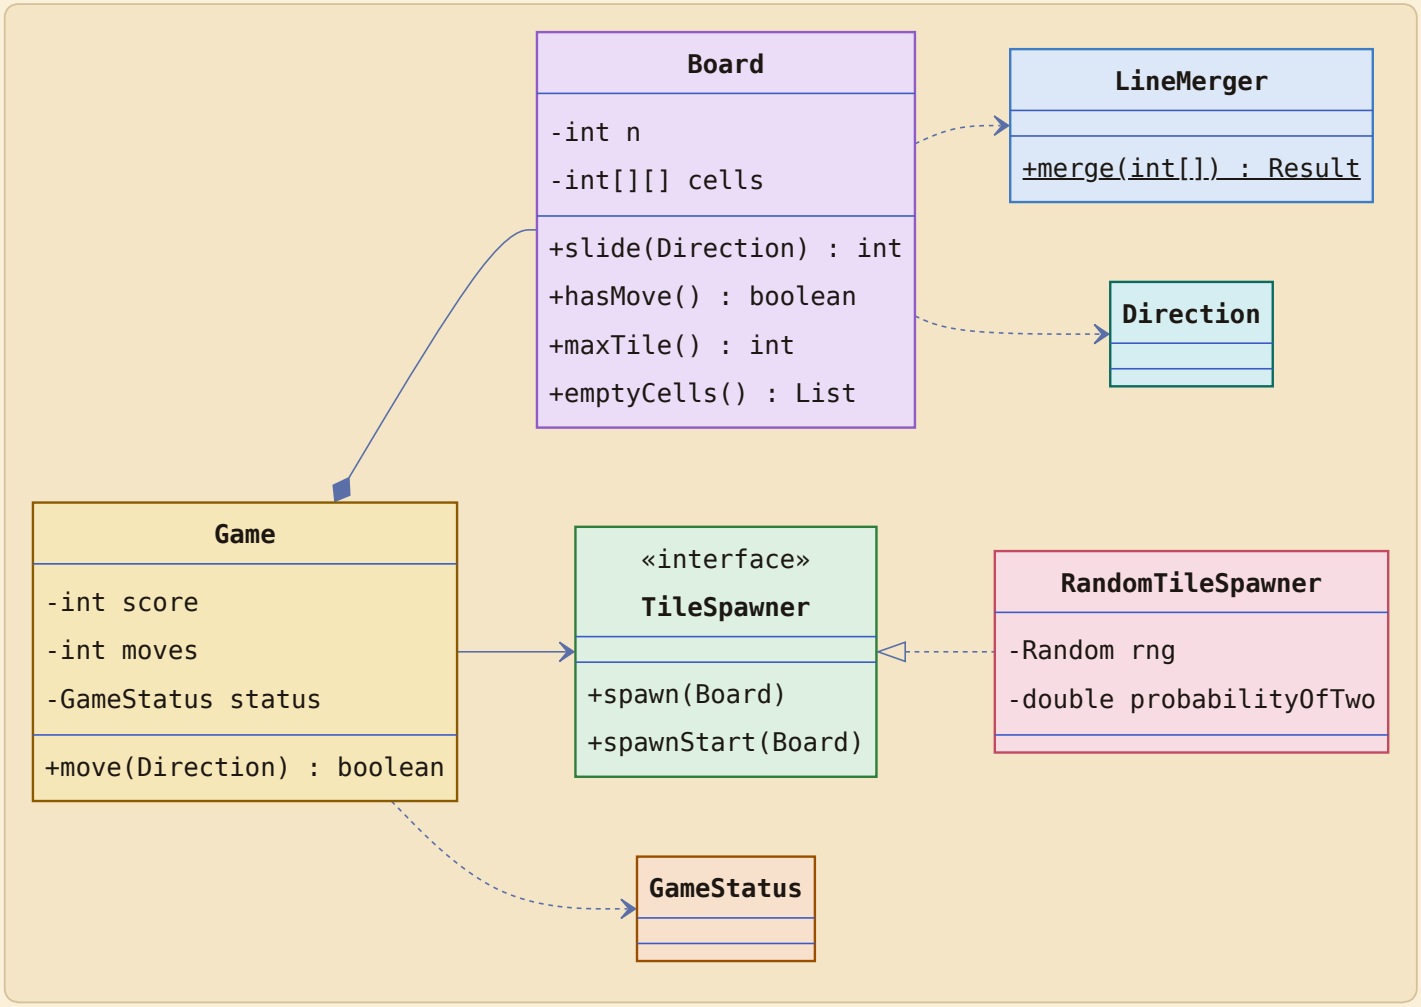
Use cases

Actor: **Player**. Use cases: *start new game*, *make a move* (includes *slide and merge*, *spawn tile*, *update score*), *see win*, *see game over*, *restart*.

Core entities

Class	Responsibility
`Direction` (enum)	LEFT, RIGHT, UP, DOWN; `fromKey(0..3)` maps the command-line codes.
`LineMerger`	Pure function (output depends only on input; changes nothing else): slide and merge **one line toward index 0**; returns the new line and points.
`Board`	N×N values; maps each direction onto lines for `LineMerger`; `slide`, `hasMove`, `maxTile`, `emptyCells`, `render`.
`TileSpawner` (interface) / `RandomTileSpawner`	Adds a new tile; seeded `Random`, 90% twos. `spawnStart` places the two starting tiles (always 2s).
`GameStatus` (enum)	PLAYING, WON, LOST.
`Game`	Score, move count, status; ties slide + spawn + status together.

Class diagram



Key flows

Merging one line (toward index 0) — the whole game in one function:

1. Walk the line from the wall outward, skipping zeros.

2. Keep one **pending** tile. If the next non-zero tile equals it, write the doubled value, add it to the points, and clear pending — so the new tile **cannot merge again this move**.
3. If it differs, write the pending tile and make the new tile pending.
4. At the end, write any pending tile; the rest of the line is zeros.

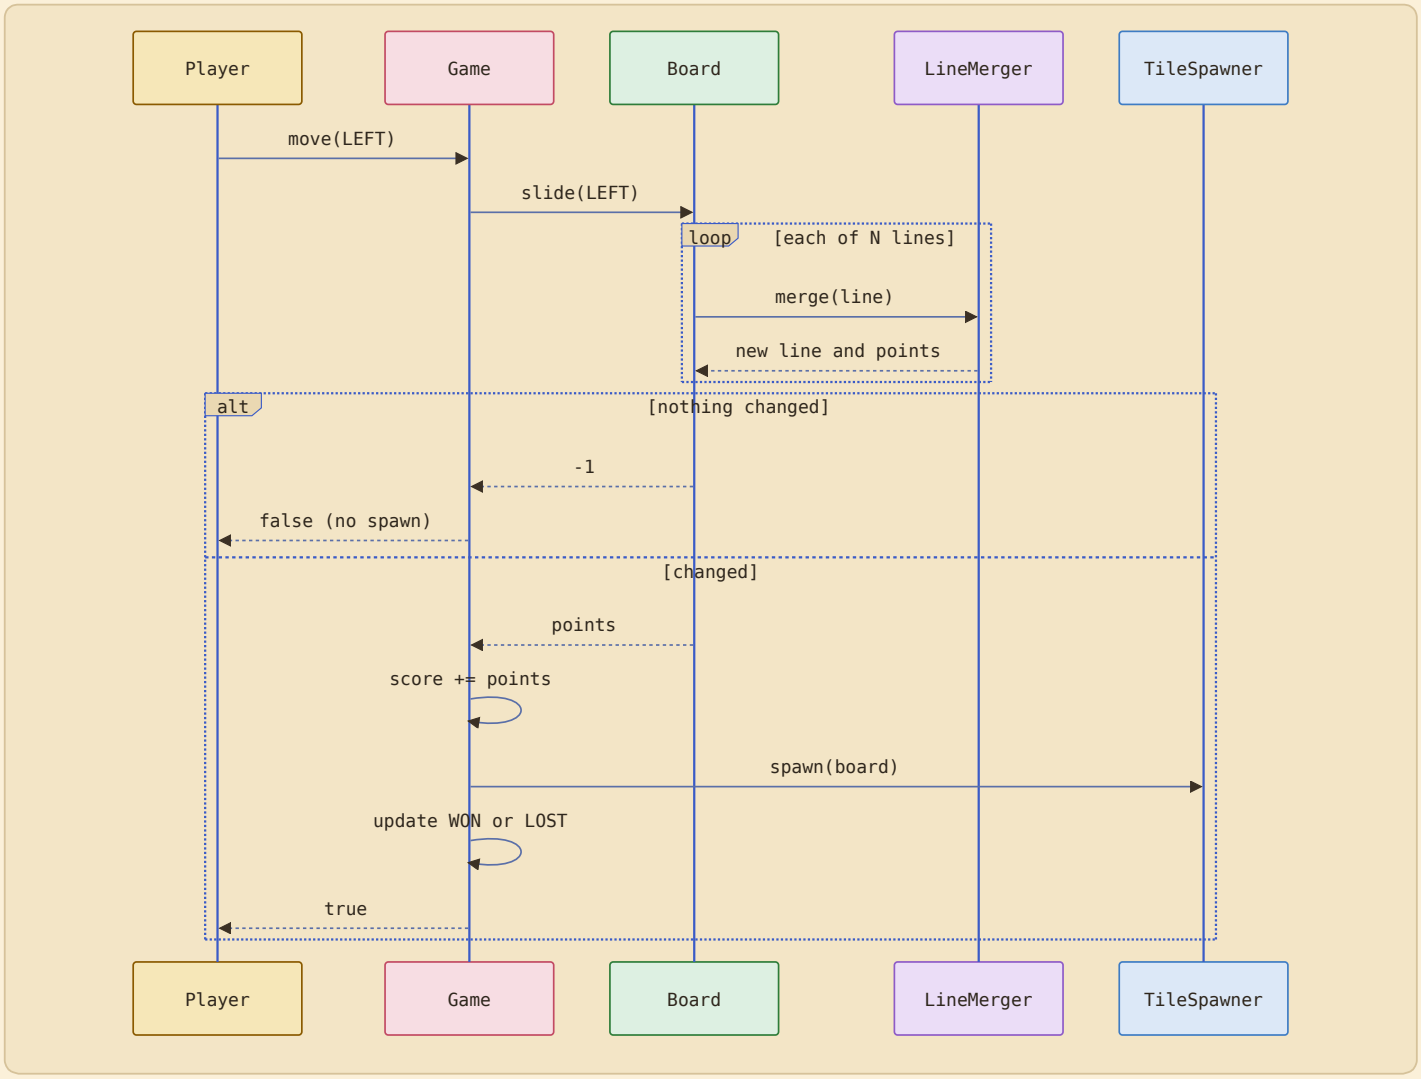
Examples (moving left): `[2,2,2,2] → [4,4,0,0]` (two merges, not one 8), `[2,2,2,0] → [4,2,0,0]` (of three equal tiles, the pair nearest the wall merges), `[2,2,4,0] → [4,4,0,0]` (the new 4 does not merge with the old 4), `[4,0,4,8] → [8,8,0,0]`.

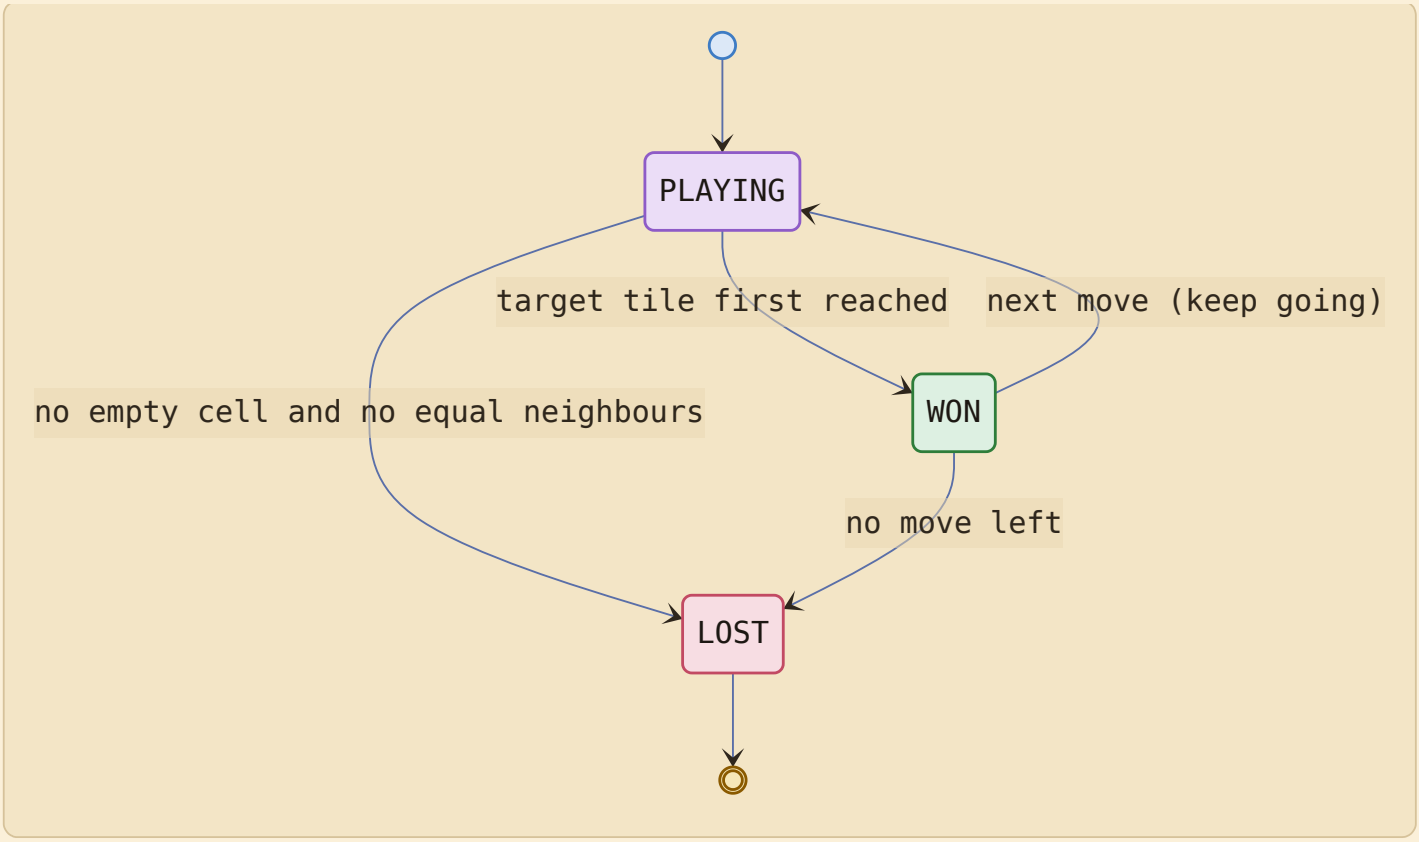
One function for four directions. `Board.coords(direction, i, j)` maps "line `i`, position `j` counted from the wall" to a real cell:

Direction	Line i is	j = 0 is
LEFT	row i	column 0
RIGHT	row i	column N-1
UP	column i	row 0
DOWN	column i	row N-1

Read each line in that order, merge it with `LineMerger`, write it back. No duplicated slide code.

A move





Game-over check. A move is possible if **any cell is empty** or **any two neighbours are equal**. It is enough to compare each cell with its right and lower neighbour (the other two directions are covered by the neighbour's own check). O(N²).

Design decisions & patterns used

Decision	Why	Alternative rejected
One pure `LineMerger` + direction→coordinates mapping.	The tricky rule is written and tested once (DRY — "Don't Repeat Yourself").	Four copies of nested loops (`moveLeft`, `moveRight`...) — classic bug farm.
`LineMerger` is a **pure function** (no state).	Trivial to unit test (test one small piece of code on its own; Part 1 of the output).	Merge logic mixed with board mutation.
Strategy for spawning (`TileSpawner`).	Seeded tests, "evil" spawner, different probabilities for variants.	`Math.random()` inside `Board`.
"No change = no turn" detected by comparing each written cell.	Matches the real game; prevents spawning on a no-op.	Always spawning — makes the game unwinnable/unfair.
`Board.of(int[][])` factory for preset boards.	Game-over and edge-case tests without playing to that position.	Only random starts — untestable edge cases.
Status updated after each move; WON only once.	The player can continue past 2048, as in the original game.	Ending the game at 2048.

Java implementation

Package `lld.ch17.game2048`.

```java
// File: code/lld/ch17/game2048/Direction.java
package lld.ch17.game2048;

public enum Direction {
    LEFT, RIGHT, UP, DOWN;

    /** Command-line input of the common machine-coding statement: 0 = left, 1 = right, 2 = up, 3 = down. */
    public static Direction fromKey(int key) {
        return switch (key) {
            case 0 -> LEFT;
            case 1 -> RIGHT;
            case 2 -> UP;
            case 3 -> DOWN;
            default -> throw new IllegalArgumentException("unknown move " + key + " (use 0-3)");
        };
    }
}
```

```java
// File: code/lld/ch17/game2048/LineMerger.java
package lld.ch17.game2048;

/**
 * The heart of 2048, written for ONE line moving toward index 0.
 * Every direction is reduced to this by reading the line in the right order.
 * Rule: slide tiles together, merge equal neighbours once per move, the merge nearest the wall first.
 */
public final class LineMerger {
    private LineMerger() {}

    /** Result: the new line and the points earned (sum of merged tile values). */
    public record Result(int[] line, int points) {}

    public static Result merge(int[] in) {
        int n = in.length;
        int[] out = new int[n];

            }
        }
        System.out.println("  game over after " + g.moves() + " moves, score " + g.score() + ", max tile " +
g.board().maxTile());
        System.out.println(g.board().render());
    }
}
```

Output:

```
== 1. Merge rules for one line moving left ==
  [2, 2, 2, 2] -> [4, 4, 0, 0]  +8
  [2, 2, 2, 0] -> [4, 2, 0, 0]  +4
  [2, 2, 4, 0] -> [4, 4, 0, 0]  +4
  [4, 0, 4, 8] -> [8, 8, 0, 0]  +8
  [2, 0, 0, 2] -> [4, 0, 0, 0]  +4
  [8, 4, 2, 2] -> [8, 4, 4, 0]  +4
  [2, 4, 8, 16] -> [2, 4, 8, 16]  +0

== 2. A move that changes nothing does not count and spawns nothing ==
  move LEFT changed board? false, moves=0
  move DOWN changed board? true, moves=1
       .    .    .    .
       .    .    .    .
       .    2    .    .
       2    4    8   16

== 3. Game-over detection ==
  checkerboard, no empty cell, no equal neighbours -> LOST
  same but last row ends 4,4 -> PLAYING

== 4. Keyboard codes from the problem statement ==
  0=LEFT  1=RIGHT  2=UP  3=DOWN

== 5. Seeded game (seed 42), corner strategy LEFT > DOWN > RIGHT > UP, target 128 ==
  start:
       .    .    .    2
       .    .    .    .
       .    .    .    2
       .    .    .    .
  reached 128 after 85 moves (status WON), score 852
       8    2    .    .
      16    4    4    .
       2    8    4    .
     128    4    .    .
  game over after 232 moves, score 2584, max tile 256
      16    8    4    2
       8   32    8    4
      16    2   16    8
     256   64   32   16
```

Reading the output. Part 1 unit-tests the merge rule (note `[2,2,2,2]` becomes `[4,4,0,0]`, not `[8,0,0,0]`, and `[2,2,2,0]` becomes `[4,2,0,0]`). Part 2 shows that a move changing nothing does not count. Part 3 checks game-over detection on preset boards. Part 4 prints the command-line key mapping. Part 5 plays a whole seeded game that starts from two 2s, using a simple "keep tiles in the bottom-left corner" priority strategy; it reaches the 128 target after 85 moves (status `WON`) and keeps playing until the board locks after 232 moves with a 256 tile.

Concurrency & edge cases

- Single-player and single-threaded by nature. If a UI thread (the thread that draws the screen) and an input thread both call `move`, make `move` `synchronized` (or post moves to the UI event queue — the list of pending clicks, key presses and redraws that the UI thread handles one by one).
- **Key repeat / double input:** a no-op move returns `false` and changes nothing, so extra key presses are harmless.
- **Spawning needs an empty cell:** guaranteed, because a changed board after sliding always has at least one empty cell (tiles only move into gaps or merge, which frees a cell). The spawner still checks and throws if not.
- **Integer overflow** (a number growing past the largest value its type can hold, so it wraps around to a wrong value): not reachable on 4×4 (the maximum possible tile is 2^17 = 131072); a very large board would still fit an `int` for any practical game.
- **Merge order matters:** `[2,2,2]` moving left is `[4,2,0]` — the pair nearest the wall merges first.

Extensions & follow-up questions

- **"Add undo."** — Memento: push a copy of the board and score before each successful move; undo pops it (the spawned tile disappears too).

- **"Different sizes / targets?"** — Already parameters (`new Game(5, 4096, spawner)`).
- **"An AI player?"** — Expectimax search (max over your moves, average over random spawns) is the well-known approach; plug it in as a move-choosing strategy like the corner strategy in `Main`.
- **"Animations?"** — Have `LineMerger` also return where each tile came from (a list of moves/merges) and publish them to the view (Observer, MVC).
- **"High scores / leaderboard?"** — A separate service; the game only emits "game over with score X".
- **"Why is `[2,2,4]` left `[4,4,0]` and not `[8,0,0]`?"** — Each tile merges at most once per move; the new 4 was created this move.

Real-world example

2048 was created by Gabriele Cirulli in 2014 and released as open-source (its code is public for anyone to read and reuse) JavaScript; its code has the same separation: a grid model, a game manager that handles moves, merges, score and "keep playing" after a win, and a separate view that animates tiles. Its new tiles are 2 with 90% probability and 4 with 10%, the same rule our `RandomTileSpawner` uses.

In the interview

> **30-second answer:** "The core is one pure function that slides and merges a single line toward index 0: skip zeros, merge equal neighbours once, score the merged values. The board maps each direction to lines in the right order, so the function is reused four times. After a move that changes the board, a `TileSpawner` — seeded for tests — adds a 2 (90%) or a 4. The game is won when the target tile appears and over when there's no empty cell and no equal neighbours."

Time plan: 5 min rules (merge once, no-op move) → 5 min entities → 15 min `LineMerger` + direction mapping (write the tests first: `[2,2,2,2]`, `[2,2,4,0]`) → 10 min game loop, spawning, game over → 5 min extensions.

Self-check

1. **Q:** What does `[4,4,8,8]` become moving left, and how many points? **A:** `[8,16,0,0]`, 24 points.
2. **Q:** Why must a no-op move not spawn a tile? **A:** It is not a turn in the real game; spawning would punish harmless key presses and change the game's balance.
3. **Q:** How do you avoid four copies of the slide code? **A:** Map each direction to lines read from the wall, then call one line-merge function.
4. **Q:** When is the game over? **A:** No empty cell and no two equal adjacent tiles.
5. **Q:** How do you make a 2048 test repeatable? **A:** Inject `new Random(seed)` into the spawner, or start from `Board.of(...)`.

TL;DR

- One pure `LineMerger` (merge once per move, from the wall) + a direction→line mapping.
- Spawn only after a real change; 2 (90%) or 4 (10%), seeded spawner for tests.
- WON once at the target (keep playing); LOST when no empty cell and no equal neighbours.

Chapter summary

Game	Core rule object	Pluggable strategies	Randomness for tests	Signature technique
Blackjack	`Hand` scoring + `BlackjackScoring`	`PlayerStrategy`, `DealerPolicy`	Seeded `Shoe`, stacked shoe	Soft/hard totals; generic `Deck<T>`
Chess	`Rules` (legal-move filter)	(bot would be a move strategy)	None needed — deterministic game	Polymorphic pieces; checkmate = in check + no legal move; Command + Memento undo
Tic-Tac-Toe	`Board` counters	`MoveStrategy`	Seeded `RandomStrategy`, scripted players	O(1) win with row/col/diagonal counters
Snake & Ladder	`Board` + `Rules` record	`Dice`, `OverflowRule`, `WinStrategy`	Seeded `RandomDice`, `LoadedDice`	Validated config; queue-based turns
2048	`LineMerger`	`TileSpawner`	Seeded spawner, `Board.of` presets	One merge function reused for 4 directions

Patterns you used in this chapter: Strategy (everywhere), Factory Method (`Deck.standard52`, `Piece.create`, `Board.of`), Template-style shared base (`SlidingPiece`), Command + Memento (chess undo), State (game-status enums; a full State pattern is the suggested upgrade for blackjack rounds), Observer (the event log hooks; suggested for UIs and spectators).

The three habits interviewers look for in game designs:

1. **Put every rule in exactly one place** — and be able to say where.
2. **Inject randomness** — seeded or scripted — so the design is testable.
3. **Model the game's states explicitly** — and reject actions that are invalid in the current state.

Chapter 18 — Case Studies: Platforms & Feeds (Part 1)

> **Where this fits.** Chapters 14–17 designed *things* (a parking lot, a vending machine), *bookings* (movies, hotels, flights) and *games*. This chapter and the next one design **platforms**: websites where many people create content, react to each other's content and build up a history. The objects are no longer machines with buttons; they are people, posts, votes, relationships and feeds. Chapter 19 continues with more platforms.

What you will learn

#	Problem	What makes it interesting	Main patterns and ideas
18.0	What platform problems test	The common toolkit you will reuse in every social or community design	Facade, Observer, Strategy, services for two-sided operations, inverted index
18.1	Design Stack Overflow	Reputation unlocks privileges; one vote per member; moderation; bounties	Shared `Post` base class, Strategy (reputation rules), Observer (badges), privilege table
18.2	Design Cricinfo (+ Udaan "Cricket Match Dashboard")	Modelling a real sport's rules; live scorecards; stats derived from balls	Template Method (formats and stat queries), Observer (live feeds), "derive, don't store"
18.3	Design LinkedIn	Profiles, connections and their degrees, invitations, messaging, jobs, search, feed	Service for two-sided operations, State (invitation), BFS for degrees, Strategy (feed ranking)
18.4	Design Facebook	Friends vs followers, privacy lists, pages, groups, news feed, friend suggestions	One visibility policy for feed + search, sealed `Audience`, pull-model feed, suggestions

How to run every example in this chapter

```
cd chapters/18-case-platforms-1/code
javac --release 21 -d /tmp/lld_18 $(find . -name '*.java')
java -cp /tmp/lld_18 lld.ch18.stackoverflow.Main       # or cricinfo, cricketdashboard, linkedin, facebook
```

`javac` is the Java **compiler** (it turns `.java` source files into `.class` files the Java runtime can execute); `--release 21` says which Java version to target, and `-d` names the output folder. `java -cp` runs a program, where the **classpath** (`-cp`) is the list of folders in which Java looks for compiled classes. The **standard library** is the set of classes that ships with Java itself, so nothing extra has to be downloaded.

All five `Main` classes compile with Java 21 (standard library only) and run. The output printed under each design is the real output of that program.

> **Code-style note.** To keep a whole design readable in one place, a file sometimes holds several small package-private types (for example `Posts.java` holds `Post`, `Question`, `Answer`, `Comment`, `Tag` and `Bounty`). That is legal Java. In a production codebase you would usually give each public top-level type its own file.

> **Key term — Java vocabulary used in this chapter:** A **package** is a named folder of related classes (`lld.ch18.stackoverflow`); a **package-private** type has no `public` / `private` keyword and can be used only by classes in the same package. A **top-level type** is a class, interface, enum or record not nested inside another one. An **interface** lists methods a class promises to provide, without the code; a class that provides them *implements* it. An **abstract class** can never be created directly — only its subclasses can. An **enum** is a type with a fixed list of named values (`OPEN`, `CLOSED`). A **record** is a short way to declare a class that just carries data that never changes. A **sealed** type names exactly which subclasses are allowed, so the compiler knows every possible kind.

18.0 What platform problems test

What it is

A **platform problem** asks you to design a website or app where *users produce the content* — questions and answers, posts and comments, match commentary, job postings. Stack Overflow, Cricinfo, LinkedIn and Facebook are the classic examples. Unlike a vending machine, there is no single "machine" object in the middle. Instead there is a **rich domain model**: many small classes (profile, post, comment, vote, tag, badge, invitation, group, page…) that each hold a little data and a little behaviour.

Everyday analogy: a vending machine is like a toaster — one box with a few buttons. A platform is like a town — many people, many buildings, rules about who may enter where, a notice board (the feed), a post office (notifications) and a library catalogue (search).

The problem it solves

Interviewers pick platform problems to check six skills at once. The table names each one, defines it, and shows where this chapter practises it.

Skill tested	What it means	Where you practise it
Rich domain model	Turning a long list of nouns into classes with clear responsibilities, and knowing which noun is *just data* (a record) and which has *behaviour*	Cricinfo's `Over` knows a wide is not one of its six balls
User roles	Different people may do different things: guest, member, moderator, admin, commentator	Stack Overflow's reputation-based privileges; Facebook's admin who blocks members
Feeds	A **feed** is a personalised, ranked list of recent content from the people and pages you are linked to	LinkedIn and Facebook feed services with a ranking Strategy
Notifications	Telling a user that something happened (new message, friend request, comment) through one or more **channels** (in-app, email, push — a pop-up alert sent to a phone or browser)	Observer + Strategy in every design
Search	Finding things by words. Built with an **inverted index**: a map from each word to the items that contain it	Question search, member search, privacy-aware post search
Reputation / trust	Numbers that summarise past behaviour and unlock abilities (reputation, badges, endorsements, ratings)	Stack Overflow reputation and badges; LinkedIn endorsements; Facebook page ratings

How it works — the reusable toolkit

These ideas repeat in every design in this chapter. Learn them once.

1. **A facade in front.** A **facade** is one class that offers the simple operations the UI (user interface — the screens and buttons people use) needs (`ask`, `vote`, `post`, `invite`) and hides the many classes behind it (Chapter 9). It is also the natural place to check "is this account active?" and "is this person allowed?" before anything changes.
2. **Behaviour shared by content goes in a base class.** Questions, answers and comments are all voted on; posts and comments are all liked. Write that once in a base class (`Post`, `SocialContent`) and let the content-specific parts stay in subclasses.
3. **Store *who*, not *how many*.** Keep likes and votes as a **set of member ids**, not an integer counter. A set blocks double voting, allows "unlike", and still gives the count as `set.size()`.
4. **Derive, don't store.** If a number can be computed from data you already keep (follower count, a batter's runs, a page's rating), compute it. A stored copy will one day disagree with the source and nobody will know which is right. If it is too slow to compute every time, keep a **cache** (a saved copy of a computed answer, kept so it can be read quickly instead of recomputed) that you can always rebuild from the source. See System Design Fundamentals for caches at scale.
5. **An operation that changes two objects lives in a service.** Accepting a connection or friend request changes *both* members. Put it on neither — put it in a small **service** class (a class whose job is to perform an operation, not to hold data) so there is exactly one place that keeps both sides consistent.

6. **Notifications through Observer + Strategy.** The domain *publishes* events ("answer posted"); **observers** (Chapter 10) react. The **Observer** pattern means objects *subscribe* to another object and are called back automatically whenever it announces an event, so the announcer does not need to know who is listening. The **Strategy** pattern means putting each interchangeable way of doing a job (here: each delivery method) behind one interface, so you can swap or add ways without editing the caller. How a message is *delivered* (email, push, in-app) is a **Strategy** (Chapter 11) so adding a channel means adding a class, not another `if`.
7. **Search is its own class.** An **inverted index** (word → items) belongs in a `SearchIndex`, not on the entity. Rule from the course: every key maps to a *collection*, even when only one item matches, so the second "Sharma" never breaks the index.
8. **Privacy and permissions are asked in one place.** If both the feed and the search must hide private posts, write `canSee(viewer, post)` once and call it from both.

Trade-offs

Choice	Benefit	Cost
Rich model (many small classes)	Each rule has one home; easy to test	More classes to explain in 45 minutes
Sets of voter ids instead of counters	Correct: no double votes, reversible	Memory grows with votes; real systems store votes in a table and cache the count
Derive stats from raw events	Never inconsistent	Slow for large data; needs a cache
Services for two-sided operations	Symmetry guaranteed in one place	One more class; entities become thinner ("anemic") if you overdo it

When not to use it

Do not bring the whole toolkit to a tiny problem. If the interviewer asks only for "a like button", a set on the post is enough — no services, no observers.

Common mistakes

- Putting search as a static method on `Question` ("`Question.search()`"), so the entity must know every other question.
- Storing `likeCount` as a constructor argument — a post can then be created "with 1,000 likes".
- Forgetting that the privacy rule also applies inside search and the feed.
- Writing `acceptInvitation` on the sender (or the receiver) and updating only one side.

Real-world examples

- **Kafka** (a system that stores streams of events and delivers them to any program that wants to read them) was created at LinkedIn to move activity events (page views, posts, connections) between systems — the industrial version of the Observer idea used here.
- **Facebook's TAO** is a graph store (a database built for a **graph** — items joined by links, like people joined by friendships) built to serve the social graph (users, friendships, likes) at very large scale — the production version of our in-memory friend graph.
- **Stack Overflow** publishes its reputation-to-privilege table on its help pages — exactly the data-driven `Privilege` enum used in 18.1.

In the interview

> **30-second answer:** "Platform problems test whether I can model a domain with many small classes, put each rule in one place, and handle roles, feeds, notifications and search. I'll start with requirements and actors, then the core entities, then the tricky flows — voting, accepting requests, privacy — and I'll say which operations need a service because they touch two objects."

Follow-ups:

- *Why a set instead of a counter for likes?* — A bare number does not record *who* liked, so it can neither block a repeat like nor undo one. The set gives the count for free.
- *Where does the notification code go?* — Not inside the domain methods directly; the domain raises an event and a notification service with pluggable channels delivers it.

Self-check

- **Q:** What is an inverted index? **A:** A map from each word to the items containing that word; used to answer "which items contain these words?" quickly.
- **Q:** Why is "accept a friend request" not a method on `Member`? **A:** It changes two members; putting it on one of them means one object edits another's state, and the two halves can drift. A service updates both together.
- **Q:** Name two ways to deliver a notification and the pattern that makes adding a third easy. **A:** Email and push; Strategy (a `NotificationChannel` interface).

TL;DR

Platform problems = rich domain model + roles + feed + notifications + search + reputation. Share behaviour in a content base class, store *who* not *how many*, derive numbers, put two-sided operations in services, notify via Observer + Strategy, keep search and privacy each in one place.

18.1 Design Stack Overflow

Figure — The Stack Overflow logo that opens this case study (course diagram)

Stack Overflow is a huge question-and-answer community for programmers. Members can **upvote** or **downvote** questions and answers, and anyone with enough standing can edit posts, much like a wiki (a website whose pages any permitted reader can edit). Members earn **reputation** (a points score) and **badges** (named awards) for useful contributions. Higher reputation unlocks **privileges** — voting, commenting anywhere, editing other people's posts, voting to close questions. For scale: an upvote on an answer is worth 10 points to its author. The course says a question upvote is worth 5; that was true until November 2019, when Stack Overflow raised it to 10 as well, and this chapter's code uses today's value.

Problem & clarifying questions

Ask these before drawing anything. The answers are the assumptions this design uses.

Question to ask	Answer we assume
Who uses the system?	Guests (not logged in), members, moderators, admins, and the system itself (notifications, badges)
What can a guest do?	Search and read only. Posting or voting requires membership
What can be voted on?	Questions, answers and comments (comments: upvote only, as on the real site)
How much reputation does a vote give?	Upvote +10 on a question or an answer (question upvotes were +5 before November 2019), downvote −2 to the author, −1 to whoever downvotes an answer (downvoting a question is free), accepted answer +15 (and +2 to the asker)
Does reputation unlock actions?	Yes — a privilege table (vote up at 15, comment everywhere at 50, set bounty at 75, vote down at 125, create tag at 1,500, edit at 2,000, close votes at 3,000, delete votes at 10,000)
How are questions closed?	3 close votes from members with the privilege, or one moderator. Moderators can also reopen, delete and undelete
What is a bounty?	Reputation a member (usually the asker) stakes, 50 to 500 points, to attract answers. It runs for 7 days (the real site adds a 24-hour grace period) and goes to the answer the sponsor picks. The staked points are taken at once and are never refunded; if the sponsor picks nobody, the real site may auto-award half to a qualifying new answer
Do we need search?	Yes: by keyword and by tag, plus "most used tags"
Scale?	Read-heavy (many more views than posts); votes must never double-count

Requirements

Functional (the course's thirteen, in our words)

1. Guests can search and view questions; to post or upvote they must become members.
2. Members can post new questions.
3. Members can answer an **open** question.
4. Members can comment on any question or answer.
5. Questions, answers and comments can all be upvoted by members.
6. Members can **flag** any question, answer or comment that has a serious problem or needs a moderator to look at it.
7. A member can attach a **bounty** to a question they asked.
8. Members earn **badges** for being helpful.
9. Members can cast votes to **close** a question; a moderator can close or reopen any question on their own.
10. Members can add **tags** (a word or phrase naming the topic) to questions.
11. Members can vote to **delete** far off-topic or very low-quality questions.
12. Moderators can close questions and restore (undelete) deleted ones.
13. The system can report the **most frequently used tags**.

Plus from the real site (added so the privilege rules have somewhere to live): downvotes, accepting an answer, reputation-gated privileges, blocking accounts.

Non-functional

- **Correctness of counts:** one member, one vote per post; reputation changes must be reversible when a vote changes.
- **Read-heavy performance:** search and "top tags" must not scan every question.
- **Concurrency** (several pieces of work running at the same time — for example two requests handled by two **threads**, the independent paths of execution inside one program)**:** two members voting on the same post at the same instant must both be counted exactly once.
- **Abuse resistance:** you cannot vote on your own post; blocked accounts can do nothing.
- **Extensibility** (how easily new features can be added without rewriting old code)**:** reputation rules, badge rules and notification channels change often — changing them should not touch voting code.

Use cases

The five actors:

- **Guest** — searches and views questions.
- **Member** — everything a guest can do, plus ask, answer, comment, vote, flag, add bounties and tags, and delete or undelete their own posts.
- **Moderator** — everything a member can do, plus close, reopen, delete and undelete *any* question.
- **Admin** — blocks and unblocks members.
- **System** — sends notifications and assigns badges.

Top use cases: search questions; ask a question (with tags and an optional bounty); write or edit answers; add comments; moderators close, delete and undelete questions.

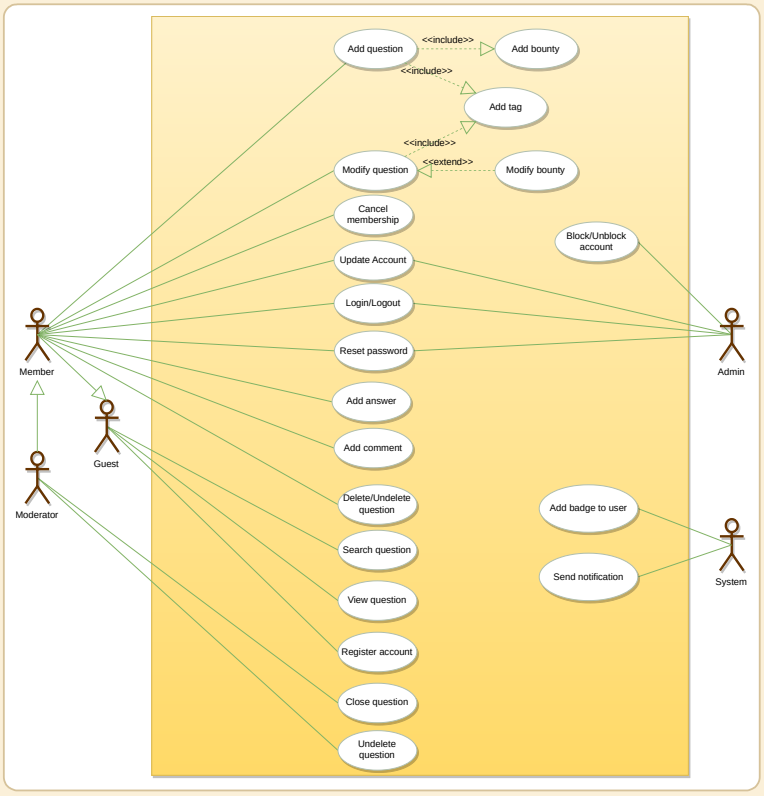

Figure — Use cases per actor: Guest (search, view, register), Member (add/modify question, answer, comment, bounty, tag), Moderator (close, delete/undelete), Admin (block/unblock), System (send notification, add badge) (course diagram)

A **use-case diagram** is a UML picture of the actors (stick figures) and the things each one can do (ovals). In the figure above, notice the `<<include>>` from "Add question" to "Add tag" (adding a tag is part of asking) and the `<<extend>>` for bounties (an optional extra on a question).

An **activity diagram** is a flowchart of the steps and yes/no decisions in one task; a **sequence diagram** shows, top to bottom in time order, the messages objects send to each other.

Activity — post a new question. The member clicks *Ask Question*, types a title and body, and adds tags. For each tag, the system checks whether it already exists; if not, it checks whether the member has **enough reputation to create a tag**. Then it validates the question and either saves and posts it or shows an error.

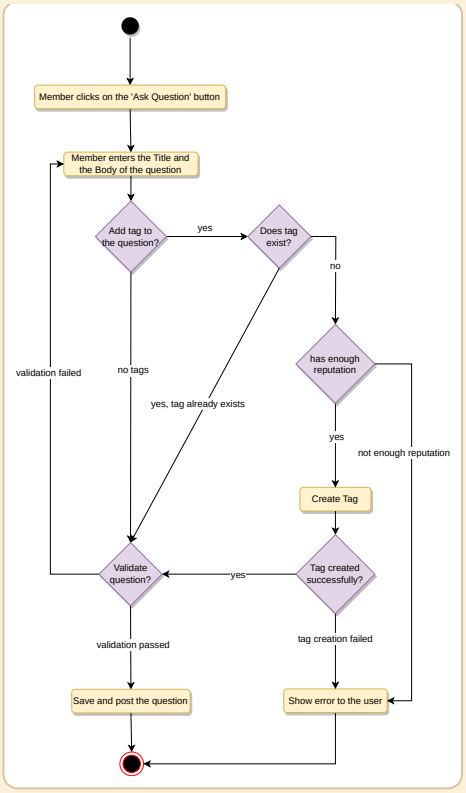

Figure — Activity diagram for posting a question, including the "does the tag exist?" and "has enough reputation?" decisions (course diagram)

Sequence — create a question. The member sets the title and body, looks up tags (creating one if missing), creates the question with a bounty value, the question creates its `Bounty`, and finally the question is published.

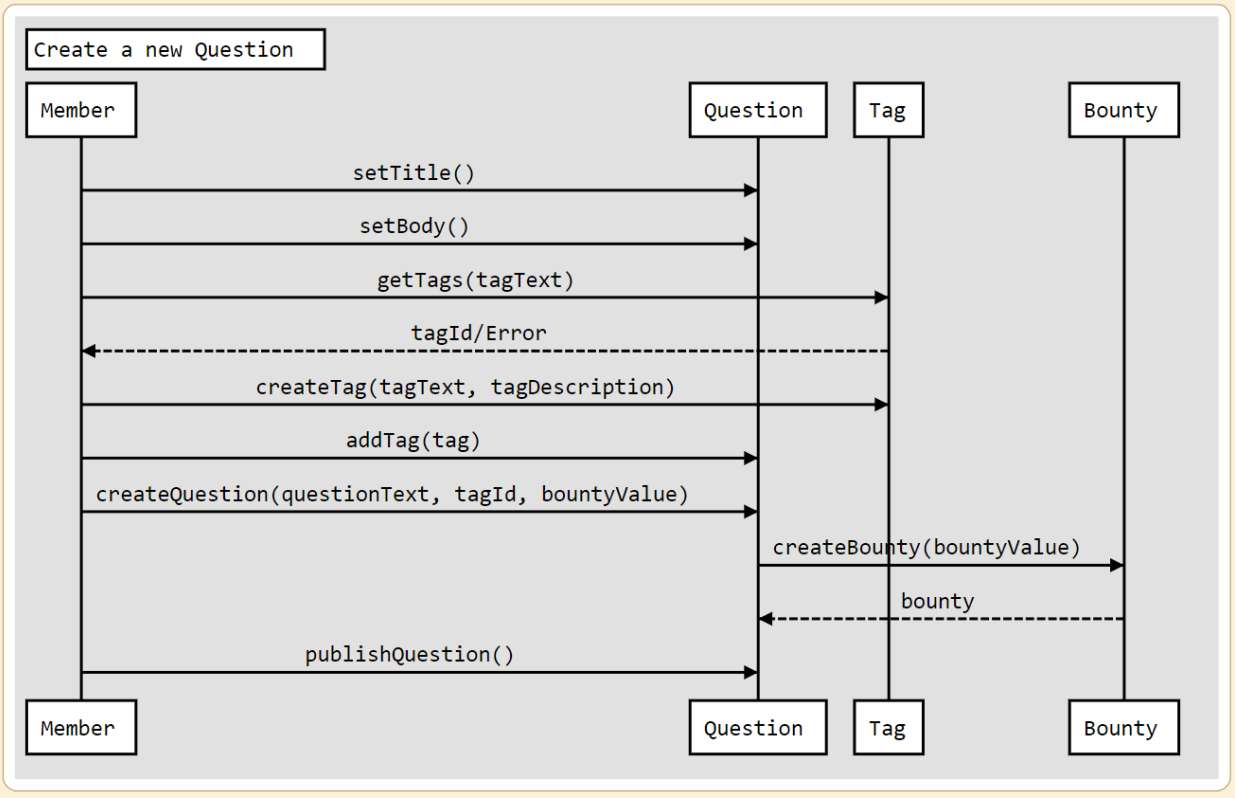

Figure — Sequence diagram: Member → Question (setTitle, setBody), Member → Tag (getTags / createTag), Question → Bounty (createBounty), then publishQuestion (course diagram)

Our Java code follows the same order: `ask()` resolves each tag, creating it only if the asker holds the `CREATE_TAG` privilege, and then builds the question; `offerBounty()` attaches the bounty.

Core entities

Class	Responsibility
`Member` (+ `Moderator`, `Admin`)	Identity, reputation (atomic — safe when updated by many threads at once), badges, account status; `hasPrivilege(p)`
`Privilege` (enum)	The reputation needed for each action — a data table, not scattered `if`s
`Post` (sealed, abstract)	Shared behaviour: author, body, votes per voter, flags, comments
`Question`	Title, tags, answers, status (OPEN / CLOSED / DELETED…), closing remark, close/delete voters, bounty, view count
`Answer`	Belongs to one question; can be *accepted*. (The course also gives answers and comments a view count and vote/flag counts; our code derives the vote and flag counts from the voter and flagger sets)
`Comment`	Belongs to a question or answer
`Tag`	Name + description; counts its own uses (for "top tags")
`Bounty`	Staked reputation, sponsor, expiry date, winner
`Badge` (record)	Name + description
`ReputationPolicy` / `DefaultReputationPolicy`	Strategy: how many points each event is worth
`ReputationListener` / `BadgeAwarder`	Observer: reacts to reputation changes (awards badges)
`Notifier` + `NotificationChannel` / `EmailChannel`	Sends notifications through pluggable channels
`Search` / `QuestionIndex`	Inverted index by word and by tag
`StackOverflow`	Facade: checks status + privilege, delegates, applies reputation

Class diagram

The course builds the class diagram in **five stages**, each adding a few classes for a few requirements. Classes from earlier stages are drawn in grey, so the picture fills in step by step.

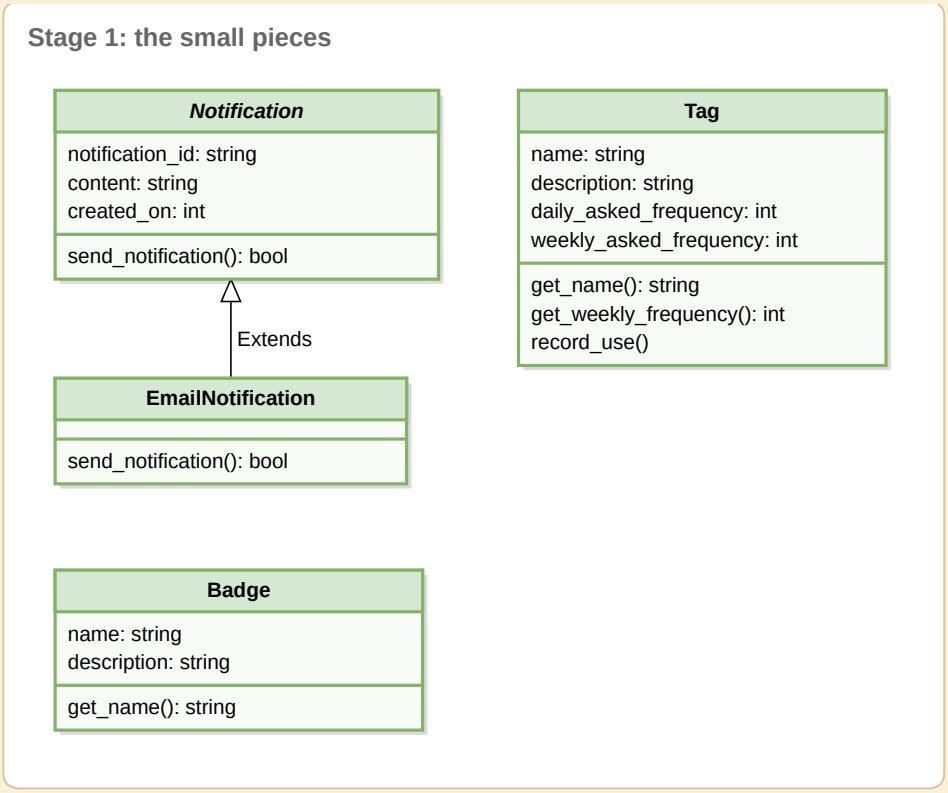

Figure — Stage 1: `Badge`, `Tag` (with daily and weekly usage counters and `record_use`) and abstract `Notification` with its `EmailNotification` subclass (course diagram)

Stage 1 covers requirements 8, 10 and 13. None of these classes depends on anything yet. The key idea is in `Tag`: it counts its own uses when attached to a question, so "most used tags" becomes a quick read rather than a scan of every question. `Notification` is abstract with one subclass per delivery method — an email notification genuinely is a notification that can be sent, so the inheritance passes the substitution test (the Liskov Substitution Principle: a subclass object must work correctly anywhere its parent class is expected).

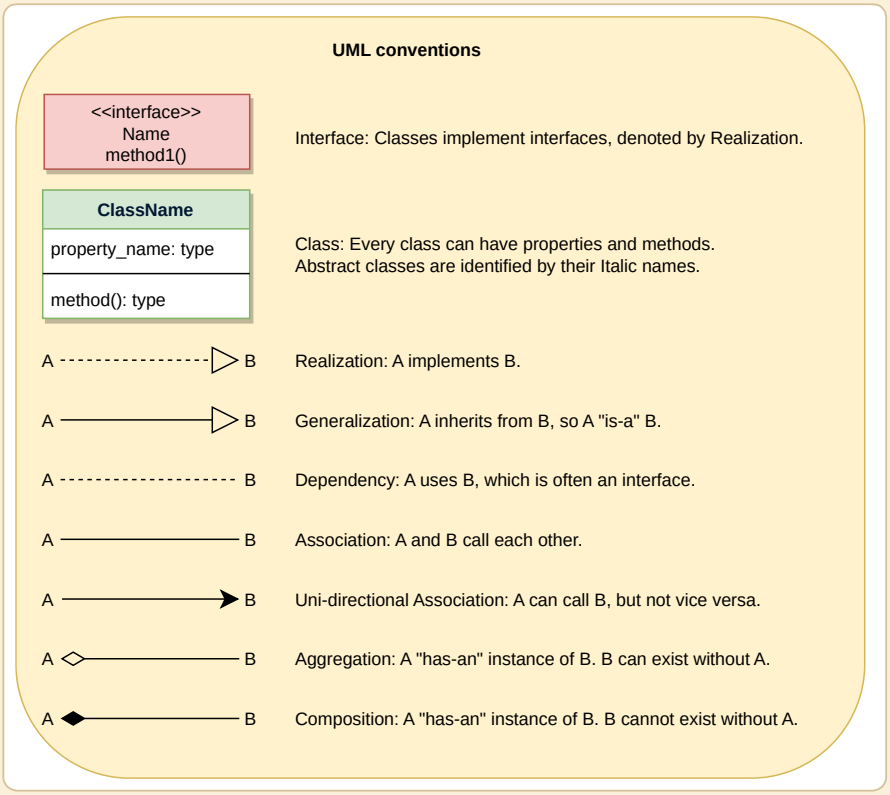

Figure — The UML legend used in these diagrams: class, interface, realization, generalization, dependency, association, aggregation and composition arrows (course diagram)

UML (Unified Modeling Language) is the standard notation for drawing classes and their links. In short: **generalization** is the inheritance arrow ("is a kind of"); **realization** means a class implements an interface;

dependency means one class merely uses another for a moment; **aggregation** (hollow diamond) means "has, but does not own"; **composition** (filled diamond) and **association** are explained in Stage 3 below.

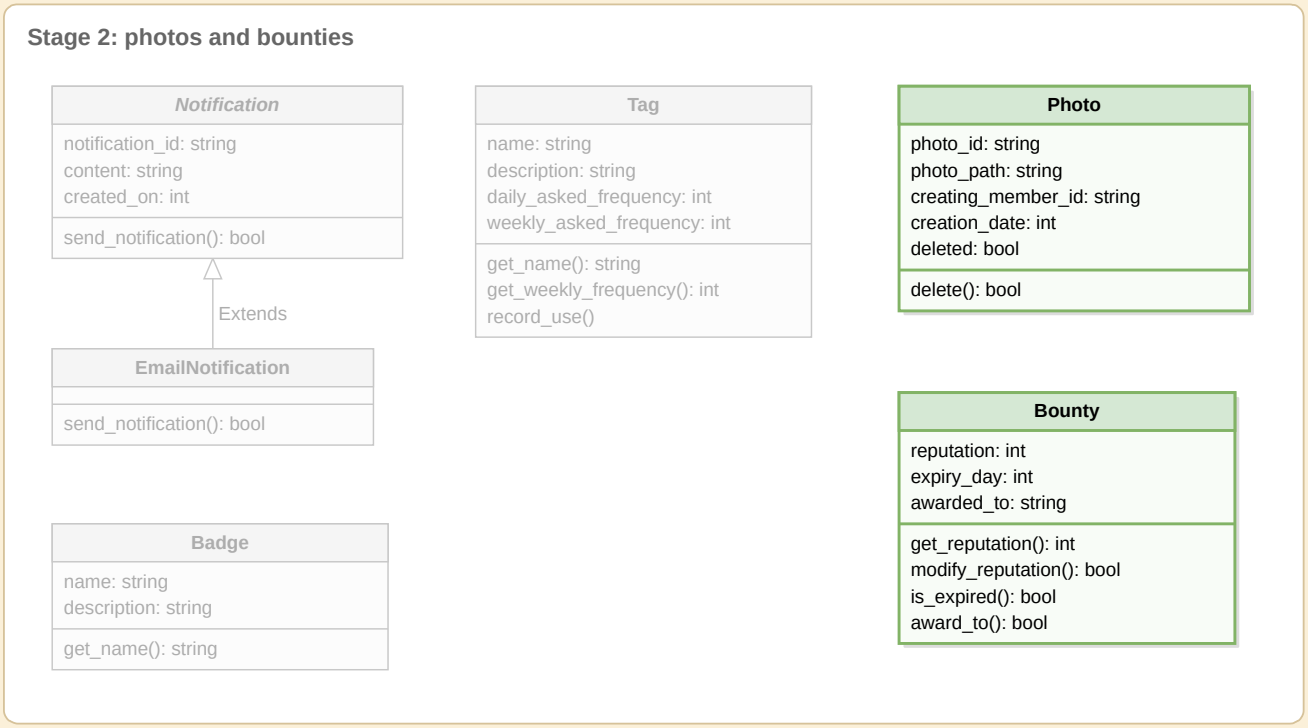

Figure — Stage 2 adds `Photo` (attachments on questions and answers) and `Bounty` (reputation held until awarded or expired) (course diagram)

Stage 2 covers requirement 7. The bounty keeps the staked amount itself rather than on the question, so the money-like value has one owner until it is settled. The course's reason for this is that the amount can then go back to the sponsor if nobody earns it. Be careful in an interview: on the real site a bounty is *not* refundable, so our code deducts the points when the bounty starts and never returns them.

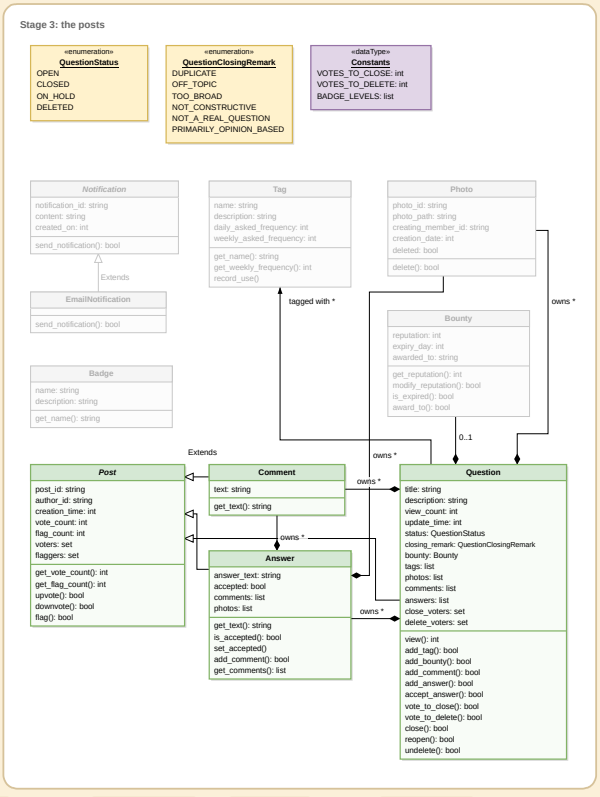

Figure — Stage 3: abstract `Post` with `Question`, `Answer` and `Comment` below it; filled diamonds from `Question` to its answers, comments, photos and bounty; a plain association from `Question` to `Tag` (course diagram)

Stage 3 is the heart of the design. Requirements 5 and 6 say that upvoting and flagging work the *same way* on three classes, so that behaviour is written once in `Post`. What *differs* is what each one contains, so they remain three separate classes instead of a single class plus a "kind" field. `Post` also remembers **who** voted —

otherwise one member could vote ten times. The filled diamonds are **composition**: deleting a question also deletes its answers, comments, photos and bounty. `Tag` is linked by a plain **association** instead: many questions use the same tag, and the tag lives on after any one of them is deleted. Because `Post` keeps only the author's id, the diagram has no arrow from a post to a member.

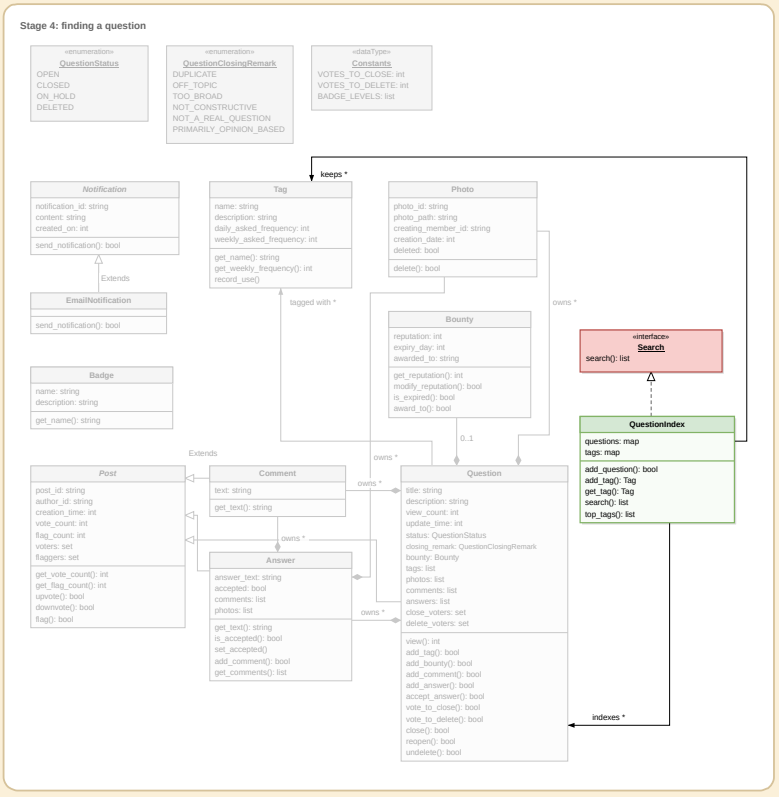

Figure — Stage 4: the `Search` interface and `QuestionIndex`, which holds (but does not own) questions and tags (course diagram)

Stage 4 covers search and requirement 13. A tempting first attempt makes search a static method (a method that belongs to the class itself rather than to any one object) on `Question`, which forces `Question` to know every question in existence — not its job. The index implements `Search` (dashed line with hollow head = realization). Its arrows are plain associations: deleting the index deletes no question.

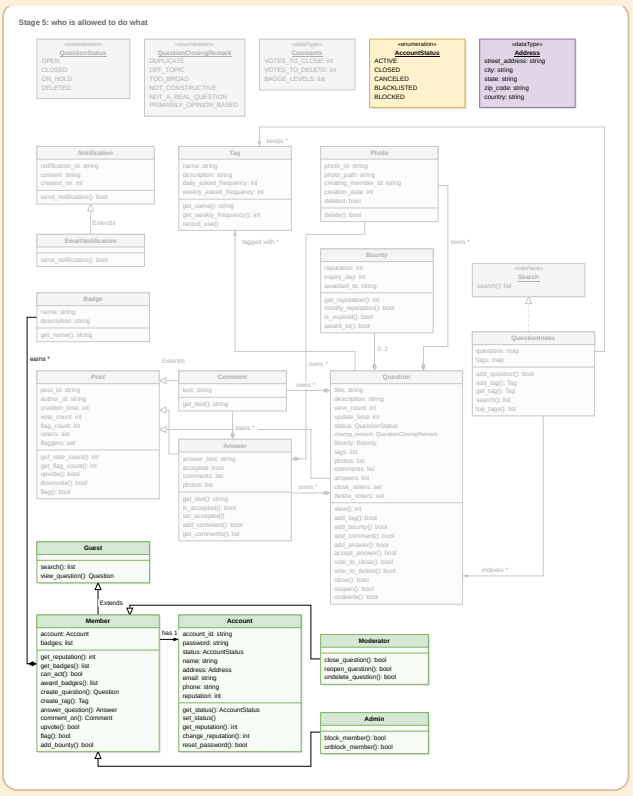

Figure — Stage 5: `Account`, `Guest`, `Member` (extends Guest), `Moderator` and `Admin` (extend Member); `Member` owns its badges (course diagram)

Stage 5 covers requirement 1 by the *shape* of the classes: the methods a guest may call sit on `Guest`, and `Member` inherits them and adds posting and voting. A guest simply has no `createQuestion` method, so no check can be forgotten. `Moderator` and `Admin` inherit from `Member` since each of them may do anything a member may (the substitution test passes). `Member` owns its badges (filled diamond): a badge is awarded to that one member. The link from a member to its `Account` is a plain association, because the account is created elsewhere and handed to the member.

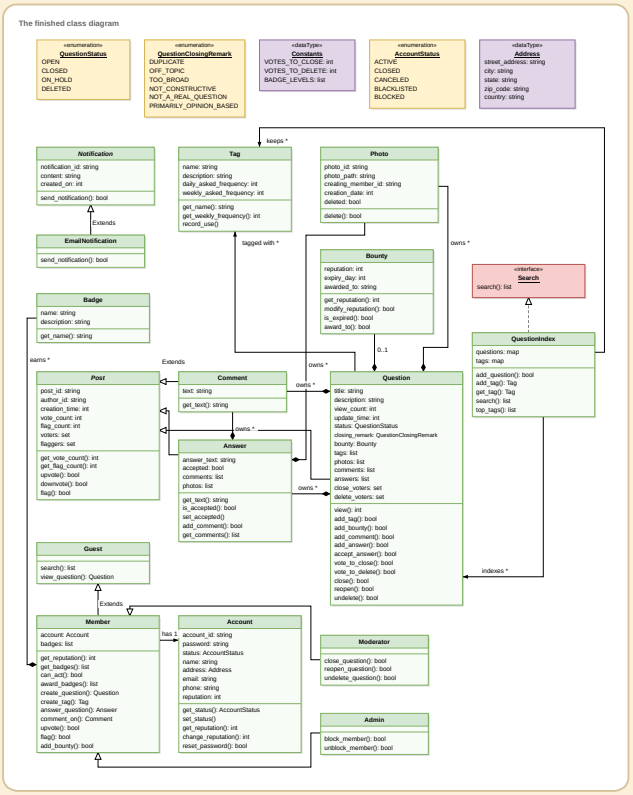

Figure — The finished Stack Overflow class diagram: enums (QuestionStatus, QuestionClosingRemark, AccountStatus), Constants, the posts, tags, badges, bounty, photo, notification, search index and the account hierarchy (course diagram)

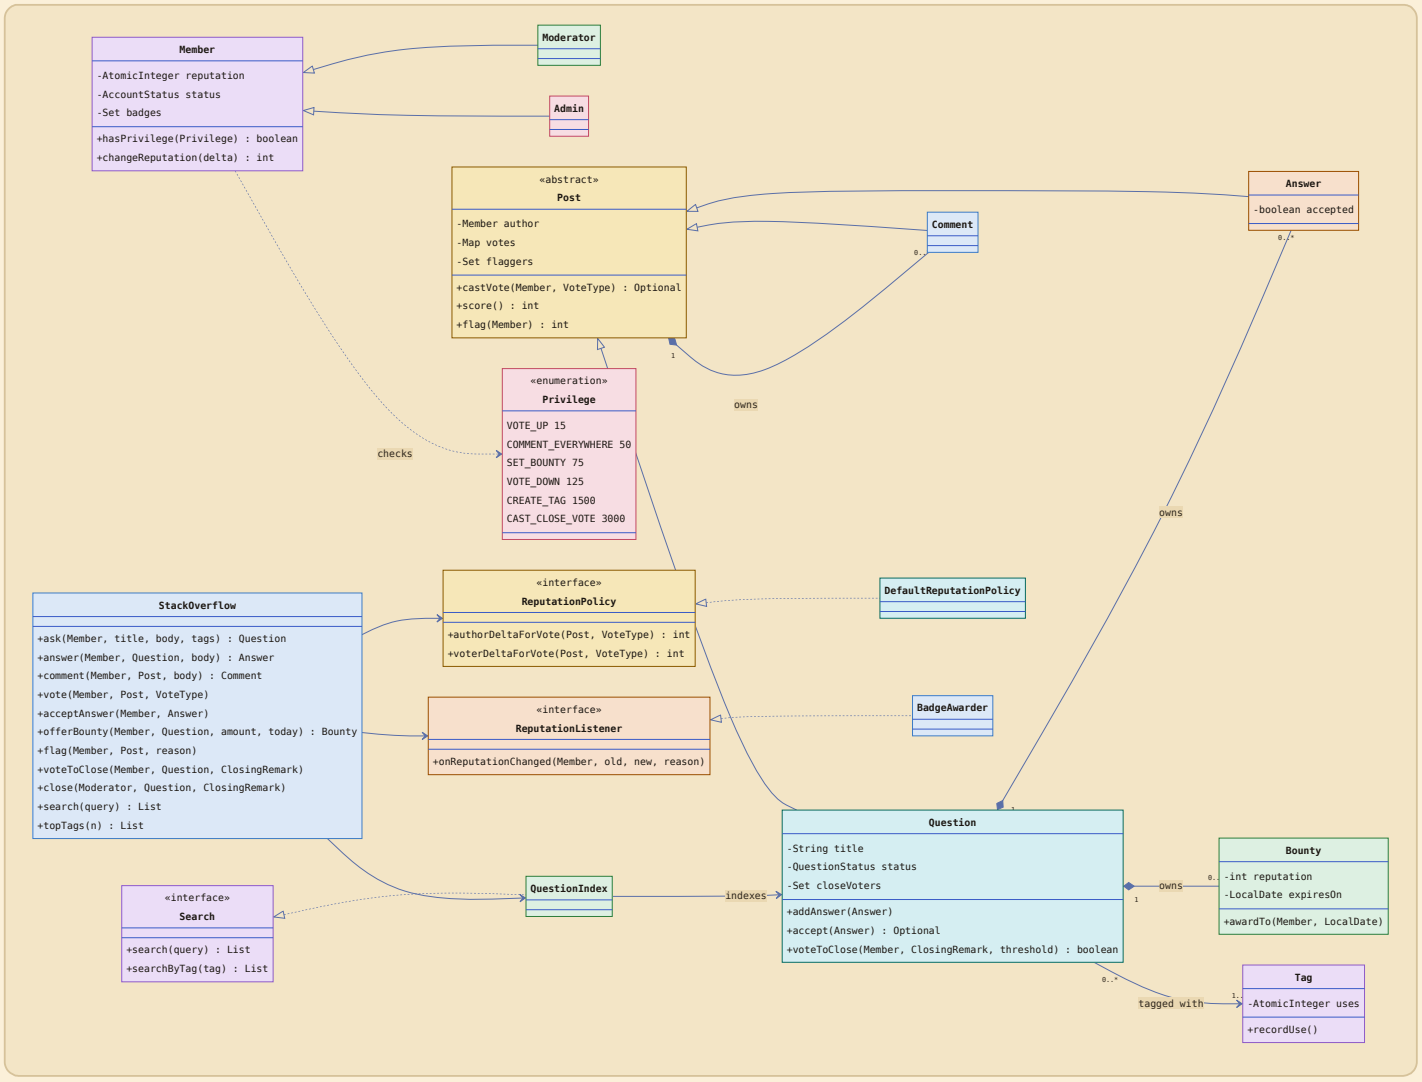
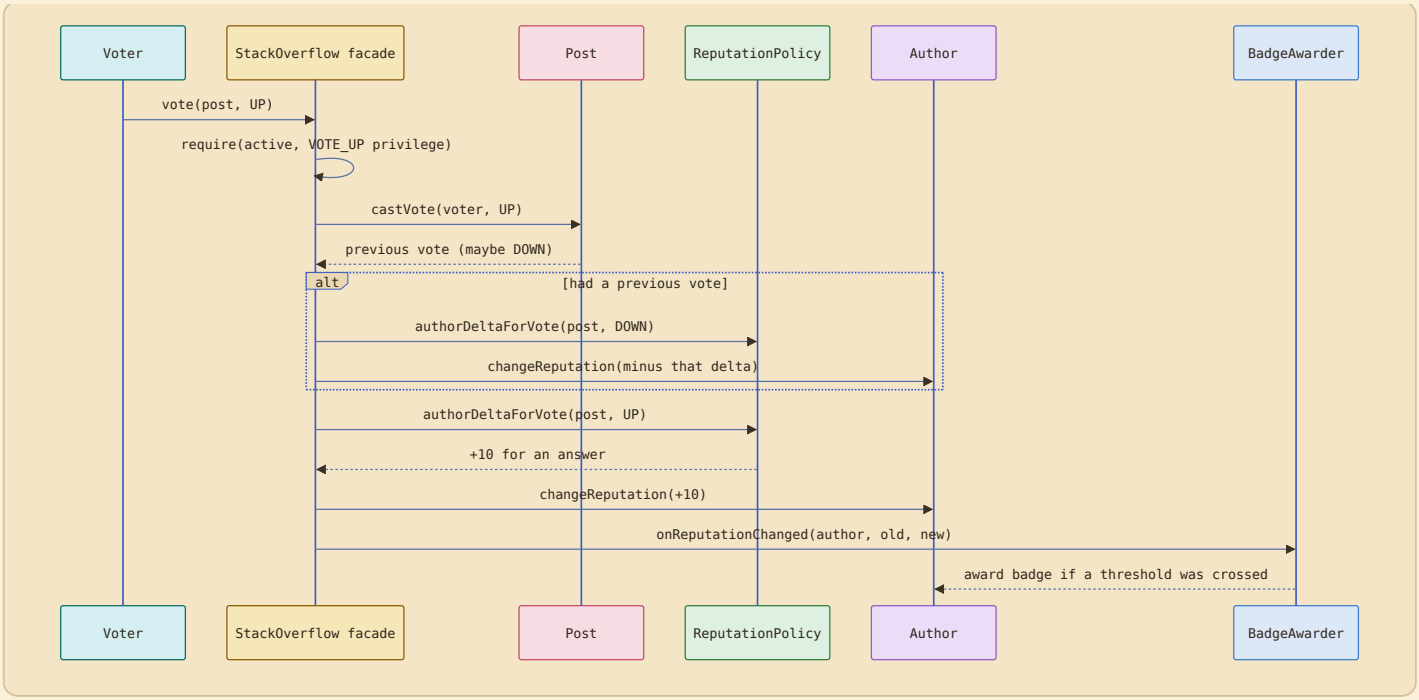
Our Java design. It keeps the course's structure and adds three things the course's "what we left out" section invites: a reputation **Strategy**, a badge **Observer**, and a data-driven **privilege table** (because on the real site privileges depend on reputation, not only on account type). A guest in our code is simply "no `Member` object": every write operation on the facade requires a `Member` argument, so the type system still enforces requirement 1. The course also lists what it deliberately leaves out: edit history, revision review, linking duplicates, chat, and the reputation a downvoter pays. We add the downvote cost (it is one line in the policy); edit history and duplicate links are covered under Extensions below; chat stays out of scope.

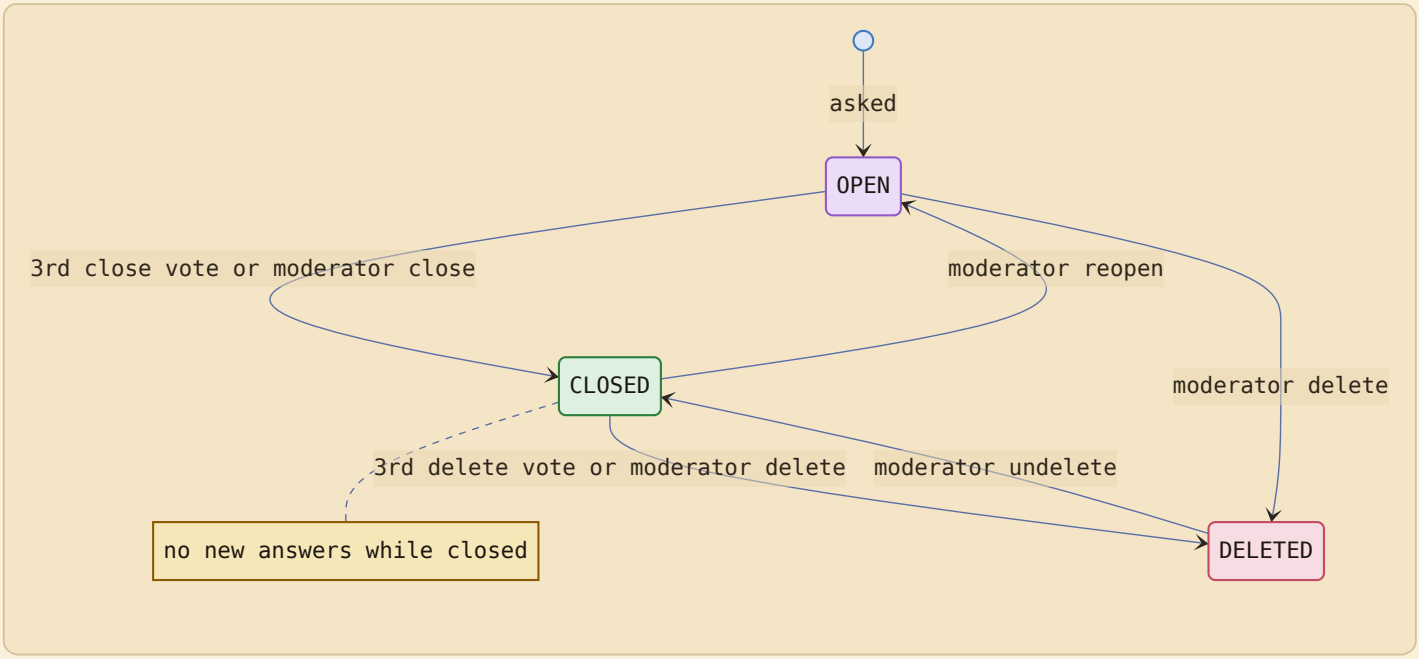


Key flows

Voting (with a changed vote). The facade checks privilege first, then asks the post to record the vote. The post returns the voter's *previous* vote, so the facade can reverse its reputation effect before applying the new one.



Question lifecycle.



Bounty. `offerBounty` checks the `SET_BOUNTY` privilege and the 50–500 range, attaches the bounty to the (open) question, and *immediately* deducts the amount from the sponsor. Later `awardBounty` (sponsor only, not to their own answer, before expiry) credits the winner.

Design decisions & patterns used

Decision	Pattern / principle	Why	Alternative rejected
`Post` base class for question, answer, comment	Inheritance (passes the substitution test), `sealed`	Voting, flagging and commenting are identical on all three	One `Post` class with a `type` field — then every method needs `if (type == …)`
Votes stored as `Map<voterId, VoteType>`	"Store who, not how many"	Blocks double votes; lets a vote be changed and its reputation reversed	An `int voteCount` — cannot tell who voted
`ReputationPolicy` interface	**Strategy**	Scoring rules change (Stack Overflow really did change them); voting code should not	Hard-coded numbers inside `vote()` — the course calls this out as a weakness
`ReputationListener` + `BadgeAwarder`	**Observer**	Badges, notifications, analytics all react to reputation without the facade knowing them	Calling `awardBadges()` directly inside `vote()`
`Privilege` enum with thresholds	Table-driven design	One place holds the rules; `hasPrivilege` is one comparison	`if (rep >= 125)` scattered across methods
Moderator-only methods take a `Moderator` parameter	Type-level permission	You cannot even call `close(…)` without a moderator object	A runtime role check that someone might forget
`QuestionIndex` separate from `Question`	Single Responsibility	Search can later be swapped for Elasticsearch (a popular search-engine server) behind `Search`	Static `Question.search()`
`Tag` counts its own uses	Maintain an aggregate at write time	"Top tags" becomes a sort of a small collection	Scanning all questions on every request
`StackOverflow` facade	**Facade**	One entry point that validates, delegates and logs	Letting the UI call `Question`, `Member`, `Bounty` directly
Pattern matching `switch` over the sealed `Post`	Exhaustive dispatch	The compiler forces us to handle each post kind in the policy	`instanceof` chains that silently miss a new type

Java implementation

Package `lld.ch18.stackoverflow`. Read the files in this order: the enums and privilege table (`Types.java`), accounts, posts, reputation Strategy/Observer, the search index, then the facade and the demo.

```java
// File: lld/ch18/stackoverflow/Types.java
package lld.ch18.stackoverflow;

/** Lifecycle of a question. ON_HOLD is the older name Stack Overflow used for a freshly closed question. */
enum QuestionStatus { OPEN, ON_HOLD, CLOSED, DELETED }

/** Why a question was closed. */
enum ClosingRemark {
    DUPLICATE, OFF_TOPIC, TOO_BROAD, NOT_CONSTRUCTIVE, NOT_A_REAL_QUESTION, PRIMARILY_OPINION_BASED
}

enum AccountStatus { ACTIVE, CLOSED, CANCELED, BLACKLISTED, BLOCKED }

enum VoteType { UP, DOWN }

/**
 * Reputation needed to unlock an action. The numbers follow the public
 * privileges page of stackoverflow.com, so "reputation unlocks privileges"
 * is data here, not if-statements spread over the code.
 */
enum Privilege {
    ASK_OR_ANSWER(1),
    VOTE_UP(15),
    FLAG(15),
    COMMENT_EVERYWHERE(50),
    SET_BOUNTY(75),
    VOTE_DOWN(125),
    CREATE_TAG(1500),
    EDIT_ANY_POST(2000),
    CAST_CLOSE_VOTE(3000),
    CAST_DELETE_VOTE(10000);

    final int minReputation;

    Privilege(int minReputation) { this.minReputation = minReputation; }
}

/** A badge is just a name and a description; members own the badges they earn. */
record Badge(String name, String description) {}
```

```java
// File: lld/ch18/stackoverflow/Accounts.java
package lld.ch18.stackoverflow;

Walking through the important parts

- `Post.castVote` is `synchronized` (Java lets only one thread at a time run a synchronized method on the same object; others wait their turn) and uses `votes.put(...)`, which returns the previous vote. That single call both records the vote and tells us whether this is a *change* (so the facade can undo the old reputation effect). Voting the same way twice throws.
- `DefaultReputationPolicy` uses a Java 21 **pattern-matching switch** (a `switch` that picks a branch by the *type* of the value and hands you that typed value) over the sealed `Post`. Because `Post` permits exactly `Question`, `Answer` and `Comment`, the compiler rejects the switch if a case is missing.
- `Member.changeReputation` uses `AtomicInteger.updateAndGet` (an `AtomicInteger` is a number whose read-change-write happens as one indivisible step) so concurrent changes never lose an update, and it enforces the site's floor of 1.
- `BadgeAwarder` fires only when a threshold is *crossed* (`oldValue < level && newValue >= level`), so members who already had high reputation are not showered with badges, and each badge is added once (`Set.add` returns `false` for duplicates).
- `ask()` shows the activity diagram's decision "does the tag exist? has enough reputation?": in the output, Alice (200 rep) cannot create the new tag `hashmap`, so her first attempt is rejected.
- In section 2 of the output, Erin downvotes Carol's answer (Carol −2, Erin −1), then changes her vote to up: the old effect is reversed (+2, +1) and the new one applied (+10).
- `voteToClose` closes the question on the third vote; answering a closed question is then refused; a moderator reopens it.

Concurrency & edge cases

- **Two votes at the same time on one post.** `castVote`, `score` and `flag` are `synchronized` on the post, so the vote map is never corrupted and each voter is counted once. Reputation uses `AtomicInteger`, so two simultaneous reputation changes to the same author both apply.
- **Reputation updates are not in the same lock as the vote.** A reader could briefly see the new vote before the author's reputation changes. That is acceptable (**eventual consistency** for a score: the copies may disagree for a moment but will match shortly — see System Design Fundamentals). In a database you would put both in one **transaction** (a group of changes that either all succeed or all fail together), and enforce "one vote per member per post" with a **unique constraint** (a database rule that refuses a second row with the same values) on `(post_id, voter_id)`.
- **Reputation floor.** Because reputation cannot go below 1, reversing a vote on a member who was at the floor is not perfectly symmetric. The real site has the same quirk; if exact reversal matters, keep a ledger (an append-only list of every change, in order) of reputation events and recompute.
- **Accepting a different answer.** `Question.accept` returns the previously accepted answer so the facade removes its +15; the asker's +2 is given only once.
- **Self-actions.** Voting on your own post and awarding your own bounty are rejected.
- **Closed and deleted questions.** Closed: no new answers. Deleted: hidden from search results.
- **Blocked accounts.** Every write goes through `requireActive`, so a blocked member can do nothing.
- **Bounty expiry.** `awardTo` refuses after the expiry date. On the real site, bounty reputation is never refunded; if the sponsor does not award it, the system may auto-award half to a qualifying answer.

Extensions & follow-up questions

- **"How do you stop one person voting twice?"** — The per-post map of voter ids (the course's key follow-up). In a database: a unique key on `(post_id, voter_id)`.
- **"Add edit history."** — Store each version as an immutable `Revision` (author, time, body) in a list on the post; editing appends a revision. This is close to the **Memento** idea: the past states are kept so they can be shown or rolled back.
- **"Daily reputation cap."** — The real site caps reputation from votes at 200 per day. Wrap the policy: a `CappedReputationPolicy` decorator (the **Decorator** pattern: an object that wraps another object with the same

interface and adds behaviour before or after passing the call on) that tracks today's total per member and trims the delta. No voting code changes.

- **"Mark as duplicate and link."** — Add `duplicateOf: Question` to `Question` and a `ClosingRemark.DUPLICATE`; closing as duplicate sets the link.
- **"Review queues."** — Flags already reach moderators at a threshold; turn that into a `ReviewQueue` that holds flagged posts, with reviewers voting to keep or delete.
- **"Hot questions."** — A ranking Strategy over recent votes, answers and views with time decay (older activity counts for less and less), just like the feed rankers in 18.3 and 18.4.
- **"Tag frequency per day and week."** — The course's `Tag` keeps daily and weekly counters. Keep a counter per time bucket and roll the buckets over with a scheduled job (a task the system runs automatically at set times, e.g. every midnight).

Real-world example

On stackoverflow.com, the numbers in this design are real product rules. The help centre lists privileges by reputation (vote up at 15, comment everywhere at 50, set bounties at 75, vote down at 125, create tags at 1,500, edit at 2,000, cast close and reopen votes at 3,000, moderator tools at 10,000). In November 2019 the company raised question upvotes from +5 to +10 ("rewarding the question askers") — a change that, in our design, touches only the `ReputationPolicy` (one number, or a new policy class) and nothing in the voting code. After a 2019 experiment the number of close votes needed was lowered from 5 to 3, which in our code is one constant.

In the interview

How to spend 30–45 minutes

Minutes	What to do
0–5	Clarify actors and the reputation rules; write the requirement list
5–10	Use cases per actor; say "guest has no posting method"
10–20	Class diagram: `Post` base with three subclasses, `Member` hierarchy, `Tag`, `Bounty`, `QuestionIndex`, facade
20–30	Walk through `vote()` and `acceptAnswer()` including reversal; question state machine
30–40	Code the core: `Post.castVote`, the policy, the facade's `vote`
40–45	Concurrency (per-post lock, atomic reputation, DB unique key) and extensions

30-second answer: "Questions, answers and comments share voting and flagging, so they extend one `Post` that stores votes per voter — that stops double voting and lets me reverse a changed vote. Reputation rules are a Strategy so they can change without touching voting; badges are an Observer on reputation changes. Privileges come from a reputation table; moderator actions take a `Moderator` parameter so a guest or member cannot call them. Search is a separate inverted index, and tags count their own uses for 'top tags'."

Follow-ups with answers

- *Why not store `voteCount` only?* — It cannot prevent duplicates or support vote changes; derive the count from the voter map (or cache it next to a votes table).
- *Where does reputation get awarded — in `upvote`?* — Not inside the post. The facade asks the policy; that keeps posts ignorant of scoring (the course names this as the improvement to make).
- *How would you scale search?* — Keep the `Search` interface and replace `QuestionIndex` with a search engine fed by events when questions are created or edited.

Self-check

- **Q:** Which requirement is enforced by the *shape* of the classes rather than by an `if`? **A:** Guests cannot post or vote: guests have no `Member` object, and every write method needs one (course version: `Guest` has no `createQuestion`).
- **Q:** Why is `Post` abstract and sealed? **A:** Abstract because a bare "post" is never created; sealed so switches over post kinds are checked for completeness.
- **Q:** What happens to reputation when Erin changes a downvote into an upvote on an answer? **A:** The old effect is reversed (author +2, Erin +1) and the new one applied (author +10).

- **Q:** Why does `Tag` count its own uses? **A:** So "most used tags" is a sort of the tags, not a scan of all questions.
- **Q:** What makes a comment different from an answer in voting? **A:** Comments can only be upvoted and earn no reputation (policy returns 0).

> **TL;DR**

Stack Overflow = `Post` base (votes per voter, flags, comments) + `Question`/`Answer`/`Comment` + reputation **Strategy** + badge **Observer** + reputation **privilege table** + moderator-typed methods + inverted-index search + a facade that checks, delegates and scores.

18.2 Design Cricinfo

Figure — A ball hitting the stumps under the ESPNcricinfo logo, the cover image of this case study (course diagram)

Cricinfo (today ESPNcricinfo) is a sports news site only for cricket. It gives **live ball-by-ball commentary** of matches, keeps a database of every historic match, and publishes news and articles.

Before we start, a two-minute cricket primer, because this design is graded on whether you model the *rules*, not just the nouns:

Term	Meaning
Delivery / ball	One throw ("bowl") of the ball by the **bowler** to the **batter** on strike
Over	Six **legal** deliveries by one bowler. A **wide** (too far from the batter) or a **no ball** (illegal delivery, e.g. overstepping the line) gives the batting side a penalty run and must be bowled again, so it does not count toward the six
Striker / non-striker	Two batters are in at once. The striker faces the ball; they change ends whenever they complete an odd number of runs (1, 3, 5), and again after every over
Runs	Off the bat (credited to the batter) or **extras** — wides, no balls, **byes** and **leg byes** (credited to the team, not the batter)
Wicket / dismissal	A batter is out: bowled, caught, LBW (leg before wicket), stumped, hit wicket, run out, obstructing the field. A **run out is not credited to the bowler**
Innings	One team's turn to bat, ending when 10 batters are out ("all out"), the overs run out, or the target is reached
Formats	**T20** (20 overs per side), **ODI** (One Day International, 50 overs per side), **Test** (no over limit, two innings per side, over several days)
Squad / playing eleven	Before a tournament each team names a **squad**; for every match it chooses exactly **eleven** of those players

Problem & clarifying questions

Question to ask	Answer we assume
Which formats?	T20, ODI and Test
Who enters the data?	An **Admin** (scorer) records every ball; a **Commentator** adds text for each ball
Do we follow real cricket rules?	Yes — the international rules, at least: six legal balls per over, extras, who gets credit for a wicket, strike rotation, bowler limits
Live updates?	Yes — the scorecard and commentary update after every ball (push to subscribers, i.e. readers who asked for updates)
Stats?	Per player, match and tournament, plus global questions such as "highest wicket taker of all time"
Tournaments?	Yes, with squads and a points table
Out of scope?	The course leaves these out on purpose: rain rules (Duckworth–Lewis–Stern, a formula that resets the target when rain shortens a match), the follow-on and declarations in a Test, powerplays and fielding restrictions, free hits after a no ball, telling a leg-side wide from an off-side one, partnerships, net run rate (a team's scoring rate minus its opponents', used to break ties in a points table), and the site's news articles. (Our code adds a simple `declare()`; several others appear under Extensions)

Requirements

Functional (the course's eight, in our words, plus the rules they imply)

1. Track every team that plays cricket, and every match it plays.
2. Show live ball-by-ball commentary.
3. Follow international cricket rules.
4. Each team announces a squad for each tournament.
5. For each match, each team announces its playing eleven from the tournament squad.
6. Keep statistics for players, for matches and for tournaments.
7. Answer global statistics questions, such as "which bowler has taken the most wickets ever?" or "which batter has made the most Test hundreds?"
8. Track ODI, Test and T20 matches.

Non-functional

- **Accuracy:** stats must match the ball-by-ball record exactly (a scorer's correction must fix every derived number).
- **Low-latency live updates** (**latency** = the delay between something happening and the reader seeing it)**:** thousands to millions of readers see a new ball within seconds.
- **Consistency of recording:** two scorers must not interleave balls in the same match.
- **Extensibility:** a new stat question, a new format, or a new subscriber (push alerts) should be a new class.

Use cases

Two actors: the **Admin** adds or modifies players, teams, tournaments and matches and records the ball-by-ball details; the **Commentator** writes the text commentary for each ball.

Top use cases: add/modify teams and players; add tournaments and matches; add ball; add stadium, umpire and referee; add/update stats (some generated by the system); add commentary.

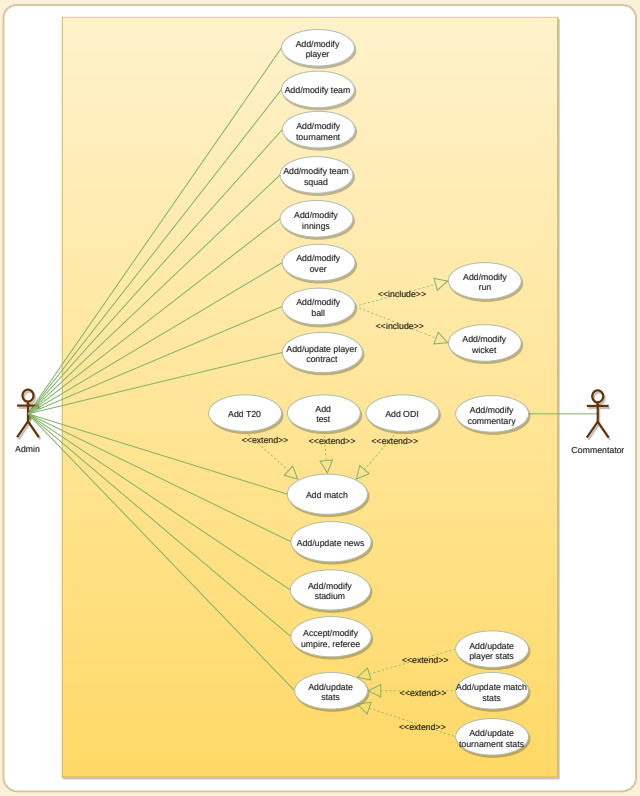

Figure — Cricinfo use cases: the Admin adds tournaments, matches (extended by Test, T20 and ODI), teams, squads, players, stadiums, umpires, innings, overs, balls (which include runs and wickets) and stats; the Commentator adds commentary (course diagram)

In the figure above, "Add match" is *extended* by the three formats, and "Add ball" *includes* adding its runs and wicket — a ball is recorded together with what happened on it.

Activity — record a ball. The scorer selects *Add Ball*; picks the ball type (normal, wide, no ball, or wicket-taking); if a wicket fell, adds wicket details; if runs were scored, adds a run record for each run type; adds commentary; saves the ball.

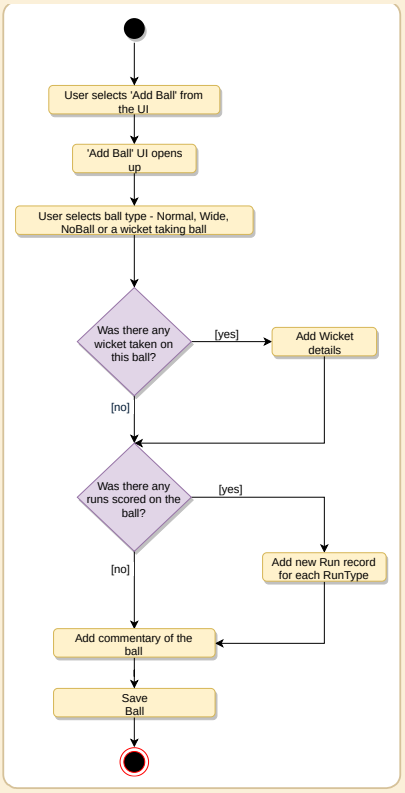

Figure — Activity diagram "record a ball of an over": choose ball type, add wicket details if any, add run records if any, add commentary, save (course diagram)

Core entities

Class	Responsibility
`Person` (record)	A human: name, country. Roles *hold* a person
`Player`	A role holding a `Person` (the course's `Player` also keeps a basic profile and contract details)
`MatchOfficial` (abstract) → `Umpire`, `Referee`, `Commentator`	Shared "assign to a match" behaviour; each says its role
`Team`	Every player the team has ever picked
`TournamentSquad`	Who a team may use in one tournament (must be team members)
`Playing11`	Exactly eleven, all from the squad, in batting order
`Tournament`	Owns squads, lists matches, keeps the points table
`BallOutcome` (record)	What happened: runs off the bat, extra type and runs, boundary?, wicket type, which batter was out, commentary text. Validates the laws (no bowled off a no ball)
`Ball` (record)	A recorded delivery: over, delivery number, bowler, striker, outcome, wicket
`Wicket` (record) + `WicketType`	Who was out, how, off whose bowling; `creditedToBowler()`
`Over`	One bowler's six **legal** deliveries; runs conceded; maiden?
`Innings`	Owns overs; decides striker, end of over, new batter, bowler limits, and when the innings ends
`Match` (abstract) → `T20`, `ODI`, `Test`	Holds everything; formats say only overs per innings and innings per side
`Result` (sealed) → `Win`, `Tie`, `Draw`	The outcome
`MatchObserver` → `CommentaryFeed`, `LiveScorecard`	Subscribers to ball / over / innings / match events
`PlayerStats`, `StatsService`	Numbers derived from balls
`StatQuery` (abstract) → `MostRuns`, `MostHundreds`, `MostWickets`, `MostSixes`	Template Method: one question per class

Class diagram

The course builds this design in **six stages**.

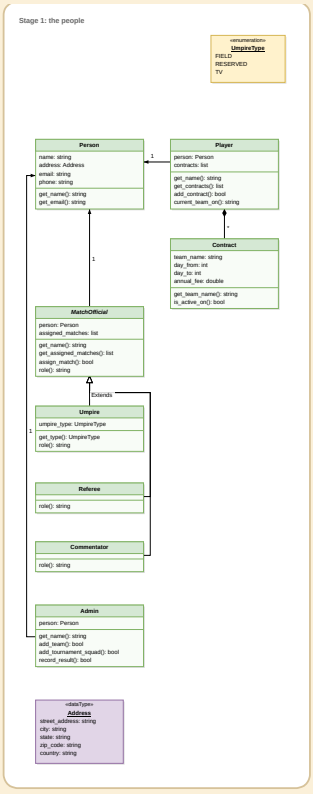

Figure — Stage 1: `Person`, `MatchOfficial` with `Umpire`, `Referee` and `Commentator`, `Admin`, and `Player` holding a `Person` (course diagram)

`Stage 1 — the people.` A player *holds* a person instead of extending one: one real human can play today and commentate after retiring, and composition lets them take both roles without copying. Umpires, referees and commentators all do one thing in common — get assigned to matches — so that lives once in `MatchOfficial`.

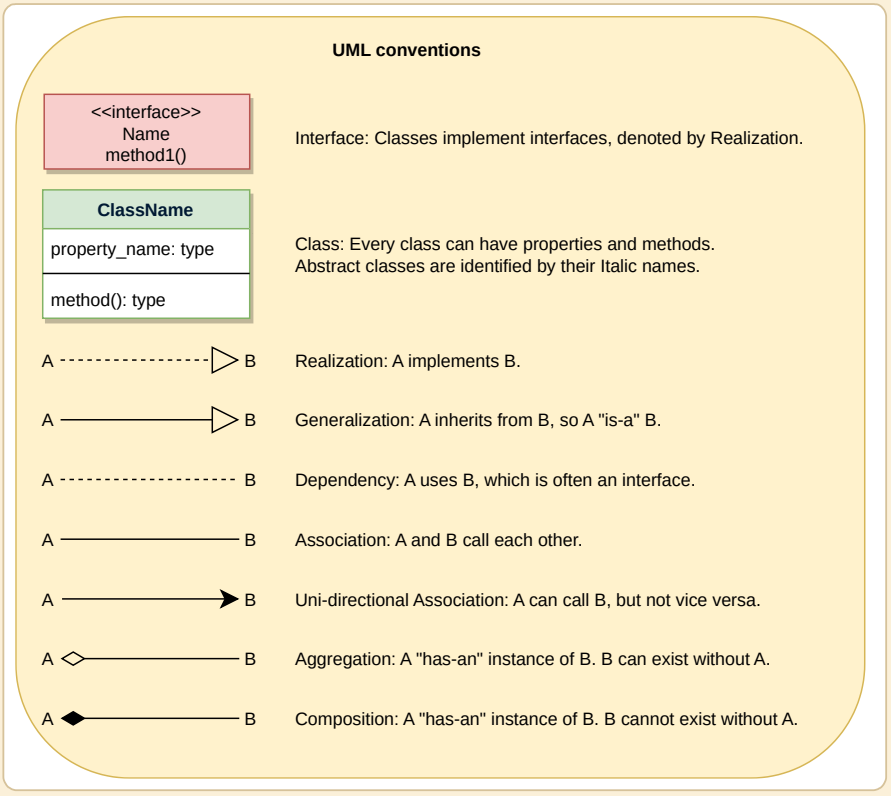

Figure — UML legend for reading the arrows in these diagrams (course diagram)

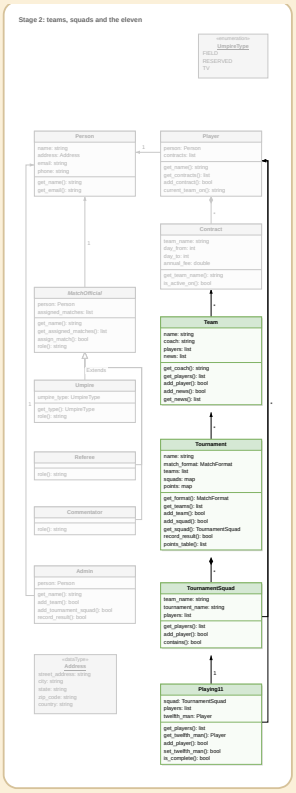

Figure — Stage 2: `Team`, `TournamentSquad`, `Playing11` and `Tournament`; only the tournament owns anything (its squads) (course diagram)

Stage 2 — teams, squads and the eleven. Requirements 4 and 5 look like one idea but are three nested sets: the team (everyone ever picked) ⊇ the squad (one tournament) ⊇ the eleven (one match). `Playing11` keeps a reference to its squad, which lets it reject anyone outside the squad, and it also rejects a twelfth pick. Requirement 5 thus lives in code rather than in a comment.

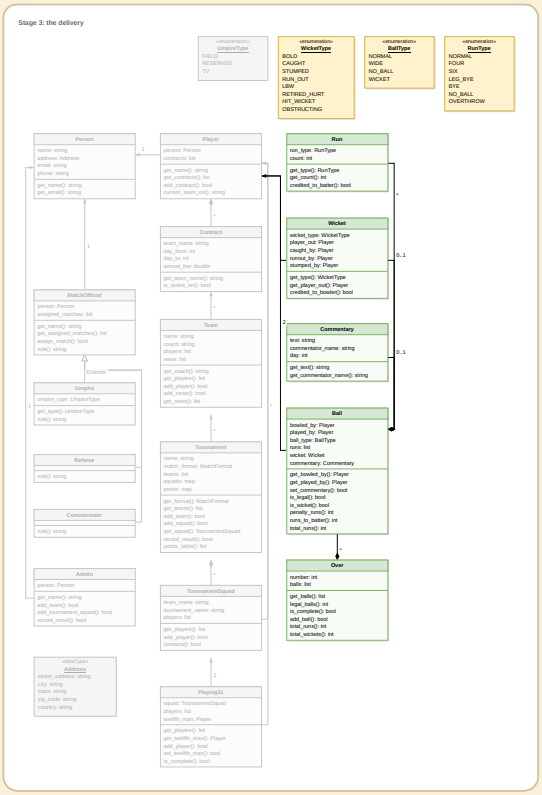

Figure — Stage 3: enums `WicketType`, `BallType`, `RunType`, and classes `Run`, `Wicket`, `Commentary`, `Ball` (owning its runs, wicket and commentary) and `Over` (course diagram)

Stage 3 — the delivery. This stage decides whether the design understands cricket. Three rules hide in it: (1) an over is six *legal* deliveries, so `Over.isComplete` counts only legal balls, and an over with two wides takes eight deliveries; (2) a run out is credited to the fielding side, *not the bowler* — get this wrong and "highest

wicket taker" is silently wrong for years; (3) byes and leg byes belong to the team, not the batter, so each run carries a type that says who gets the credit. `Ball` owns its runs, wicket and commentary (composition); it only *refers* to the bowler and batter.

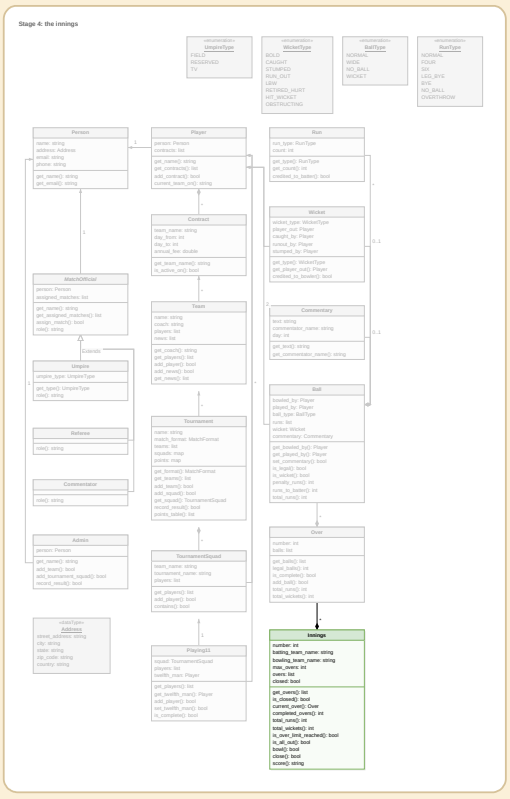

Figure — Stage 4: `Innings` owns its overs and prints the score (course diagram)

Stage 4 — the innings. Because the innings owns the overs, it alone decides when an over is finished and a new one starts; if that rule lived anywhere else, it would soon exist in two slightly different copies. Its `score` uses scorecard notation: runs/wickets, then full overs and the legal balls of the over in progress.

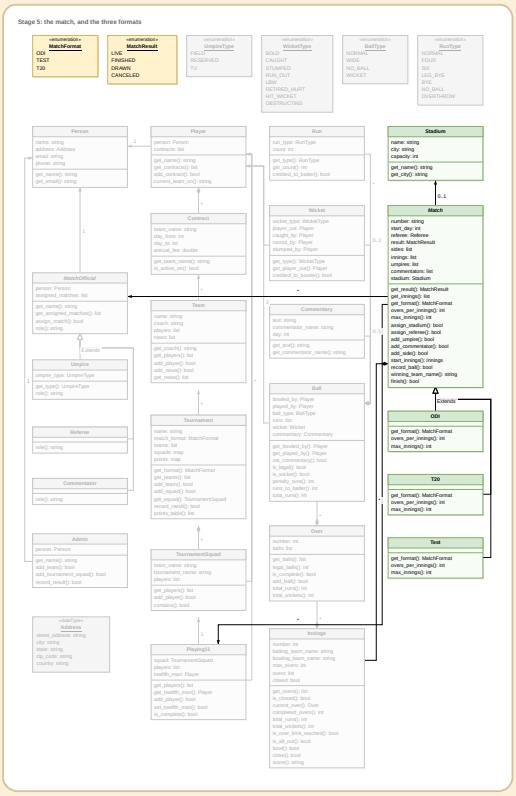

Figure — Stage 5: `Stadium`, abstract `Match` owning its innings, and the `ODI`, `T20` and `Test` subclasses (course diagram)

Stage 5 — the match and the formats. Before creating three classes, check what really changes between the formats. Starting an innings, recording a ball and deciding the winner are the same. Only two numbers differ: overs per innings and innings per match. So `Match` is abstract and holds everything; each format overrides two short methods. A Test returns zero overs (meaning "no limit") and four innings in total.

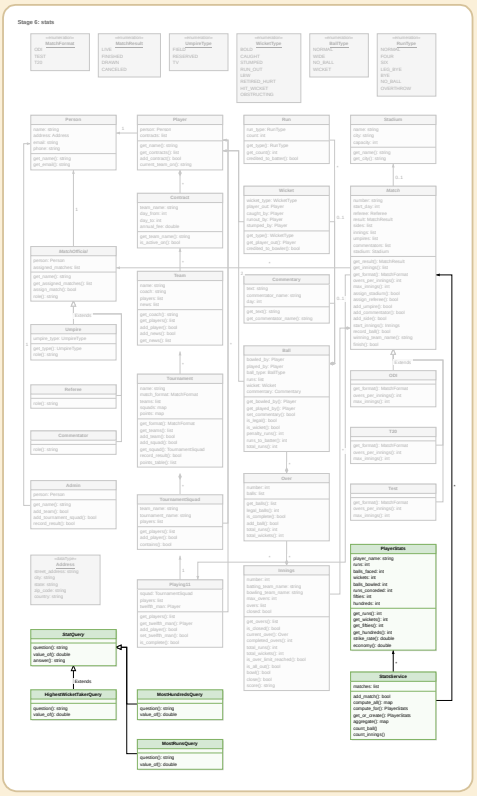

Figure — Stage 6: `PlayerStats`, `StatsService` and the `StatQuery` hierarchy (course diagram)

> **Key term — Template Method:** a design pattern where a base class writes the fixed outline of an algorithm in one method and leaves one or more steps as abstract methods for subclasses to fill in. Every subclass reuses the outline and changes only its own step. In this design `StatQuery.answer()` is the outline (loop over players, keep the best) and each subclass supplies only `valueOf()` — "runs", "wickets" and so on.

Stage 6 — stats. Stats are **worked out from the balls**, not stored beside them. Keep a separate counter and it will drift from the ball record as soon as a scorer fixes a mistake, and after that nobody can say which number is correct. Fifties and hundreds are per-innings milestones, so they are counted after each innings

(`countInnings`) next to the per-ball counting (`countBall`). Each global question is one small `StatQuery` subclass.

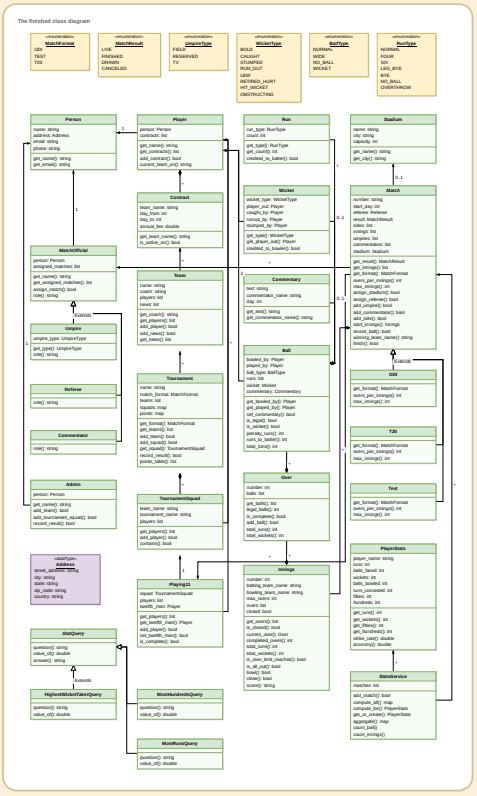

Figure — The finished Cricinfo class diagram, with every class from the six stages in full colour (course diagram)

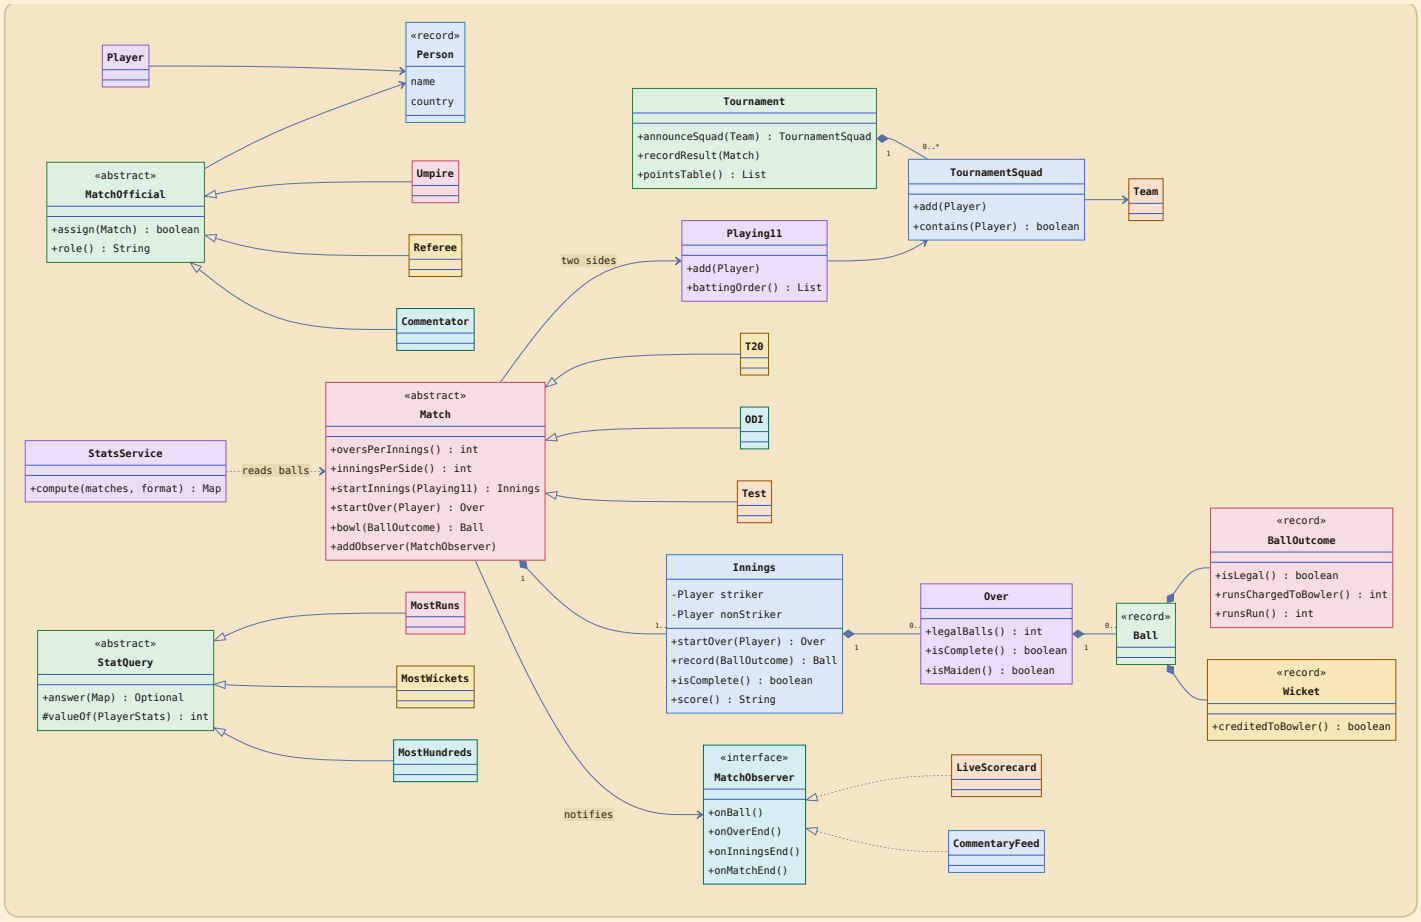
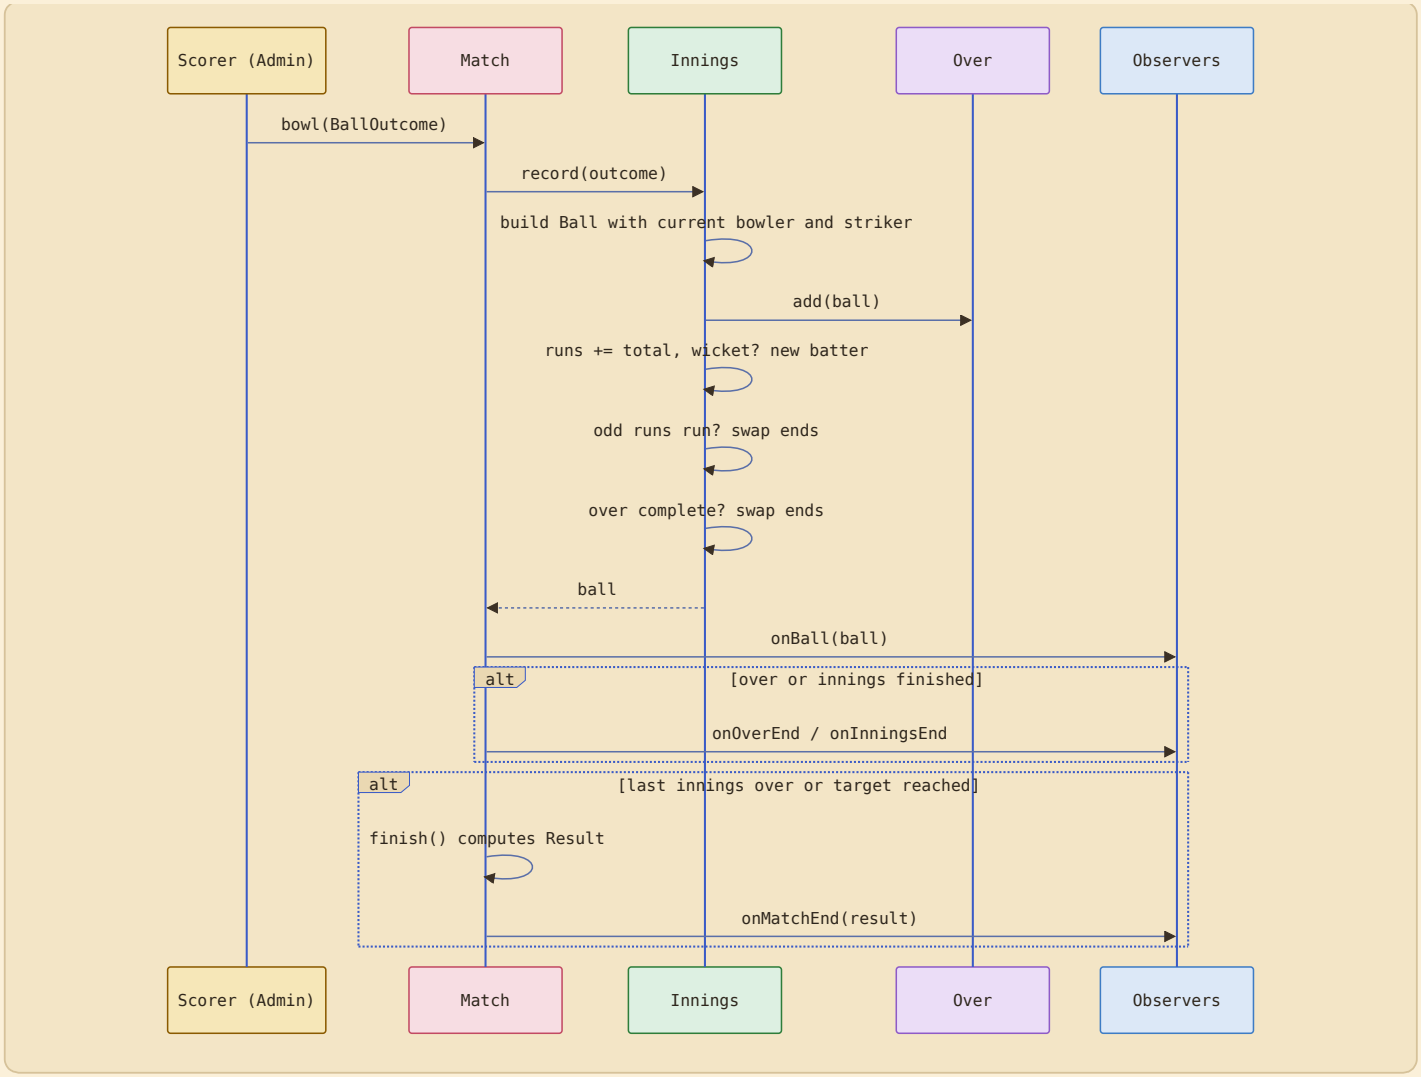
Our Java design keeps all six stages and adds what the course flags as missing: **strike rotation** (who is on strike), bowler rules (not two overs in a row; 4 overs per bowler in a T20, 10 in an ODI), the laws about which dismissals are possible off a wide or no ball, a result calculation, and **Observers** for live updates. Instead of separate `Run` objects per run type, a `BallOutcome` record carries bat runs, extra type and extra runs — the same information in one immutable value (an object that can never be changed after it is created).

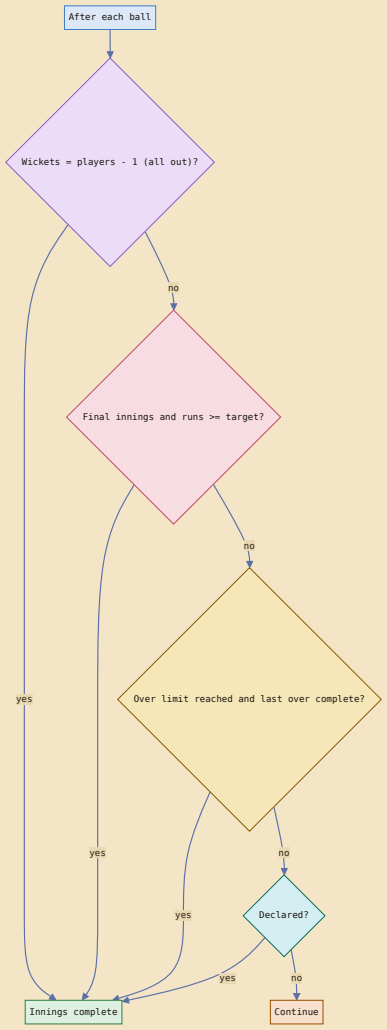


Key flows

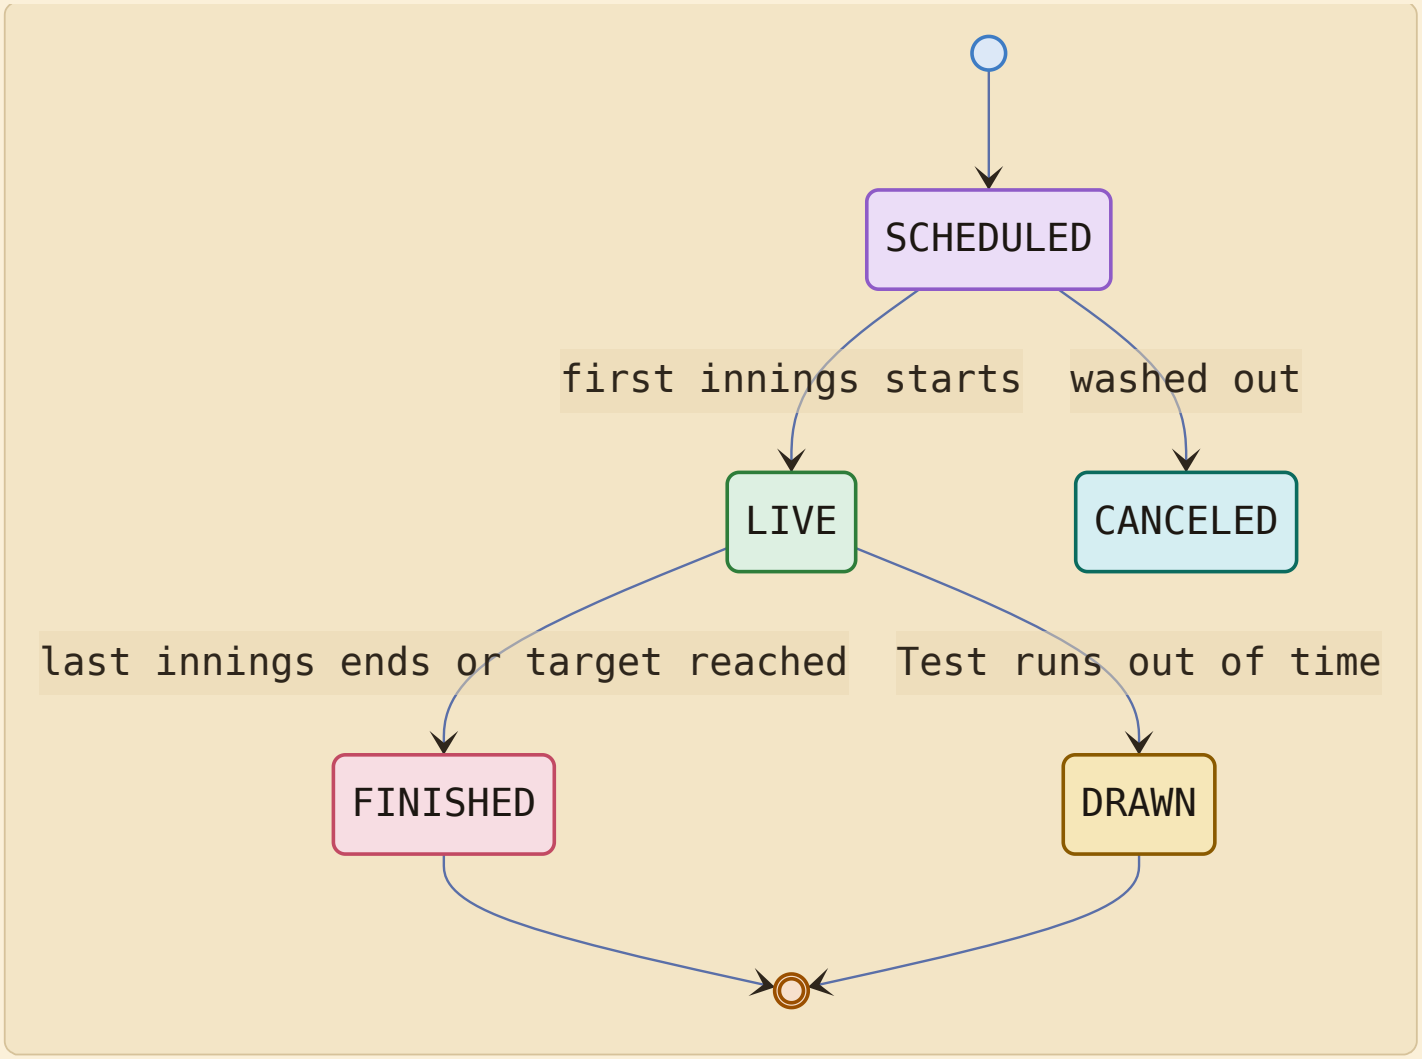
Recording one ball (the scorer's "Add Ball"):



Innings end conditions (checked by `Innings.isComplete`):



Match status:



SCHEDULED
first innings starts
washed out
LIVE
CANCELED
last innings ends or target reached
Test runs out of time
FINISHED
DRAWN

Design decisions & patterns used

Decision	Pattern / principle	Why	Alternative rejected
`Player` and `MatchOfficial` hold a `Person`	Composition over inheritance	One human, many roles over time	`Player extends Person` — a player who becomes a commentator must be copied
`Match` abstract; `T20` / `ODI` / `Test` override two numbers	Template-style base class (the course notes it is not a named pattern here)	Only what differs is overridden	Three full `Match` copies
`StatQuery.answer()` final, `valueOf()` abstract	**Template Method**	A new statistic is one tiny subclass; the search loop is written once (Open/Closed: open to new features, closed to editing old code)	A `switch (questionType)` inside the service
Stats derived from balls	Single source of truth	Corrections fix every number automatically	Stored counters that drift; a cache is fine if it is rebuildable
`Innings` owns the over rule and strike	Information Expert (GRASP — guidelines for deciding which class gets a job)	The class with the data makes the decision	Scorer UI deciding when an over ends
`BallOutcome` validates the laws in its constructor	Fail fast, immutable value	Impossible deliveries (bowled off a no ball) never enter the record	Checking later in the stats code
`MatchObserver` with default methods	**Observer**	Commentary feed, live scorecard, push alerts subscribe without the match knowing them	The match printing to the console itself
`Result` is a sealed interface of records	Algebraic data type (a value that is exactly one of a closed set of shapes)	`switch` over results is exhaustive (see `Tournament.recordResult`)	Strings like "Team A won"
`Match.bowl` is `synchronized`	Monitor lock (Java's built-in per-object lock) per match	Two scorers cannot interleave balls	Unsynchronised updates that corrupt the over

Java implementation

Package `lld.ch18.cricinfo`. The demo builds two teams, a tournament, squads and elevens (showing both refusals), then plays a scripted first over (a wide and a no ball make it **eight deliveries**; a bowled that counts for the bowler; a run out that does not), and simulates the rest with a fixed random seed (the starting number for the random generator; the same seed always gives the same "random" sequence) so the output is repeatable. An ODI is simulated too, so the global stat queries have data from two formats.

```java
// File: lld/ch18/cricinfo/People.java
package lld.ch18.cricinfo;

import java.util.ArrayList;
import java.util.List;

/** A human being. Roles (player, umpire, commentator) HOLD a person instead of extending it. */
record Person(String name, String country) {}

final class Player {
    private final Person person;
    Player(Person person) { this.person = person; }
    String name() { return person.name(); }
    Person person() { return person; }

== ODI Tigers v Lions at Riverside Oval ==
```

```
  [live] Tigers 181/3 (25 ov)
  [live] Tigers 348/9 (50 ov)
  [innings 1 over] Tigers 348/9 (50 ov)
  [live] Lions 159/1 (25 ov)  need 190 to win
  [live] Lions 349/5 (49.4 ov)
  [innings 2 over] Lions 349/5 (49.4 ov)
  [result] Lions won by 5 wickets

== Global stat queries (all formats) ==
  Most runs: Chetan (131)
  Most hundreds: Chetan (1)
  Highest wicket taker: Kiran (5)
  Most sixes: Nabil (5)
  Most runs in ODIs: Chetan (130)
  Ravi is assigned to 1 match(es)
```

Walking through the important parts

- Ball numbers follow the scorecard convention "completed overs . ball", so the first ball of the match is `0.1`. A wide or no ball carries the number of the ball that must be re-bowled, which is why `0.2` and `0.3` each appear twice.
- In over 1 of the output, there are eight lines but the over ends at `0.6`: the wide and the no ball did not count toward the six (`Over.isComplete` counts legal balls).
- Chetan is **run out** after completing one run: `Innings.record` first swaps ends for the completed single, then replaces the dismissed batter, so the new batter (Dev) comes in at the correct end and Arun faces the next ball. In the scorecard, Chetan's line says "run out" and Tarun's bowling figures show only **1** wicket (the bowled), because `WicketType.RUN_OUT.creditedToBowler()` is `false`.
- Trying to give Tarun the second over is rejected ("cannot bowl two overs in a row"). The simulation rotates five bowlers, so each bowls exactly 4 overs in the T20 (`maxOversPerBowler() = 20 / 5`).
- `LiveScorecard` prints every 5 overs and the chase line ("need 112 to win") comes from the target set automatically for the final innings (`first-innings total + 1`). The random ball generator is tuned to about 6.5 runs an over, so totals look like real matches (151 and 128 in the T20; 348 and 349 in the ODI, which the Lions win by 5 wickets with two balls to spare).
- The batting card lists every batter who faced a ball or was out, plus the two batters at the crease (Sameer is "not out 0 (0)": he walked in but never faced).
- The global queries (`MostRuns`, `MostHundreds`, `MostWickets`, `MostSixes`) are each a one-line subclass; "Most runs in ODIs" reuses the same service with a format filter.

Machine-coding variant: Cricket Match Dashboard (Udaan)

A **machine-coding round** asks you to write a *working, runnable* program in 60–90 minutes, judged on correctness, readability and extensibility. This problem was set by Udaan (an Indian B2B — business-to-business — e-commerce company) and appears in the kumaransg/LLD collection.

Problem statement (in our words)

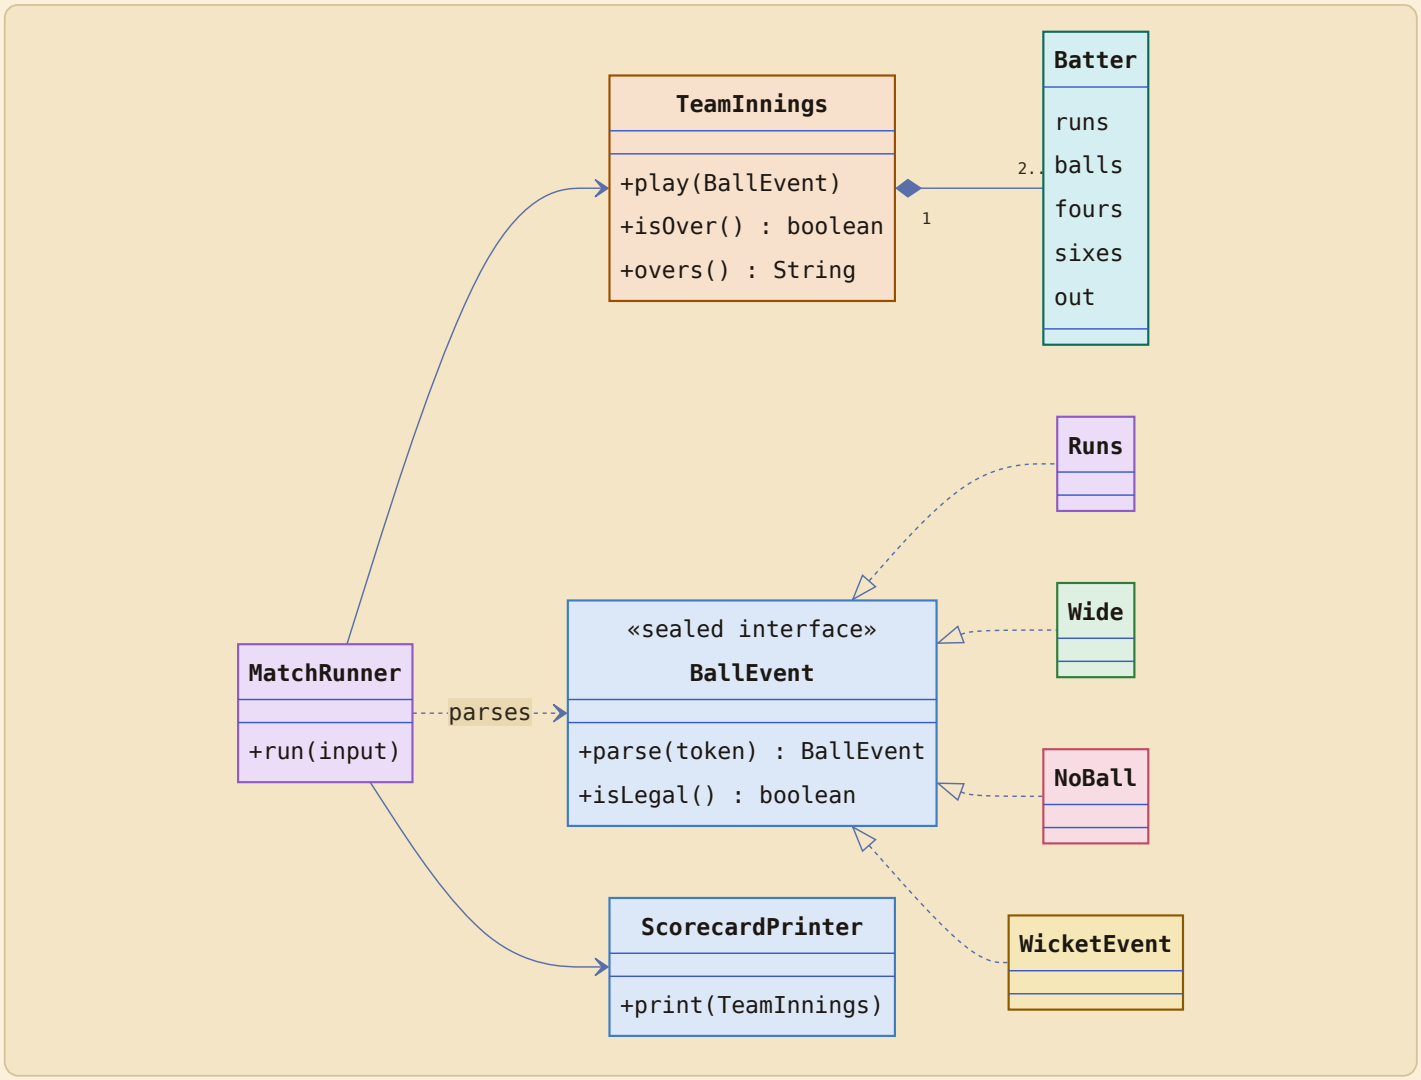
Build a cricket **scorecard** for a two-team, limited-overs match.

- **Input:** number of players per team, number of overs, then for each team its batting order, followed by the balls of each over, one per line: a number of runs (`0`–`6`), `W` (wicket), `Wd` (wide) or `Nb` (no ball).
- **Output after every over:** for each batter of the batting side — runs, 4s, 6s, balls faced — with a `*` on the two batters currently at the crease; then team total/wickets and overs.
- **Rules to handle:** strike changes on 1s and 3s and at the end of every over; wides and no balls add one run and are re-bowled (they do not count toward the six); the innings ends when the team is all out, the overs run out, or (second innings) the target is passed.
- **At the end:** print the winner and the margin (by runs or by wickets).
- **Good to have:** bowler figures (overs, runs, wickets, maidens, dot balls, economy), team extras, batter strike rates.

How the full Cricinfo design shrinks to a 90-minute solution

Cricinfo class	Machine-coding version	Why it is enough here
`BallOutcome` with extras, wickets, validation	`BallEvent` sealed interface: `Runs`, `Wide`, `NoBall`, `Wicket` with a `parse(token)` factory (a method that builds the right object from one input word)	Input has only four kinds of token
`Innings` (strike, over rule, end conditions)	`TeamInnings` — same responsibilities, ints instead of objects	Same rules, no bowler data in the input
`Scorecard` derived from balls	`Batter` counters + `ScorecardPrinter`	Only batting card needed; printer separated so another view could replace it
`Match` + `Result`	`MatchRunner` (reads input, plays two innings, prints result)	One format, two innings

This is the lesson of machine coding: keep the *same responsibilities in the same places* (the innings owns strike and the over rule; parsing is separate from scoring; printing is separate from both), but use the simplest data that satisfies the input.



(In the code the wicket record is called `BallEvent.Wicket`; it is shown as `WicketEvent` above only to keep the diagram label unique.)

Code

Package `lld.ch18.cricketdashboard`. `Main` feeds the problem's sample input as a text block.

```java
// File: lld/ch18/cricketdashboard/Model.java
package lld.ch18.cricketdashboard;

import java.util.ArrayList;
import java.util.List;

/** One input token, parsed once. Factory method: BallEvent.parse("Wd") etc. */
sealed interface BallEvent {
    record Runs(int runs) implements BallEvent {}
    record Wide() implements BallEvent {}
    record NoBall(int batRuns) implements BallEvent {}
    record Wicket() implements BallEvent {}

    static BallEvent parse(String token) {
        String t = token.trim();
        if (t.equalsIgnoreCase("W")) return new Wicket();
        if (t.equalsIgnoreCase("Wd")) return new Wide();
        if (t.regionMatches(true, 0, "Nb", 0, 2)) return new NoBall(t.length() > 2 ?
Integer.parseInt(t.substring(2)) : 0);
        int runs = Integer.parseInt(t);
        if (runs < 0 || runs > 6) throw new IllegalArgumentException("bad runs: " + t);
        return new Runs(runs);
    }

    default boolean isLegal() { return !(this instanceof Wide || this instanceof NoBall); }
}

/** A batter's line on the scorecard. */
final class Batter {
    final String name;
    int runs, balls, fours, sixes;
    boolean out;

    Batter(String name) { this.name = name; }

    void faced(int batRuns) {
        runs += batRuns;
        balls++;
        if (batRuns == 4) fours++;
        if (batRuns == 6) sixes++;
    }

    String strikeRate() { return balls == 0 ? "-" : String.format("%.1f", 100.0 * runs / balls); }
}

/** One team's batting innings: owns strike rotation, extras, and the "is it over?" rule. */
final class TeamInnings {
    private final String team;
    private final List<Batter> order = new ArrayList<>();
    private final int maxOvers;

Result: Team 1 won the match by 4 runs
```

Notes on the sample and on correctness

- Leaving aside the strike-rate and extras columns we add, our output matches the published sample for team 1 exactly, and for team 2 in every line except two places where the published sample itself is inconsistent: after team 2's first over it prints `12/1`, but the over contains **two** `W` tokens (P6 and P8 were both out), so the correct total is `12/2`; and in the final card it shows P6 with 2 balls after 3 in the previous card. Following the stated rules gives `12/2` and 3 balls, which is what our program prints. Pointing out such inconsistencies calmly is a plus in a machine-coding round.
- Team 2's second over stops after four balls because the fourth wicket leaves only one batter (5 players → all out at 4 wickets), so "Overs: 1.4".
- The loop that reads an over counts **legal** balls (`legalThisOver < 6`), so a wide in team 1's second over makes that over seven tokens long.
- Extras and strike rate (two of the "good to have" items) are printed; bowler figures would need bowler names in the input — add a `Bowler` class with the same counters and a line per over naming the bowler.

Concurrency & edge cases

- **Two scorers, one match.** `Match.bowl`, `startOver` and `startInnings` are `synchronized` on the match, so balls are applied one at a time in order. Different matches never block each other.
- **Many readers.** Observers are held in a `CopyOnWriteArrayList` (a list that makes a fresh copy on every change, so readers never see it half-updated), which is safe to iterate while another thread subscribes. At web

scale, the match would publish each ball to a **message broker** (a middleman service that receives messages and passes them on to every subscriber) and readers would receive it over **WebSockets** (a connection the browser keeps open so the server can send data at any time) or **server-sent events** (a one-way stream of updates from server to browser); the scorecard would be a cached view rebuilt from balls.

- **Illegal sequences rejected:** starting an over while one is in progress; the same bowler twice in a row; a bowler over his quota; bowling after the innings ended; a bowler from the batting side; a twelfth player; a player outside the squad.
- **Impossible dismissals rejected:** bowled, caught, LBW, stumped or hit wicket off a no ball; bowled, caught or LBW off a wide.
- **Wicket on the last ball of an over:** the new batter comes in, then ends change for the new over — both handled in `Innings.record`.
- **Tie:** equal totals give `Result.Tie` (a super over would be an extension).
- **Test matches:** `oversPerInnings() = 0` means no limit; the demo's `declare()` lets a captain close an innings; `declareDraw()` ends a Test that runs out of time.

Extensions & follow-up questions

- **"Who is on strike?"** — The course leaves this out; our `Innings` tracks it (odd runs and end of over swap ends).
- **"Stats are slow to recompute from every ball."** — Keep a running total per player as a cache, updated by an Observer on each ball, and rebuild it from balls whenever a scorer corrects a ball. The balls stay the truth; the total is only a cache.
- **"Add Duckworth–Lewis–Stern."** — A `TargetCalculator` Strategy on the match: the default returns "opponent total + 1"; a DLS implementation recomputes the target from overs lost.
- **"Add a free hit after a no ball."** — The innings remembers "next legal ball is a free hit"; `BallOutcome` validation then allows only run-out-type dismissals on that ball.
- **"Add partnerships and fall of wickets."** — Derive from balls: split the ball list at each wicket and sum.
- **"Add net run rate to the points table."** — Derive from innings totals and overs faced/bowled; still no stored numbers.
- **"Push notifications for wickets and milestones."** — A new `MatchObserver` that sends a push when `ball.wicket() != null` or a batter crosses 50/100.

Real-world example

ESPNcricinfo (founded in 1993 and bought by ESPN in 2007) is the reference site for cricket statistics; its **Statsguru** tool answers questions like the ones in requirement 7 across every recorded international match. Live pages update ball by ball with commentary lines very much like our `CommentaryFeed`, and millions follow big matches on phones — which is why the push-based Observer design (and, at scale, message brokers and caches) matters.

In the interview

Minutes	What to do
0–5	Clarify formats, actors, and that the real rules matter; say early: **"an over ends after six *legal* balls, however many deliveries that takes"**
5–10	Team ⊇ squad ⊇ playing eleven; people hold a `Person`
10–20	Class diagram: match (abstract) → innings → over → ball; formats differ in two numbers
20–30	Ball-recording flow, strike rotation, **the bowler gets no credit for a run out**, byes are not the batter's runs
30–40	Stats derived from balls; Template Method for stat queries; Observers for live feed
40–45	Concurrency (one scorer lock per match, broadcast to readers) and extensions

30-second answer: "I model cricket's rules, not just its nouns. An over is six legal balls; a wide or no ball is re-bowled. Because the overs belong to the innings, only the innings decides when an over ends, who is on strike and when the innings is over. Formats differ only in overs per innings and innings per match, so they override two methods. Stats are derived from the balls so corrections propagate, and each stat question is a Template Method subclass. Live pages subscribe as observers."

Follow-ups with answers

- *Why not store `wickets` on `Player`?* — It would drift from the ball record and cannot be filtered by format or tournament; derive it.
- *How do you add "most catches"?* — Add the fielder to `Wicket`, count it in `PlayerStats`, and write `MostCatches extends StatQuery` — no change to the service's loop.
- *Is Template Method the right name for `Match`/formats?* — The course says only `StatQuery` is a named pattern here; the formats are plain abstract-class specialisation. Be precise about that.

Self-check

- **Q:** A bowler bowls a wide and a no ball in an over. How many deliveries does the over have? **A:** Eight — six legal plus the two illegal ones.
- **Q:** Who is credited with a run-out wicket? **A:** The fielding side, not the bowler; it counts in the team's wickets but not in the bowler's figures.
- **Q:** Are leg byes added to the batter's score? **A:** No — they are extras for the team, and they are not charged to the bowler either.
- **Q:** Why does `Playing11` hold its `TournamentSquad`? **A:** So it can refuse a player not in the squad (requirement 5) — the rule lives in code.
- **Q:** What two methods distinguish `T20`, `ODI` and `Test`? **A:** `oversPerInnings()` (20, 50, 0 = unlimited) and `inningsPerSide()` (1, 1, 2).
- **Q:** In the Udaan variant, what is the correct team 2 score after over 1 of the sample? **A:** 12/2 — the over contains two wickets.

TL;DR

Cricinfo = people hold a `Person`; team ⊇ squad ⊇ eleven; `Match` (abstract, formats override two numbers) → `Innings` (owns overs, strike, end rules) → `Over` (six **legal** balls) → `Ball` (outcome + wicket). Run outs are not the bowler's; byes are not the batter's. Stats are derived from balls; stat questions are **Template Method** subclasses; live pages are **Observers**. The Udaan dashboard is the same responsibilities in a 90-minute, input-driven form.

18.3 Design LinkedIn

Figure — A tablet showing the LinkedIn logo surrounded by a network of professionals, the cover image of this case study (course diagram)

LinkedIn is a networking site for people's **working lives**. Members link up with colleagues and contacts they trust, and they use the site to find their next career move. A profile lists a member's skills, jobs and schooling; the home page shows a **feed** of updates from the member's network, arranged in sections (modules) the

member can reorder. It works much like Facebook, with features specialised for careers: **connections** (mutual, both sides agree), **follows** (one-sided), **endorsements**, **recommendations**, **company pages** and **job postings**.

Problem & clarifying questions

Question to ask	Answer we assume
Is a connection mutual?	Yes: an **invitation** is sent, and the receiver accepts or rejects it. Following is one-sided and needs no approval
Do we show degrees of connection?	Yes: 1st (direct), 2nd (connection of a connection), 3rd; beyond that "out of network"
Who can message whom?	A member can message their connections (messaging most non-connections needs LinkedIn's paid *InMail*, out of scope)
Who can endorse a skill?	Only 1st-degree connections, once per skill
Recommendations?	A member *requests* one from a connection; only that person can write it
Profile stats?	Profile views, number of connections, search appearances
Companies and jobs?	Members create company pages; page admins post jobs; members apply once per job
Feed?	Posts from connections and followed members, ranked (the course leaves the feed out; we add a simple one)

Requirements

Functional (the course's twelve, in our words)

1. A member fills in a profile: basic details, jobs held, schooling, skills and accomplishments.
2. Any user can search for members or companies by name (and jobs by title).
3. Members send, accept (or reject) connection requests.
4. Members can request a recommendation from other members.
5. The system shows profile stats: profile views, total connections, search appearances.
6. Members create posts to share with their connections.
7. Members can comment on posts; they can like or share both posts **and comments**.
8. Members send messages to other members.
9. A member gets a notification for each new message, each connection invitation, and each comment left on one of their posts.
10. Members create company pages and add job postings.
11. Members create groups and join any group.
12. Members follow other members or companies.

Non-functional

- **Symmetry:** a connection must always appear on *both* members, never only one.
- **Fast reads:** feed, search and degree lookups are far more frequent than writes.
- **Privacy/abuse:** blocked members' content disappears; you cannot spam strangers with messages.
- **Extensibility:** new notification channels and feed-ranking rules plug in without edits.

Use cases

Three actors: **Member** (search, connect, post, message, follow…), **Admin** (block and unblock members) and **System** (sends notifications for new messages, invitations and so on).

Top use cases: add/update profile; search members, companies or jobs and send connection requests; follow or unfollow a member or company; send a message to connections; create a post, like and comment; send notifications.

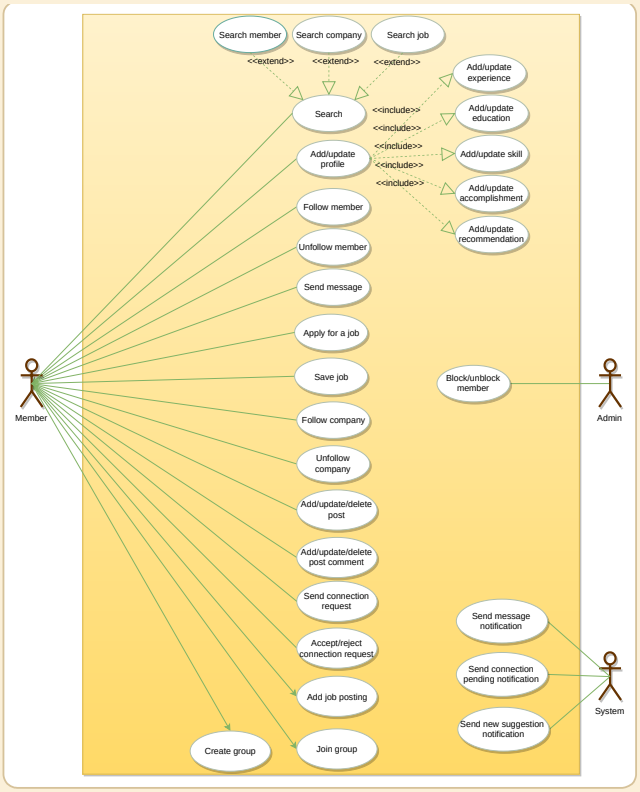

Figure — LinkedIn use cases for Member, Admin and System, including follow/unfollow member, with `<<include>>` and `<<extend>>` relationships (course diagram)

Activity — add experience to a profile. The member opens *Add Experience*, enters title, company, location, dates and description, optionally uploads a document or photo with a description, and presses save. The system verifies the data; if anything is missing it notifies the member, otherwise it saves the experience.

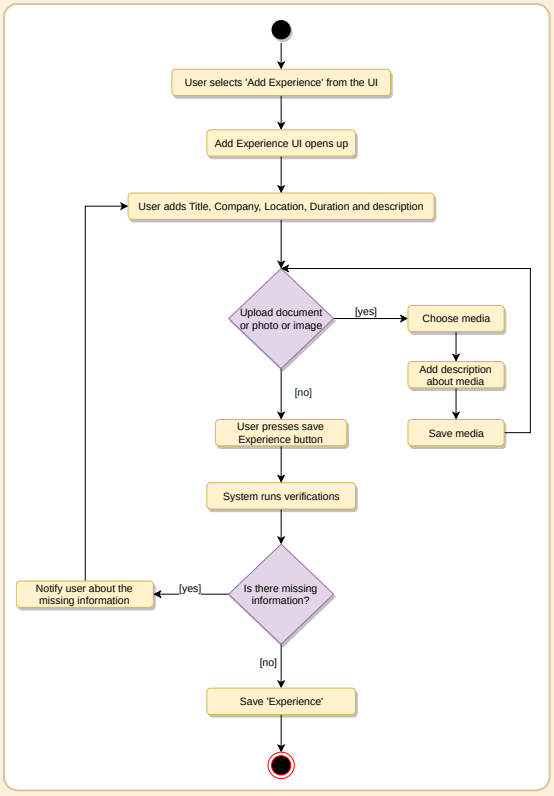

Figure — Activity diagram "add experience to profile" with optional media upload and a verification loop (course diagram)

Activity — send a message. The member composes a message, picks one or more recipients, adds a body and optional media, and presses send. After verification the message goes to every recipient, and each gets an email and a push notification.

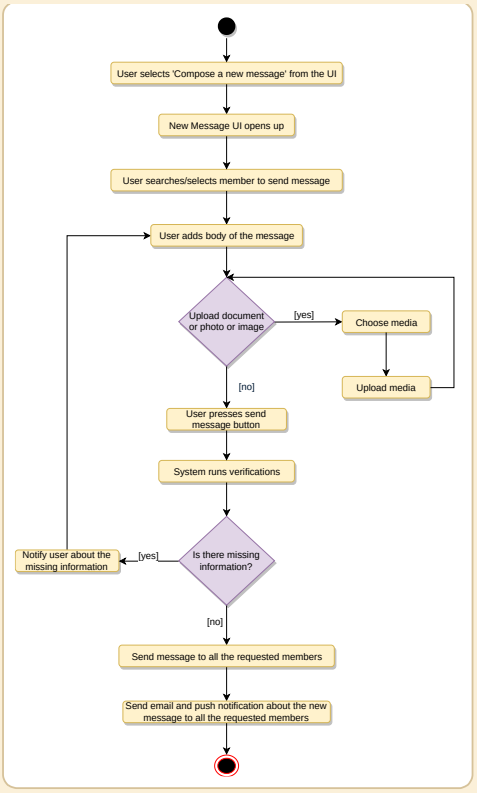

Figure — Activity diagram "send message": choose recipients, add body and media, verify, deliver to all recipients, notify them by email and push (course diagram)

Core entities

Class	Responsibility
`Member`, `Admin`	Identity, profile, connection set (changed only by the service), follows, posts, inbox, notifications
`Profile`	Owns `Experience`, `Education`, `Skill`, `Accomplishment`, `Recommendation`, `ProfileStats`
`Skill`	Name + set of endorsers (no double endorsement)
`Recommendation`	Created empty on request; only the named author writes it (REQUESTED → WRITTEN)
`ProfileStats`	View and search-appearance counters pushed in from where the events happen
`SocialContent` (abstract) → `Post`, `Comment`	Author, text, time, likes as a set; posts own comments and can be shares of another post
`Message` (record)	Sender, recipients, text — not "social content" (nobody likes a message). The course allows media on messages and posts too; our code keeps text only
`ConnectionInvitation` + `InvitationStatus`	State over time: PENDING → ACCEPTED / REJECTED / CANCELED
`ConnectionService`	Invite, accept, reject, withdraw; degree (BFS); mutual connections; people-you-may-know
`Company`, `JobPosting`, `JobApplication`, `Group`	Pages, jobs (apply once), groups (owner cannot leave)
`Notification`, `NotificationService`, channels	One notification class with a *type* field; delivery Strategy
`SearchIndex`	Word → set of members / companies / jobs
`FeedService` + `FeedRanker`	Pull-model feed with pluggable ranking
`LinkedIn`	Facade

Class diagram

The course builds LinkedIn in **six stages**.

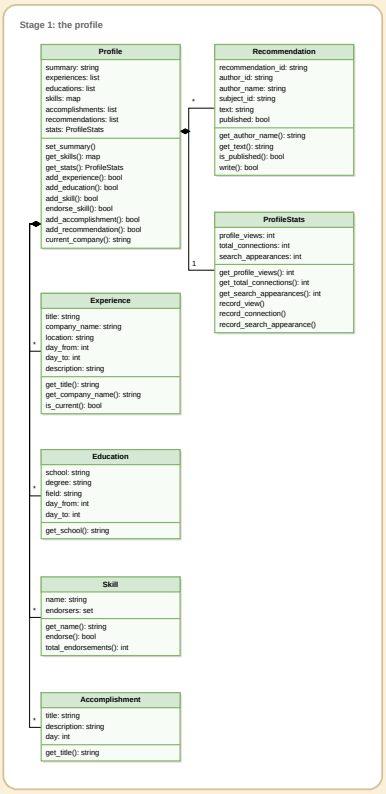

Figure — Stage 1: `Profile` owning `Experience`, `Education`, `Skill`, `Accomplishment`, `Recommendation` and `ProfileStats` (course diagram)

Stage 1 — the profile. Each of requirement 1's five parts is a small class, not a line of text, because other code uses them (search looks up the current employer; endorsements are counted on the skill). Two details matter. You cannot pass text when creating a `Recommendation`: requirement 4 is about *asking* for one, so the object is born empty and the author fills it in later. And the profile never updates `ProfileStats` itself: whoever witnesses the event bumps the counter — the code that shows a profile, the code that accepts an

invitation, the code that returns search results — because an object cannot count events it never sees. All arrows out of `Profile` are composition: delete the profile and its parts go with it.

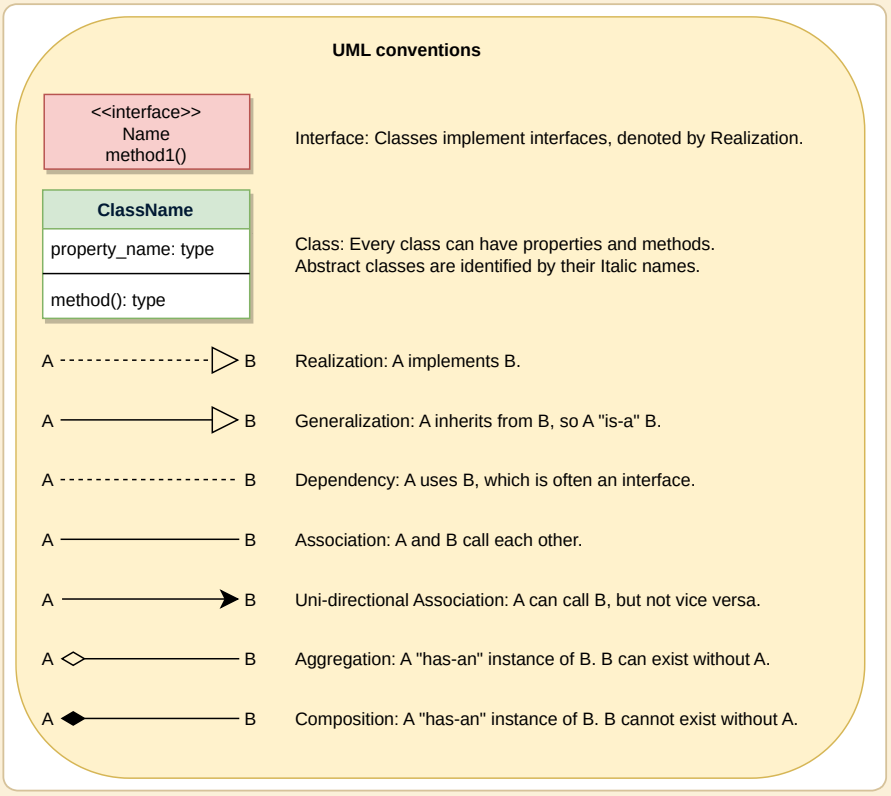

Figure — UML conventions: interface, class, abstract class, realization, generalization, dependency, association, aggregation and composition (course diagram)

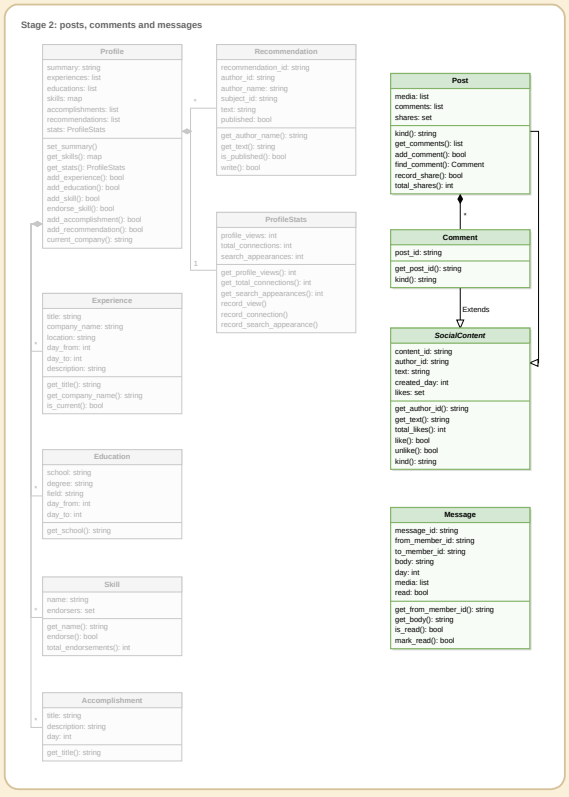

Figure — Stage 2: `SocialContent` with `Post` and `Comment`; `Post` owns its comments; `Message` stands apart (course diagram)

`Stage 2 — posts, comments and messages.` Requirement 7 hides a detail: *comments get likes as well.* Put likes only on `Post` and part of the requirement has no home. So both classes extend one parent, `SocialContent`, which holds the author, the text and the likes. The likes are kept as the **ids of the members who liked**, not as a

number, which makes a second like by the same person impossible and lets a like be taken back. `Message` is not part of this family: it is delivered to people rather than published, and no one likes a message.

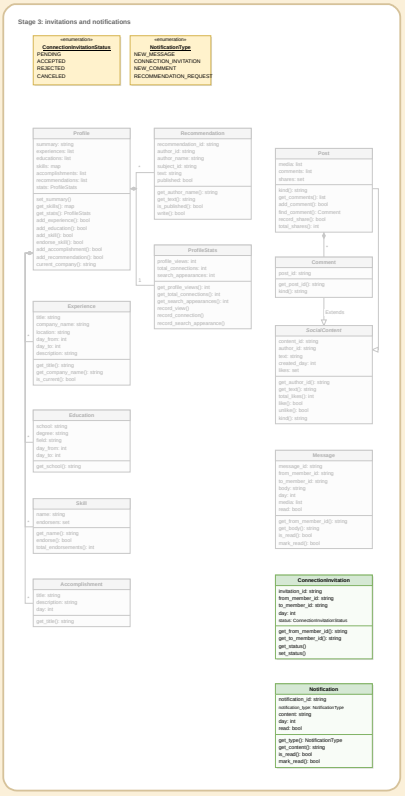

Figure — Stage 3: `ConnectionInvitation` (with a status) and `Notification` (with a type) (course diagram)

`Stage 3 — invitations and notifications.` An invitation to connect starts pending and later becomes accepted or rejected. Because it **changes state as time passes**, it deserves its own object (this is the idea behind the **State** pattern: an object's allowed actions depend on which state it is in, and only certain moves between states are legal) rather than a true/false field on a member, and that object can still record, afterwards, that the answer was no. Requirement 9 lists three notification events, but *delivering* them is identical, so the kind is a **field**, not three subclasses. The general rule: **subclass when behaviour differs; use a field when only data differs.**

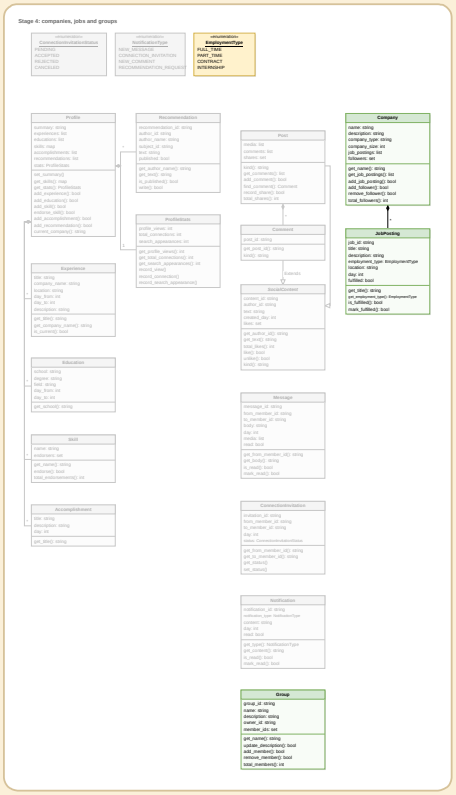

Figure — Stage 4: `Company` owning its `JobPosting`s, with followers as ids; `Group` with members and an owner (course diagram)

Stage 4 — companies, jobs and groups. A company page owns its job postings (a posting means nothing once the page is gone) and keeps followers as a set of ids. A group records who created it, and that creator is never allowed to leave or be removed.

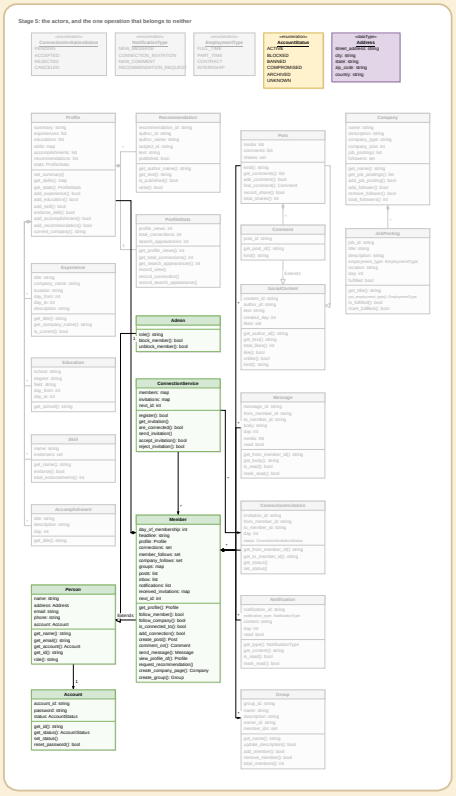

Figure — Stage 5: `Account`, `Person`, `Member`, `Admin` and `ConnectionService`, which points at both invitations and members (course diagram)

Stage 5 — the actors, and an operation that fits neither of them. Nearly every requirement becomes a method on `Member`. **Accepting an invitation does not**: it edits two members together. If the sender's class did it, the receiver's connection list would be changed by a different object; if each side did half, a bug would one day update only one half, leaving a one-way link. So the operation goes into a small `ConnectionService`, and that

single class is responsible for keeping connections **symmetric** (A lists B exactly when B lists A). Following is different: it is one-sided and needs no agreement, so it is just a set on the follower, no service needed.

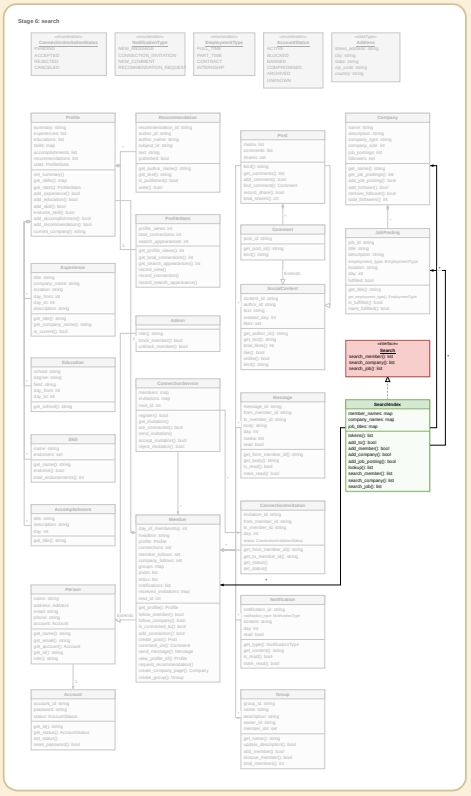

Figure — Stage 6: the `Search` interface and `SearchIndex` with three maps from key to list (members, companies, job postings) (course diagram)

Stage 6 — search. The course shows a real bug from an earlier version: on the first occurrence of a name the index saved *one* member object, and on the next occurrence it tried to "add" to that object — fine for the first Sharma, broken for the second. The cure is a rule: **an index value is always a collection, even when it holds one item.** Keys are single lowercase words, so first and last names both work.

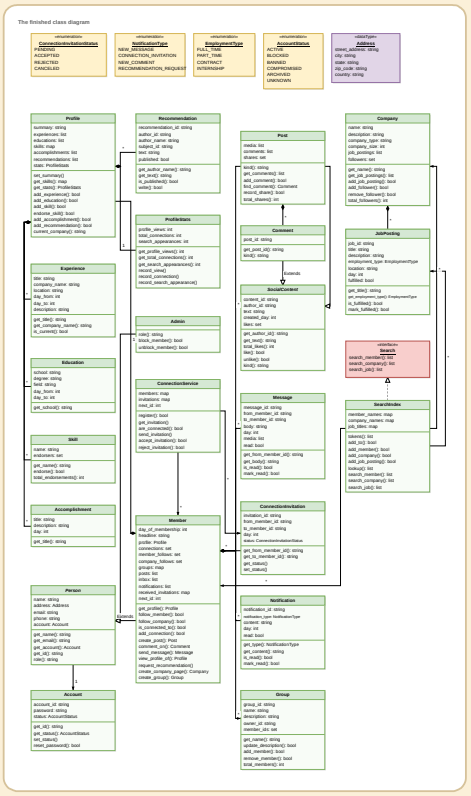

Figure — The finished LinkedIn class diagram, with all six stages in full colour (course diagram)

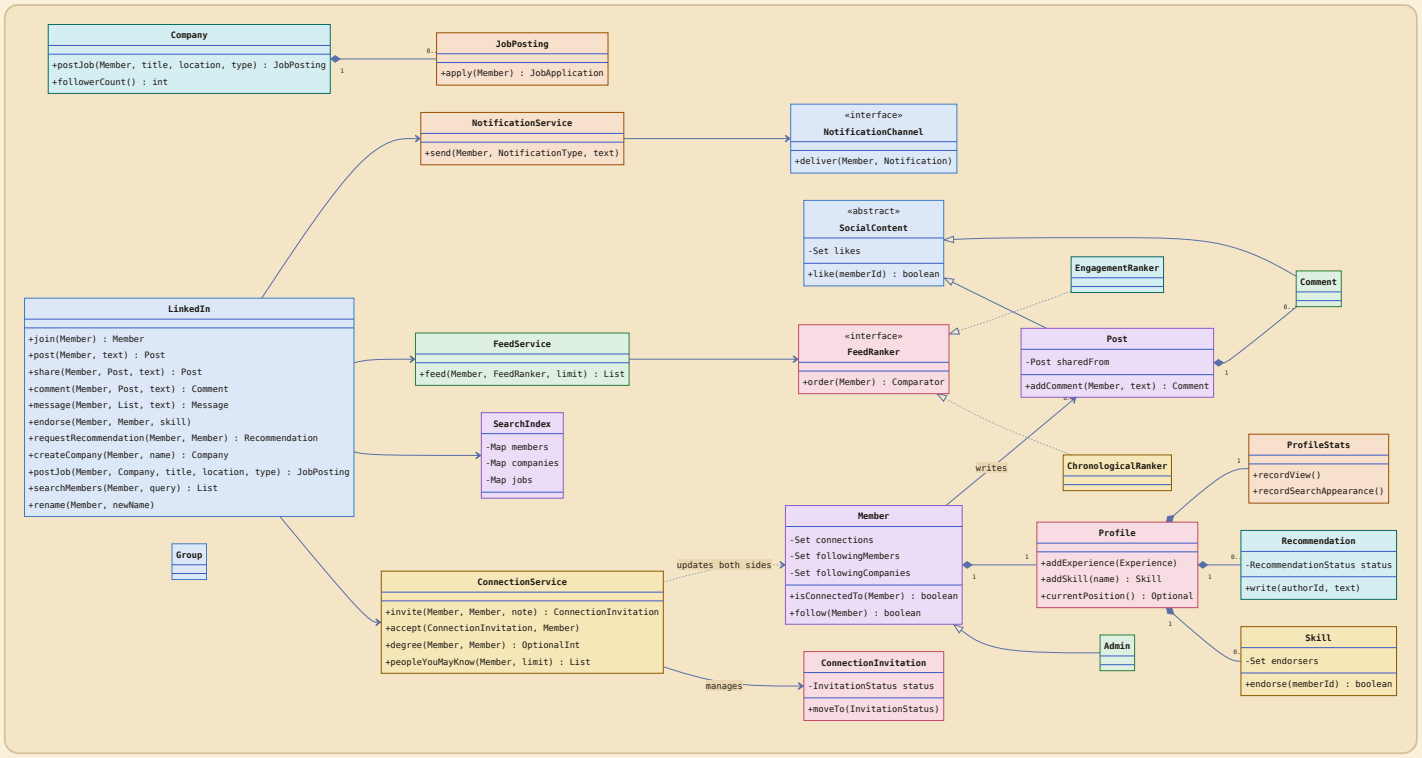
The course deliberately omits several features: the feed and how it is ranked, suggested connections, degrees of separation, applying for jobs and tracking applicants, privacy controls, and one member blocking another. It

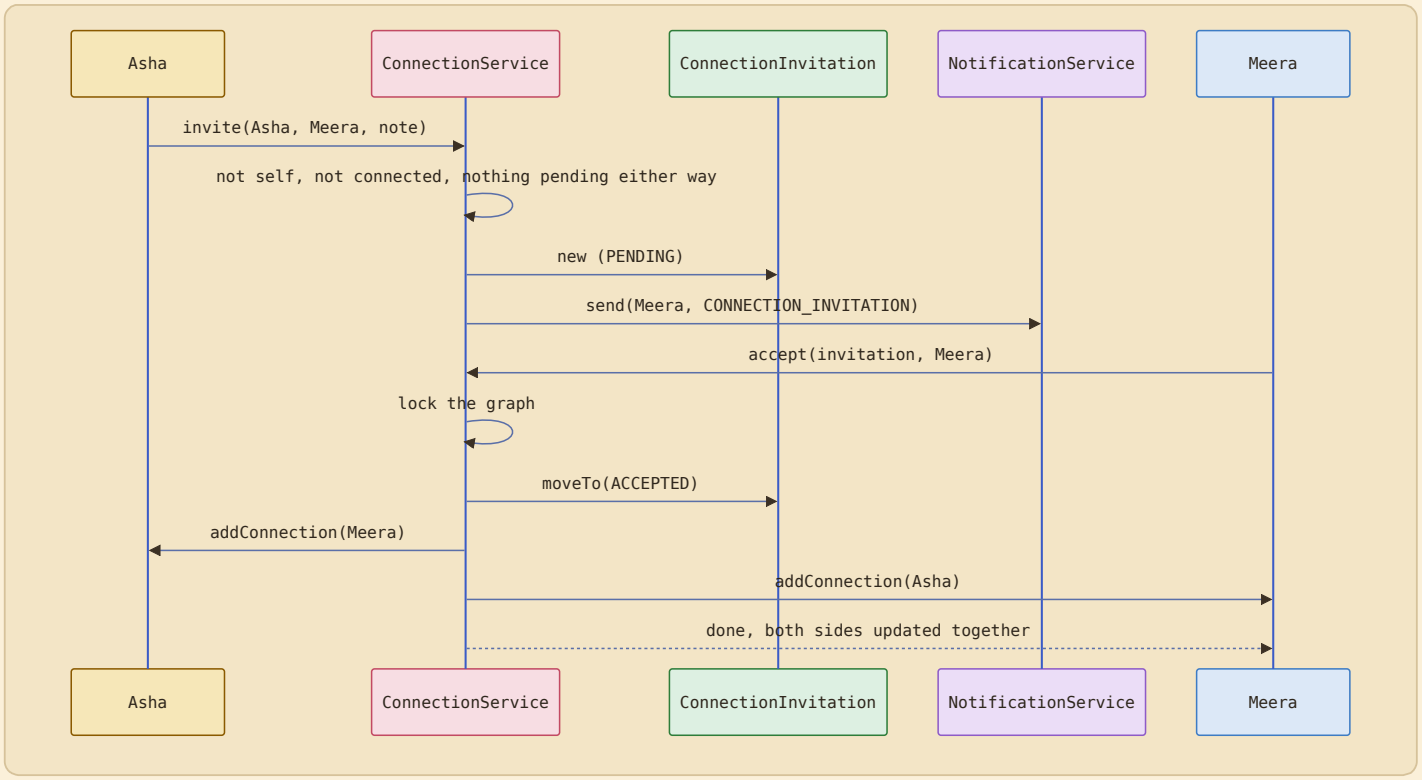
also admits two weak spots a reviewer will probe. First, there is no feed; building one means either gathering the connections' posts at the moment the page loads, or copying each new post into all the connections' feeds when it is written, and which is better depends on how many connections a typical member has. Second, the search index goes stale (out of date) when a member changes their name, because nothing informs it.

Our Java design follows the six stages and fills the gaps the course names: a **feed** (pull model — the feed is gathered when the member opens it — with a ranking Strategy), **degrees of connection** (breadth-first search, described under Key flows), **people you may know**, a **rename that updates the index**, job **applications**, and connection-count derived from the set instead of a stored counter.

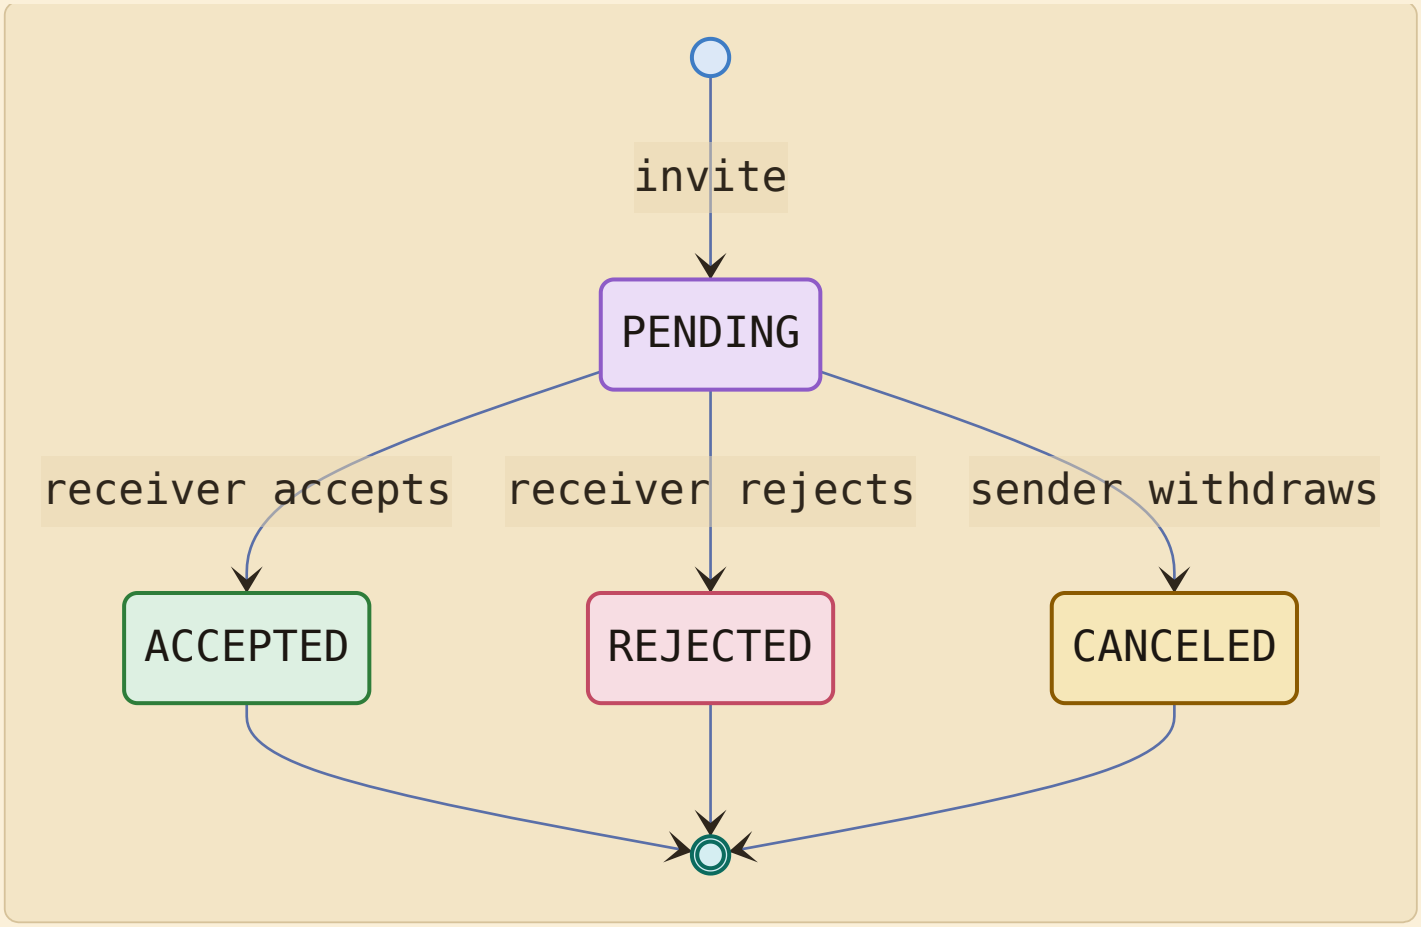


Key flows

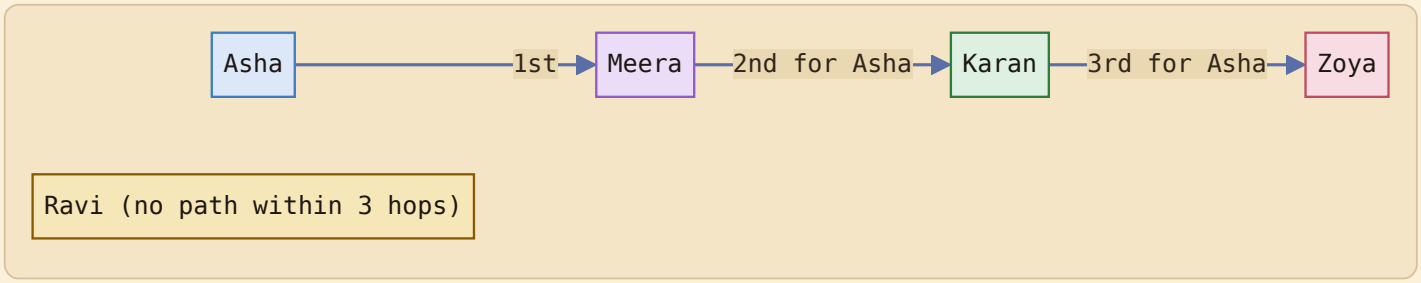
Invite and accept (the two-sided operation):



Invitation states:



Degree of connection — breadth-first search (**BFS**: explore all 1-hop neighbours, then all 2-hop, and so on) from the viewer, stopping at depth 3:



Design decisions & patterns used

Decision	Pattern / principle	Why	Alternative rejected
`ConnectionService.accept` updates both members under one lock	Service for a two-object operation; Information Expert at the right level	Symmetry has one guardian	`member.accept(inv)` editing the other member
Following is a set on the follower	Simplicity	One-sided relationship needs no agreement or service	Reusing invitations for follows
`ConnectionInvitation` with explicit states	**State** (as an enum with allowed transitions)	Accept-twice and accept-after-reject are rejected	A boolean `accepted` flag
`SocialContent` base for `Post` and `Comment`	Inheritance for shared behaviour	Requirement 7: comments are liked too	Likes only on `Post`
One `Notification` class with a `type` field	"Field when only data differs"	Delivery is identical	A subclass per event
`NotificationChannel` interface	**Strategy**	In-app, email, push are interchangeable	`if (email) … else if (push) …`
`FeedRanker` interface	**Strategy**	"Recent" vs "Top" ranking swap at run time	Sorting code inside the feed service
Index maps key → set	Robust inverted index	Two people named Sharma both found	Key → single member (the course's bug)
`LinkedIn.rename` tells the index	Keep derived structures in sync at the write point	Search is never stale	Rebuilding the index nightly
Connection count = `connections().size()`	Derive, don't store	Cannot disagree with the set	A separate counter bumped on accept

        li.block(admin, karan);
        attempt(() -> li.post(karan, "spam spam"));
        System.out.println("feed(meera) hides blocked Karan's share: " + li.feeds.feed(meera, new
ChronologicalRanker(), 5));
    }

    static void section(String t) { System.out.println("\n== " + t + " =="); }

    static void attempt(Runnable r) {
        try { r.run(); } catch (RuntimeException e) { System.out.println("  REJECTED: " + e.getMessage()); }
    }
}
```

Output:

```
== 1. Profile ==
  REJECTED: experience ends before it starts
Asha Sharma: Backend engineer | Java | Distributed systems, now at Acme Cloud

== 2. Connections ==
    [email to meera@example.com] CONNECTION_INVITATION: Asha Sharma wants to connect: "We met at the Java meetup"
  REJECTED: invitation is already ACCEPTED
    [email to karan@example.com] CONNECTION_INVITATION: Meera Iyer wants to connect: "Ex-colleague"
    [email to zoya@example.com] CONNECTION_INVITATION: Karan Mehta wants to connect: "Hi"
    [email to ravi@example.com] CONNECTION_INVITATION: Asha Sharma wants to connect: "Same surname!"
  REJECTED: an invitation between Ravi Sharma and Asha Sharma is already pending
  REJECTED: only Ravi Sharma can accept
degree asha->meera=1, asha->karan=2, asha->zoya=3, asha->ravi=out of network
people asha may know: [Karan Mehta]

== 3. Endorsements and recommendations ==
  REJECTED: Meera Iyer already endorsed Java
  REJECTED: only 1st-degree connections can endorse Asha Sharma
    [email to meera@example.com] RECOMMENDATION_REQUEST: Asha Sharma asked you for a recommendation
  REJECTED: only Meera Iyer can write this recommendation
Java endorsements=1, recommendation from Meera Iyer: Asha owns problems end to end. [WRITTEN]

== 4. Posts, comments, likes, feed ==
    [email to meera@example.com] NEW_COMMENT: Asha Sharma commented: "Sharing with my network"
double like accepted? false
feed(asha, latest): ["We are hiring Java engineers at Acme Cloud!" by Meera Iyer]
feed(karan, top):   ["Tip: prefer composition over inheritance." by Asha Sharma, "We are hiring Java engineers at
Acme Cloud!" by Meera Iyer]

== 5. Messaging ==
    [email to meera@example.com] NEW_MESSAGE: from Asha Sharma: Coffee on Friday?
  REJECTED: Karan Mehta is not a connection (that would need InMail)

== 6. Companies, jobs, groups ==
  REJECTED: Asha Sharma is not an admin of Acme Cloud
search jobs 'java engineer': [Senior Java Engineer @ Acme Cloud (Bengaluru, FULL_TIME)]
  REJECTED: Asha Sharma already applied to Senior Java Engineer
  REJECTED: the owner cannot leave their own group
Acme Cloud followers=1, applicants=1, group members=2

== 7. Search and profile stats ==
search 'sharma' (by meera): [Asha Sharma, Ravi Sharma]
search 'khan' after rename: [], search 'ali': [Zoya Ali]
asha stats: views=2, connections=1, search appearances=1
meera's in-app notifications: [CONNECTION_INVITATION, RECOMMENDATION_REQUEST, NEW_COMMENT, NEW_MESSAGE]

== 8. Admin ==
  REJECTED: Karan Mehta is BLOCKED
feed(meera) hides blocked Karan's share: ["Tip: prefer composition over inheritance." by Asha Sharma]
```

Walking through the important parts

- `ConnectionService.invite` refuses a request when one is already pending *in either direction* — in the output Ravi's counter-invite to Asha is rejected.
- `accept` checks that the caller is the receiver, moves the invitation to ACCEPTED (a second accept fails because only PENDING can move), and adds each member to the other's set inside one `synchronized` block.
- `degree` is a BFS over connection sets that stops at depth 3: Asha → Meera is 1st, Karan 2nd, Zoya 3rd, and Ravi (only a pending invitation) is "out of network".
- `peopleYouMayKnow` counts mutual connections for every 2nd-degree member, skips anyone with a pending invitation, and sorts by count then name, so the list is stable.
- `endorse` requires a 1st-degree connection and uses the skill's endorser set to reject a second endorsement.
- `Recommendation.write` accepts only the named author and only once.
- `SearchIndex` maps each lowercase word to a *set*, so "sharma" returns both Asha and Ravi; `rename` removes the old words before adding the new ones, so "khan" finds nobody after Zoya's rename.

- `FeedService` is a **pull** feed: it gathers posts from connections and followed members when asked, drops blocked authors, then sorts with the chosen `FeedRanker`. Karan sees Asha's tip because he *follows* her, even though they are not connected.

Concurrency & edge cases

- **Symmetric connections:** all graph changes (`invite`, `accept`, `reject`, `withdraw`, `removeConnection`) are `synchronized` on the single service, so two concurrent accepts or an accept racing a withdraw cannot leave a one-way edge. In a distributed system (one spread across many machines that talk over a network), write both edges (an **edge** is one link in a graph) in one database transaction (or one row keyed by the ordered pair of ids).
- **Double invitations** in either direction are refused while one is pending.
- **Likes, endorsements, applications:** sets and maps keyed by member id make repeats harmless or rejected; their mutators are `synchronized`.
- **Collections on `Member`** are concurrent sets or `CopyOnWriteArrayList`, and getters return copies, so callers cannot mutate internal state.
- **Stale search:** handled by `rename`; the general rule is "whatever changes the data tells the index" (in production, via an event).
- **Blocked members:** writes are refused and their posts vanish from feeds.
- **Validation:** an experience that ends before it starts is rejected; blank posts are rejected.

Extensions & follow-up questions

- **"Build the feed for 900 million members."** — Two classic strategies. **Fan-out on write (push):** when someone posts, append the post id to each connection's precomputed feed list — fast reads, expensive for members with huge followings. **Fan-out on read (pull):** assemble the feed when it is opened, as our `FeedService` does — cheap writes, slower reads. Large networks use a **hybrid**: push for ordinary members, pull for very popular accounts, merged at read time.
- **"People you may know at scale."** — Compute suggestions offline (in a background batch job, not while the user waits) on a schedule (friends-of-friends plus signals such as shared companies and schools) and store them; the live page reads the stored list.
- **"Connection limit."** — LinkedIn caps members at 30,000 connections; enforce in `accept`.
- **"InMail to non-connections."** — A premium credit balance on `Member`; `message` spends a credit instead of rejecting.
- **"Who viewed my profile."** — Store view events (viewer, time) instead of a bare counter, then derive the count.
- **"Job recommendations."** — A Strategy that matches a member's skills and current title against open postings, ranked by overlap.

Real-world example

LinkedIn shows 1st, 2nd and 3rd-degree badges next to names in search results — the exact BFS depth our `degree` computes — and its "People You May Know" panel is driven by shared connections and other signals. Messaging someone who is not a connection usually requires paid **InMail** (some members open their profile to free messages). And the event stream that feeds notifications, analytics and the feed at LinkedIn gave rise to **Apache Kafka**, which LinkedIn open-sourced (published free, with its source code, for anyone to use) in 2011.

In the interview

Minutes	What to do
0–5	Clarify connect vs follow, degrees, who can message and endorse
5–15	Profile composition, `SocialContent` (comments can be liked), invitation as an object with state
15–25	**Say it out loud:** accepting changes two objects, so it belongs to neither — `ConnectionService`; following is one-sided, so it needs no service
25–35	Search index (key → list), degrees by BFS, people you may know
35–45	Feed: pull vs push vs hybrid; notifications via Strategy channels; concurrency

> **30-second answer:** "Members own profiles made of small parts. Posts and comments share a base class because both are liked, with likes as a set. A connection request is an object with states. Accepting changes both

members, so it lives in a `ConnectionService` that updates both sides under one lock; following is one-sided, just a set. Search is an inverted index mapping each word to a list. Degrees come from a BFS to depth 3. The feed is a pull model with a pluggable ranking Strategy, and I'd move to a push/pull hybrid at scale."

Follow-ups with answers

- *Why not store `connectionCount` on the profile?* — It is `connections.size()`; a stored copy can drift.
- *How do you compute a 2nd-degree badge quickly for every search result?* — Precompute or cache each member's 1st-degree set; a result is 2nd-degree if its connection set intersects yours.
- *What if the same name appears twice?* — The index maps words to lists (sets), never to a single member.

Self-check

- **Q:** Why is accepting an invitation not a method on `Member`? **A:** It updates two members; a service keeps both sides consistent in one place.
- **Q:** What is the difference between connecting and following? **A:** Connecting is mutual and needs acceptance; following is one-sided and immediate.
- **Q:** Why does `Recommendation` start without text? **A:** Because it is *requested* first; the author fills it in later.
- **Q:** What is the rule for search index values? **A:** Always a collection, even for one match.
- **Q:** Pull vs push feed — which does `FeedService` implement, and what is its cost? **A:** Pull; cheap writes, but reading scans every connection's posts each time.

TL;DR

LinkedIn = profile composition + `SocialContent` (likes as sets) + invitation **State** + `ConnectionService` for the two-sided accept (following is just a set) + BFS degrees + people-you-may-know + inverted-index search (key → list) + notification and feed-ranking **Strategies** + a facade.

18.4 Design Facebook

Figure — A browser showing the Facebook home page, the cover image of this case study (course diagram)

Facebook is an online social network where users connect with **friends** (a mutual relationship), **follow** people and **pages**, join **groups**, and read and write posts through a website or mobile apps. Compared with LinkedIn, the new challenges are **privacy** (who may see each post), a real **news feed**, **pages** with ratings, **groups** (public and private), and **friend suggestions**.

Problem & clarifying questions

Question to ask	Answer we assume
Friend vs follow?	Friendship is mutual (request + accept); following is one-sided
Who can see a post?	The author chooses an **audience**: Public, Friends, a custom **privacy list**, or Only me
What is a privacy list?	A named subset of the author's friends (e.g. "Close friends"); a post linked to it is visible only to those friends
Pages?	Created by members; others follow them and add **recommendations** (a 1–5 rating and text)
Groups?	Public (join at once) or private (owner approves); posts inside a private group are visible only to members
Search?	Members, groups and pages by name; posts by a word — respecting privacy
News feed?	Posts from friends, followed members, followed pages and joined groups, filtered by privacy, ranked
Extended requirement?	Suggest people you may know (friends of friends)

Requirements

Functional (the course's twelve plus the extended one, in our words)

1. A member fills in a profile: basic details, jobs, schooling and places lived.
2. Any user can search members, groups or pages by name.
3. Members send friend requests and accept or reject them.
4. Members can follow other members without becoming friends.
5. Members create groups and pages, join groups, and follow pages.
6. Members create posts to share with their friends.
7. Members can comment on posts; posts **and comments** can both be liked or shared.
8. Members create privacy lists of friends; a post linked to a list is visible only to that list.
9. Members send messages to other members.
10. Members add a recommendation to any page.
11. A member is notified about each new message, each friend request, and each comment on one of their posts.
12. Members can search posts for a word.
13. **Extended:** write a function that suggests connections for a member.

Non-functional

- **Privacy is never leaked** — through the feed, search, comments, likes or shares.
- **Feed latency** — the feed must load fast even for members with hundreds of friends.
- **Consistency of the friend graph** — friendship is symmetric.
- **Stable output** — suggestions and feeds must not reshuffle randomly between page loads.

Use cases

Three actors: **Member**, **Admin** (blocks/unblocks members) and **System** (sends notifications).

Top use cases: add/update profile; search members, groups, pages and posts; send friend requests; follow/unfollow a member or page; send messages to friends; create posts, like and comment on visible posts; send notifications; create a page; recommend a page.

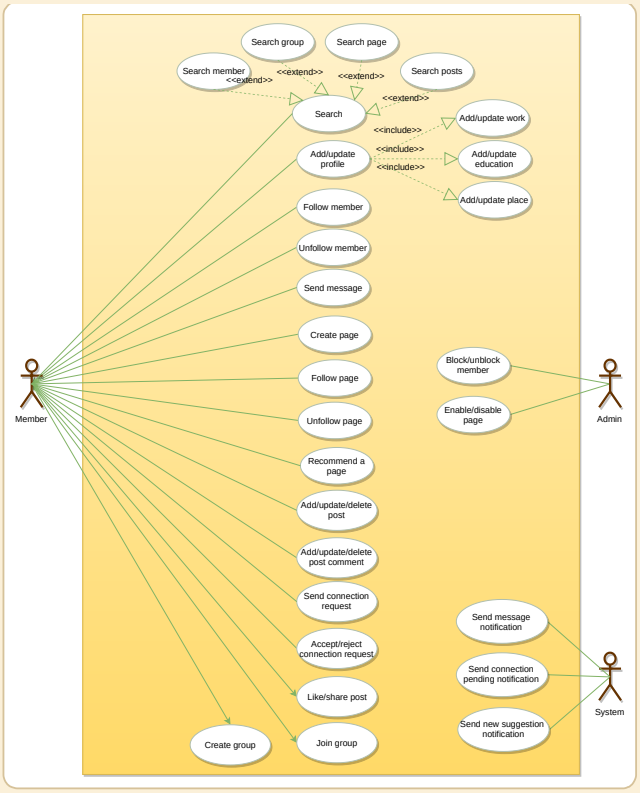

Figure — Facebook use cases for Member, Admin and System, including "Create page", "Recommend a page" and "Unfollow member" (course diagram)

Activity — add work experience. The member opens *Add Work*, enters position, company, location, dates and description, and presses save; the system verifies, asks for missing information if needed, then saves.

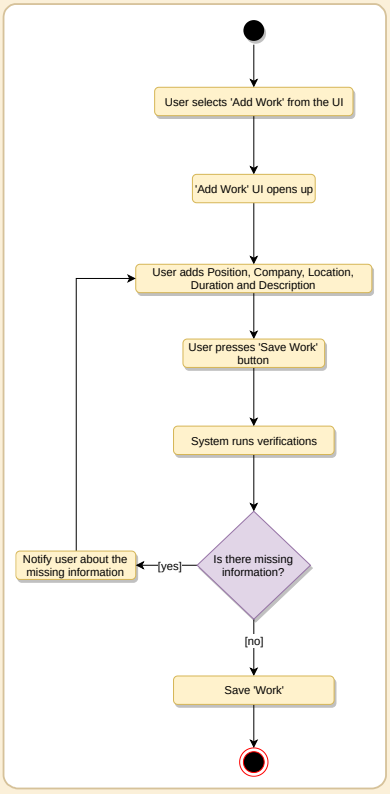

Figure — Activity diagram "add work to profile" with a verification loop (course diagram)

Activity — create a post. The member opens *New Post*, writes the text, optionally uploads a photo or video, **chooses the privacy list** that may see it, and presses publish. After verification the post is published to the chosen audience, who receive an email or push notification.

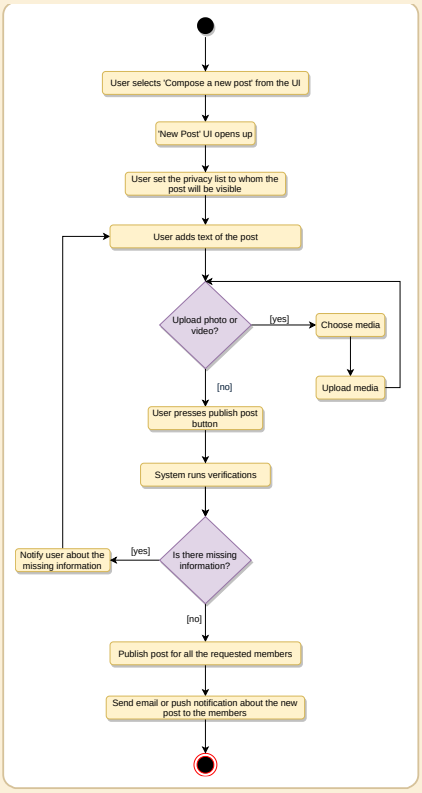

Figure — Activity diagram "create a new post": add text, optional media, set the privacy list, verify, publish, notify (course diagram)

Core entities

Class	Responsibility
`Member`, `Admin`	Identity, profile, follows (members and pages), groups, posts, privacy lists, inbox, notifications (the course's messages may carry photos and videos; ours are text only)
`Profile` (+ `Work`, `Education`, `Place`)	Defaults for every field, lists of parts
`PrivacyList`	Owner + named set of friend ids
`Audience` (sealed) → `Public`, `Friends`, `Custom(list)`, `OnlyMe`	Who may see a post
`SocialContent` → `Post`, `Comment`	Likes as a set; posts own comments; a post may belong to a group or page or be a share
`FriendRequest` + `FriendService`	Requests with both ends, the friend graph, `areFriends`, `pendingBetween` (both ways)
`VisibilityService`	The single `canSee(viewer, post)` rule, combining the post's privacy list and the friend graph
`Page` (+ `PageType`, `PageRecommendation`)	Followers (counted), one recommendation per member, average rating, page posts
`Group` (+ `GroupPrivacy`)	Members, join requests, owner approval, group posts
`NotificationService` + `PushChannel` / `EmailChannel`	Routes each notification type to channels
`SearchIndex`	Names of members/groups/pages; post words — `searchPosts` takes the viewer
`NewsFeedService` + `FeedRanker`	Gathers candidates, filters by `canSee`, ranks
`SuggestionService` + `Suggestion`	Friends-of-friends by mutual count
`Facebook`	Facade

Class diagram

The course builds Facebook in **five stages plus the extended requirement**.

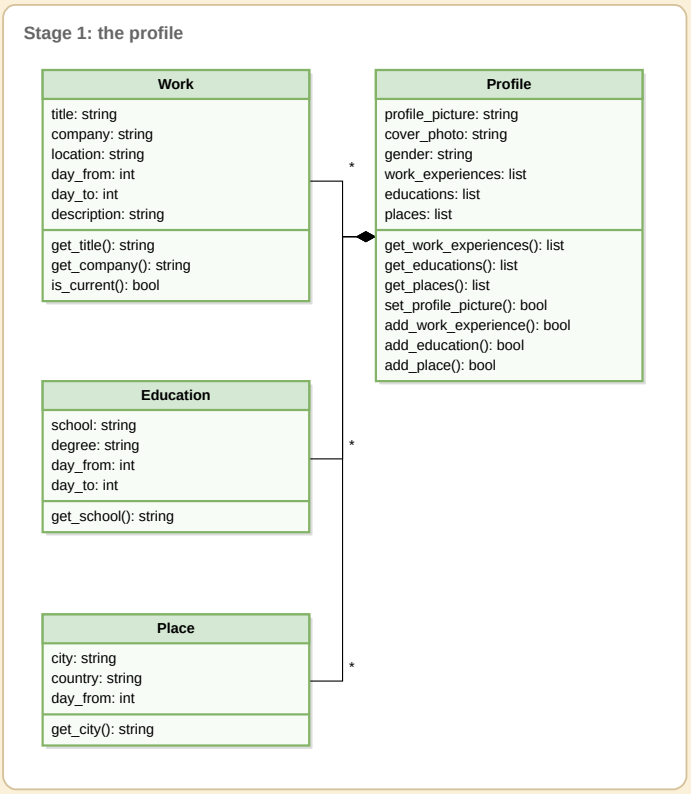

Figure — Stage 1: `Profile` holding lists of `Work`, `Education` and `Place` (course diagram)

Stage 1 — the profile. Work, education and places are small classes held in lists (composition). Every profile field starts with a **default** value, so a brand-new account already has a working profile, and no other code needs to make up a placeholder picture for someone who never uploaded one.

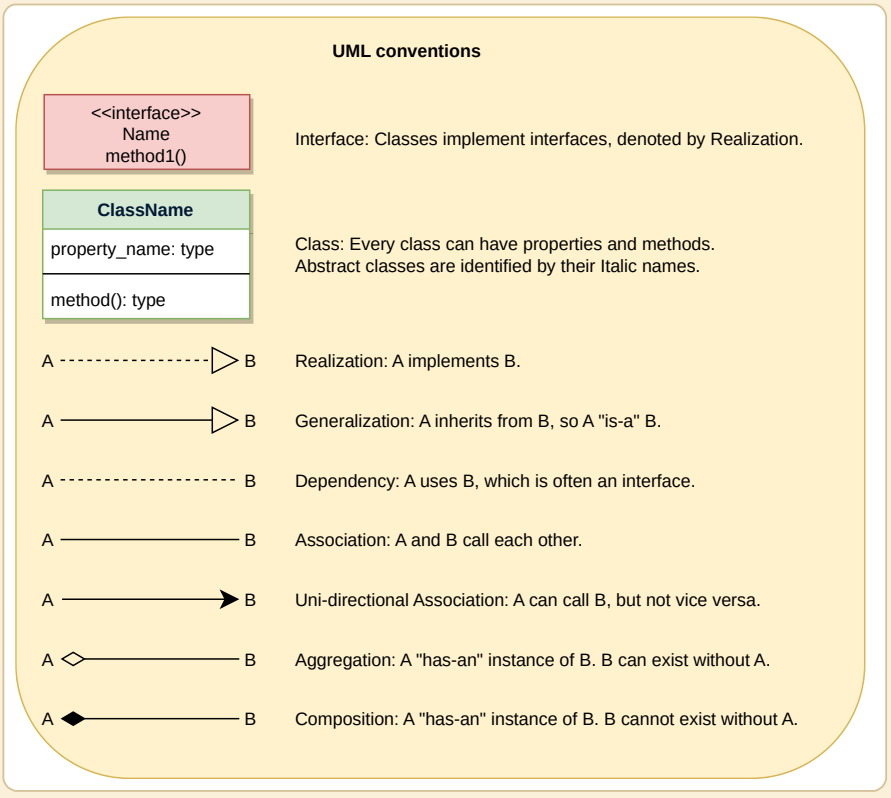

Figure — UML conventions used in these diagrams (course diagram)

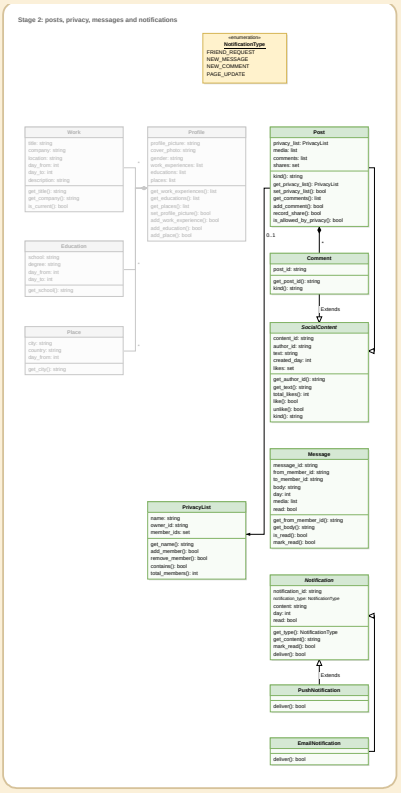

Figure — Stage 2: `SocialContent` with `Post` and `Comment`, a `0..1` association from `Post` to `PrivacyList`, `Message`, and abstract `Notification` (course diagram)

Stage 2 — posts, privacy, messages and notifications. Three choices here repair bugs in older versions. (1) **Store the likers, not a like count** — an old `Post` received its like count through the constructor, so a fresh post could start with a thousand likes, and there was no way to know whether you had liked it already. (2) **Comments get likes too**, so the likes set lives in the shared `SocialContent` parent. (3) **Privacy is checked by the post itself** — `isAllowedByPrivacy` is a method on the post, not something each screen must remember. Yet it can answer only part of the question, because a post has no idea who is friends with whom; stage 5 supplies the rest. The link from `Post` to `PrivacyList` is marked `0..1`: a post might have no list (it is public), and one

list is reused by many posts and survives them. `Notification` is abstract, with a subclass for each delivery method.

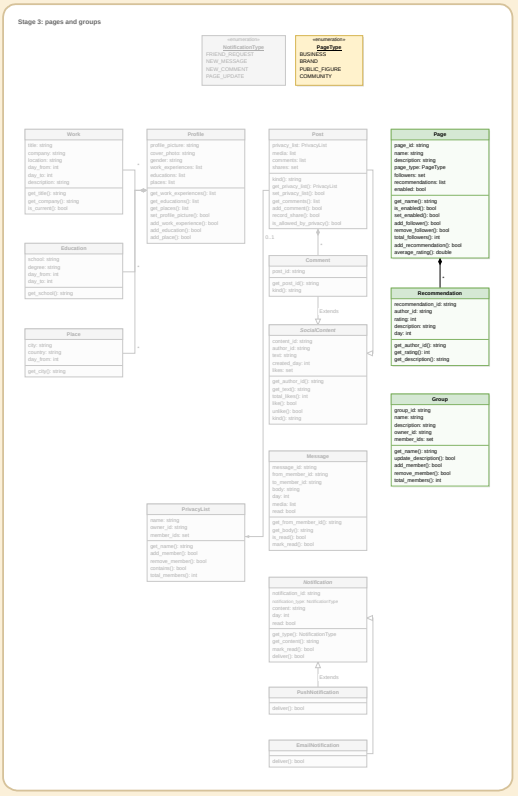

Figure — Stage 3: `Page` owning its `Recommendation`s, followers as ids, and `Group`; no member-count fields (course diagram)

`Stage 3 — pages and groups.` Look at what these classes do *not* have: a member-count field. An earlier version accepted the count in its constructor *and* also stored the members, so the two numbers could be different from day one. The rule: **if a number can be computed by counting a collection, do not keep it as a separate field; keep the collection and count it when asked.**

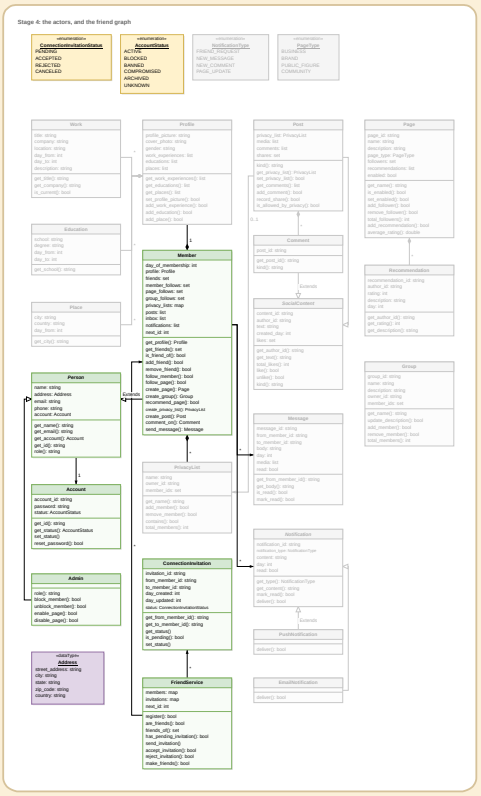

Figure — Stage 4: `Account`, `Person`, `Member`, `Admin`, `ConnectionInvitation` and `FriendService`, which owns the friend graph (course diagram)

Stage 4 — the actors and the friend graph. An earlier invitation class remembered only the person invited, not the person inviting, so there was no way to accept it properly. Since acceptance updates two members, it belongs in `FriendService`; that service therefore holds the **friend graph** (who is friends with whom) and is the obvious class to ask "are these two friends?" and "is a request already waiting between them?". Following (requirement 4) is deliberately different: one-sided, a set on the follower, no service.

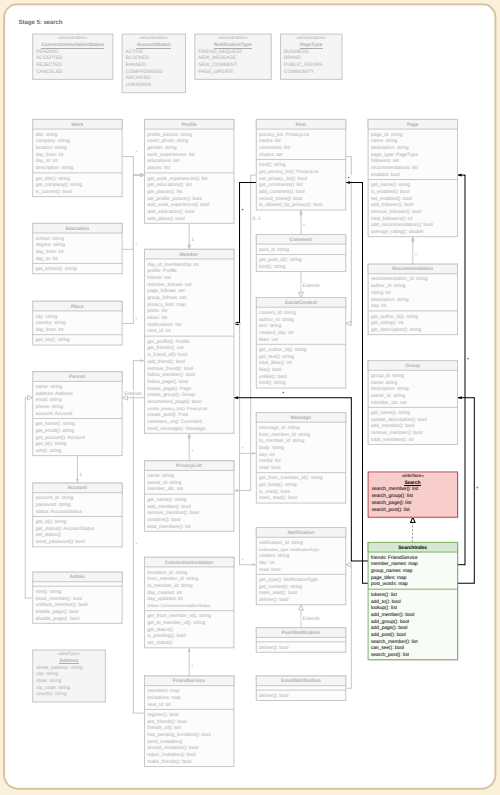

Figure — Stage 5: `Search` and `SearchIndex`, which holds a `FriendService` so post search can respect privacy (course diagram)

Stage 5 — search. The most important detail is small: **`searchPost` needs the viewer as a parameter.** The privacy rule (requirement 8) still applies when someone searches; a keyword search that skips it would let anyone read posts that were never shared with them. Deciding visibility therefore needs two sources — the post's own privacy

list, and the friendship data that only the friend service holds — and neither source can answer for the other. The index follows the same rule as LinkedIn's: each key maps to a collection.

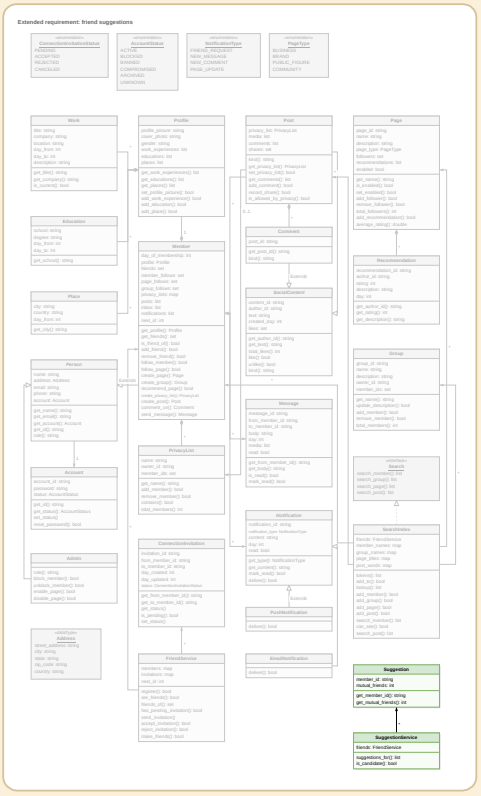

Figure — Extended requirement: `SuggestionService` reading the friend graph and producing `Suggestion` objects, with no change to existing classes (course diagram)

Extended requirement — friend suggestions. Friends of friends, **scored by mutual friends** (someone reached through three of your friends beats someone reached through one). Never suggest yourself, an existing friend, or anyone with a request pending **in either direction** (the one candidates forget — showing someone you invited yesterday is a visible bug). Sort by mutual count, then by id, so equal scores do not reshuffle between page loads. Notice that the feature arrives as two new classes with no edits to existing ones; if a design must be modified every time a new question is asked, it will keep being modified.

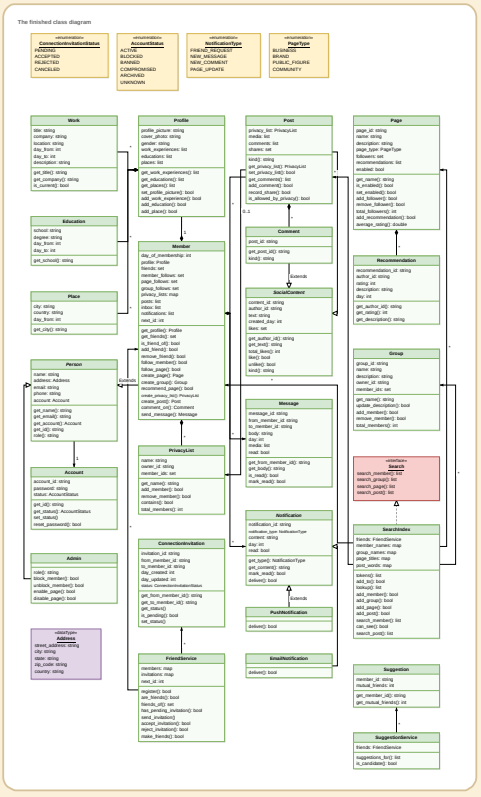

Figure — The finished Facebook class diagram with every class in full colour (course diagram)

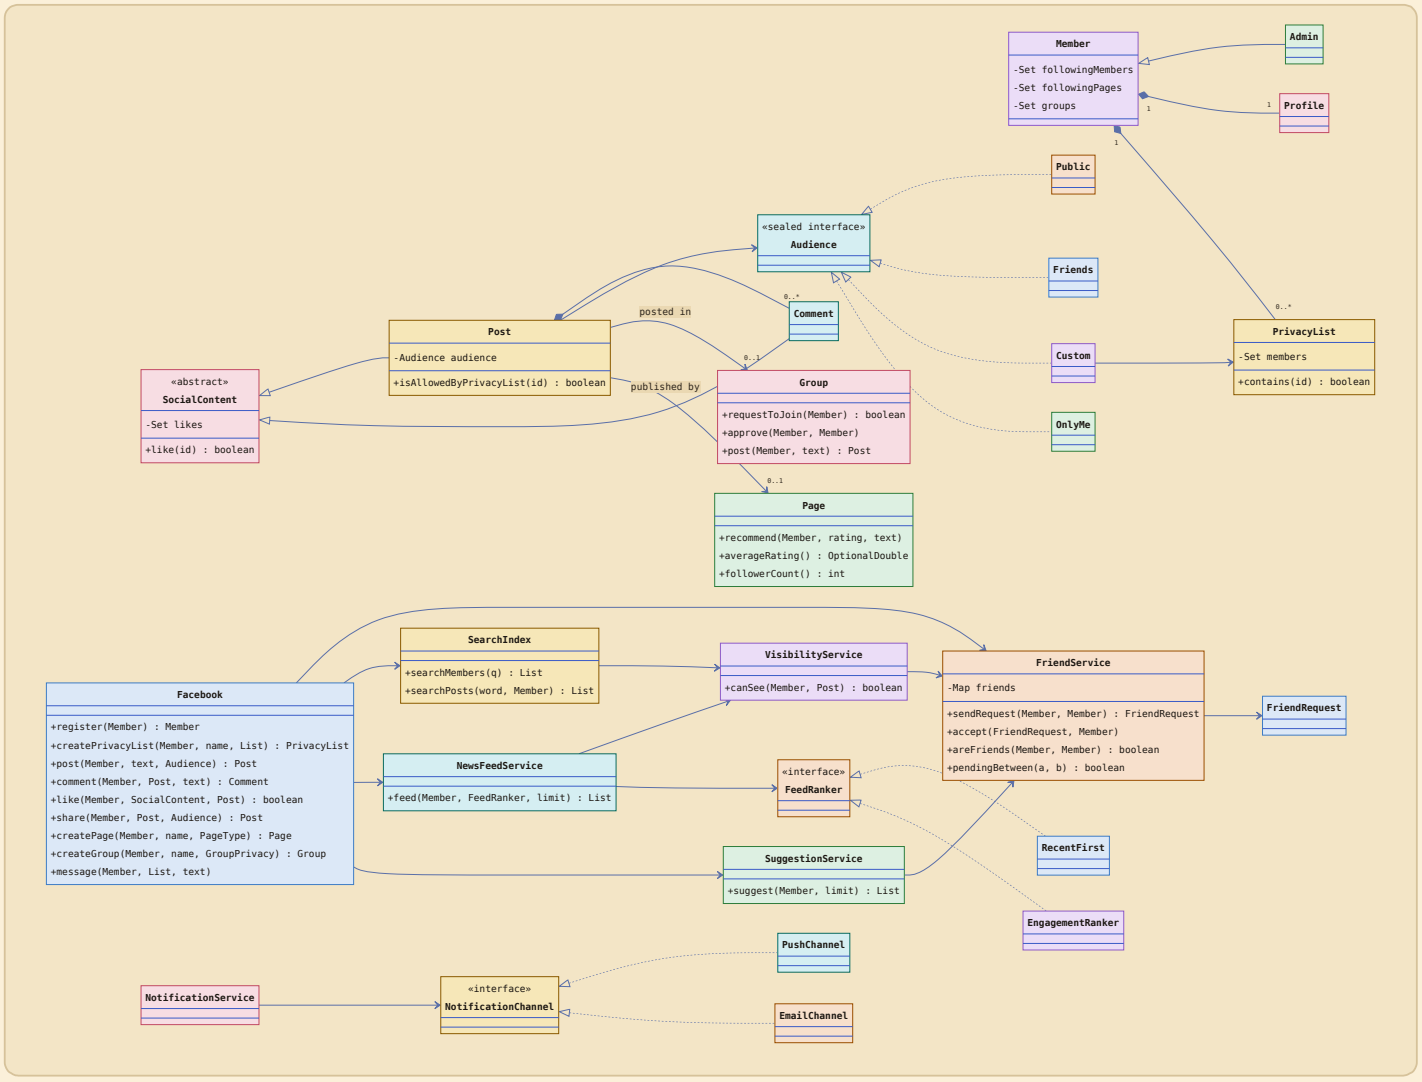
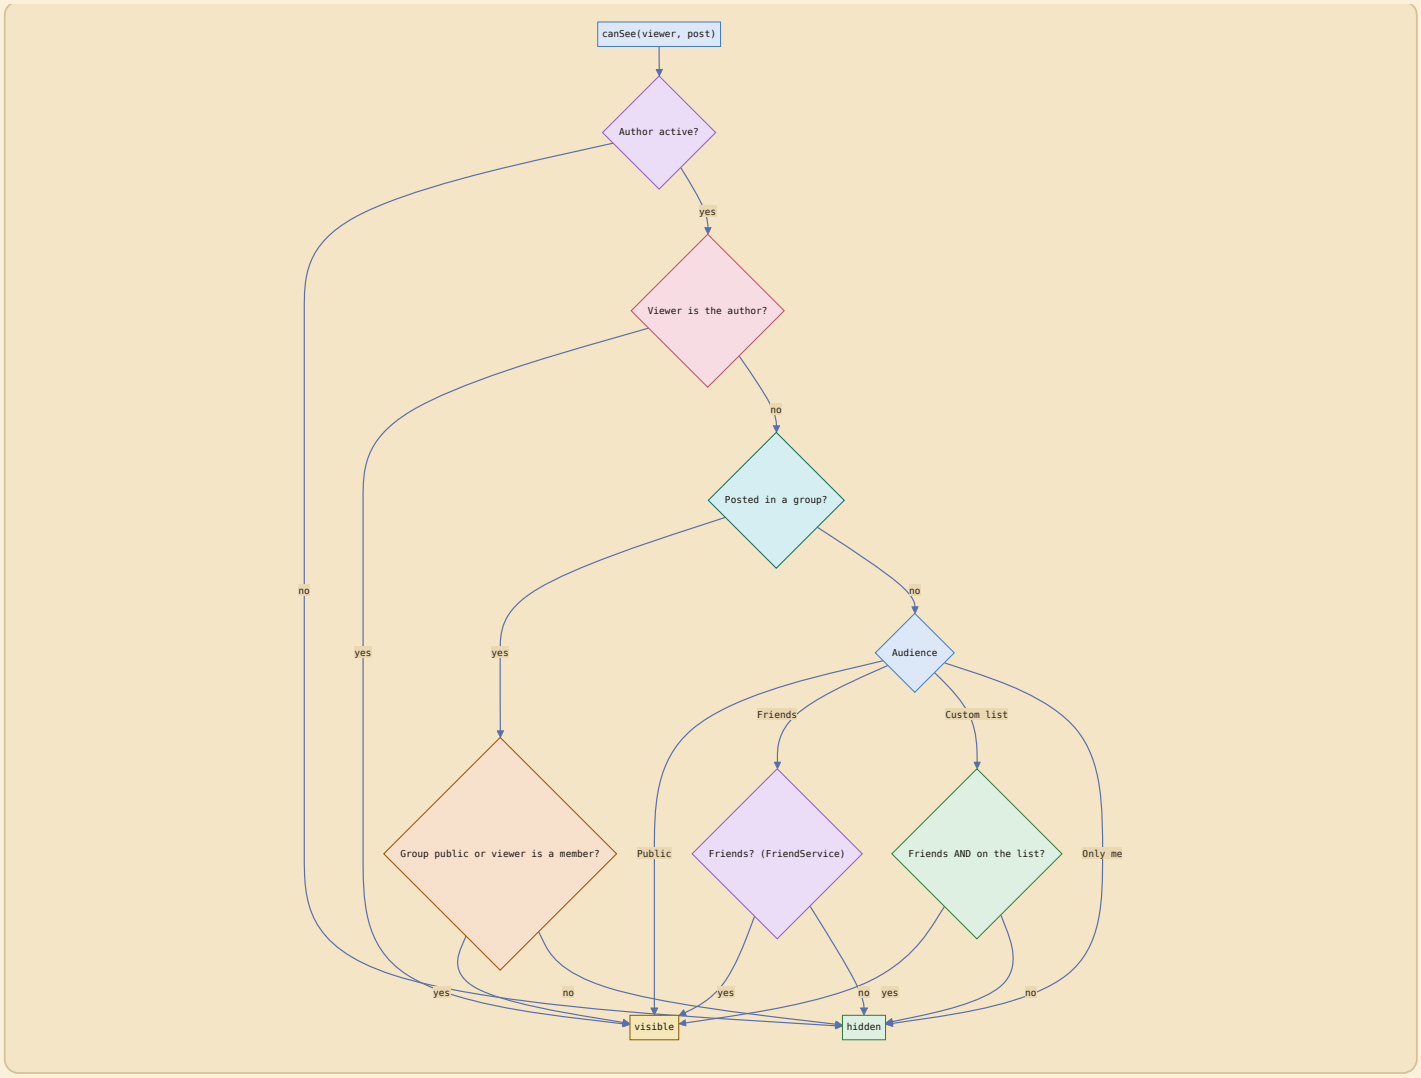
Our Java design keeps the course's structure and makes three things explicit: a sealed `Audience` type (Public / Friends / Custom list / Only me), a single `VisibilityService` used by the feed, search, comments, likes and shares, and a `NewsFeedService` (the course leaves the feed out) with ranking Strategies. Private groups with owner approval and page posts in the feed are added too. The course lists what it leaves out on purpose: the news feed and its ranking, one member blocking another, reactions other than a plain like, tagging people, events, marketplace, stories, and photo albums that carry separate privacy settings. We add the feed; the rest are sketched under Extensions.

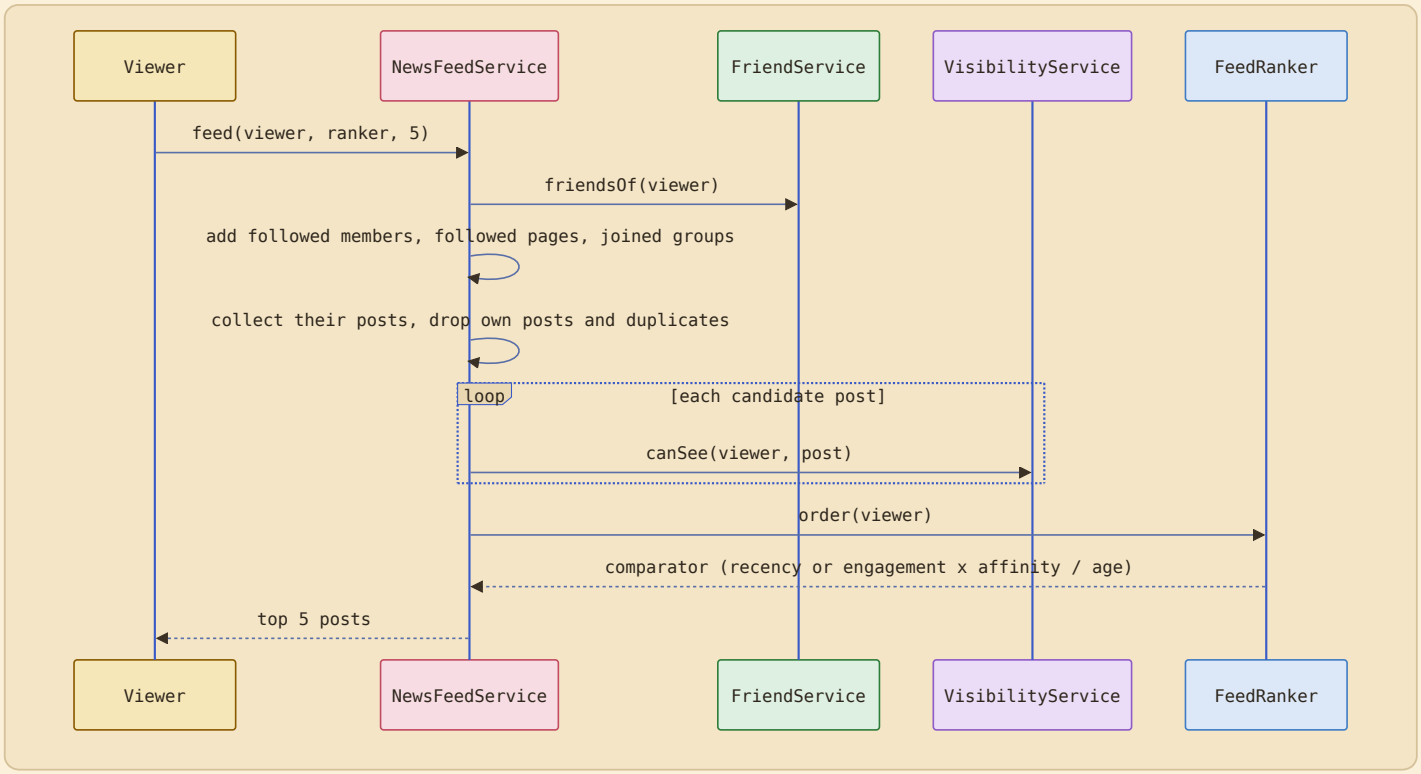


Key flows

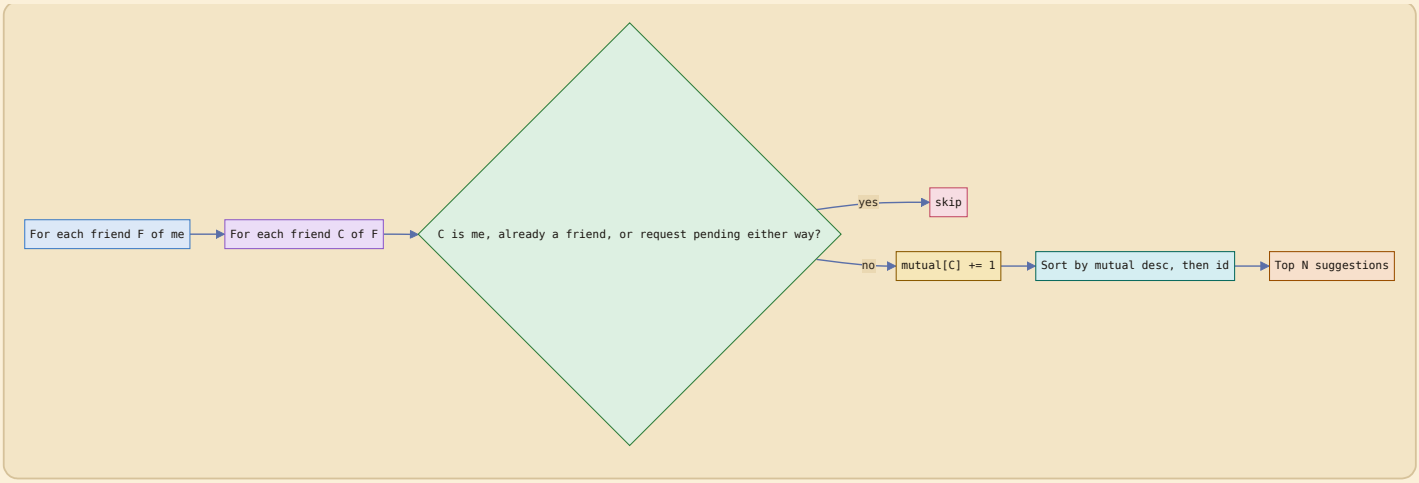
Can this viewer see this post? (used by feed, search, comment, like and share):



Building a news feed (pull model):



Friend suggestions:



Design decisions & patterns used

Decision	Pattern / principle	Why	Alternative rejected
`VisibilityService.canSee` used everywhere	Single point of policy (a **Specification**-like rule object — one object that answers a yes/no business question)	The privacy rule is written once; search and feed cannot leak	Checking privacy in each screen
`Audience` sealed interface of records	Algebraic data type + exhaustive `switch`	Adding an audience forces every decision point to handle it	Integer or string codes
`Post.isAllowedByPrivacyList` + `FriendService.areFriends`	Each object answers what it knows (Information Expert)	Neither half pretends to know the other's data	Post holding a reference to the whole friend graph
`FriendService` owns the graph	Service for two-sided operations	Symmetric friendships; one place for "pending either way"	`member.acceptFriend()`
Likes as a set	"Store who, not how many"	No fake like counts, no double likes	`likeCount` field
No stored member/follower counts	Derive, don't store	Counts cannot disagree with lists	Constructor-supplied counts (the course's bug)
`NotificationService` routes types to channels	**Strategy** + configuration map	Friend requests go by push *and* email, comments by push only	`if/else` on type inside each domain method
`FeedRanker`	**Strategy**	"Most recent" vs ranked feed swap at run time	Ranking code inside the feed
`SuggestionService` added without editing others	Open/Closed Principle	The extended requirement is two new classes	Adding suggestion fields to `Member`
`Facebook` facade	**Facade**	One entry point, account-status checks	UI talking to every service

Output:

```
== 1. Profile and search by name ==
Alice's picture before upload: default-avatar.png
search 'lee': [Frank Lee, Grace Lee]

== 2. Friend requests ==
    [push -> Bob Das] Alice Rao sent you a friend request
    [email -> bob@example.com] Alice Rao sent you a friend request
  REJECTED: request is already ACCEPTED
    [push -> Carol Nair] Alice Rao sent you a friend request
    [email -> carol@example.com] Alice Rao sent you a friend request
    [push -> Erin Shah] Alice Rao sent you a friend request
    [email -> erin@example.com] Alice Rao sent you a friend request
    [push -> Dave Paul] Bob Das sent you a friend request
    [email -> dave@example.com] Bob Das sent you a friend request
    [push -> Dave Paul] Carol Nair sent you a friend request
    [email -> dave@example.com] Carol Nair sent you a friend request
    [push -> Grace Lee] Erin Shah sent you a friend request
    [email -> grace@example.com] Erin Shah sent you a friend request

== 3. Friend suggestions (extended requirement) ==
before: [Dave Paul(2 mutual), Grace Lee(1 mutual)]
    [push -> Grace Lee] Alice Rao sent you a friend request
    [email -> grace@example.com] Alice Rao sent you a friend request
after inviting Grace: [Dave Paul(2 mutual)]
  REJECTED: a request between Grace Lee and Alice Rao is pending

== 4. Posts and privacy ==
  REJECTED: Frank Lee is not a friend of Alice Rao
  Alice Rao  public=true  friends=true  closeFriends=true
  Bob Das    public=true  friends=true  closeFriends=true
  Erin Shah  public=true  friends=true  closeFriends=false
  Frank Lee  public=true  friends=false closeFriends=false
search posts 'party' as Bob:  ["Planning a surprise party for Erin" by Alice Rao]
search posts 'party' as Erin: []

== 5. Comments, likes, shares ==
    [push -> Alice Rao] Bob Das commented on your post
Bob likes: true / again: false
  REJECTED: Erin Shah cannot see that post

== 6. Pages and groups ==
  REJECTED: Alice Rao already recommended Joe's Pizza
Joe's Pizza: followers=1, rating=4.5 from 2 recommendations
Frank joined at once? false
  REJECTED: Alice Rao is not a member of Chess Club
search posts 'chess' as Alice: [], as Dave: ["Chess tournament on Sunday" by Frank Lee [group Chess Club]]

== 7. News feeds ==
Alice (recent): ["Two-for-one pizza on Friday" by Carol Nair [page Joe's Pizza], "shared: New portfolio is live!"
by Erin Shah]
Bob   (ranked): ["Planning a surprise party for Erin" by Alice Rao, "Moving to Pune next month" by Alice Rao, "New
portfolio is live!" by Alice Rao]
Frank (recent): ["New portfolio is live!" by Alice Rao]

== 8. Messages and admin ==
Dave before Frank is blocked: ["Chess tournament on Sunday" by Frank Lee [group Chess Club]]
    [push -> Alice Rao] new message from Bob Das
    [push -> Carol Nair] new message from Bob Das
Dave after Frank is blocked: []
Alice's notifications: [NEW_COMMENT, NEW_MESSAGE]
```

Walking through the important parts

- **The visibility table in section 4** is the course's key scenario, with four viewers. Alice is the author, so she sees all three of her posts. Bob is a friend *and* on the "Close friends" list, so he sees all three posts. Erin is a friend but *not* on the list, so she sees the public and friends posts but not the close-friends one.

Frank is not Alice's friend, so only the public post is visible to him. Two rules, both applied, neither written twice.

- **Search respects privacy:** searching "party" returns Alice's close-friends post for Bob and nothing for Erin, because `searchPosts` takes the viewer and calls `canSee`.
- `createPrivacyList` refuses Frank because a privacy list may contain only friends.
- **Comments, likes and shares go through `canSee` too:** Erin cannot comment on the close-friends post. Without this, "comment" would be a side door into private content.
- **Suggestions:** before inviting Grace, Alice sees Dave (2 mutual: Bob and Carol) and Grace (1 mutual: Erin). After Alice invites Grace, Grace disappears (pending), and Grace cannot send a request back while one is pending.
- **Pages:** one recommendation per member (`putIfAbsent`), follower count and average rating computed from the stored data.
- **Private group:** Frank's join waits for Dave's approval; Alice (not a member) cannot post there and cannot find the group's post by search, while Dave can.
- **Feeds:** Alice's feed includes the page she follows and Erin's share; Bob's ranked feed puts the most-engaged, most recent friend posts first; Frank (who only follows Alice) sees only her public post.
- **Blocking:** once Frank is blocked, `canSee` hides his posts, so his group post disappears from Dave's feed.
- **Notification routing:** friend requests go to push *and* email; comments and messages go to push only — configured with a `Map<NotificationType, List<NotificationChannel>>`.

Concurrency & edge cases

- **Friend graph:** `sendRequest`, `accept`, `reject` and `unfriend` are `synchronized` on the service, and adjacency sets (each member's set of directly linked members) are concurrent, so an accept cannot leave a one-way friendship. In a database, a friendship is one row keyed by the ordered pair `(min(id), max(id))`, which makes symmetry automatic.
- **Pending in both directions:** checked by `pendingBetween(a, b)` for both requests and suggestions.
- **Privacy changes after posting:** because visibility is computed at read time, removing someone from a list or unfriending them hides the post immediately. (A push-model feed that copied posts into feeds would need to re-check `canSee` at read time anyway.)
- **Shares:** sharing requires seeing the original; a share of a friends-only post should not expose it to the sharer's audience — a production rule would cap the share's audience at the original's.
- **Deterministic ordering** (the same input always produces the same order)**:** suggestions tie-break by id; feeds tie-break by creation time; our logical `Tick` clock (a counter that goes up by one per event and stands in for real time) makes demo output repeatable.
- **Blocked or deleted authors:** `canSee` returns false for inactive authors.

Extensions & follow-up questions

- **"Scale the news feed."** — **Fan-out on write**: when a member posts, push the post id into each friend's feed cache (fast reads; costly for accounts with millions of followers). **Fan-out on read**: assemble at open time (our design). Real systems mix them: push for normal users, pull for celebrities, merge at read, and always re-check privacy.
- **"Rank the feed better."** — Add signals (affinity = how often the viewer interacts with the author, content type, recency decay) behind the same `FeedRanker` interface; that is the idea behind Facebook's early **EdgeRank** (affinity × weight × time decay).
- **"Suggestions at scale."** — Precompute friends-of-friends offline on a schedule and store them (the course notes the original diagram had a `memberSuggestions` field for exactly this), adding signals like shared groups, schools and workplaces.
- **"Blocking one member from another."** — Add a per-member block set; `canSee` and `sendRequest` check it both ways.
- **"Reactions beyond like."** — Change the like set to `Map<memberId, Reaction>`, exactly like Stack Overflow's vote map.
- **"Tagging people in posts."** — Add tagged ids to `Post`, notify them, and (a privacy decision) optionally widen the audience to their friends.
- **"Events, stories, marketplace, albums with their own privacy."** — Each is a new content type extending `SocialContent` with its own `Audience`.

Real-world example

Facebook launched **News Feed** in 2006, turning profiles you had to visit into a stream pushed to you — the feature this design adds. Posts carry an audience selector (Public, Friends, specific friends, Only me, custom lists), and a personal profile is capped at **5,000 friends** (beyond that people use followers or pages). The social graph itself is served by **TAO**, a distributed store Facebook built for objects (users, posts) and associations (friendship, likes) — the production-scale version of our `FriendService` plus `SocialContent` likes.

In the interview

Minutes	What to do
0–5	Clarify friend vs follow, the audience options, pages, groups, feed
5–15	Profile, `SocialContent` (likes as set, comments liked too), `PrivacyList`, `Audience`
15–25	`FriendService` owns the graph (accept is two-sided); following is a set
25–35	**The strongest point:** the post holds its list and the friend service holds friendships, so `canSee` must consult both — and search, feed, comments and shares all call it
35–45	Feed (pull, push, hybrid), suggestions (mutual count, exclude pending both ways, stable sort), concurrency

30-second answer: "Posts and comments share a likes set. A post has an audience — public, friends, a custom privacy list, or only me. The post can check its own list, but only the friend service knows friendships, so one `VisibilityService.canSee` asks both, and every read path — feed, search, comment, like, share — calls it. The friend service owns the graph because accepting changes two members; following is one-sided. The feed gathers from friends, follows, pages and groups, filters by `canSee`, and ranks with a Strategy. Suggestions are friends of friends by mutual count, excluding pending requests either way, with a stable tie-break."

Follow-ups with answers

- *How could a private post leak?* — Through any read path that forgets privacy: search, feed, comment threads, shares, notifications. That is why `canSee` is one method used by all of them.
- *Why exclude pending requests in suggestions?* — Re-suggesting someone you already invited is a visible bug; and the check must look both ways.
- *Why the second sort key?* — Without it, people with the same mutual count can swap places between page loads, and a list that reshuffles itself looks broken.

Self-check

- **Q:** Erin is Alice's friend but not on "Close friends". Can she see a close-friends post? **A:** No — she must be a friend *and* on the list.
- **Q:** Why does `searchPosts` take a viewer? **A:** Because privacy applies inside search; otherwise search leaks private posts.
- **Q:** Where are follower counts stored? **A:** Nowhere — they are the size of the follower set.
- **Q:** Which three people are excluded from suggestions? **A:** Yourself, existing friends, and anyone with a pending request in either direction.
- **Q:** Name the two feed-building strategies and one weakness of each. **A:** Push (fan-out on write): expensive for accounts with huge audiences. Pull (fan-out on read): slower reads because it gathers at open time.

TL;DR

Facebook = LinkedIn's structure + **privacy**: a sealed `Audience`, privacy lists of friends, and one `VisibilityService.canSee` (post's list AND friend graph) called by feed, search, comments, likes and shares. `FriendService` owns the symmetric graph; following is a set. Pages and groups store collections, not counts. The news feed gathers, filters, and ranks with a Strategy; suggestions are friends-of-friends by mutual count, excluding pending requests both ways, with a stable tie-break.

18.5 Chapter summary

The four designs side by side

Aspect	Stack Overflow	Cricinfo	LinkedIn	Facebook
Core content	Question / answer / comment	Ball / over / innings / match	Post / comment / message	Post / comment / message / page post / group post
Relationship between users	None (votes and reputation)	Team membership, officials	Connection (mutual) + follow	Friendship (mutual) + follow
Two-sided operation → service	—	—	`ConnectionService.accept`	`FriendService.accept`
Role / permission model	Reputation privileges + Moderator/Admin types	Admin scorer, Commentator	Member / Admin	Member / Admin + audiences
"Derive, don't store"	Score from votes, tag counts	All stats from balls	Connection count, follower count	Member, follower counts, ratings
Strategy	Reputation policy, channels	(Target calculator as extension)	Feed ranker, channels	Feed ranker, channels
Observer	Reputation listeners (badges)	Match observers (live feed)	Notifications	Notifications
Template Method	—	`StatQuery`	—	—
Search	Words and tags	Stat queries	Members, companies, jobs	Members, groups, pages, privacy-aware posts

Common mistakes across all four

- Counters instead of sets (votes, likes, endorsements) — cannot stop duplicates.
- Stored counts next to the collections they summarise — they drift.
- Two-sided operations on one entity — asymmetric graphs.
- Privacy or permission checks in one read path but not another.
- Search index values that are a single object instead of a list.
- Modelling the nouns but not the rules (six balls vs six *legal* balls; run outs; byes).

Chapter TL;DR

Platforms are rich domain models. Share behaviour in a content base class; keep votes and likes as sets of ids; derive every number you can; put operations that change two objects in a service; notify through Observer with Strategy channels; rank feeds with a Strategy; keep search in an inverted index that maps words to lists; and write each permission or privacy rule exactly once, then call it from every read path.

Chapter 19 — Case Studies: Commerce & Marketplaces (Part 2 of Platforms)

> **Where this fits.** Chapter 18 designed platforms where people *talk* (Q&A sites, social networks, sports scores). This chapter designs platforms where people *buy, sell and trade*. Money moves, stock runs out, prices change every second, and two people often want the same last thing at the same moment. Those three pressures — **money must be exact, state must follow rules, and shared things must not be double-sold** — shape every design here.

What you will learn

#	Problem	The one idea that makes it work	Main patterns
19.1	Amazon — online shopping	An order is an immutable copy of the cart, moved through a **state machine**	State machine (enum), Strategy (payment), Observer (notifications), Facade
19.2	Online stock brokerage + stock-exchange matching engine	Four order types differ in only **two questions**; a book matches by **price, then time**	Template Method, Observer, Strategy (price policy)
19.3	Online auction	"Read highest bid, compare, replace" must be **one atomic step**	Monitor lock, Observer, Specification
19.4	Music streaming (Spotify)	Play order is a **pluggable strategy**; plan rules live **in the plan**	Strategy, Observer, enum-with-behaviour
19.5	Food delivery (Swiggy) + FoodKart	Capacity and riders are **claimed atomically**; selection is a **strategy**	Strategy, Observer, State machine, CAS
19.6	Grocery store (POS & checkout)	A **pure pricing engine**: best offer per product, then a coupon spread over items so tax and refunds stay exact	Strategy (offers, tax, payment), Facade, Observer, enum state machine

How to run every example in this chapter

```
cd chapters/19-case-platforms-2/code
javac --release 21 -d /tmp/lld_19 $(find . -name '*.java')
java -cp /tmp/lld_19 lld.ch19.amazon.Main          # or brokerage, stockexchange, auction, music, fooddelivery, foodkart, grocery
```

`javac` is the Java compiler (it turns `.java` files into runnable `.class` files); `-d` names the output folder, and `java -cp` runs a class, where the **classpath** (`-cp`) is the list of folders Java searches for compiled classes.

All eight `Main` classes compile with Java 21 (standard library only — only the classes that ship with Java) and run. The output under each implementation is the real output of that program. The stock-exchange `Main` also runs a small test suite (a set of automatic checks that confirm the code behaves as expected; no JUnit — the usual Java testing library — needed).

> **Code-style note.** To keep each case readable, one file sometimes holds several small package-private types (for example `Payments.java` holds `Payment`, its two subclasses and `Shipment`). That is legal Java. In production you would usually give each top-level type its own file.

> **Key term — Java vocabulary used in this chapter:** A **package-private** type has no access keyword and is visible only inside its own package (folder of classes). A **top-level type** is a class, interface, enum or record not nested in another. An **interface** lists methods a class promises to provide. An **enum** is a type with a fixed list of named values. A **record** is a compact class that just carries data that never changes. A **sealed** type

> lists exactly which subclasses are allowed (the `permits` clause), so the compiler knows every possible kind. `synchronized` means only one thread at a time may run that code on the same object.

> **Key term — the design patterns named in this chapter: Strategy** puts each interchangeable way of doing a job (each payment method, each play order) behind one interface so it can be swapped or added without editing the caller. **Observer** lets objects subscribe to events from another object and be called back automatically, so the publisher does not know who listens. **Facade** is one simple class that hides many classes behind a few easy methods. **Template Method** is a base-class method that fixes the outline of an algorithm and lets subclasses fill in one or two steps. **Specification** turns each business rule or search condition into a small yes/no object that can be combined with others.

Four rules that apply to every design in this chapter

1. **Money is `BigDecimal`, never `double`.** `double` is Java's floating-point number type: it stores numbers in binary, so most decimal fractions are only approximated. `BigDecimal` is Java's exact decimal-number class. A `double` cannot store 0.1 exactly, so `0.1 + 0.2` prints `0.30000000000000004`. With `BigDecimal` you choose the scale (number of decimal places) and the rounding mode yourself. Two traps: build it from a `String` (`new BigDecimal("0.10")`), not from a `double`; and compare with `compareTo`, not `equals` — `new BigDecimal("2.0").equals(new BigDecimal("2.00"))` is `false` because the scales differ.
2. **Status changes follow a state machine.** A **state machine** is a fixed list of states plus the allowed moves between them. We put the allowed moves *inside the enum*, so an illegal move (for example "cancel a delivered order") throws immediately instead of silently corrupting data.
3. **Check-then-act on shared stock must be atomic.** "Is there one left? Then take it" is two steps. If two threads (independent paths of execution running at the same time inside one program) run step 1 together, both see "yes" and both take it — a **race condition**, where the result depends on which thread happens to get there first. The fix is to do both steps under one lock (a guard that only one thread can hold at a time; the others wait), or with one atomic compare-and-set (CAS: "set to B only if it is still A").
4. **Copy prices into orders.** An order remembers the price that was paid, and is **immutable** (it cannot be changed after it is created). If the menu or catalog price changes later, old orders must not change.

Design Amazon — Online Shopping System

Problem & clarifying questions

Amazon started as an online bookshop and now sells almost every kind of consumer product and digital media. We design the **online retail part**: people list products, other people find them, put them in a cart, pay, and track the parcel.

Questions worth asking before you draw anything (with the answers we assume):

Question	Assumed answer
Can someone buy without an account?	No. Browsing and filling a cart are open to everyone; placing an order needs a **registered member** account.
Who sells?	Members can list products for sale (a marketplace, not only first-party — goods sold by the platform itself).
How do people pay?	Credit card or electronic bank transfer. Cards clear at once, transfers clear later.
Can an order be cancelled?	Yes, until it has shipped.
Do we notify people?	Yes, on every order or shipping status change.
Returns, wish lists, seller payouts, recommendations, stock spread over several warehouses?	Out of scope — a deliberate choice, and you should say so out loud.

Requirements

Functional

1. Members can add new products to sell.
2. Anyone can search products by **name** or **category**.
3. Anyone can search and view products; only registered members can buy.
4. Users can add, remove and change the quantity of items in their shopping cart.
5. Users can check out and buy everything in the cart.
6. Members can rate and review a product.
7. Members give a shipping address for delivery.
8. A member can cancel an order that has not shipped.
9. Members are notified each time the status of their order or of its shipment changes.
10. Members pay with a credit card or with an electronic bank transfer.
11. Members can track the shipment and see the current order state.

Non-functional

- **Correctness of stock:** two buyers can never both get the last unit.
- **Exact money:** totals are computed with `BigDecimal`.
- **Auditability** (being able to prove later exactly what happened and when)**:** every order and shipment keeps a history of its states, not just the latest one.
- **Extensibility** (how easily new features can be added without rewriting old code)**:** adding a payment method or a notification channel must not change the checkout code.

Use cases

Four actors:

- **Admin** — manages accounts (block / unblock) and adds or changes product categories.
- **Guest** — searches the catalog, adds and removes cart items, and can register to become a member.
- **Member** — everything a guest can do, plus placing orders and listing products to sell.
- **System** — sends order and shipment notifications.

Top use cases: add or update products (each change also updates the catalog), search products (by name, or by category), put items into the cart or take them out, check out, pay, add a product category, and send shipment notifications.

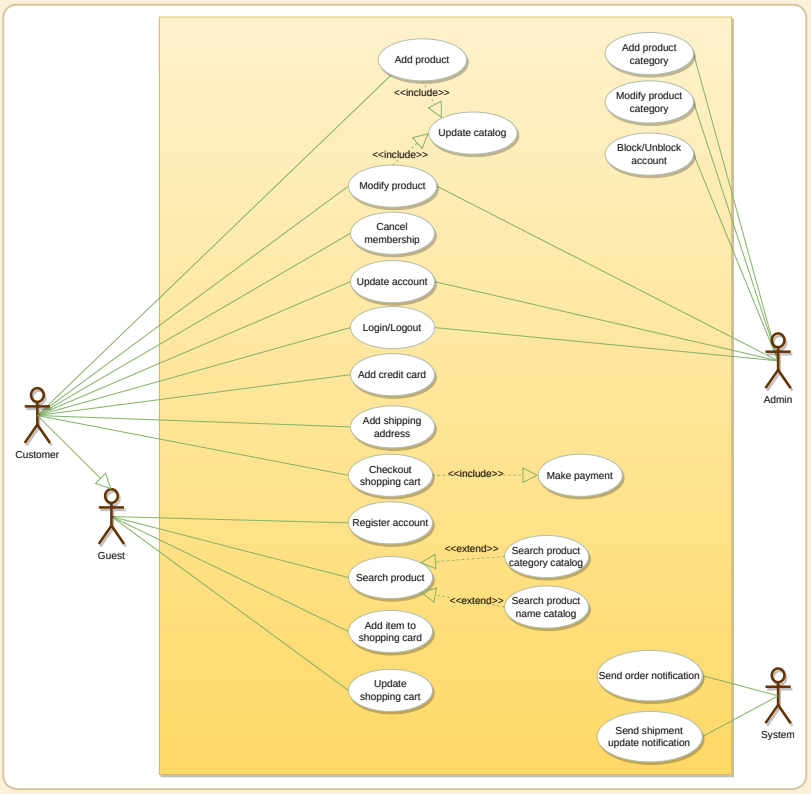

Figure — Use-case diagram for the online shopping system: Admin, Guest, Member and System and what each may do (course diagram)

In the figure above, notice that "Checkout" *includes* "Make payment" and "Add shipping address": you cannot check out without them. Search by name and search by category *extend* the general "Search product" use case.

Core entities

Class	Responsibility
`ProductCategory`	A named group such as Books or Electronics. Exists whether or not any product uses it.
`Product`	The thing sold: price, seller, stock count. **Owns** its reviews and guards its own stock (`reserve` / `release`).
`ProductReview`	Rating 1–5 plus text. Records the reviewer **by id**, so `Product` never depends on `Member`.
`Search` / `Catalog`	Interface with two search methods. The catalog keeps one index (a lookup map built in advance) per search (name words → products, category → products), so a lookup reads a map instead of scanning every product, and `addProduct` updates both indexes together so they cannot drift apart. The catalog only *points to* products; it never owns them.
`ShoppingCart`	Mutable (changeable) working area. **Owns** its items; clearing the cart destroys them.
`Item`	One line: product id, name, quantity, unit price (an immutable `record`). A pen is a *product*; ten pens in stock are ten product *items*.
`Order`	Immutable **copy** of the cart lines + address + a status that moves only along legal edges.
`OrderLog`	One entry per status change (unshipped, pending, complete, cancelled...).
`Payment` (`CreditCardPayment`, `BankTransferPayment`)	Takes the money. A card clears immediately; a bank transfer comes back `PENDING` from `process()` and clears later.
`Shipment` / `ShipmentLog`	A parcel and its tracking history (pending, shipped, delivered, on hold). The last log entry is "where is it now".
`Notification` channel (`EmailChannel`, `SmsChannel`)	One way of delivering a message. (The course draws an abstract `Notification` class with one subclass per channel; we use an interface — same idea.)
`Account`	Login data, addresses, status (active, blocked, banned...).
`Customer` → `Guest`, `Member`	`Customer` has only what *anyone* may do; ordering lives on `Member`.
`Admin`	Adds categories, blocks and unblocks members.
`OrderService`	Application service (a class that coordinates domain objects to carry out one user action) that turns a cart into an order and drives its state machine.

Class diagram

The course builds the model in five stages (products → catalog → payment/shipment/notification → cart/order → accounts). Here is the finished picture:

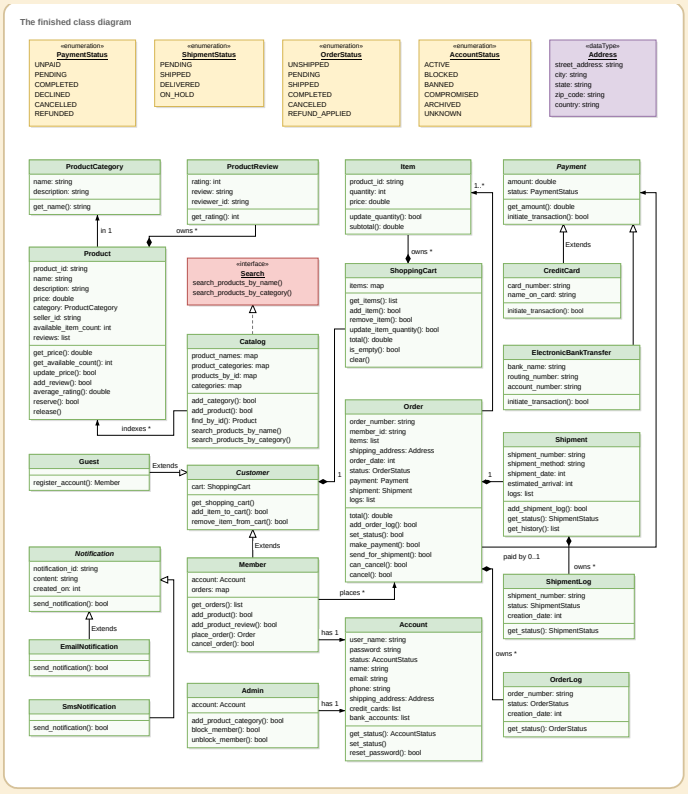

Figure — The finished class diagram of the online shopping system (course diagram)

In the figure above, read the arrows this way: a **filled diamond** means *composition* (the part belongs to the whole and is destroyed along with it — `Product` owns its reviews, `ShoppingCart` owns its items, `Order` owns its log and shipment). A **plain arrow** is *association* (a link without ownership — a product points at its category; an order only *refers to* the payment it was handed). The hollow triangle is inheritance (`Guest` and `Member` extend `Customer`).

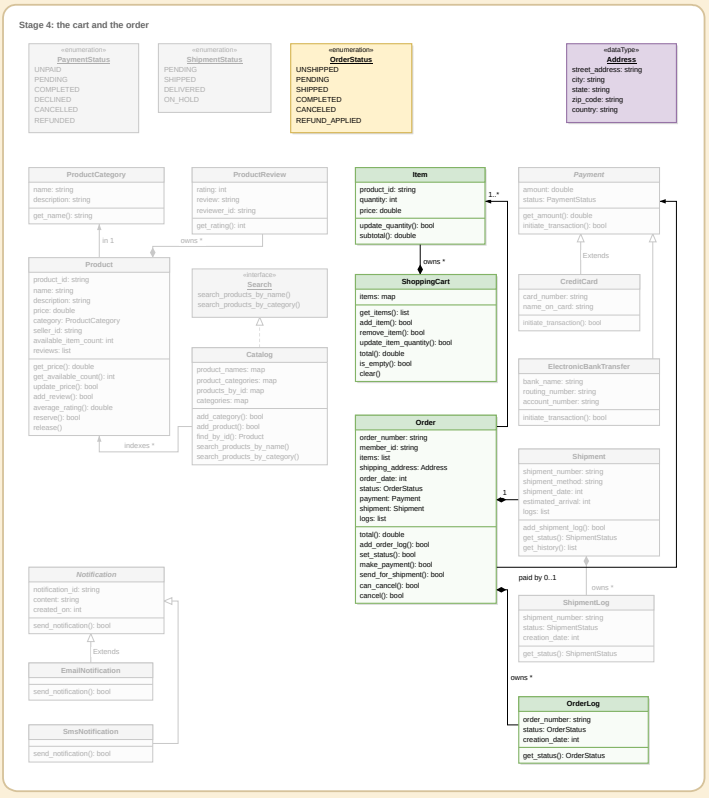

Figure — Stage 4: the cart owns its items, while the order holds its own copy of what was bought (course diagram)

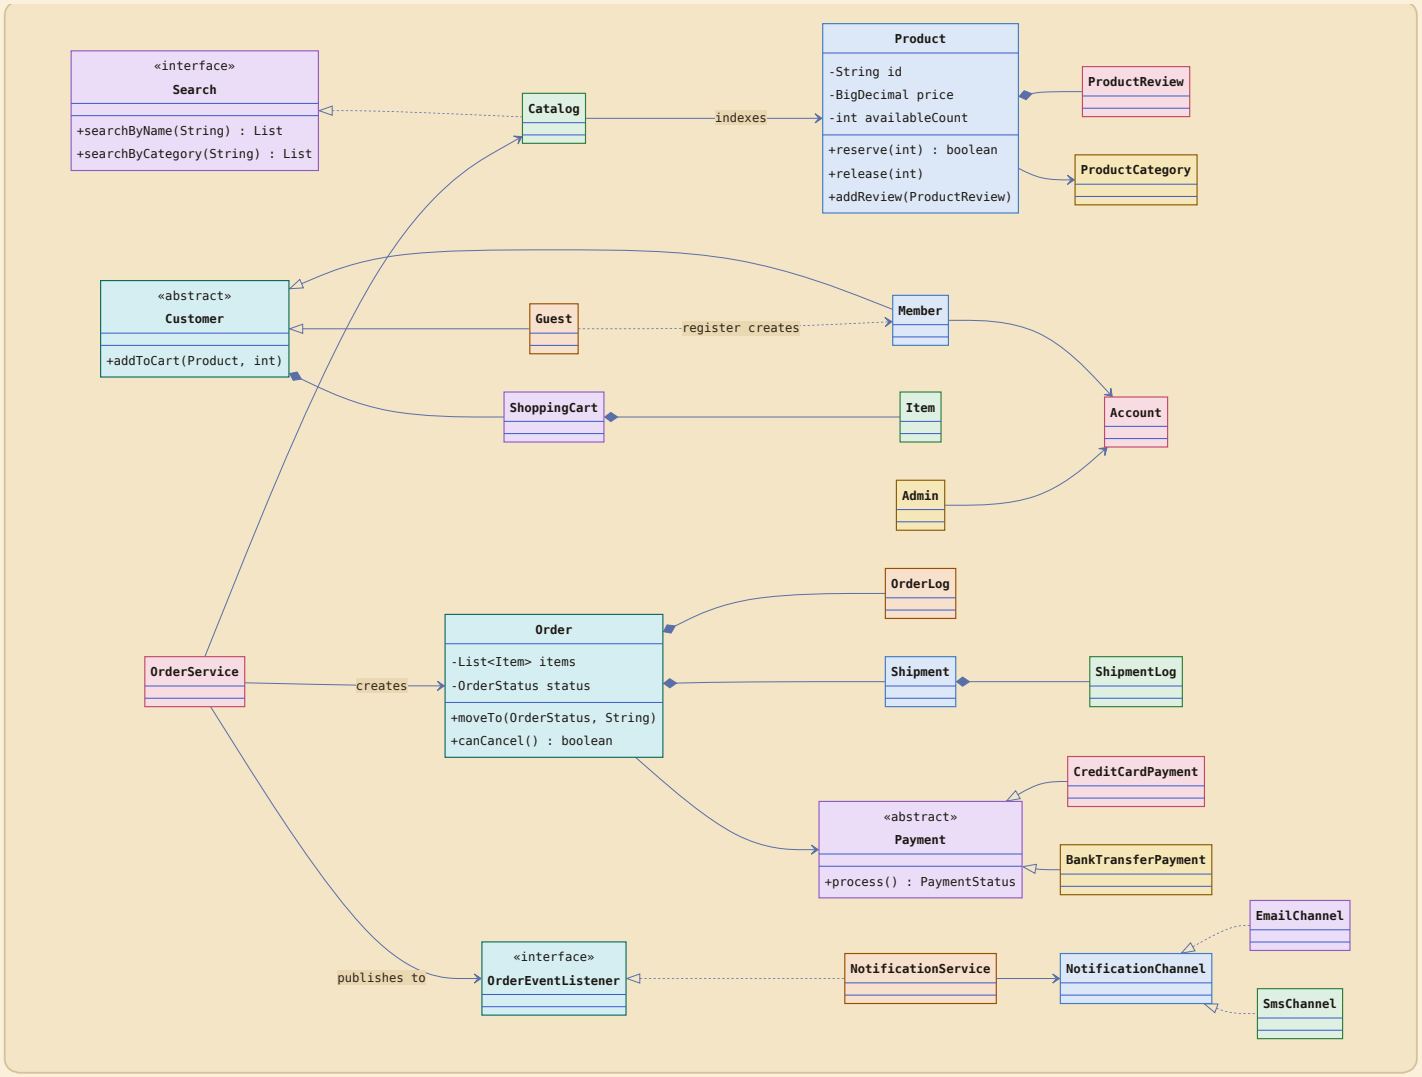
Our Java design follows the same shape:



Key flows

Shopping activity. The course's activity diagram shows the loop a shopper goes round: search, view, add to cart, update the cart, "more shopping?", and finally checkout.

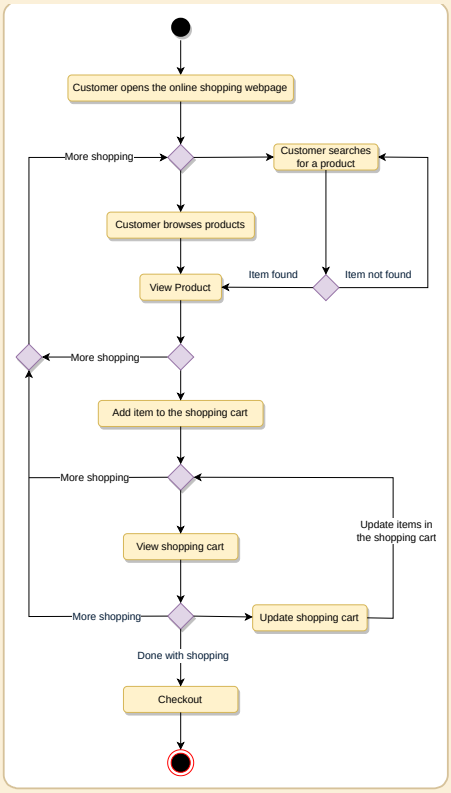


Figure — Activity diagram of a customer shopping online, from opening the site to checkout (course diagram)

Searching the catalog, and adding to the cart. The first two course sequence diagrams show the simple read path (customer → catalog → matching products) and the cart update path (customer → cart → item).

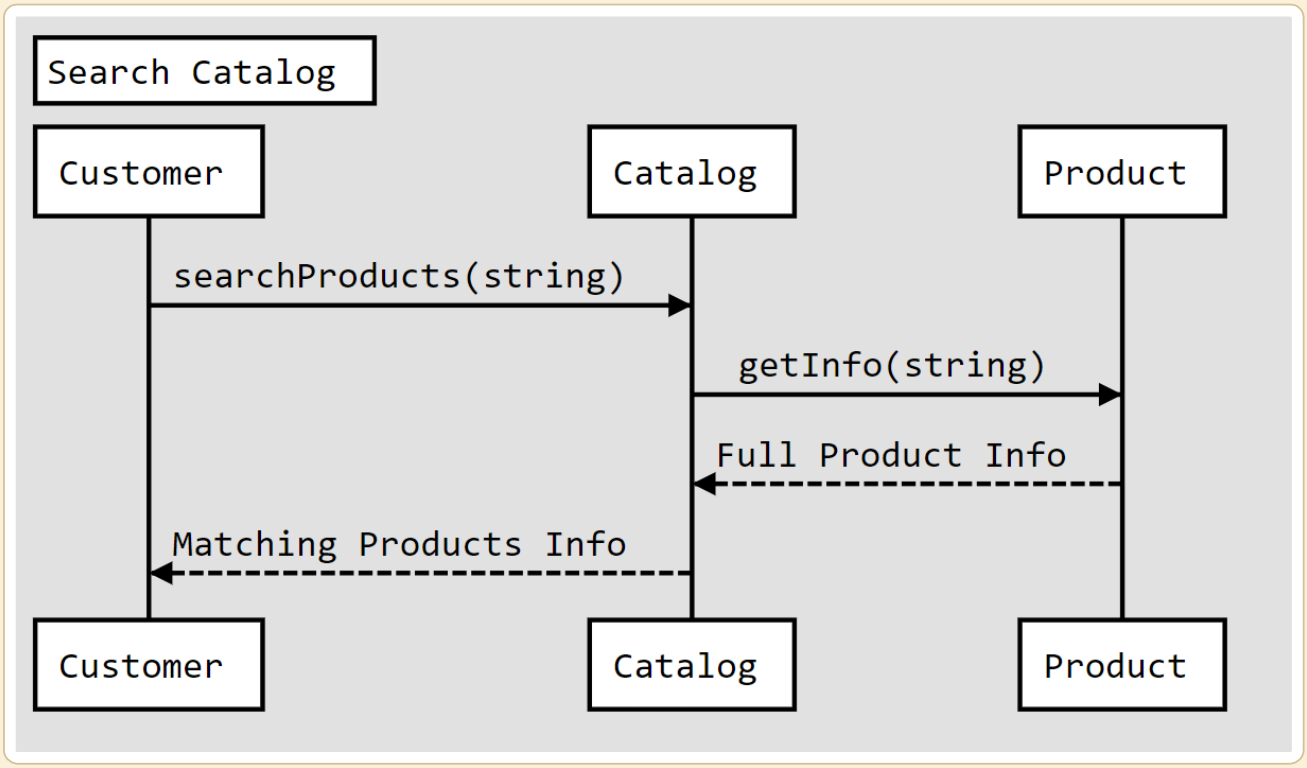

Figure — Sequence diagram for searching the catalog (course diagram)

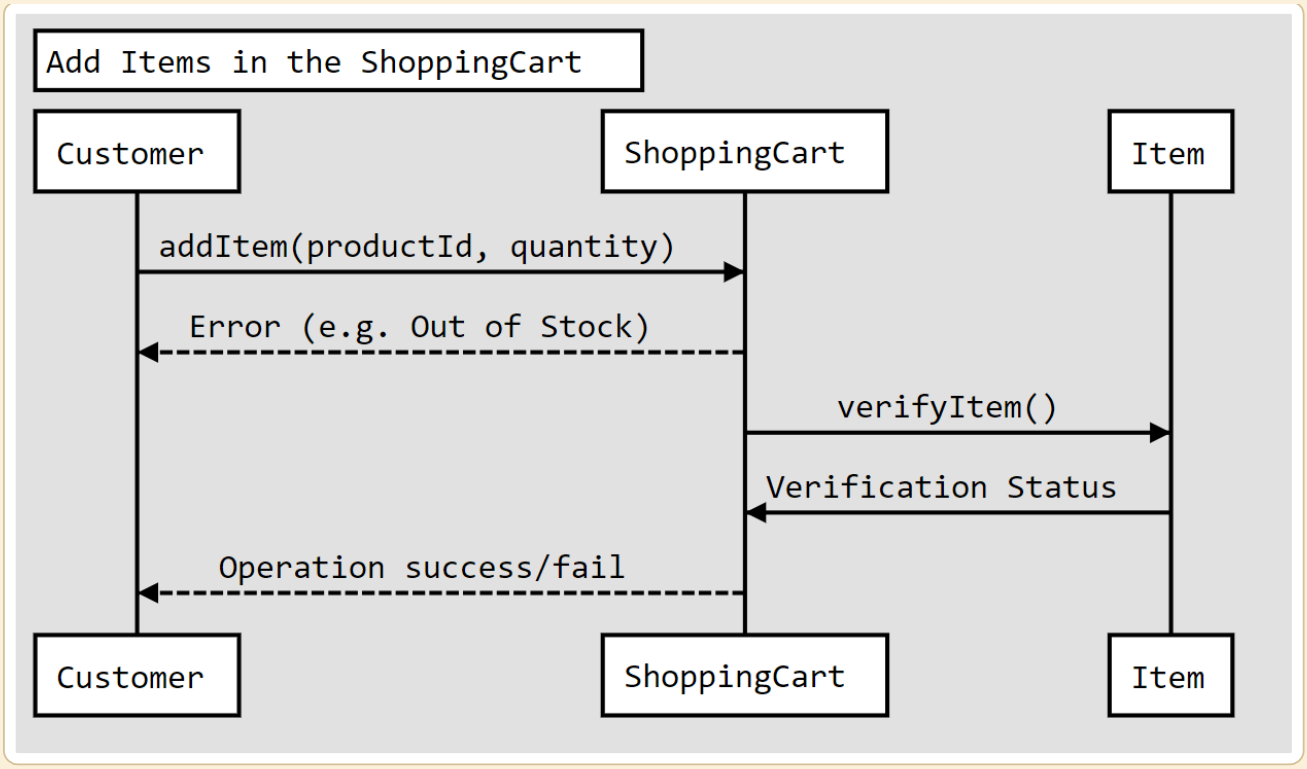

Figure — Sequence diagram for adding an item to the shopping cart (course diagram)

Checkout. The third course sequence diagram shows the important one: get the cart items, get billing and shipping info, create the order, verify every item, process the payment, create the shipment, and return the order status — with an error path after item verification and after payment.

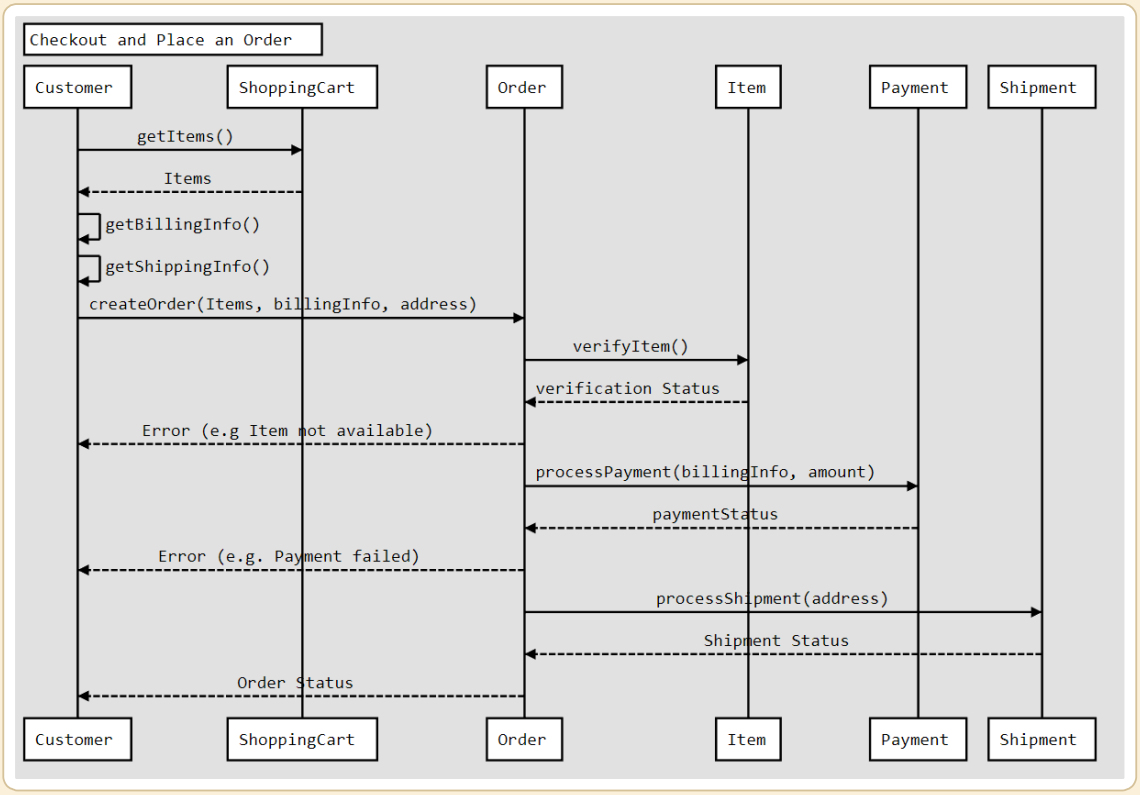

Figure — Sequence diagram for checkout: verify items, take payment, create shipment (course diagram)

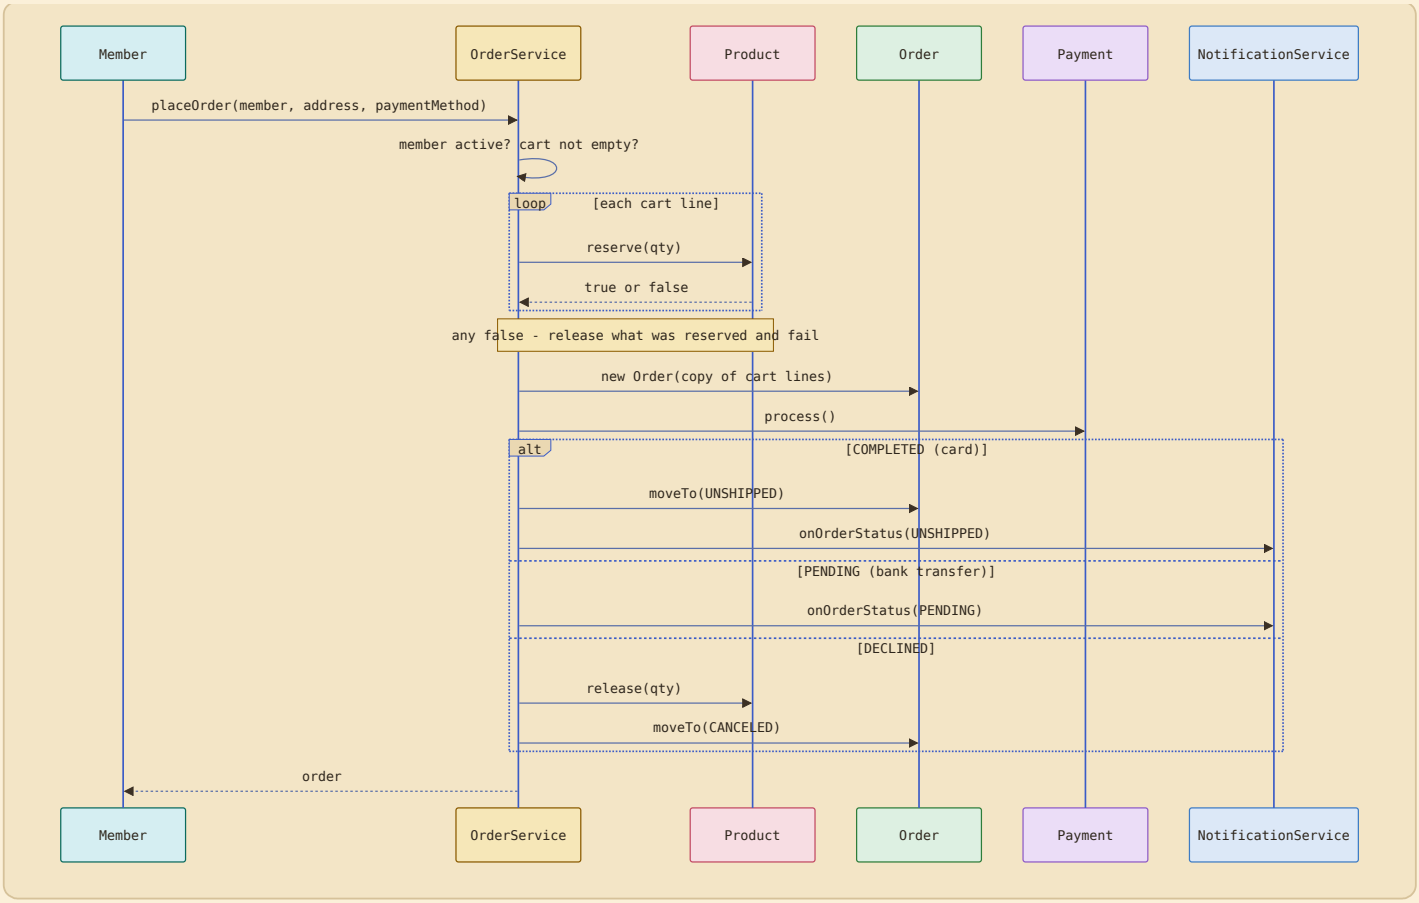
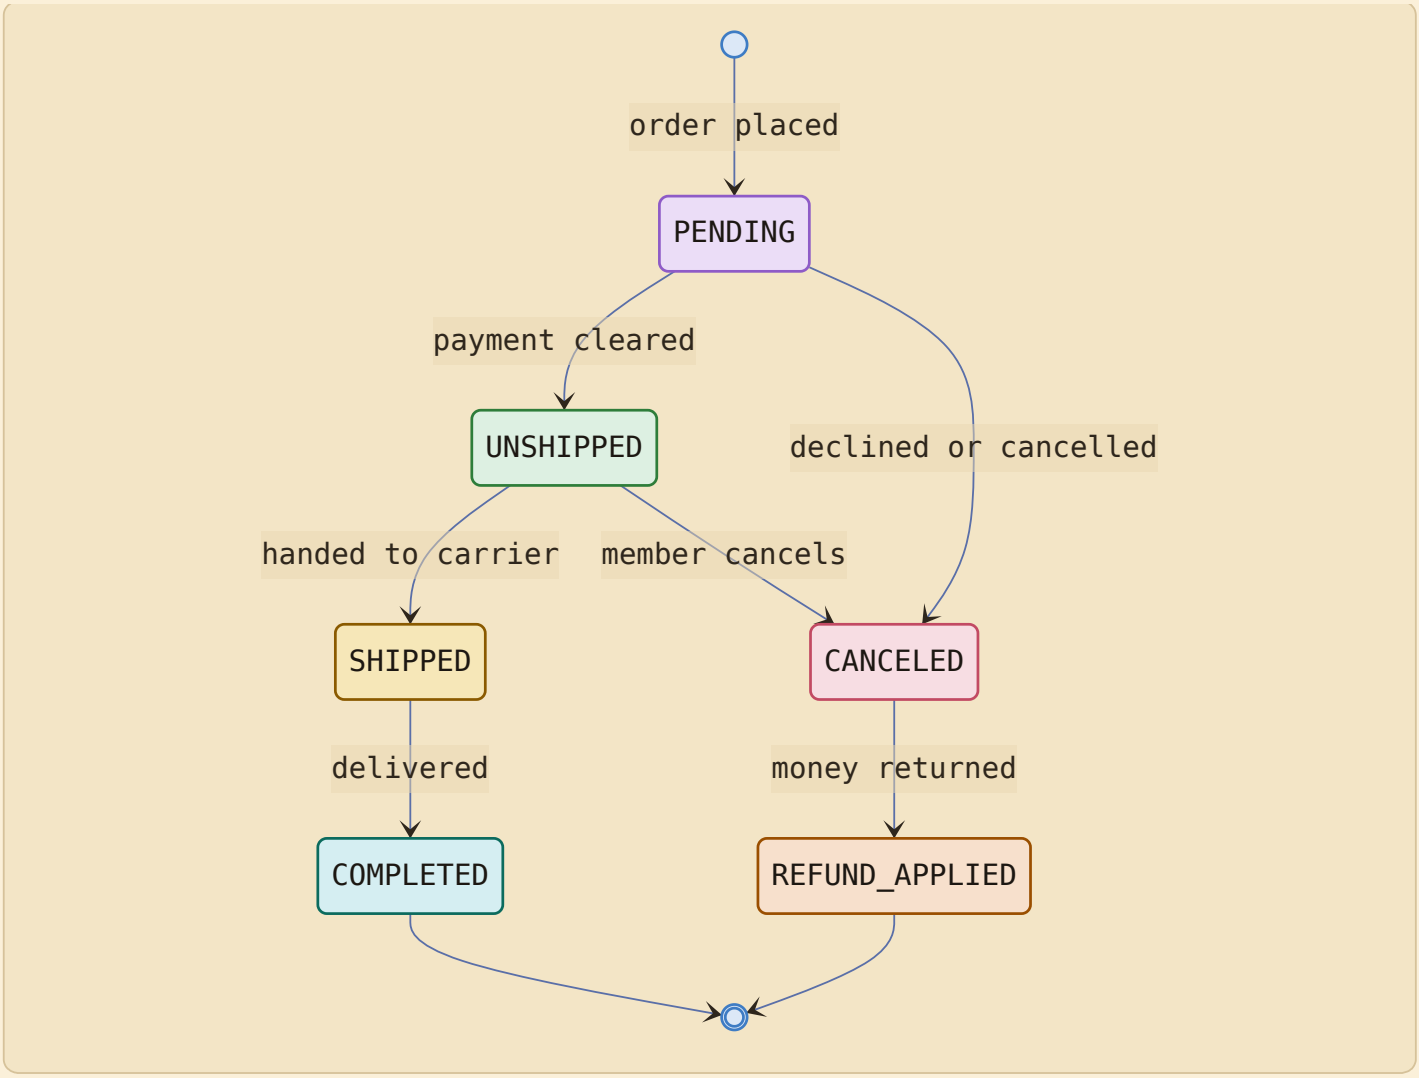
Our `OrderService.placeOrder` follows that order, with one addition: stock is **reserved** during verification (not merely checked), so the check cannot go stale before payment.



The order state machine. Every legal move is listed in `OrderStatus.next()`. Anything else throws.



Requirement 8 ("cancel only if not shipped") is now one line: `canCancel()` returns `status.canMoveTo(CANCELED)`. There is no `SHIPPED → CANCELED` edge, so it is impossible by construction.

Design decisions & patterns used

Decision	Why	Alternative rejected
Ordering lives on `Member`, not `Customer`	A `Guest` *is a* `Customer`. If `Customer` had `placeOrder`, every guest would inherit an operation it has to reject — breaking the **Liskov Substitution Principle** (a subclass must be usable wherever its parent is, without surprises).	`Customer.placeOrder()` that throws for guests (the classic LSP smell).
`Guest.register()` returns a new `Member` and carries the cart across	Registration is a real-world moment where the cart must survive.	Mutating a guest into a member (Java objects cannot change class).
`Order` copies the cart lines	An order documents a *finished purchase*; it must stay fixed even if the cart is edited later.	Sharing `Item` objects — cheaper, but editing the cart would silently rewrite a finished order.
Stock reserved at order time, not at payment time	Prevents two shoppers from both getting the final unit. Cost: an abandoned order holds stock until cancelled; real systems release it on a timer.	Check stock, then pay, then decrement (a race window between check and decrement).
State machine inside `OrderStatus`	One place owns the rules. `moveTo` rejects illegal edges.	`if` checks scattered over `cancel`, `ship`, `deliver`.
`Payment` is an abstract (sealed) class, one subclass per method — a **Strategy**	The two methods *behave* differently (card clears now, transfer is pending). An **abstract class** cannot be instantiated itself — only its subclasses can — so every payment is a real card or transfer. Each subclass passes the substitution test (it can genuinely stand in for `Payment`: both really take money), and the same holds for the notification channels. A new method = a new subclass; checkout does not change (Open/Closed Principle: code should be open to extension but closed to modification). The course calls this out: it is why `Payment` is not an enum.	`enum PaymentType` + `switch` in checkout.
Payment passed in as `Function<BigDecimal, Payment>` (a function object: give it an amount, get a `Payment` back)	Checkout knows the total only after building the order, so it asks the caller's factory (a piece of code whose job is to create objects) for a payment of that amount.	Creating the payment before the total is known.
Observer for notifications	`OrderService` publishes events; `NotificationService` decides who to tell and how. Adding push notifications = a new `NotificationChannel`.	Calling email and SMS code directly inside `OrderService`.
`Shipment` keeps a log	Requirement 11 = read the last entry; the whole history stays for support and disputes.	A single `status` field (history lost).
Reviews store `reviewerId`	Avoids a two-way dependency `Product ↔ Member`; each class can be understood alone.	`ProductReview` holding a `Member` object.
`OrderService` as a Facade	One simple entry point hides stock, payment, shipment and notification steps.	Callers orchestrating five objects themselves.

Java implementation

Files: `Money.java` (BigDecimal helpers), `Catalog.java` (category, product, review, search, catalog), `Order.java` (address, item, cart, order status machine, order), `Payments.java` (payments, shipment), `Accounts.java` (account, customer, guest, member, admin), `OrderService.java` (listeners, notifications, service), `Main.java` (demo).

    [email -> alice@mail.test] Order ORD-1002 is now REFUND_APPLIED
    [sms   -> +1-555-0101] Order ORD-1002 is now REFUND_APPLIED
  cancel before shipping? true -> REFUND_APPLIED, payment REFUNDED, Refactoring stock back to 2
  order log: [PENDING, UNSHIPPED, CANCELED, REFUND_APPLIED]

== 6. Illegal transition is rejected by the state machine ==
  ORD-1002: REFUND_APPLIED -> SHIPPED is not allowed

== 7. Review ==
  Clean Code average rating = 4.5

== 8. Blocked member cannot buy ==
  rejected: account BLOCKED

== 9. Ten members race for the last copy ==
  winners=1 losers=9 stock left=0
```

Reading the output. Step 1 answers both searches from indexes (a name search matches every query word, so `usb cable` finds "USB-C Cable"). Step 2 shows the guest's cart surviving registration. Step 3 prints two notifications (email + SMS) because both channels are registered. Step 5 walks the full cancel path `PENDING → UNSHIPPED → CANCELED → REFUND_APPLIED`, and the stock returns to 2. Step 6 proves the state machine refuses `REFUND_APPLIED → SHIPPED`. Step 9 starts ten threads at the same instant (a `CountDownLatch` — a gate that keeps threads waiting until a counter reaches zero — releases them together) and exactly one wins the last copy.

Concurrency & edge cases

Risk	What could go wrong	How the code prevents it
Last unit, two buyers	Both see `availableCount == 1`, both decrement → stock −1	`Product.reserve` is `synchronized`: check and decrement are one step. Step 9 proves it.
Multi-line cart, one line out of stock	Lines 1–2 reserved, line 3 fails → stock leaked	`placeOrder` remembers what it reserved and releases it all on failure (all-or-nothing).
Cancel and ship at the same time	Order shipped *and* stock released	`cancel` and `ship` both lock the `Order` object around check-then-move.
Payment declined	Stock stays reserved forever	Declined path releases stock and moves the order to `CANCELED`; the cart is kept so the member can retry.
Bank transfer never clears	Stock held forever	Mention a timeout job that cancels `PENDING` orders after N hours.
Price changes after adding to cart	Customer charged a price they never saw	`Item` stores the unit price at add time; production systems re-validate prices at checkout and show changes.
Blocked member	Places orders anyway	`Member.canBuy()` checks `AccountStatus.ACTIVE` first (step 8).
Deadlock (two threads each waiting forever for a lock the other holds)	Two locks taken in different orders	Each lock (product, order, cart) is held briefly and never while waiting for another object's lock in the opposite order.

Real-world example

On Amazon's "Your Orders" page, the *Cancel items* button is offered only while an order has not yet entered the shipping process — the same edge our state machine removes after `SHIPPED`. Amazon also treated the shopping cart as something that must *always* accept writes: its 2007 Dynamo paper (the key-value store — a database that simply maps a key to a value — behind services such as the cart) chose **availability** (staying usable even when some machines fail; see System Design Fundamentals) so that "add to cart" works even during failures, and merges conflicting cart versions later. Our in-memory design shows the object model; at Amazon's scale the cart, catalog and orders live in separate services.

Extensions & follow-up questions

- **"Add a new payment type, e.g. gift cards or UPI (India's instant bank-to-bank mobile payment system)."** Add a `GiftCardPayment extends Payment` (and list it in `permits`). `OrderService` is untouched, because it only calls `process()`.
- **"How do you prevent two shoppers from both buying the final unit?"** Reserve at order time inside a lock (`Product.reserve`). In a distributed system (one spread over many machines): a conditional database update (`UPDATE ... SET stock = stock - 1 WHERE id = ? AND stock >= 1`) or **optimistic locking** with a version column (no lock is held; each row carries a version number, and an update succeeds only if the version is still the one you read — otherwise you retry).
- **"Abandoned orders hold stock."** Give each reservation an expiry. A scheduled job cancels `PENDING` orders older than, say, 30 minutes and releases stock.
- **"Returns after delivery."** Add `COMPLETED → RETURN_REQUESTED → RETURNED → REFUND_APPLIED` edges; the enum change is local.
- **"Multiple warehouses."** Replace `Product.availableCount` with an `Inventory` per warehouse; checkout picks a warehouse per line (a Strategy: nearest, cheapest shipping).
- **"Split shipments."** One `Order` owns many `Shipment`s, each with its own item subset and log.
- **"Search at scale."** The in-memory `Catalog` becomes a search index (for example Elasticsearch/OpenSearch, popular search-engine servers) fed by product change events; the `Search` interface stays.
- **"Seller payouts, recommendations, wish lists."** Separate modules listening to order events (Observer again).

In the interview

30–45 minute plan

1. (3 min) Clarify: guest vs member, payment types, cancel rule, notifications, what is out of scope.
2. (5 min) Actors and use cases; name the four actors.

3. (10 min) Class diagram. **Say the LSP sentence out loud**: "Ordering is on `Member`, not `Customer`, otherwise every guest inherits an ordering method it is not allowed to use."
4. (5 min) The order state machine; show that "cancel after ship" has no edge.
5. (10 min) Code `placeOrder` (reserve all-or-nothing, copy items, pay, notify) and `cancel`.
6. (5 min) Concurrency: last-item race; abandoned-order timeout; extensions.

> **30-second answer:** "Catalog with name and category indexes; a cart per customer; ordering only on `Member`; checkout reserves stock for every line atomically, copies the lines into an immutable order, then takes payment through a `Payment` strategy. The order moves through a state machine that forbids cancelling after shipping, and every status change is published to a notification observer."

Follow-ups with answers

- *Why is `Payment` abstract rather than an enum?* Because the methods behave differently (clears now vs pending). New methods are new classes — Open/Closed.
- *Why does `Order` copy items?* So later cart edits or price changes cannot rewrite history.
- *Where would you put tax and discounts?* A `PricingRule` chain (Chain of Responsibility — a pattern where a request is passed along a line of handlers, each doing its part — or a list of Strategies) applied when building the order; the order stores the final line prices.
- *How do you make checkout idempotent (safe to repeat: doing it twice has the same effect as doing it once) if the user double-clicks?* Accept a client-generated idempotency key (a unique id the browser sends with the request); if an order with that key exists, return it instead of creating a second one.

Self-check

1. **Q:** Why can't `placeOrder` live on `Customer`? **A:** `Guest extends Customer` and guests must not order; inheriting a method you must refuse violates LSP.
2. **Q:** What does the filled diamond between `Order` and `OrderLog` mean? **A:** Composition — the order owns its log entries; they are created and destroyed with it.
3. **Q:** Name two things wrong with "check stock, take payment, then decrement stock". **A:** A race window lets two buyers pass the check; and a payment can succeed for goods that are no longer there.
4. **Q:** Which status edges allow a cancel? **A:** `PENDING → CANCELED` and `UNSHIPPED → CANCELED`.
5. **Q:** Why `compareTo` and not `equals` on `BigDecimal`? **A:** `equals` also compares scale, so `2.0` and `2.00` are "not equal".
6. **Q:** What pattern lets you add push notifications without touching `OrderService`? **A:** Observer (listener) plus a new `NotificationChannel` implementation.

TL;DR

- Guests browse and fill carts; **only members order** (LSP).
- Checkout = **reserve all lines atomically → copy into an immutable order → pay (Strategy) → publish (Observer)**.
- `OrderStatus` is a **state machine**; "cancel after ship" is impossible because the edge does not exist.
- Money in `BigDecimal`; histories in logs; stock guarded by a lock.

Design an Online Stock Brokerage System

This problem has two halves, and interviews ask both:

- **Part A — the brokerage** (what the course designs): members, money in and out, watchlists, the four order types, lots and positions, statements.
- **Part B — the exchange's matching engine** (a machine-coding problem — write a working program in about 90 minutes — originally from Geektrust, an Indian coding-assessment platform, kept in kumaransg/LLD under a project named "Navi"; we call it "the Navi statement" below): an **order book** (the list of all waiting buy and sell orders for one stock) that matches buy and sell orders by **price-time priority**, implemented and tested.

A **broker** is the company you trade *through* (it holds your cash and shares and forwards your orders). An **exchange** is the market where buy and sell orders from all brokers *meet* and are matched. Keep the two apart in your head;

the design keeps them apart in code.

Problem & clarifying questions

An online brokerage lets people buy and sell stocks without a human middleman. Members track and carry out their transactions, see charts of how the stocks they hold are performing, and get an alert when a stock moves by an amount they chose. The platform must keep those transactions secure. Because computers replace the phone call to a broker, each trade is quicker and cheaper, and members get fast access to real-time (updated the moment they change) prices, market trends and stock reports.

Question	Assumed answer
Which order types?	Market, limit, stop-loss, stop-limit (explained in the table under Key flows).
Can one order fill at several prices?	Yes — an order can be filled in parts.
Do we track separate purchases of the same stock?	Yes — each purchase is a **lot**, because tax depends on which lot you sell.
How does money come in and out?	Check, wire (a direct bank-to-bank transfer), or electronic bank transfer, each with a per-transfer limit.
Reports?	Quarterly statements and a yearly tax statement.
Notifications?	When an order executes.
Margin, short selling, options, dividends and stock splits, real-time streaming quotes, the settlement delay, the wash-sale tax rule?	Out of scope — a deliberate decision, say so.

For reference, those out-of-scope terms: **margin** is trading with money borrowed from the broker; **short selling** is selling borrowed shares, hoping to buy them back cheaper; **options** are contracts giving the right to buy or sell later at a fixed price; **dividends** are profits a company pays to its shareholders; a **stock split** turns each share into several cheaper ones; **settlement** is the actual swap of cash and shares, which happens a day or so after the trade; the **wash-sale rule** is a US tax rule that blocks claiming a loss if you rebuy the same stock within 30 days.

Requirements

Functional (brokerage)

1. Any member can buy and sell stocks.
2. A member can have **multiple watchlists** (named lists of stocks to keep an eye on), each with multiple stock quotes (a quote is a stock's latest price).
3. Orders can be **market, limit, stop-loss, stop-limit**.
4. A member can hold **multiple lots** of the same stock; the system keeps them apart.
5. The system generates **quarterly** updates and **yearly tax** statements.
6. Money goes in and out of the account in three ways: **check, wire, or electronic bank transfer**.
7. A notification is sent whenever an order executes.

Functional (matching engine, Navi variant)

8. Orders arrive as `<id> <time> <symbol> <buy/sell> <price> <qty>`, e.g. `#1 09:45 BAC sell 240.12 100`. They are read from a text file whose path is given as the program's argument; trades are printed to the console.
9. On every new order, match against the opposite side. Lower sell prices and higher buy prices go first; at the same price, **earlier orders go first** (price-time priority).
10. A trade happens when buy price ≥ sell price. In the Navi statement the trade is recorded at the **sell order's price**.
11. Print each trade as `<buy_id> <price> <qty> <sell_id>`; unmatched quantity stays in the book.

Non-functional

- Money is never over-committed: ten $1,000 orders cannot all pass a $1,000 balance check.
- Matching is deterministic (no randomness or timing luck): same input, same trades.
- The engine is safe under concurrent submissions and conserves quantity (shares bought = shares sold).

Use cases

Three actors:

- **Admin** — administrative jobs such as blocking or unblocking members.
- **Member** — searches the stock inventory, buys and sells, manages watchlists.
- **System** — sends order notifications and periodically fetches quotes from the exchange.

Top use cases: register / cancel membership; add, remove or edit a watchlist; search stocks by symbol; place an order; cancel an order; deposit or withdraw money.

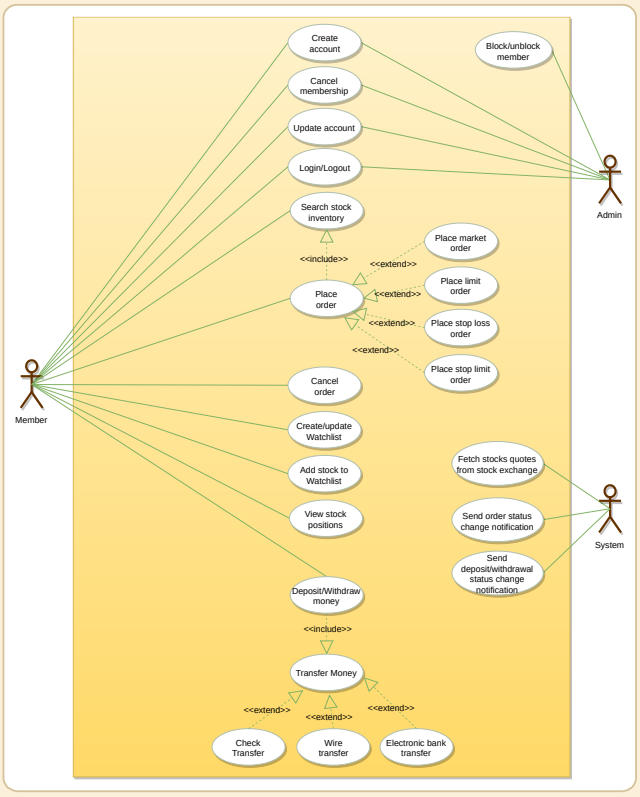

Figure — Use-case diagram for the stock brokerage: Admin, Member and System (course diagram)

Core entities

Class	Responsibility
`MoneyTransfer` → `CheckTransfer`, `WireTransfer`, `ElectronicBankTransfer`	Move money in or out. They differ only in name and clearing days (5 / 1 / 3 in our code); the per-transfer limit (100,000) is a single rule, so it lives only in the base class.
`Notifier` / `EmailNotifier`	Delivers "your order filled" messages. The course draws one base with two delivery ways (email and SMS); an `SmsNotifier` would be a second implementation.
`Order` (abstract)	Shared by all order types: member, symbol, side (buy or sell), quantity, time-in-force (how long the order stays live), status, list of fills. Declares the **two questions**.
`MarketOrder`, `LimitOrder`, `StopLossOrder`, `StopLimitOrder`	Each answers "may I trade now?" and "what is my worst price?". `StopLimitOrder extends StopLossOrder`.
`OrderPart`	One fill: quantity, price, day. A 100-share order might be filled as 70 @ 10.00 plus 30 @ 10.05.
`Stock`, `StockInventory`	Symbol + latest price; the inventory is the **single source of truth** (the one place whose value counts if copies disagree) for prices.
`StockExchange`	Holds open orders; on each new order or price tick tries to fill them; calls back through `OrderListener`.
`OrderListener`	Interface the exchange calls (`onFill`, `onCancelled`). The exchange never learns what a member is.
`StockLot`	One purchase at one price.
`StockPosition`	All lots of one symbol; sells from the oldest lot first (FIFO — first in, first out) unless a lot is named. Returns a `LotSale` per lot touched.
`LotSale`	Shares taken from one lot, buy price, sell price → realised gain (profit actually locked in by selling).
`Watchlist`	A named set of **symbols** (not `Stock` objects, so it never goes stale).
`Trade`	One fill as the member sees it (sells carry their `LotSale`s).
`Statement` → `QuarterlyStatement`, `TaxStatement`	Base class filters trades by day range; subclasses write their own lines.
`Member`	Cash, **reserved funds**, positions, watchlists, trades. Implements `OrderListener`. (The course's `Account` also stores name, address, e-mail and phone; we keep only what the demo uses.)
`Admin`	Blocks / unblocks members.
(engine) `OrderBook`, `MatchingEngine`, `Trade`, `ExecutionPricePolicy`	Price levels with FIFO queues per symbol; routing and locking; who sets the trade price.

Class diagram

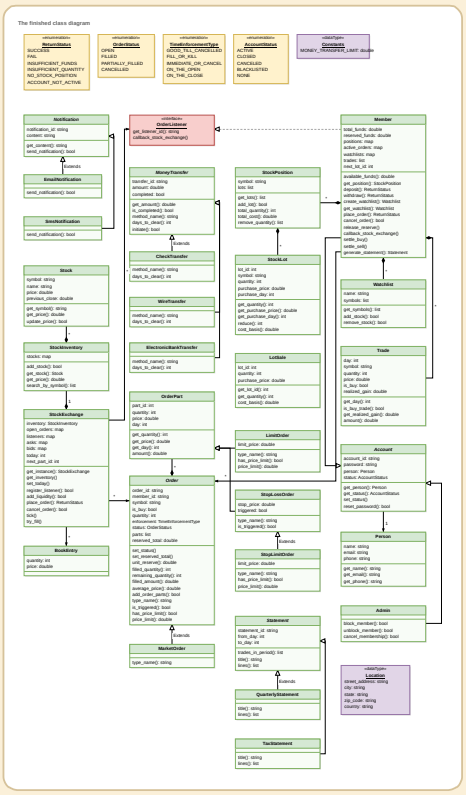

Figure — The finished class diagram of the online stock brokerage (course diagram)

The course builds this model in six stages: money transfers and notifications → the order hierarchy → stock, inventory and exchange → lots and positions → watchlists, trades and statements → members and admins. In the figure above, `Member` extends `Account` and implements `OrderListener` (dashed arrow): the exchange reports fills through that interface and never needs the `Member` type. The filled diamonds from `Member` mean each position, watchlist and trade is owned by exactly one member; the plain arrow to `Order` says the exchange shares those orders.

The course singles out stage 2 — the order hierarchy — as the part that earns the most credit in an interview:

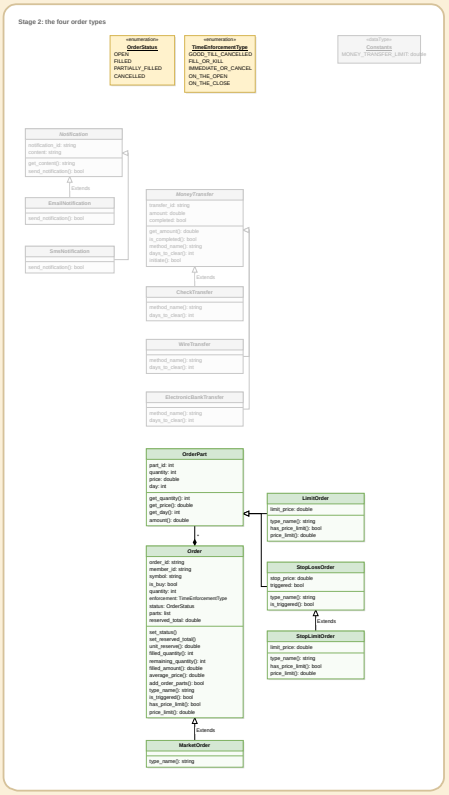

Figure — Stage 2: one abstract Order and four small subclasses that differ only in two answers (course diagram)

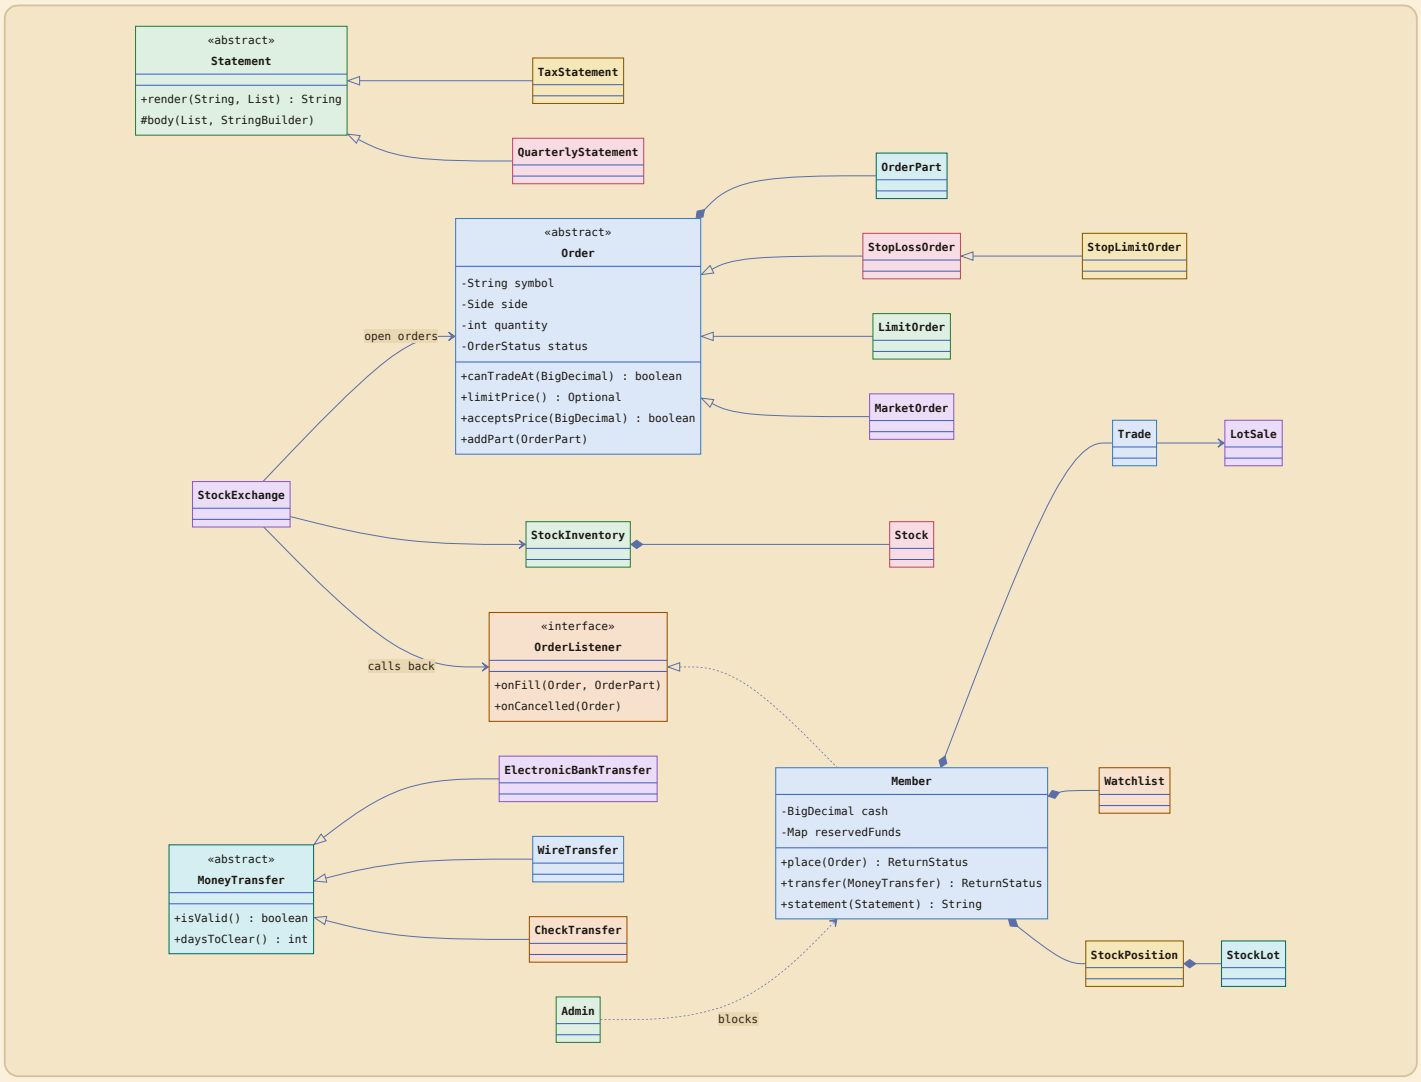
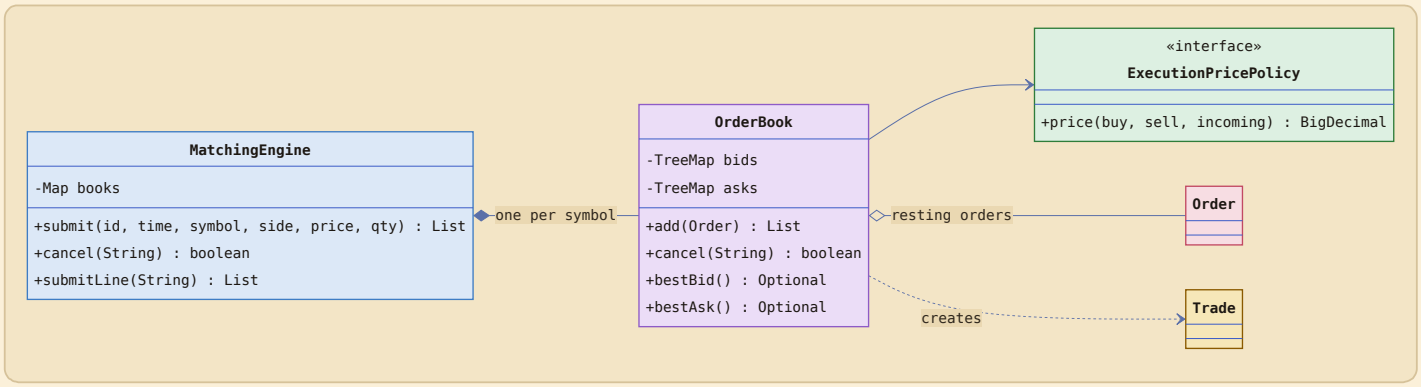
Our brokerage code:



And the matching engine (Part B):



Key flows

Placing a buy order. The course's activity diagram: pick a stock, pick the order type (market, limit, stop-loss, stop-limit), enter quantity, price limit and time enforcement; the system checks there is enough money, then deducts it (we *reserve* it) and sends the order to the exchange; when the exchange acknowledges, the member sees "order placed". The member can then update the order.

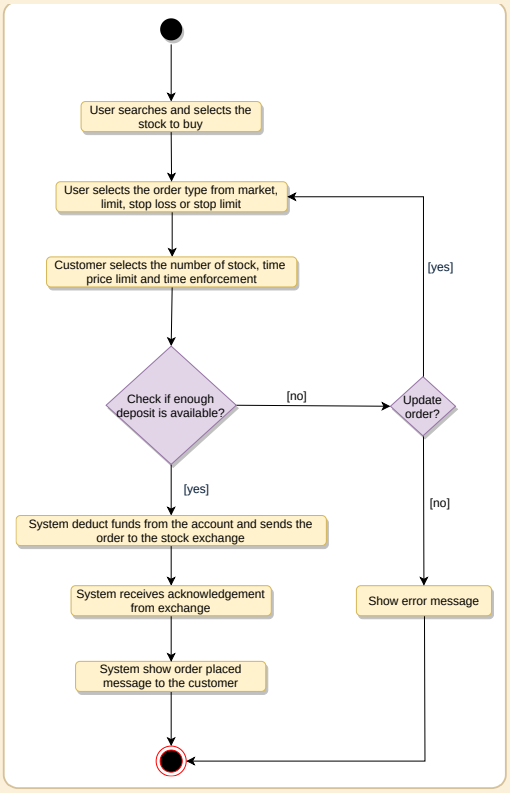


Figure — Activity diagram for placing a buy order (course diagram)

Placing a sell order is the mirror image, with one extra step: the member picks **which lots** to sell, and the check is "do I own enough shares?" rather than "do I have enough money?".

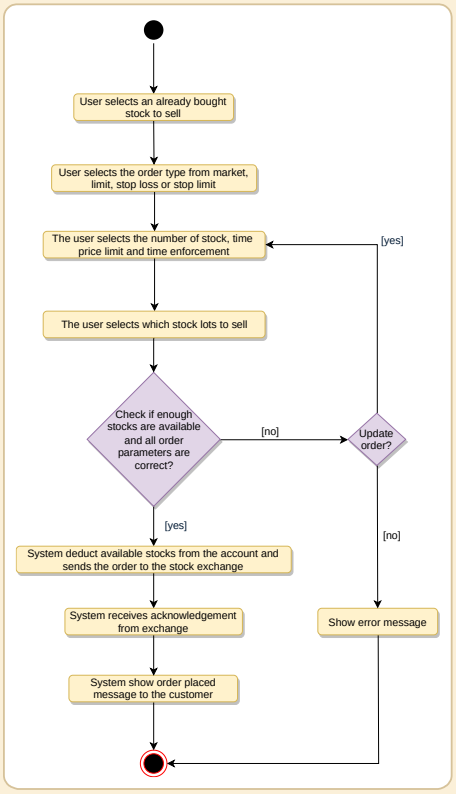

Figure — Activity diagram for placing a sell order, including choosing lots (course diagram)

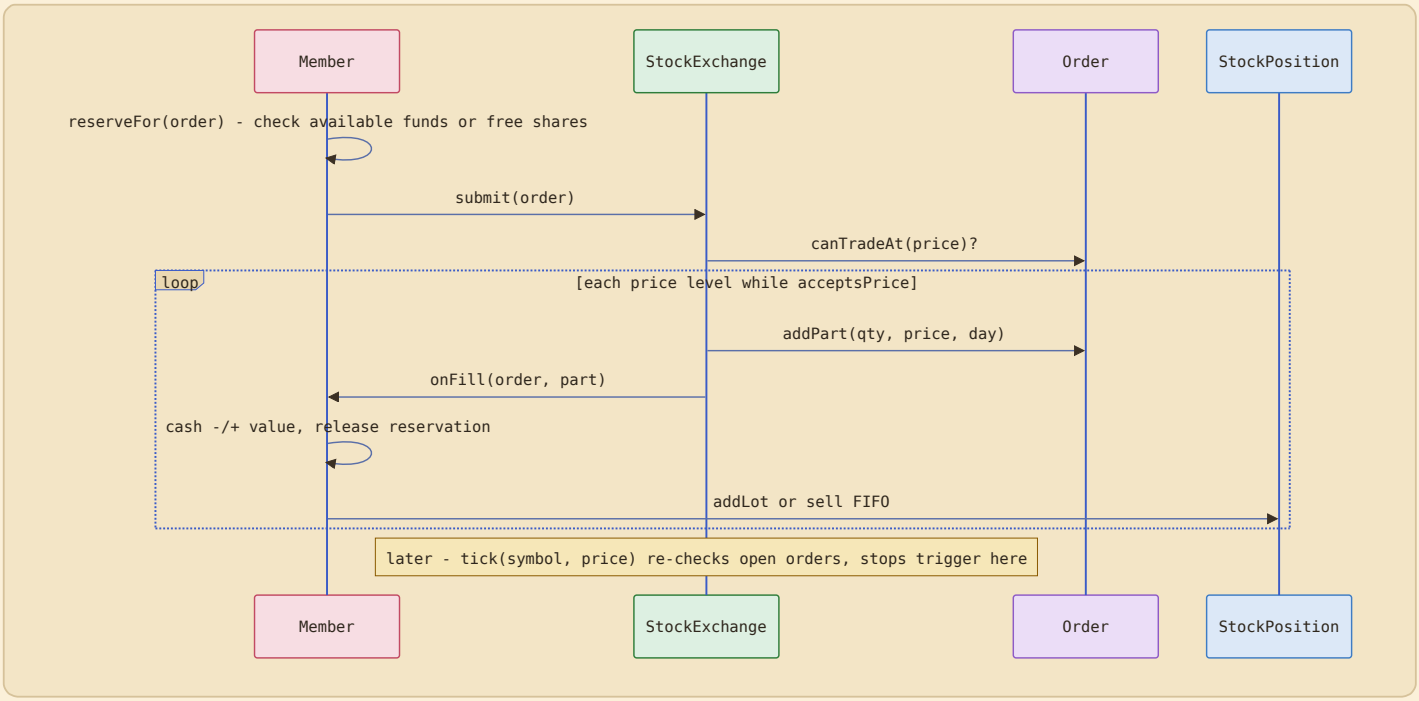
The four order types in one table. They share everything except two answers:

Type	Q1: may it trade at this market price?	Q2: worst acceptable price	Plain words
Market	Always	None	"Buy/sell now at whatever the market gives."
Limit	Always	The limit	"Buy at 9.50 or less / sell at 10.90 or more."
Stop-loss (stop)	Only after the price **reaches the stop**, then forever	None (becomes a market order)	"If it falls to 10.00, get me out."
Stop-limit	Only after the stop is reached	The limit	"If it rises to 305, buy — but pay no more than 306."

A SELL stop triggers when price ≤ stop; a BUY stop triggers when price ≥ stop. Once triggered it stays triggered (the code "latches" a boolean).

Fill → money and lots move (Observer callback).

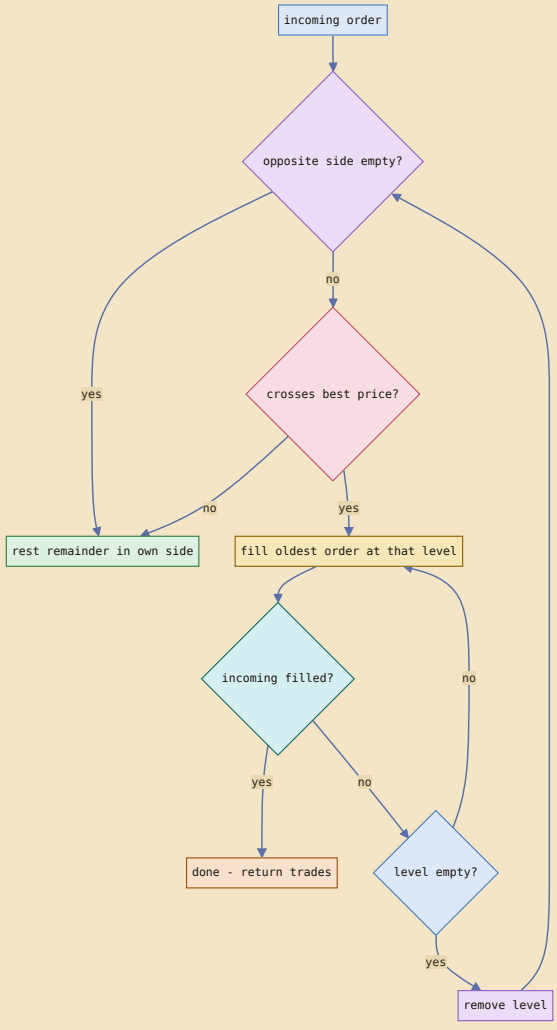


Matching engine: price-time priority. Each symbol has an `OrderBook` with two sides. Each side is a `TreeMap` (a map that keeps its keys sorted) from price to a FIFO queue (`ArrayDeque`, Java's fast double-ended queue). **Bids** (buy orders) are sorted highest-first, **asks** (sell orders) lowest-first. For an incoming order:

1. Look at the best price on the opposite side.
2. If it does not **cross** (buy price < best ask, or sell price > best bid), stop.
3. Otherwise fill against that level's queue, **oldest order first**, for `min(incoming remaining, resting remaining)`.
4. Remove fully filled resting orders; drop empty price levels; repeat from step 1.
5. If the incoming order still has quantity, add it to the back of its own price level's queue.

Walk-through of the sample input:

Order	Book before (asks / bids)	What happens
#1 sell 240.12 × 100	empty	rests on asks
#2 sell 237.45 × 90	asks 240.12×100	rests; best ask now 237.45
#3 buy 238.10 × 110	asks 237.45×90, 240.12×100	crosses 237.45 → trade `#3 237.45 90 #2`; 20 left; 240.12 > 238.10 so stop; rests 20 @ 238.10
#4 buy 237.80 × 10	best ask 240.12	no cross; rests
#5 buy 237.80 × 40	same	no cross; rests **behind #4** at 237.80
#6 sell 236.00 × 50	bids 238.10×20, 237.80×(10, 40)	fills #3 for 20, then #4 for 10, then #5 for 20 — all at 236.00 (the sell price)



Design decisions & patterns used

Decision	Why	Alternative rejected
One abstract `Order` + two abstract questions	The four types differ only in "may I trade?" and "worst price?". Each subclass is a few lines. The course stresses this is just a type hierarchy (plain polymorphism — calling the same method on different subclasses and each running its own version), not a named pattern: every subclass answers for itself whether the current price lets it trade, and no order ever turns into another kind — so it is not the State pattern either. (The only named patterns the course lists are Observer and Singleton — a class that allows exactly one instance; the Template Method and Strategy labels in this table are our additions.)	Four unrelated classes with copied fields; or one class with a `type` field and `switch`es.
`StopLimitOrder extends StopLossOrder`	A stop-limit is a stop that becomes a *limit* instead of a *market* order: it inherits the trigger, overrides only `limitPrice()`.	Duplicating the trigger logic.
`OrderPart` per fill	One order can fill at several prices/days; each fill needs its own price and quantity (and becomes its own lot).	Storing only an average price (loses tax information).
Observer: `OrderListener`	The exchange tells whoever placed the order; it does not import `Member`. Exchange and account code change independently.	The exchange updating member balances directly.
Reserved funds / reserved shares	Without it, a member with $1,000 could place ten $1,000 orders and all would pass the check. Money is reserved at placement and released as fills or cancellations arrive. Money and shares actually move only in `onFill`, which the **exchange** calls (the course's `callbackStockExchange`) — so the moment an order is *placed* and the moment it is *paid for* are different.	Checking the balance only at fill time (over-commitment).
Lots, FIFO by default	Tax depends on *which* shares you sold; each `LotSale` records it.	Merging all purchases into one average-cost position.
Template Method: `Statement`	Filtering by day range is shared; only the lines differ. `render` is `final`; subclasses fill in `body`.	Two statement classes each re-implementing the filter.
`MoneyTransfer` base class holds the limit rule	One rule, three delivery methods.	Copying the limit check into each subclass.
Singleton?	The course makes `StockExchange` a Singleton (one gateway to the real exchange). We pass one instance into `Member` instead (**dependency injection**: an object is handed the things it needs from outside rather than creating or looking them up itself) — same "only one" in practice, but testable with a fake exchange.	A global `getInstance()` that tests cannot replace.
Engine: `TreeMap<price, ArrayDeque>` per side	Best price in O(log n) (Big-O notation: how the work grows with n items — here, very slowly); FIFO inside a level gives time priority for free.	One `PriorityQueue` (a structure that always hands back the smallest item first) sorted by (price, time) — works, but cancel is O(n) (time grows in step with the number of orders) and levels are not visible.
Engine: lock per symbol	Orders for different symbols match in parallel; same-symbol orders are strictly serialised (handled one at a time, in order), so "time priority" is well defined.	One global lock (slower) or no lock (corrupt book).
Engine: `ExecutionPricePolicy` (Strategy)	The Navi statement prices trades at the **sell** order's price; real continuous-trading exchanges use the **resting** (already-in-book) order's price. Both are one-line policies.	Hard-coding one rule.

Java implementation

Part A — Brokerage (`lld.ch19.brokerage`)

Files: `Orders.java` (enums, money helper, `OrderPart`, the order hierarchy), `Market.java` (stock, inventory, listener, simulated exchange), `Holdings.java` (lots, positions, watchlists, trades, statements), `Accounts.java` (transfers, notifier, member, admin), `Main.java`.

The simulated exchange offers a fixed depth of shares per price level (70 shares at each level, 5 cents apart, 3 levels) so fills come back in parts, like a real book. Part B builds a real matching engine.

```java

Tax statement for Alice (days 1-365)
  AAPL L1: 70 sh bought @ 10.00 sold @ 11.00 gain $70.00
  AAPL L2: 30 sh bought @ 10.05 sold @ 10.95 gain $27.00
  AAPL L3: 20 sh bought @ 9.40 sold @ 10.95 gain $31.00
  AAPL L3: 30 sh bought @ 9.40 sold @ 9.95 gain $16.50
  realised gain: $144.50
```

Reading the output. Step 1: the 200,000 check fails the 100,000 transfer limit. Step 3 reproduces the course's example: a market order for 100 fills as 70 @ 10.00 and 30 @ 10.05 and creates **two lots**. Notice the course's warning in action: the order reserved $1,000.00 (100 × last price 10.00) but cost $1,001.50 — a market order can spend more than was reserved. Step 4: a limit buy waits until the price tick to 9.40. Step 5 sells 120 shares FIFO across three lots. Step 6: the stop does nothing at 10.50 and fires at 9.95. Step 7: the stop-limit triggers at 310 but its 306 limit blocks the fill until 305.50. Step 8: the reserve blocks a second $2,000 order; cancelling returns the money. Step 10: the tax statement lists the gain **per lot**.

Part B — Matching engine (`lld.ch19.stockexchange`)

Files: `OrderBook.java` (side, order, trade, price policy, book), `MatchingEngine.java` (routing, per-symbol locking, line parser), `MatchingEngineTests.java` (nine tests, standard library only), `Main.java` (runs the sample — or a file given as the first argument — then the tests).

```

Output:

```
== Trades (execution price = sell order's price) ==
#3 237.45 90 #2
#3 236.00 20 #6
#4 236.00 10 #6
#5 236.00 20 #6
book after: BAC bids=[237.80x20] asks=[240.12x100]

== Same input, real-exchange rule (price of the resting order) ==
#3 237.45 90 #2
#3 238.10 20 #6
#4 237.80 10 #6
#5 237.80 20 #6

== Tests ==
  PASS  sample input gives the expected four trades
  PASS  better price wins over earlier time
  PASS  same price: earlier order fills first
  PASS  no trade when prices do not cross
  PASS  partial fill leaves the remainder resting
  PASS  cancelled order is never matched
  PASS  symbols never match each other
  PASS  duplicate id and bad quantity rejected
  PASS  concurrent submits conserve quantity
  9/9 passed
```

Reading the output. The first block matches the expected output in the problem statement exactly. The second block runs the same orders with the real-exchange rule: #6 (the incoming sell) trades at each *resting* buyer's price (238.10, 237.80), which is how a continuous limit order book normally prices trades. The tests cover price priority, time priority, no-cross, partial fills, cancel, symbol isolation, validation, and a concurrency test (8 threads × 500 orders) that checks quantity is conserved and the book is never left crossed (best bid must stay below best ask).

Concurrency & edge cases

Risk	Where	Prevention
Over-spending with many open orders	Brokerage	`reserveFor` (synchronized on the member) subtracts all reservations from cash before accepting a new buy.
Selling the same shares twice	Brokerage	Open sell orders are tracked; free shares = position − remaining quantity of open sells *of that symbol*.
Deadlock between member and exchange	Brokerage	Lock order is fixed: the member never calls the exchange while holding its own lock (`place` reserves under the lock, then submits outside it). The exchange may call the member (exchange → member), never the reverse.
Market order costs more than reserved	Brokerage	Known gap (shown in step 3). Fix: reserve a buffer (e.g. +5%) or reject prices too far above the last price ("price band").
Time in force not enforced	Brokerage	The enum has five values (GTC, fill-or-kill, immediate-or-cancel, on-the-open, on-the-close) and no code reads them — every order behaves as good-till-cancelled within the demo. A GTC order should survive into the next trading day; FOK must be cancelled if it cannot be filled in full; IOC cancels whatever is left after one pass. All of this belongs in the exchange, next to the fill loop.
Two orders at the same price arrive "together"	Engine	Whichever thread gets the book's lock first is appended to the level's queue first, so lock-acquisition order = time priority. The `sequence` number is taken inside the same lock, so it records exactly that order (useful for logs and audits).
Cancel racing a match	Engine	Cancel takes the same per-symbol lock; an order is either matched or cancelled, never both.
Duplicate id / zero quantity / negative price	Engine	Validated before the id is registered (test `validation`).
Trade publishing slowing matching	Engine	Trades are collected under the lock and published after releasing it.
Floating-point prices	Both	`BigDecimal` everywhere; `TreeMap` keys compare with `compareTo`, so `237.8` and `237.80` land on the same level.

Real-world example

Indian brokers such as Zerodha offer the same stop order types to retail users (individual investors): **SL** (stop-loss *limit*) and **SL-M** (stop-loss *market*) — our `StopLimitOrder` and `StopLossOrder`. (Which segments allow SL-M has changed over time, so check the broker's current rules.) Their orders go to exchanges such as NSE (National Stock Exchange of India), whose continuous-trading order book matches on price-time priority, like our `OrderBook`. At the extreme end of performance, the LMAX exchange (described in Martin Fowler's article "The LMAX Architecture") runs its business logic, including matching, on a **single thread** that reads input events from a ring buffer (a fixed-size array used as a circular queue; LMAX's version is called the Disruptor) — the same idea as our "one lock per symbol, strictly serialised", taken to its logical end. On the tax side, US rules treat shares as sold first-in-first-out unless you identify specific lots, and FIFO is a common broker default — the reason `StockPosition.sell` takes an optional lot id.

Extensions & follow-up questions

- **"Add a trailing-stop order."** New subclass: it tracks the best price seen and moves its stop by a fixed distance. `canTradeAt` changes; nothing else does.
- **"Implement IOC and FOK."** IOC: after the fill loop, cancel any remainder. FOK: before filling, sum the quantity available at acceptable prices; if short, cancel without filling.
- **"Price alerts (the 'notify when a stock moves by X%' feature)."** A `PriceAlert` observer registered on `StockInventory`/`tick`; fires once when the move crosses the threshold.
- **"Modify an order."** On many exchanges, reducing quantity keeps time priority, but changing price (or increasing quantity) loses it — implement as cancel + new order.
- **"Make the engine faster."** Single writer thread per symbol fed by a queue (no locks on the hot path — the code that runs for every single order), pre-allocated objects, prices as `long` ticks instead of `BigDecimal`.

- **"Market orders in the engine."** Treat as a limit at +∞ (buy) or 0 (sell); never rest the remainder — cancel it.
- **"Settlement."** Trades settle later (for example T+1: one business day after the trade); add `unsettledCash` to the member so sale proceeds are not withdrawable immediately.

In the interview

30–45 minute plan (brokerage)

1. Clarify order types, lots, transfers, reports (3 min).
2. Actors and use cases (3 min).
3. Say the key sentence: *"The four order types differ in exactly two things: whether they may trade yet, and the worst price they accept."* Draw `Order` + four tiny subclasses (8 min).
4. Explain **lots** and why they exist: tax depends on which shares you sold (4 min).
5. Explain **reserved funds** (3 min).
6. Code `canTradeAt` / `limitPrice` for the four types and `StockPosition.sell` (10 min).
7. Observer callback, statements, extensions (5 min).

Machine-coding (Navi) plan, 90 minutes: parse lines → `Order`; `OrderBook` with two `TreeMap`s of `ArrayDeque`; `add()` matching loop; print trades; then tests for the sample, price priority, time priority, partial fill and cancel. Get the sample passing first, then refactor (restructure the code without changing what it does).

Follow-ups with answers

- *Why not four unrelated order classes?* They share member, symbol, quantity, side, status and fills; duplicating that invites bugs. The hierarchy isolates the two real differences.
- *Why is `StockInventory` separate from `StockExchange`?* One place to read prices, so no two components disagree about a price.
- *What data structure for the book, and the complexity?* `TreeMap` of price levels (a red-black tree — a self-balancing sorted tree): finding the best level with `firstEntry` and inserting a new level are both O(log L) for L price levels; FIFO queue per level: append O(1), match O(1) per fill. Cancel: O(log L) to find the level + O(k) in that level (use a linked structure with a handle for O(1)).
- *At what price does a trade execute?* In the Navi statement: the sell order's price. In real continuous trading: the resting order's price — the incoming order may get a better price than it asked for ("price improvement").

Self-check

1. **Q:** A SELL stop-loss at 10.00; the price goes 10.50 → 9.95 → 10.20. When does it trade? **A:** At the 9.95 tick. It stays triggered even when the price goes back up.
2. **Q:** What does a stop-limit add to a stop-loss? **A:** A worst acceptable price after triggering — it becomes a limit order, not a market order.
3. **Q:** Why does one market order create two lots in step 3? **A:** It filled at two prices, and a lot is defined by its purchase price.
4. **Q:** Two bids at 50.00 arrive, b1 then b2; a sell for 7 at 49 arrives. Trades? **A:** b1 gets 5, b2 gets 2 — time priority within the level (test `timePriority`).
5. **Q:** What does "the book is crossed" mean and why is it a bug? **A:** Best bid ≥ best ask; those two orders should already have traded.
6. **Q:** Which pattern produces the tax and quarterly statements? **A:** Template Method — shared filtering in `Statement.render`, specific lines in `body`.

TL;DR

- **Brokerage:** one abstract `Order`, four tiny subclasses answering *may I trade now?* and *worst price?*; fills are `OrderPart`s; purchases are **lots**; money is **reserved** at placement; the exchange calls back via **Observer**; statements are a **Template Method**.
- **Matching engine:** per symbol, two `TreeMap<price, FIFO queue>`; match best price first, oldest first; rest the remainder; one lock per symbol; trade price is a pluggable policy (Navi: sell price; real exchanges: resting price).

Design an Online Auction System

Problem & clarifying questions

An online auction (think eBay auctions) lets a **seller** list an item with a starting price and an end time. **Bidders** offer higher and higher amounts. When time runs out, the highest bidder wins — if the seller's hidden minimum (the **reserve price**) was reached.

Question	Assumed answer
What does a listing contain?	Item name, description, category, starting price, minimum bid increment, optional reserve price, duration.
What is a valid bid?	The first bid must be at least the starting price; later bids must beat the current highest by at least the increment.
Can the seller bid? Can the leader outbid themselves?	No and no.
When does an auction end?	At its end time. A late bid is refused even if the closing job has not run yet.
Who is told what?	The outbid bidder immediately; the winner and seller at close; the seller if unsold.
Proxy (automatic) bidding, anti-sniping (stopping last-second bids from stealing a win), payments?	Extensions — mention them.

Requirements

Functional

1. Users register and log in. (We model registration; login itself is the usual authentication (checking who a user is) service and is not coded here.)
2. Users create listings with item name, description, starting price and duration.
3. Users browse and search listings by name, category and price range.
4. Users place bids on **active** listings.
5. The system keeps the **current highest bid** up to date and notifies bidders.
6. When the duration ends, the auction closes and the **highest bidder wins** (if the reserve is met).

Non-functional

7. Many users bid on the same listing at the same moment; the system must stay consistent (one true highest bid).
8. Extensible: new bid rules, notification channels or search criteria without rewriting the core.

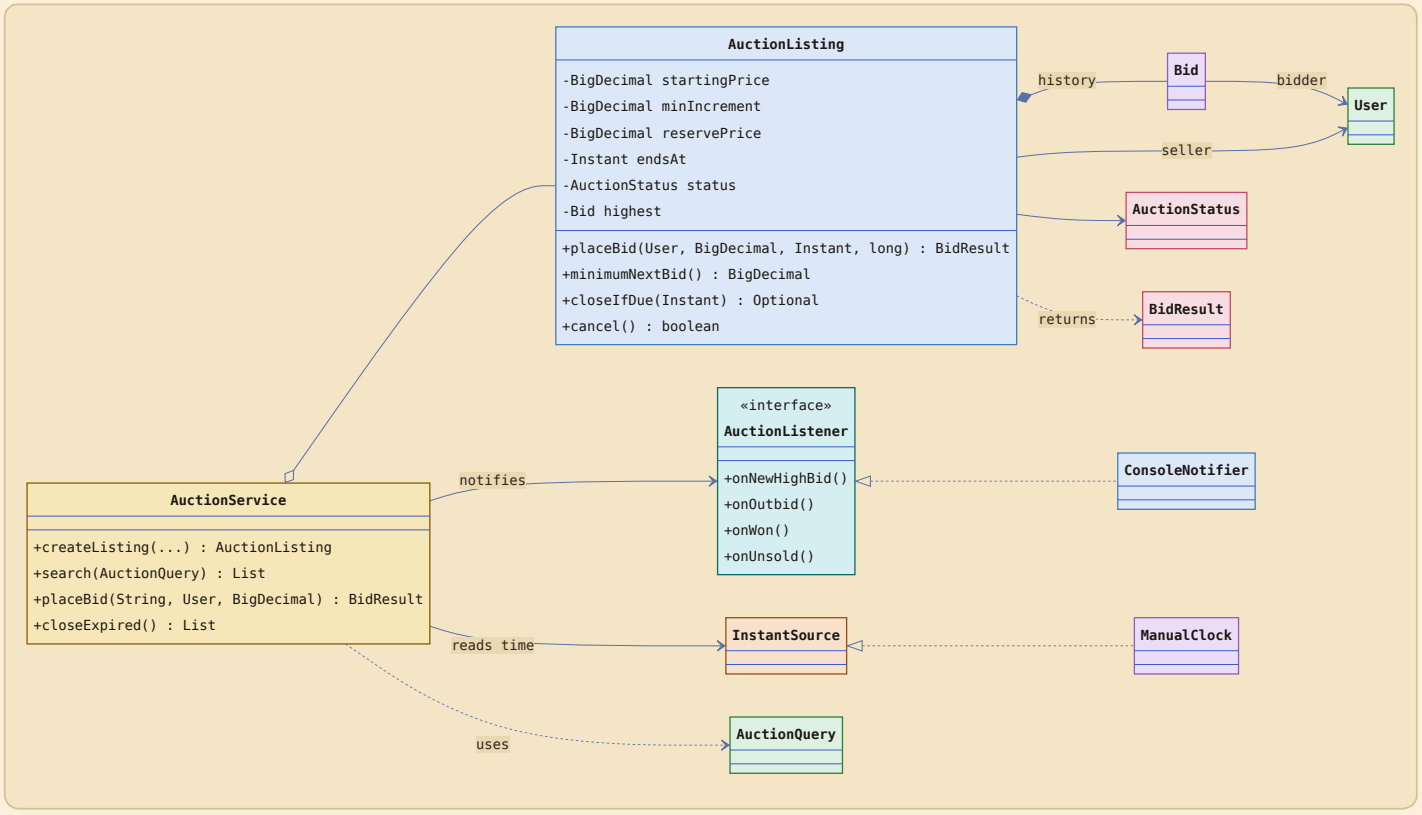
Use cases

Actor	Use cases
Seller	Create listing, cancel listing (only while nobody has bid), see result
Bidder	Search, view listing and bid history, place bid, be told when outbid or when won
System (scheduler)	Activate scheduled auctions, close expired ones, declare winner, send notifications

Core entities

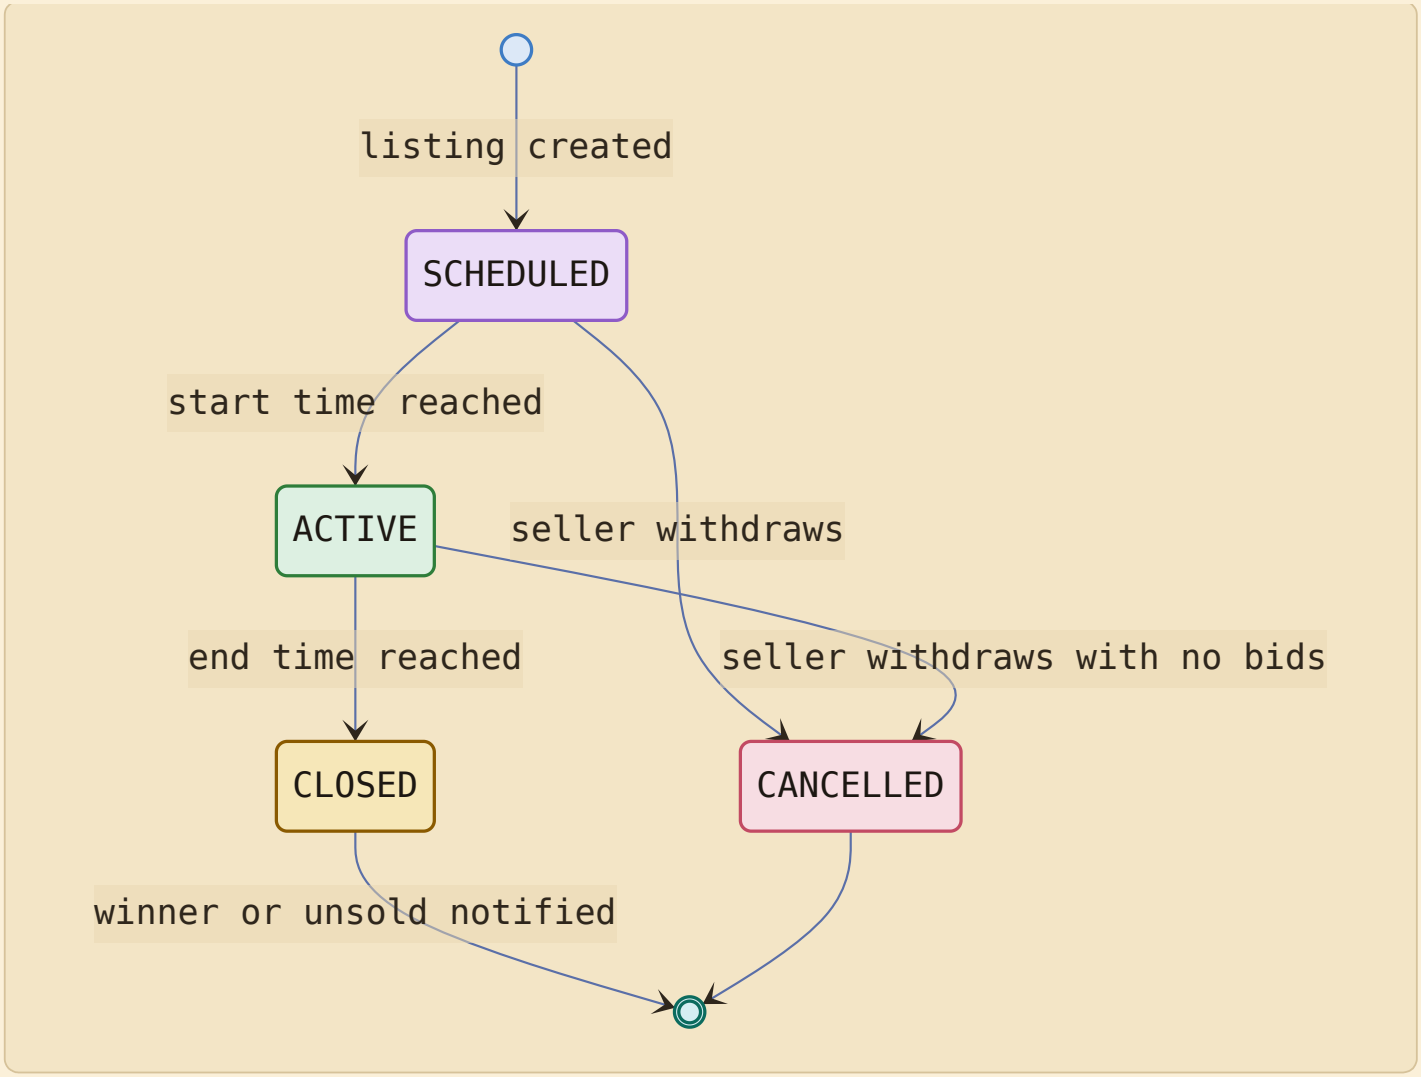
Class	Responsibility
`User`	id, name, email (a `record`).
`Bid`	bidder, amount (`BigDecimal`), time, sequence number. Immutable.
`AuctionStatus`	`SCHEDULED → ACTIVE → CLOSED`, or `CANCELLED`.
`AuctionListing`	Item details, seller, prices, times, bid history, highest bid. **Owns the bidding rules** and guards them with its own lock.
`BidOutcome` / `BidResult`	Why a bid was accepted or refused, the next minimum bid, the accepted bid, who was outbid.
`CloseResult`	Listing, winning bid (if any), whether the reserve was met.
`AuctionQuery`	Fluent (calls chained one after another) search criteria; each criterion is a `Predicate` (a function that answers true/false; Specification pattern).
`AuctionListener` / `ConsoleNotifier`	Observer: new high bid, outbid, won, unsold.
`AuctionService`	Facade: register, create, search, bid, close expired. Calls listeners **outside** listing locks.
`ManualClock`	An `InstantSource` (Java's "what time is it now?" interface) we can move forward in demos and tests.

Class diagram



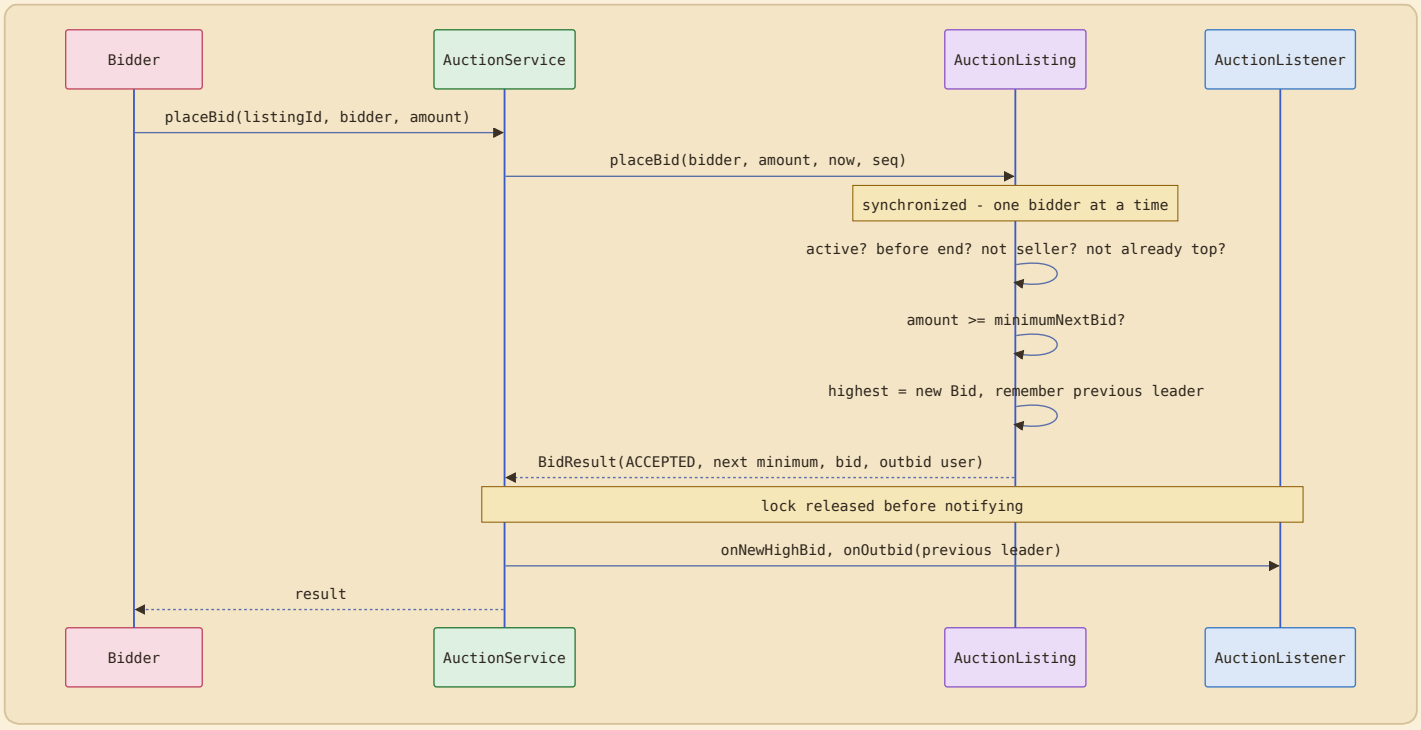
Key flows

Auction lifecycle



`SCHEDULED → ACTIVE` happens **lazily** (only when someone next touches the listing, not at the exact moment): every method first calls `refresh(now)`. No background thread is needed just to flip the state.

Placing a bid (the critical section) — a **critical section** is a piece of code that only one thread may run at a time because it reads and changes shared data.



Closing. A scheduler (in production a `ScheduledExecutorService` — Java's built-in timer that runs a task repeatedly — running every few seconds) calls `closeExpired()`. Each listing's `closeIfDue(now)` atomically moves `ACTIVE → CLOSED` and returns the winner only if the reserve is met. Notifications go out after all locks are released.

Design decisions & patterns used

Decision	Why	Alternative rejected
Bid rules live inside `AuctionListing` and run under its lock (a *monitor*: an object whose methods are all `synchronized`)	"Read highest, compare, replace" must be one atomic step. The lock is per listing, so bids on different auctions never wait for each other.	A global lock in the service (all auctions serialised); or `AtomicReference<Bid>` (a reference that can be swapped atomically) + CAS loop (retry compare-and-set until it succeeds) — valid, but the rule set (seller, leader, end time, increment) is easier to get right under one lock.
Refusals are returned (`BidOutcome`), not thrown	A too-low bid is normal business, not an exceptional error (an **exception** is Java's way of aborting a method to signal that something went wrong). The caller also gets the next minimum to show in the UI.	Throwing an exception for every low bid.
Observer for notifications, called outside the lock	Slow email or push calls must not block other bidders. `BidResult` carries a **snapshot** (a copy frozen at one moment) of the accepted bid taken inside the lock, so listeners never read a newer, unrelated value.	Notifying inside `synchronized` (slow, and risks deadlock if a listener calls back).
Minimum increment	Stops 1-cent "wars" and makes the next minimum predictable.	Any higher amount accepted.
Reserve price	Lets a seller refuse to sell too cheaply; checked only at close.	Rejecting bids below the reserve (would reveal it).
`InstantSource` injected	Time-dependent code becomes testable: the demo moves a `ManualClock` forward instead of sleeping.	Calling `Instant.now()` everywhere.
Specification pattern for search	Each criterion is a `Predicate<AuctionListing>`; they combine with `and`. New criteria = one method.	One `search(name, category, min, max, ...)` method whose parameter list keeps growing.
The service is not a Singleton	awesome-low-level-design's version uses a Singleton `AuctionSystem`; we pass one instance around instead so tests can create fresh ones.	Global state shared by all tests.

Java implementation

Files: `Auction.java` (user, bid, status, outcome records, listing, manual clock), `AuctionService.java` (listener, notifier, query, service), `Main.java`.

    }
}
```

Output:

```
== 1. Create listings ==
  A1 'Vintage Guitar' now 100.00, A2 'Pocket Watch' now 50.00

== 2. Search (name 'watch', price 0-100) ==
  [A2 'Pocket Watch' now 50.00]

== 3. Bidding rules ==
  Ana bids 90 (below start) -> TOO_LOW (next minimum 100.00)
  Ana bids 100 -> ACCEPTED (next minimum 110.00)
  Ana bids 120 (already top) -> ALREADY_HIGHEST (next minimum 110.00)
  Bob bids 105 (increment is 10) -> TOO_LOW (next minimum 110.00)
    [notify Ana] you were outbid on Vintage Guitar, now 110.00
  Bob bids 110 -> ACCEPTED (next minimum 120.00)
  Sam bids on own item -> SELLER_CANNOT_BID (next minimum 120.00)
    [notify Bob] you were outbid on Vintage Guitar, now 150.00
  Ana bids 150 -> ACCEPTED (next minimum 160.00)
  Bob bids 60 on the watch -> ACCEPTED (next minimum 65.00)

== 4. One hour later: the watch closes, reserve (500) not met ==
    [notify Sam] Pocket Watch unsold (reserve not met)
  closed A2 reserveMet=false

== 5. 50 threads bid on the guitar at once ==
  accepted=28 (varies run to run), highest=650.00 by bidder49, history strictly increasing by >= increment: true

== 6. Time is up: the guitar closes and the winner is told ==
  late bid -> AUCTION_ENDED (next minimum 660.00)
    [notify bidder49] you WON Vintage Guitar for 650.00
    [notify Sam] Vintage Guitar sold to bidder49
  status CLOSED, final price 650.00
```

Reading the output. Step 3 exercises every rule: below start, leader re-bidding, below increment, seller bidding. The outbid notices print *before* the bidder's own result line because the service notifies before returning. Step 4 closes the watch as unsold because 60 < the 500 reserve. Step 5 fires 50 concurrent bids: how many are accepted depends on thread timing (a bid that arrives after a higher one is refused as too low), but the final highest is always the maximum, 650.00, and the history is always strictly increasing by at least the

increment — the invariant (a rule that must always be true) the lock protects. Step 6 refuses a bid after the end time even though the closing job has not yet run.

Concurrency & edge cases

Case	Handling
Two bidders submit the same amount at the same time	The first one through the lock wins; the second is now below `minimumNextBid()` and gets `TOO_LOW`.
Bid arrives exactly at the end time	`!now.isBefore(endsAt)` → `AUCTION_ENDED`. The end instant is exclusive.
Close job runs late	Bids after `endsAt` are refused anyway, so a late job cannot change the winner.
Close and bid race	Both are `synchronized` on the listing; the bid either lands before the close (and counts) or after (and is refused).
Notification listener is slow or throws	Called outside the lock; in production, publish to a queue so failures are retried without affecting bidding.
Seller cancels after bids	Refused (`cancel()` returns false) — protects bidders.
Money precision	Amounts normalised to scale 2 with `BigDecimal`; compared with `compareTo`.
Very hot auction (thousands of bids per second)	One lock per listing is fine for one JVM (Java Virtual Machine — one running Java process); distributed: a single-writer per auction (partition bids by auction id — split them into separate streams so all bids for one auction go to the same place, e.g. a Kafka partition, Kafka being a widely used event-streaming system), or a conditional update `UPDATE ... SET high = ? WHERE id = ? AND high < ?`.

Real-world example

eBay auctions use **proxy bidding**: you enter the most you are willing to pay, and eBay bids on your behalf only as much as needed to stay ahead, by the current increment. eBay also supports hidden **reserve prices**, and its auctions end at a fixed time, which is why "sniping" (bidding in the last seconds) is common there. Some other auction sites use a **soft close** — a late bid extends the end time — precisely to defeat sniping.

Extensions & follow-up questions

- **"Add proxy (automatic) bidding."** Each bidder may register a `maxAmount`. After any accepted bid, inside the same lock, let the strongest proxy respond with `min(its max, competitor + increment)`. Ties go to the earlier proxy (use `Bid.seq`).
- **"Stop sniping."** Soft close: in `placeBid`, if an accepted bid arrives within the last N minutes, set `endsAt = endsAt + N` (make `endsAt` non-final, change under the same lock).
- **"Buy It Now."** A fixed price that closes the auction immediately if paid before the first bid.
- **"Dutch / sealed-bid / Vickrey auctions."** (Dutch: the price starts high and drops until someone accepts; sealed-bid: bidders cannot see each other's bids.) Extract an `AuctionRules` strategy: `validate(bid)`, `winner(bids)`, `price(bids)`. Vickrey (second-price sealed bid): highest bidder wins but pays the second-highest bid.
- **"Payment after winning."** Winner has 48 hours to pay (new state `AWAITING_PAYMENT`); if not, offer to the second-highest bidder.
- **"Scale the close job."** Keep a priority queue (or a sorted index) by `endsAt` so the scheduler only touches auctions that are due.

In the interview

30–45 minute plan

1. Clarify the bid rules (start price, increment, reserve, seller/leader restrictions) — 4 min.
2. Entities and the lifecycle state machine — 8 min.
3. Code `placeBid` under the listing lock and **say why the lock is per listing** — 12 min.
4. Closing + notifications outside the lock — 6 min.

5. Concurrency discussion and extensions (proxy bidding, soft close) — 10 min.

> **30-second answer:** "Each listing owns its bid rules and its highest bid, and `placeBid` is synchronized on the listing, so compare-and-replace is atomic and different auctions never contend. Refusals return a reason and the next minimum. The service notifies outbid users and, at close, the winner and seller, always after releasing the lock. Time comes from an injected clock, so closing and late bids are testable."

Follow-ups with answers

- *Why not `AtomicReference` + CAS?* Possible for the amount alone, but the rule also checks seller, leader and time. A tiny critical section under one lock is simpler and still fast because the lock is per listing.
- *How do you close auctions on time across servers?* A scheduler that owns a time-ordered index of end times; the close itself is idempotent (`closeIfDue` returns empty the second time), so running it twice is harmless.
- *How do you show a live price to thousands of viewers?* Push `onNewHighBid` events to a pub/sub channel (publish/subscribe: senders post messages to a topic and every subscriber receives them) and WebSockets (a connection the browser keeps open so the server can push data at any time); viewers read a cache (a fast saved copy of data — see System Design Fundamentals), not the lock-holding object.

Self-check

1. **Q:** What two conditions make a bid `TOO_LOW`? **A:** Below the starting price when there is no bid, or below highest + increment otherwise.
2. **Q:** Why are listeners called after `placeBid` returns from the listing? **A:** To keep the lock short and avoid deadlock or slowdown from notification code.
3. **Q:** A bid arrives at 12:00:00.000 and the auction ends at 12:00:00.000. Accepted? **A:** No — the end time is exclusive.
4. **Q:** Where does the reserve price matter? **A:** Only at close: if the highest bid is below it, the item is unsold.
5. **Q:** What is the Specification pattern here? **A:** Search criteria as composable `Predicate`s combined with `and`.

TL;DR

- One **lock per listing**; all bid rules inside it; refusals are values, not exceptions.
- Lifecycle `SCHEDULED → ACTIVE → CLOSED | CANCELLED`; activation is lazy, closing is idempotent.
- **Observer** notifications after the lock; **injected clock** for testable time; **Specification** for search.

Design a Music Streaming Service (Spotify)

Problem & clarifying questions

A music streaming service lets users search a huge catalog, build playlists, and play songs with the usual controls (play, pause, skip, previous, seek, shuffle, repeat). Free and paid plans behave differently. The service suggests new music.

Question	Assumed answer
What can users search?	Songs, albums, artists.
Playlists?	Users create, reorder and edit their own playlists.
Playback controls?	Play, pause, resume, skip, previous, seek; shuffle on/off; repeat off / all / one.
Plans?	FREE (ads, limited skips per hour, no downloads) and PREMIUM (no ads, unlimited skips, offline).
Recommendations?	A stub (a simple placeholder) based on listening history; real ones are an ML (machine learning — software that learns patterns from data) system.
Actual audio streaming, DRM (copy protection), CDNs (content delivery networks — servers near users that hold copies of files)?	Out of scope for LLD (low-level design: classes and their code) — the player models *what* plays, not the bytes.

Requirements

Functional

1. Browse and search songs, albums and artists.
2. Create and manage playlists.
3. User accounts and authentication (we model users and plans; login itself is the usual auth service).
4. Playback controls: play, pause, skip, seek (plus previous, shuffle, repeat).
5. Recommendations based on preferences and listening history.
6. Subscriptions: FREE vs PREMIUM with different limits.

Non-functional

7. Many users stream at once; the shared catalog is read-mostly and thread-safe (works correctly when many threads use it at once).
8. Scales to a large catalog and user base (indexes, not scans, in production).
9. Extensible: social sharing, offline mode, new play orders, new recommenders.

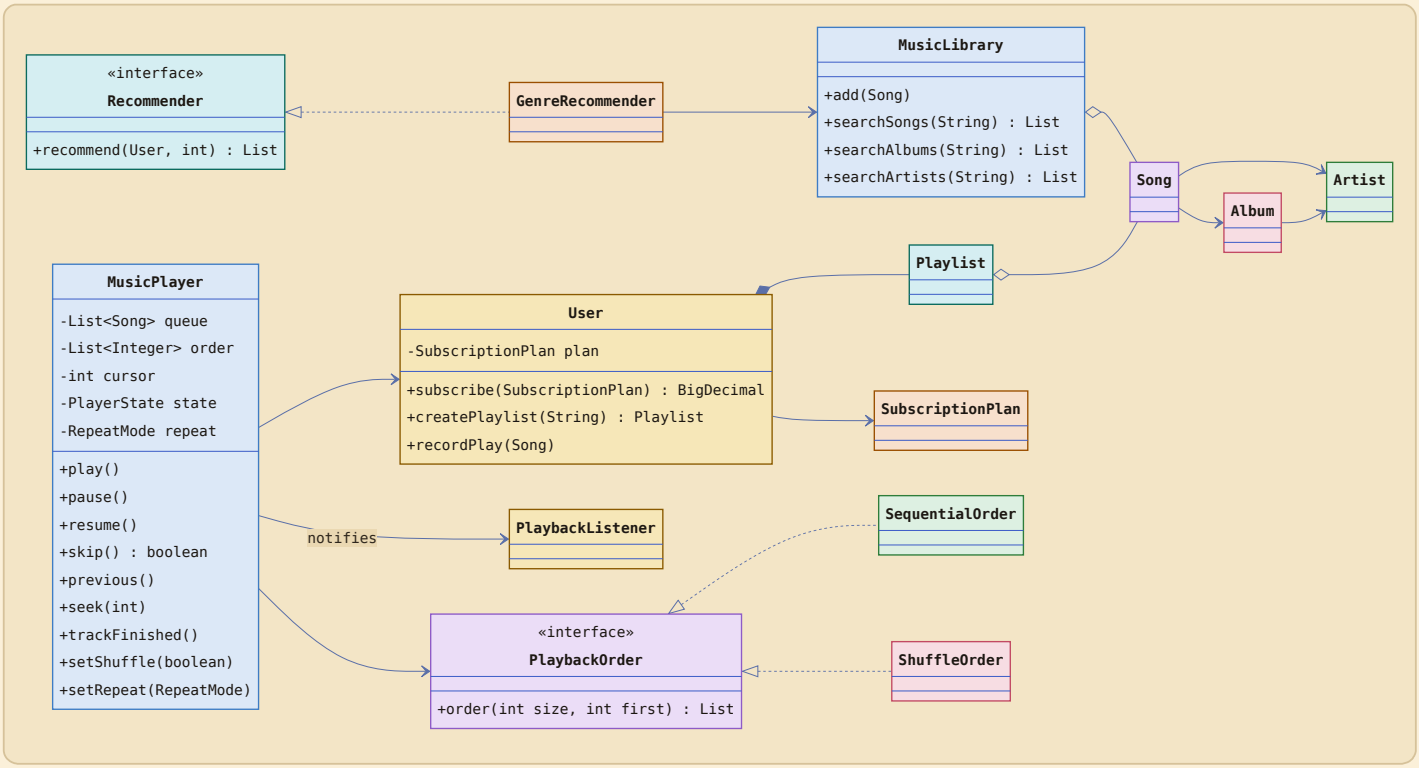
Use cases

Actor	Use cases
Listener	Search, play/pause/skip/seek, shuffle/repeat, create and edit playlists, upgrade plan
Artist / label (content admin)	Add songs and albums to the catalog
System	Record plays (history, royalties — money owed to artists per play), insert ads for free users, recommend songs

Core entities

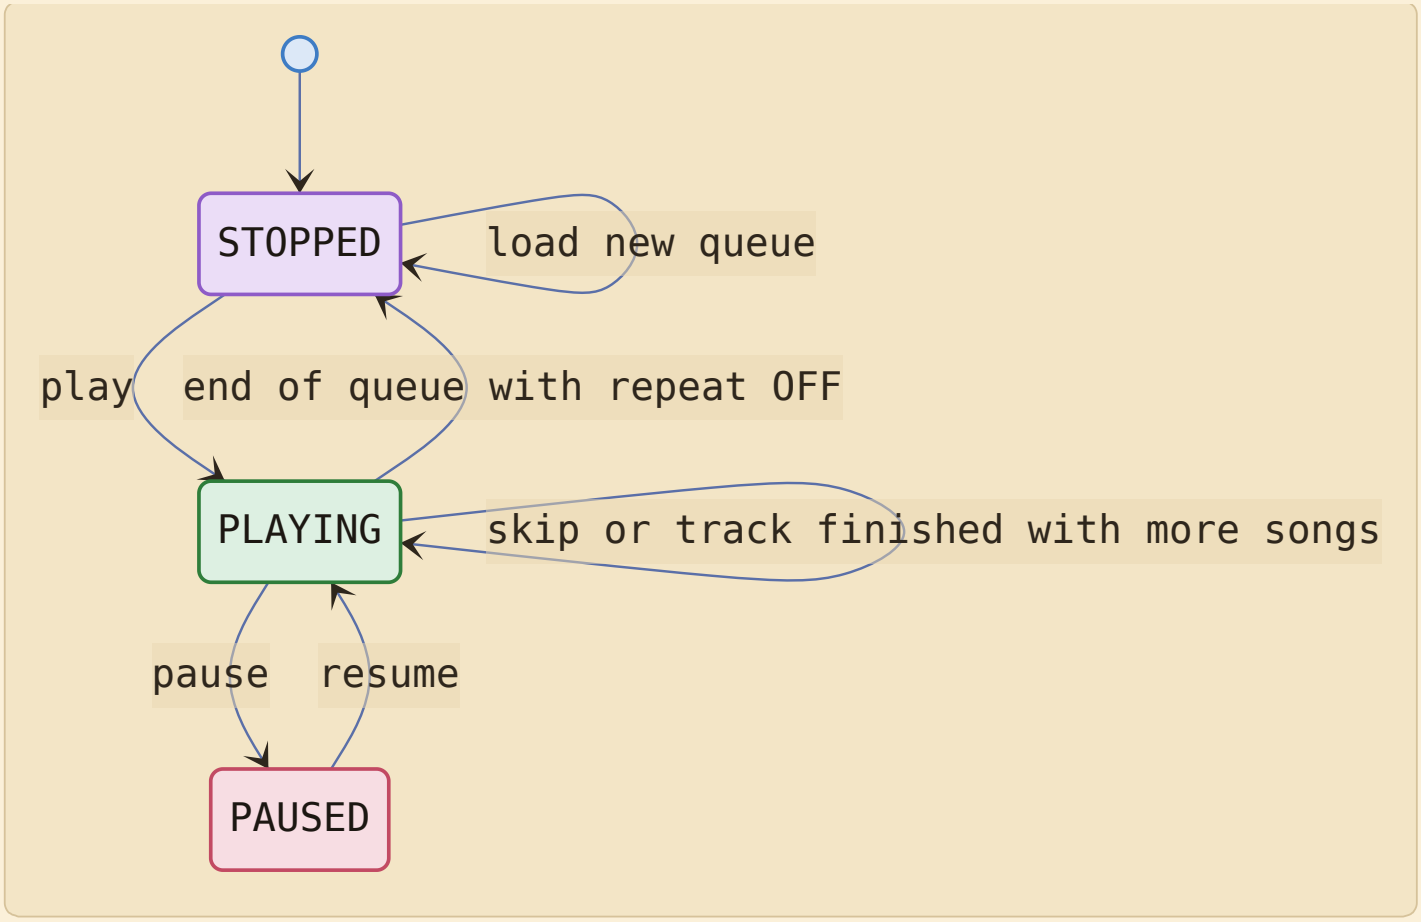
Class	Responsibility
`Artist`, `Album`, `Song`, `Genre`	Immutable catalog records.
`MusicLibrary`	Thread-safe catalog with search by song title, album title, artist name.
`SubscriptionPlan`	Enum that **carries the rules**: monthly price, skips per hour, ads, offline downloads.
`User`	Name, current plan, playlists, listening history.
`Playlist`	Ordered, user-owned song list: add, remove, move.
`PlaybackOrder` → `SequentialOrder`, `ShuffleOrder`	Strategy: produces the play order (a permutation — every song exactly once, in some order) starting from the current song.
`RepeatMode`, `PlayerState`	`OFF / ALL / ONE`; `STOPPED / PLAYING / PAUSED`.
`MusicPlayer`	One user's session: queue, play order, cursor (where we are in the play order), position, state, skip window, ad counter.
`PlaybackListener`	Observer on "song started" (history, royalties, recommendations).
`Recommender` → `GenreRecommender`	Strategy: suggest unplayed songs from the user's favourite genres.

Class diagram

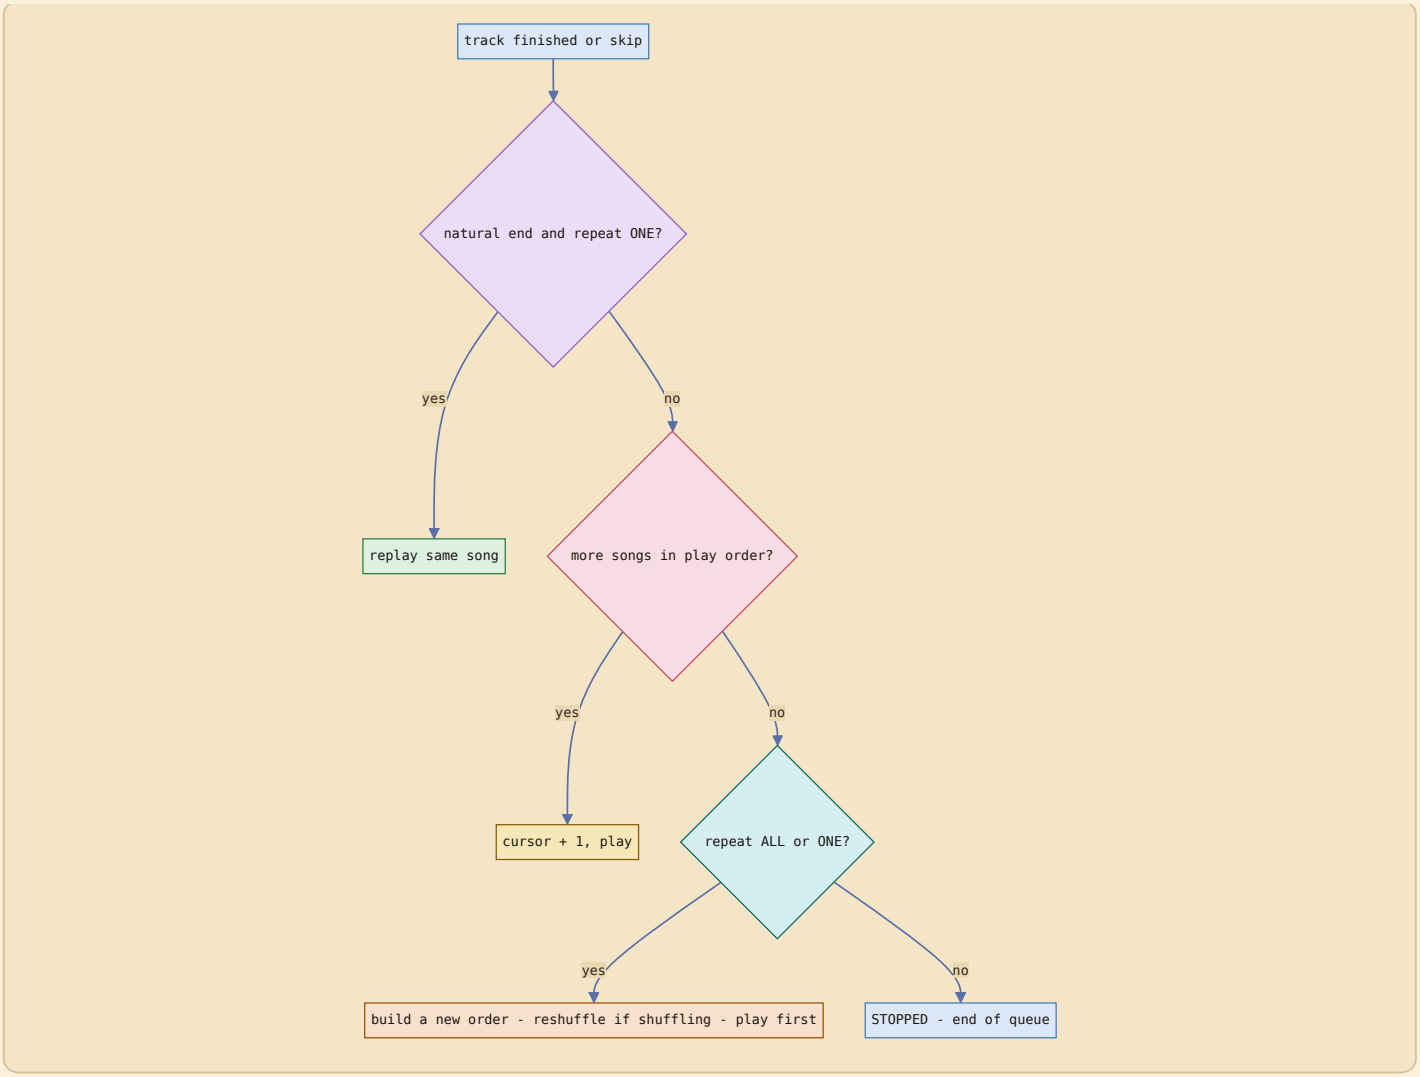


Key flows

Player states



What happens when a song ends or the user presses Next



Skip first checks the plan's rolling (always the last 60 minutes, not a fixed clock hour) one-hour limit (a deque — a queue you can add to or remove from at both ends — of skip timestamps; drop those older than an hour, compare the size with `skipsPerHour`). Pressing Next on repeat-ONE moves on — like real players, repeat-one only affects songs that end naturally.

Shuffle keeps the current song. Turning shuffle on builds a new permutation whose first element is the song playing now, and shuffles the rest with `Collections.shuffle(list, random)`. Turning it off rebuilds the sequential order starting from the current song. The queue itself never changes — only the **order** of indexes into it — so switching back and forth loses nothing.

Design decisions & patterns used

Decision	Why	Alternative rejected
Strategy for play order (`PlaybackOrder`)	Shuffle, sequential, "smart shuffle" (spread the same artist apart) are interchangeable algorithms. The player just asks for an order.	`if (shuffle) ... else ...` inside `skip`, `previous`, `wrap`.
Order as a list of indexes into an unchanged queue	Turning shuffle off/on never loses the original order; `upNext` is a simple walk.	Physically shuffling the queue list (original order lost).
Seeded `Random`	Repeatable demos and tests. Production uses an unseeded (or per-session) seed.	`Math.random()` (not testable).
Plan rules inside `SubscriptionPlan` enum	`user.plan().skipsPerHour` and `.ads` — no `if (plan == FREE)` scattered around; a new plan is one enum constant (or a class if rules get complex).	Boolean flags on `User`.
Observer for plays (`PlaybackListener`)	History, royalty counting and recommendation features all react to "song started" without the player knowing them.	Player calling each subsystem directly.
Strategy for recommendations	`Recommender` can be genre-based today, collaborative filtering ("people who liked what you like also liked…") tomorrow.	Hard-coding one algorithm in `User`.
One `MusicPlayer` per user session, all methods `synchronized`	Commands can arrive from two devices (phone + desktop "connect"). The shared `MusicLibrary` uses concurrent maps.	A single shared player object.
State as an enum, not the State pattern	Three states with trivial behaviour; the GoF ("Gang of Four", the authors of the classic 1994 *Design Patterns* book) State pattern (one class per state) pays off only when each state has substantial, different behaviour.	Three state classes for four one-line methods.
Singletons?	awesome-low-level-design makes `MusicLibrary`, `UserManager` and `MusicRecommender` Singletons. We inject single instances instead — same sharing, easier tests.	Global `getInstance()`.

Java implementation

Files: `Catalog.java` (genre, artist, album, song, library, plans, user, playlist), `Player.java` (play-order strategies, repeat/state enums, listener, player, recommender), `Main.java`.

```

Output:

```
== 1. Search ==
  songs 'blue'    -> [All Blues - Miles Davis, Blue in Green - Miles Davis]
  albums 'opera'  -> [A Night at the Opera]
  artists 'da'    -> [Miles Davis]

== 2. Playlist ==
  Road trip: [Bohemian Rhapsody - Queen, Blue in Green - Miles Davis, So What - Miles Davis, Hello - Adele, Love of
My Life - Queen]

== 3. Play in order, pause, seek, repeat-one ==
  [player] > Bohemian Rhapsody - Queen
  state PAUSED at 120s
  [player] > Bohemian Rhapsody - Queen
  [player] > Blue in Green - Miles Davis

== 4. Shuffle keeps the current song, reorders the rest ==
  now Blue in Green - Miles Davis, up next [Love of My Life - Queen, So What - Miles Davis, Bohemian Rhapsody -
Queen, Hello - Adele]

== 5. FREE plan: skip limit (6/hour) and ads, repeat-all wraps the shuffled queue ==
  [player] (30-second ad for FREE plan)
  [player] > Love of My Life - Queen
  [player] > So What - Miles Davis
  [player] > Bohemian Rhapsody - Queen
  [player] (30-second ad for FREE plan)
  [player] > Hello - Adele
  [player] > Blue in Green - Miles Davis
  [player] > Hello - Adele
  [player] skip limit reached on FREE plan

== 6. Upgrade to PREMIUM: no ads, unlimited skips ==
  charged $10.99
  [player] > Death on Two Legs - Queen
  [player] > Freddie Freeloader - Miles Davis
  [player] > Death on Two Legs - Queen
  [player] > Freddie Freeloader - Miles Davis
  [player] end of queue

== 7. Recommendations from listening history ==
  plays so far: 13
  recommended: [You're My Best Friend - Queen, All Blues - Miles Davis, When We Were Young - Adele]
```

Reading the output. Step 3: repeat-ONE replays "Bohemian Rhapsody" when it ends naturally. Step 4: shuffle keeps "Blue in Green" playing and reorders the rest. Step 5: on the FREE plan an ad plays after every three songs, repeat-ALL wraps and reshuffles the queue, and the seventh skip within the hour is refused. Step 6: PREMIUM has no ads; with repeat-ALL the second skip wraps to the start; with repeat OFF the queue ends. Step 7: the recommender suggests songs the user has **not** heard, from the genres they played most.

Concurrency & edge cases

Case	Handling
Two devices send "next" at the same instant	Player methods are `synchronized`; the two skips apply one after the other.
Catalog updated while users search	`ConcurrentHashMap` (a thread-safe hash map) for songs/albums/artists; search iterates a weakly consistent view (it may or may not show changes made during the loop, but never breaks).
Playlist edited while it is playing	`load` copies the playlist (`List.copyOf`), so the running queue is a snapshot; a real app would sync edits into "up next".
Seek past the end or before 0	Clamped to `[0, duration]`.
Previous after 3 seconds	Restarts the current song (common player behaviour); within 3 seconds goes back one song.
Skip when stopped	Refused (and does not count against the limit).
Plan changes mid-session	`plan` is `volatile` (a Java keyword that makes every thread see the latest written value); the next skip or ad check sees it.
Empty queue	`play()` throws `IllegalStateException`.

Real-world example

Spotify's free tier has historically limited skips (for example, six per hour on mobile) and inserts ads between songs, while Premium removes both and allows downloads — the rules our `SubscriptionPlan` enum carries. Spotify engineers also wrote (2014) that users complained a truly random shuffle "felt" non-random when the same artist came up twice in a row, so they changed the algorithm to spread songs by the same artist across the list. That is exactly the kind of change the `PlaybackOrder` strategy absorbs: a new `ArtistSpreadShuffle` class, no player changes. Personalised playlists such as Discover Weekly are the industrial version of our `Recommender` stub.

Extensions & follow-up questions

- **"Add 'play next' and 'add to queue'."** Keep a separate *user queue* that is consumed before the context (playlist/album) order.
- **"Offline mode."** `SubscriptionPlan.offlineDownloads`; a `DownloadManager` stores encrypted files; the player chooses a local or remote `AudioSource` (Strategy).
- **"Social sharing / collaborative playlists."** Playlist gets a collaborator set and an edit log; listeners (Observer) push changes to other users.
- **"Crossfade, gapless playback."** Player behaviour around `trackFinished`; a `TransitionStrategy`.
- **"Royalties."** A `PlaybackListener` that records a play once the user has listened for a threshold time.
- **"Search at scale."** Inverted index (a map from each word to the items containing it) / search service with prefix (typeahead — suggestions as you type) and fuzzy matching (tolerating typos); the `MusicLibrary` interface stays.
- **"Smart shuffle."** New `PlaybackOrder` that spaces out songs by the same artist.

In the interview

30–45 minute plan

1. Clarify controls, plans and scope (skip audio bytes) — 4 min.
2. Catalog entities + library search — 6 min.
3. User, playlist, subscription plan — 5 min.
4. **Player**: queue + order + cursor; state machine; shuffle/repeat as strategy/enum — 15 min.
5. Observer for history; recommender strategy; concurrency; extensions — 10 min.

> **30-second answer:** "Immutable catalog records in a thread-safe library. Each user has a player session holding the queue, a play order produced by a `PlaybackOrder` strategy, a cursor and a repeat mode. Shuffle rebuilds the order around the current song. Plan limits live in the plan enum. A playback listener records history, which feeds a pluggable recommender."

Follow-ups with answers

- *How does shuffle avoid repeating a song before all have played?* It is a permutation (each index once), not "pick a random next song".
- *Where do ads fit?* The player asks the plan whether ads apply and inserts one every N songs; in production an ad service picks which ad.
- *How would you implement "previous" in shuffle mode?* Walk back along the same order list (the cursor), so previous is the song you actually heard before.

Self-check

1. **Q:** Why store the play order as indexes rather than reordering the queue? **A:** So switching shuffle off restores the original order and nothing is lost.
2. **Q:** What does repeat-ONE do when the user presses Next? **A:** Moves to the next song; it only replays on natural end.
3. **Q:** Which pattern lets you add a smarter shuffle without touching the player? **A:** Strategy (`PlaybackOrder`).
4. **Q:** How is "6 skips per hour" enforced? **A:** A deque of skip times; drop entries older than one hour; refuse if the size has reached the limit.
5. **Q:** Why is the player's state an enum rather than the State pattern? **A:** The states have almost no distinct behaviour; the pattern would add classes without benefit.

TL;DR

> - Catalog = immutable records in a concurrent library.
> - Player = **queue + order (Strategy) + cursor + repeat mode + state**; shuffle keeps the current song.
> - Plan rules in the **enum**; plays published via **Observer**; recommendations via **Strategy**.

Design an Online Food Delivery Service (Swiggy) + FoodKart

This problem also comes in two shapes:

- **Part A — Swiggy-style delivery platform** (the awesome-low-level-design problem): restaurants with menus, a cart, orders with tracking states, payments, and **assigning a delivery rider** by a pluggable strategy. We add **kitchen capacity** (a restaurant can only cook so many items at once), the key twist in a commonly reported Flipkart food-ordering variant (it is not part of the FoodKart statement below).
- **Part B — FoodKart** (Flipkart machine-coding round, from kumaransg/LLD): a smaller, command-driven problem — users and pincodes (Indian postal codes), one-dish restaurants, ratings, `show_restaurant` sorted by rating or price, `place_order` — plus a **restaurant selection strategy** (highest rating / lowest price) filtered by remaining capacity.

Problem & clarifying questions

Question	Assumed answer
Can one cart mix restaurants?	No — one restaurant per cart (as in Swiggy/Zomato).
Who confirms an order?	The restaurant; it may refuse if its kitchen is full.
When is capacity freed?	When the food is ready (handed over), not when it is delivered.
How is a rider chosen?	By a strategy: nearest to the restaurant, or fair share (fewest deliveries today).
What if no rider is free?	The order waits in a queue; the next freed rider takes the oldest waiting order.
Can a customer cancel?	Only before the kitchen starts cooking (PENDING or CONFIRMED).
Payment types?	UPI, card, cash on delivery (COD: nothing to refund).
Live GPS, ETA (estimated time of arrival) prediction, batching two orders per rider, surge fees (higher fees at busy times)?	Extensions.

Requirements

Functional (Part A)

1. Customers browse restaurants, view menus and place orders.
2. Restaurants manage menus, prices and availability.
3. Delivery agents accept and fulfil orders.
4. Customers track order status and get notified of changes.
5. Several payment methods.
6. Real-time notifications to customers, restaurants and delivery agents.

Functional (Part B — FoodKart)

7. `register_user(name, gender, phone, pincode)` — phone is unique.
8. `login_user(phone)` — sets the context; logging in someone else logs out the previous user.
9. `register_restaurant(name, pincodes "A/B", dish, price, quantity)` — in the context of the logged-in user (the owner). A restaurant serves **one** dish to **many** pincodes.
10. `update_quantity(name, add)`, `update_location(name, pincodes)` — owner only.
11. `rate_restaurant(name, 1..5, optional comment)`; rating = average of all ratings.
12. `show_restaurant(rating|price)` — **serviceable** restaurants (deliver to my pincode **and** quantity > 0), sorted **descending** by the chosen field.
13. `place_order(name, qty)`; bonus: order history.
14. *(Variant)* place an order without naming a restaurant: pick one by a **selection strategy**, among those that deliver here **and** have capacity for the whole quantity.

Non-functional

- Handle many concurrent orders without double-booking kitchen capacity or riders.
- Keep data consistent (no negative stock, no rider on two orders).
- In-memory only for the machine-coding round; demoable driver (a small `Main` program that feeds in commands and prints results); graceful failures.

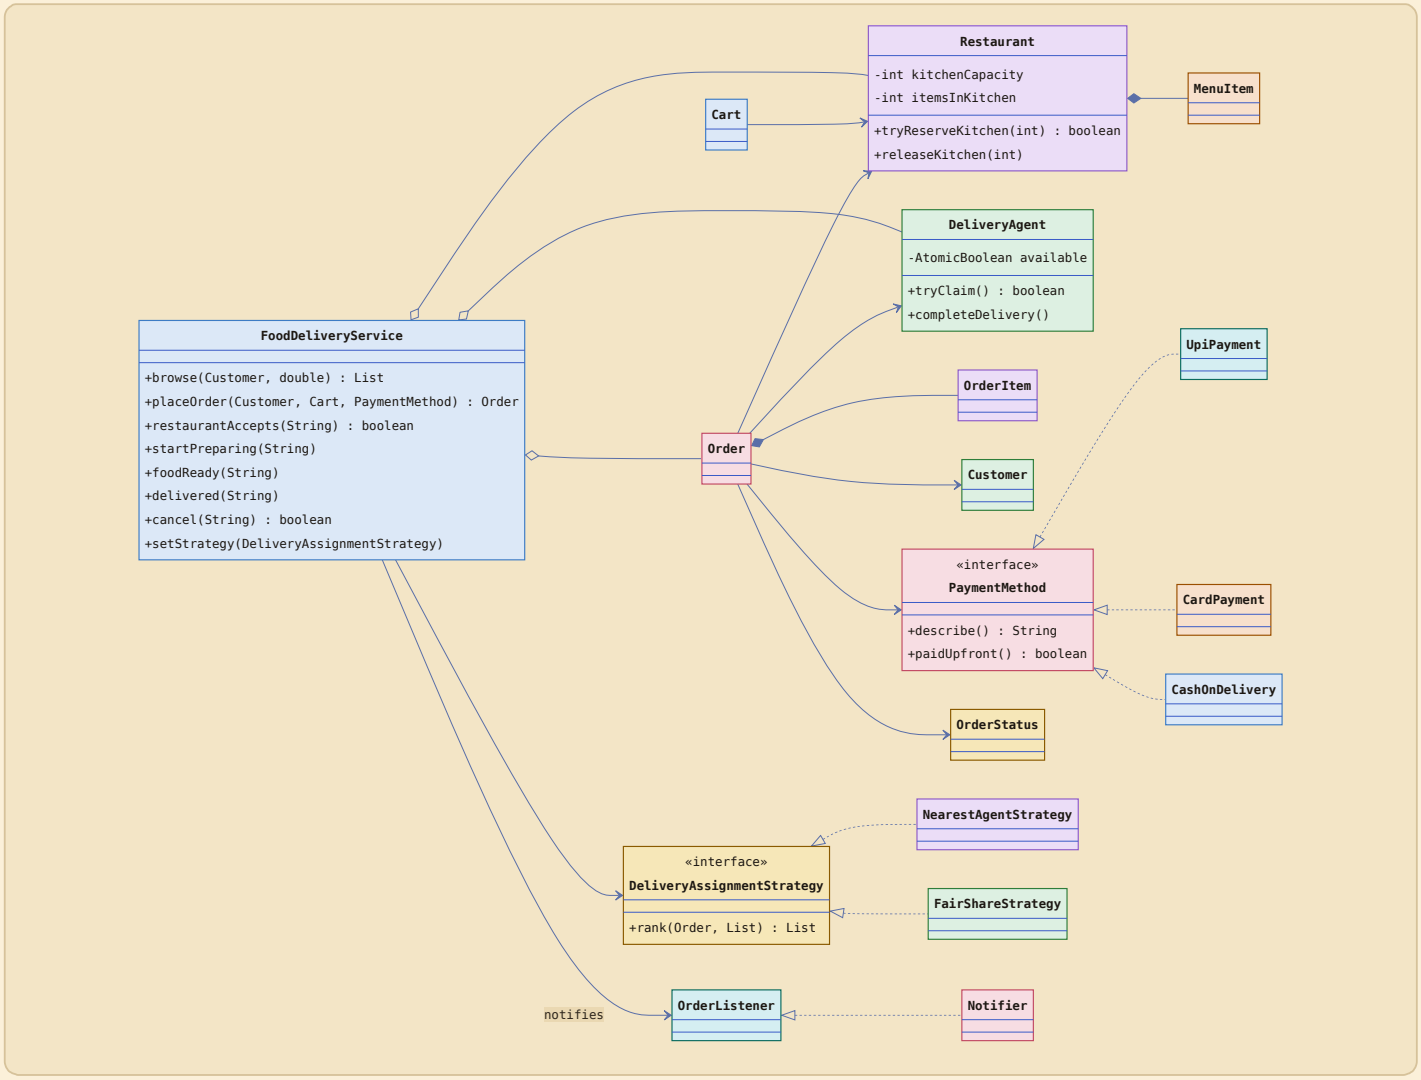
Use cases

Actor	Use cases
Customer	Browse nearby restaurants, build cart, pay, place order, track, cancel, rate
Restaurant	Manage menu/prices/availability, accept or refuse order, mark preparing, mark ready
Delivery agent	Get assigned, pick up, deliver
System	Compute fees, assign riders, queue orders when no rider is free, notify everyone

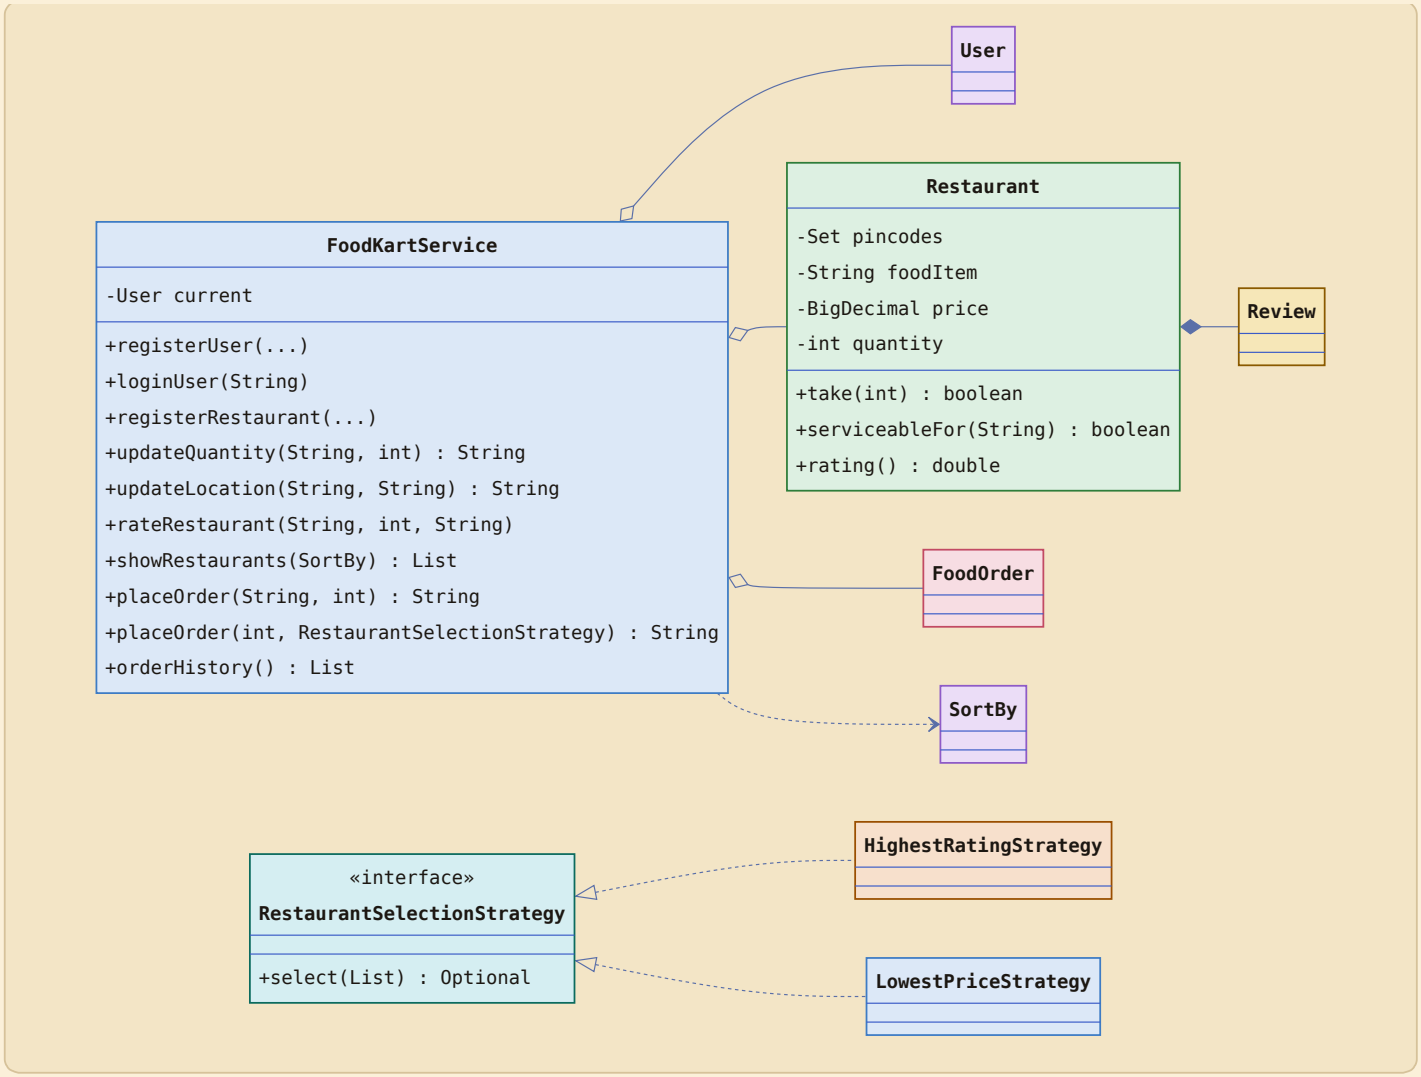
Core entities

Class	Responsibility
`Location`	A point; `distanceTo`.
`Customer`	id, name, phone, address.
`MenuItem`	Name, price, available flag (both changeable by the restaurant).
`Restaurant`	Menu, open flag, **kitchen capacity** (max items cooking at once), `tryReserveKitchen` / `releaseKitchen`.
`Cart`	One restaurant + item quantities; refuses items from a second restaurant.
`OrderItem`	Snapshot of item name, **unit price at order time**, quantity.
`OrderStatus`	State machine: PENDING → CONFIRMED → PREPARING → READY_FOR_PICKUP → OUT_FOR_DELIVERY → DELIVERED, or CANCELLED.
`Order`	Customer, restaurant, items, delivery fee, payment, status history, assigned agent.
`PaymentMethod` → `UpiPayment`, `CardPayment`, `CashOnDelivery`	Sealed interface; COD is not paid upfront.
`DeliveryAgent`	Location, `AtomicBoolean available` (a true/false flag that can be checked-and-changed atomically), deliveries today; `tryClaim()` is a CAS.
`DeliveryAssignmentStrategy` → `NearestAgentStrategy`, `FairShareStrategy`	Ranks free riders for an order.
`OrderListener` / `Notifier`	Observer for status changes.
`FoodDeliveryService`	Facade: browse, place, accept, prepare, ready, deliver, cancel; the waiting-for-rider queue.
(FoodKart) `User`, `Restaurant`, `Review`, `FoodOrder`, `SortBy`, `RestaurantSelectionStrategy`, `FoodKartService`	The machine-coding model; `Restaurant.take(q)` is the atomic capacity check.

Class diagram

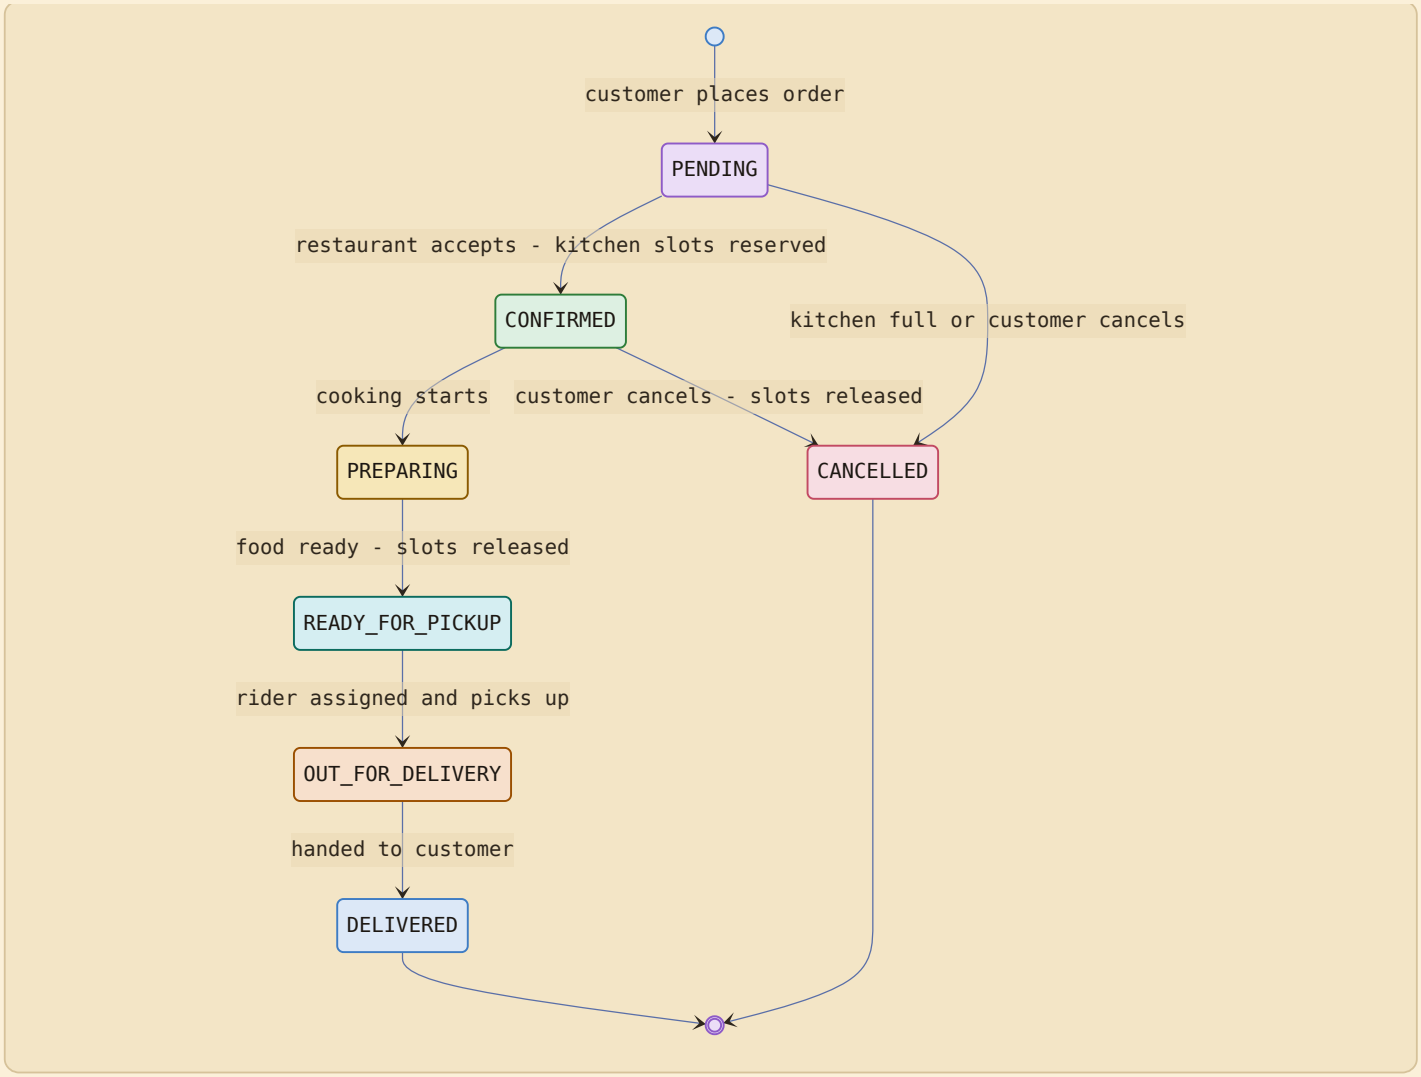


FoodKart (Part B):



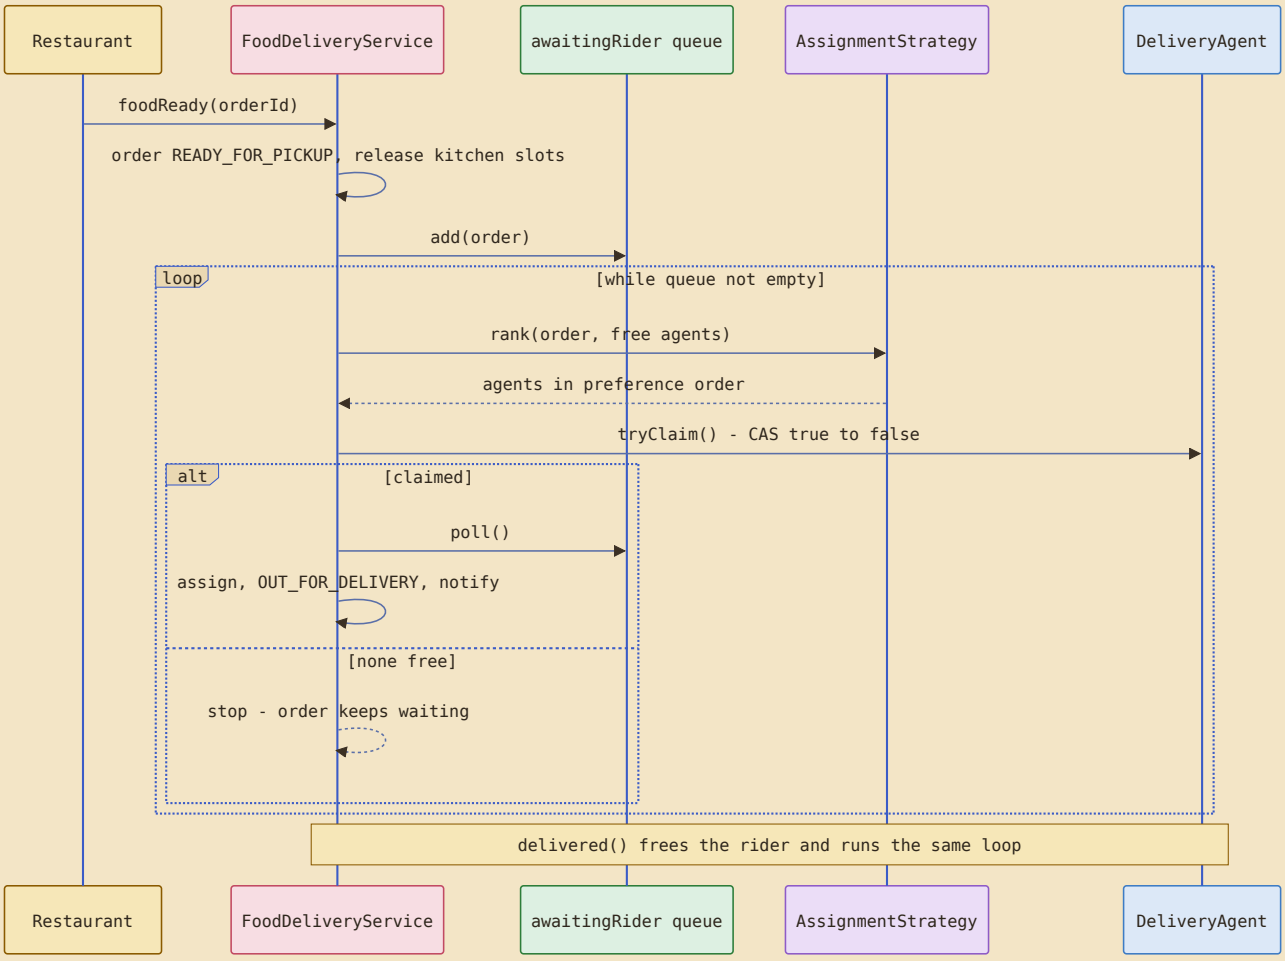
Key flows

Order tracking state machine



(Real apps often split `READY_FOR_PICKUP → OUT_FOR_DELIVERY` into "rider assigned", "arrived at restaurant", "picked up". Adding them is a local enum change.)

Food ready → rider assignment



FoodKart `place_order(name, qty)`: user logged in? → restaurant exists? → delivers to the user's pincode? → `take(qty)` atomically (quantity ≥ qty, then subtract) → record in history → "Order Placed Successfully." Otherwise "Cannot place order".

FoodKart selection variant: filter restaurants that deliver to the user's pincode and have `quantity ≥ qty` → ask the strategy to pick one → `take(qty)`; if another user took the capacity in between, drop that restaurant and ask again (bounded retries).

Design decisions & patterns used

Decision	Why	Alternative rejected
Strategy for rider assignment (`rank` returns a preference list)	Nearest vs fair-share vs rating-based are swappable at run time (`setStrategy`, step 7). Returning a *ranked list* lets the service try the next rider if the first was just taken (the free list is read before claiming, so it can be stale).	Returning one rider (fails if that rider was claimed a moment earlier).
CAS on the rider (`AtomicBoolean.compareAndSet(true,false)`)	The rider guards itself: whoever calls `tryClaim()` — this dispatcher, a second dispatcher instance, or a future "rider accepts" button — exactly one `compareAndSet` succeeds. In this code `dispatchWaiting` is also `synchronized` (to drain the queue in FIFO order), so the CAS is the safety net that keeps working even when claims come from outside that lock.	Check `isAvailable()` then set (a race as soon as two callers exist).
Kitchen capacity reserved on accept, released on ready	Models the rule "a restaurant cannot accept more items while its kitchen is full" from the capacity-based food-ordering variant.	Unlimited orders per restaurant.
Waiting queue for riders	No free rider is normal at peak; FIFO keeps it fair; freeing a rider re-runs dispatch.	Failing the order.
State machine in `OrderStatus`	Tracking states and legal moves in one place; cancel after cooking starts is impossible.	Scattered `if`s.
`OrderItem` copies the price	A later menu price change (step 3) cannot alter a placed order.	Referencing `MenuItem` directly.
Sealed `PaymentMethod` + records	A closed, known set; COD overrides `paidUpfront()` so refunds skip it.	`String paymentType`.
Observer (`OrderListener`)	Customer app, restaurant tablet and rider app all react to the same events.	The service printing/sending messages itself.
One restaurant per cart	Matches real apps; a single kitchen, single pickup, single fee.	Multi-restaurant carts (needs split orders).
FoodKart: `SortBy` enum holds its comparator (an object that decides which of two items comes first)	`show_restaurant(rating	price)`becomes`sorted(sortBy.comparator)`; both descending as the statement says; name as tie-breaker for stable output.
FoodKart: owner recorded at registration	The statement says restaurants are registered "in the context of the	Anyone updating any restaurant.

Decision	Why	Alternative rejected
	logged-in user"; only that owner may update quantity or location.	
FoodKart: `Restaurant.take(q)` synchronized	"Check quantity then subtract" is atomic — two users cannot both take the last plates.	Separate `getQuantity()` + `setQuantity()`.

Java implementation

Part A — Food delivery platform (`lld.ch19.fooddelivery`)

Files: `Model.java` (location, customer, menu item, restaurant, cart, order item, status machine, payments, order, delivery agent), `FoodDeliveryService.java` (strategies, listener, notifier, service), `Main.java`.

Output:

```
== 1. Browse within 10 km ==
  Dosa Corner
  Pizza Hub

== 2. One restaurant per cart ==
  cart has items from Dosa Corner - clear it first

== 3. Place, accept, prepare, ready, deliver ==
    [OD101 PENDING] -> restaurant Dosa Corner: new order
  subtotal 280.00 + delivery 31.20 = 311.20
  price changed after ordering; order still 311.20
    [OD101 CONFIRMED] -> customer Asha
    [OD101 PREPARING] -> customer Asha
    [OD101 READY_FOR_PICKUP] -> customer Asha
    [OD101 OUT_FOR_DELIVERY] -> customer Asha: Ravi is on the way
  rider: Ravi (nearest to Dosa Corner)

== 4. Kitchen capacity: 4 items max at Dosa Corner ==
    [OD102 PENDING] -> restaurant Dosa Corner: new order
    [OD102 CONFIRMED] -> customer Vikram
    [OD103 PENDING] -> restaurant Dosa Corner: new order
    (Dosa Corner kitchen full: needs 2 item slots, free 1)
    [OD103 CANCELLED] -> customer Asha

== 5. Only one rider free: second ready order waits ==
    [OD102 PREPARING] -> customer Vikram
    [OD102 READY_FOR_PICKUP] -> customer Vikram
    [OD102 OUT_FOR_DELIVERY] -> customer Vikram: Meena is on the way
    [OD104 PENDING] -> restaurant Pizza Hub: new order
    [OD104 CONFIRMED] -> customer Vikram
    [OD104 PREPARING] -> customer Vikram
    [OD104 READY_FOR_PICKUP] -> customer Vikram
    (OD104 waiting for a free rider)
    [OD101 DELIVERED] -> customer Asha
    [OD104 OUT_FOR_DELIVERY] -> customer Vikram: Ravi is on the way
  o4 rider: Ravi

== 6. Cancel rules ==
  cancel o2 (out for delivery)? false
    [OD105 PENDING] -> restaurant Pizza Hub: new order
    [OD105 CONFIRMED] -> customer Asha
    [OD105 CANCELLED] -> customer Asha
    refund 651.60 to card ****4242
  cancel o5 (confirmed)? true

== 7. Swap strategy at run time: fair share ==
    [OD102 DELIVERED] -> customer Vikram
    [OD104 DELIVERED] -> customer Vikram
  deliveries today: Ravi=2, Meena=1 (both now at Vikram's address)
    [OD106 PENDING] -> restaurant Dosa Corner: new order
    [OD106 CONFIRMED] -> customer Asha
    [OD106 PREPARING] -> customer Asha
    [OD106 READY_FOR_PICKUP] -> customer Asha
    [OD106 OUT_FOR_DELIVERY] -> customer Asha: Meena is on the way
  o6 rider: Meena (fewer deliveries today)
  o1 history: [PENDING, CONFIRMED, PREPARING, READY_FOR_PICKUP, OUT_FOR_DELIVERY, DELIVERED]
```

Reading the output. Step 1 hides the far-away grill (outside 10 km). Step 2 refuses a second restaurant in one cart. Step 3: the delivery fee is 20 + 8 × 1.4 km = 31.20; changing the dosa price afterwards does not change the order. Step 4: Dosa Corner holds 4 item slots; an order for 3 fits, the next order for 2 is auto-cancelled. Step 5: Meena takes OD102; OD104 waits because Ravi is still out; as soon as OD101 is delivered, Ravi is claimed for OD104. Step 6: an order out for delivery cannot be cancelled; a confirmed card order can, and is refunded. Step 7: with both riders at the same spot, the fair-share strategy picks Meena (1 delivery) over Ravi (2).

        fk.orderHistory().forEach(o -> System.out.println("  " + o));
    }
}
```

Output:

```
== Sample test case ==
show_restaurant(price):
  Food Court-2, Burger
  Food Court-1, NI Thali
place_order(Food Court-1, 2): Order Placed Successfully.
place_order(Food Court-2, 7): Cannot place order
show_restaurant(rating):
  Food Court-1, NI Thali
  Food Court-2, Burger
update_quantity(Food Court-2, 5): Food Court-2, BTM, Burger - 8
update_location(Food Court-2, BTM/HSR): Food Court-2, BTM/HSR, Burger - 8

== Extras ==
non-owner update: only the owner can update Food Court-1
rating 6: rating must be 1..5
order from a restaurant that does not deliver to BTM: Cannot place order

== Selection strategy variant (user in BTM, wants 4 plates) ==
highest rating: Order Placed Successfully from Food Court-2.
lowest price  : Order Placed Successfully from Food Court-4.
lowest price  : Order Placed Successfully from Food Court-2.
lowest price  : Cannot place order  (no one has 4 left)

== Order history of phoneNumber-3 ==
  FoodOrder[id=1, userPhone=phoneNumber-3, restaurant=Food Court-1, item=NI Thali, quantity=2, total=200]
  FoodOrder[id=2, userPhone=phoneNumber-3, restaurant=Food Court-2, item=Burger, quantity=4, total=480]
  FoodOrder[id=3, userPhone=phoneNumber-3, restaurant=Food Court-4, item=Dosa, quantity=4, total=320]
  FoodOrder[id=4, userPhone=phoneNumber-3, restaurant=Food Court-2, item=Burger, quantity=4, total=480]
```

Reading the output. The "Sample test case" block reproduces every expected line from the problem statement: price-sorted list (Burger 120 before Thali 100), the successful and failed orders, the rating-sorted list, and the owner's quantity and location updates (`Burger - 8`). The extras show owner-only updates, rating validation, a rating without comment, and a restaurant that does not deliver to the user's pincode. The variant shows the two strategies choosing **different** restaurants (highest rating → Food Court-2; lowest price → Food Court-4), capacity filtering (Food Court-1 has only 3 plates, so it is never picked for 4), and a clean refusal once no one has 4 plates left.

Concurrency & edge cases

Case	Handling
Two claims for the same rider	`tryClaim()` CAS: only one succeeds; the loser moves to the next rider in its ranked list. (Inside one service the synchronized dispatcher already serialises claims; the CAS also covers claims made outside it.)
Two dispatch loops run at once	`dispatchWaiting` is `synchronized`, so the waiting queue is drained by one thread at a time (FIFO fairness preserved).
Kitchen over-booked	`tryReserveKitchen` is `synchronized` (check + add in one step).
Cancel races with accept	Both lock the `Order`; accept re-checks `PENDING`, cancel releases slots only if they were reserved (`CONFIRMED`). No leak, no double release.
Item sold out after it was added to the cart	`placeOrder` re-checks `available` and rejects.
Restaurant closes	`browse` hides it; `placeOrder` refuses.
COD cancelled	No refund (nothing was paid).
FoodKart: no user logged in	`requireLogin()` throws a clear `IllegalStateException`.
FoodKart: duplicate phone / restaurant name	Rejected with `putIfAbsent`.
FoodKart: rating outside 1–5	The `Review` record's compact constructor (a record's short validation block that runs on creation) rejects it.
FoodKart: strategy picks a restaurant whose capacity was just taken	`take()` fails; that restaurant is dropped and the strategy asked again (bounded retries).

Real-world example

In Swiggy and Zomato the order screen walks through the same states — order placed, restaurant confirmed, food being prepared, rider assigned / picked up, delivered — and if you add a dish from a second restaurant, the app asks whether to **reset your cart**, which is our one-restaurant `Cart` rule. The rider side is a dispatch problem: these platforms assign riders using distance, rider load and fairness signals, and may batch two orders on one trip — all variations of `DeliveryAssignmentStrategy`. FoodKart itself is a Flipkart machine-coding question: a 90-minute, in-memory, driver-class exercise that rewards clean separation (service, model, strategy) over clever algorithms.

Extensions & follow-up questions

- **"Batch two orders for one rider."** A strategy that accepts a rider already carrying one order if the second pickup is on the way; the agent then has a list of orders and a capacity (e.g. 2).
- **"ETA."** An `EtaEstimator` strategy: prep time (per restaurant load) + travel time (distance / speed, or a maps API — an online service other programs call).
- **"Surge / distance-based fees."** Extract `DeliveryFeePolicy` (Strategy): base + per-km today, add surge when waiting orders exceed free riders.
- **"Rider rejects an assignment."** Put the rider back to available, add the order back to the head of the queue, and exclude that rider for this order.
- **"Multiple dishes per restaurant in FoodKart."** Replace `foodItem/price/quantity` with a `Map<String, MenuItem>`; `take` becomes per item and all-or-nothing for multi-item orders.
- **"Order split across restaurants (Flipkart variant)."** The selection strategy returns a *set* of restaurants that together cover all items; reserve capacity in each, roll back all on any failure.
- **"Live tracking."** The rider app pushes location updates; an Observer forwards them to the customer's app (WebSocket).

In the interview

Design round (45 min): clarify (5) → entities + one-restaurant cart (8) → **order state machine** (7) → **assignment strategy + CAS claim + waiting queue** (12) → payments/notifications (5) → concurrency and extensions (8).

Machine-coding round (FoodKart, 90 min): model classes first (User, Restaurant, Review, Order) → service with one method per command → the driver replaying the sample → sort enum → owner checks and validation → selection strategy → order history. Keep it runnable at every step; print exactly the expected lines.

> **30-second answer:** "Restaurants own their menus and a kitchen capacity reserved on accept and released when food is ready. Orders copy item prices and move through a state machine from PENDING to DELIVERED. When food is ready the order joins a FIFO queue; a pluggable assignment strategy ranks free riders and we claim one with a compare-and-set, so a rider can never get two orders. Every status change is published to observers for the customer, restaurant and rider apps."

Follow-ups with answers

- *Why release kitchen capacity on "ready" and not on "delivered"?* The kitchen is free once the food leaves it; delivery time is the rider's constraint, not the kitchen's.
- *Why does the strategy return a list?* Because between ranking and claiming, the top rider may be claimed by someone else (another dispatcher or the rider's own app); the list lets us fall through without re-ranking.
- *How would you scale assignment across cities?* Partition by city/zone; each zone has its own dispatcher (single writer), so there is no cross-zone contention (threads or servers fighting over the same lock or data).

Self-check

1. **Q:** Which states allow a customer cancel, and why not later? **A:** PENDING and CONFIRMED; once cooking starts the food cost is already spent.
2. **Q:** What stops two orders getting the same rider? **A:** `AtomicBoolean.compareAndSet(true, false)` in `tryClaim()`.
3. **Q:** In FoodKart, what makes a restaurant "serviceable"? **A:** It delivers to the user's pincode and has quantity > 0.
4. **Q:** Why does `show_restaurant(price)` list Burger (120) before NI Thali (100)? **A:** The statement asks for descending order.
5. **Q:** How does the selection variant avoid choosing a restaurant that cannot fulfil the order? **A:** It filters by `quantity ≥ qty` before the strategy chooses, and `take()` re-checks atomically.
6. **Q:** Which patterns appear? **A:** Strategy (assignment, selection, payment), Observer (notifications), state machine (order status), Facade (service).

TL;DR

- One-restaurant cart; order copies prices; **state machine** PENDING → … → DELIVERED.
- **Kitchen capacity** reserved on accept, released on ready; **riders** claimed with **CAS**, chosen by a swappable **strategy**, with a FIFO queue when none are free.
- FoodKart: pincode-based serviceability, one dish per restaurant, average rating, `SortBy` enum, atomic `take`, and a **selection strategy** filtered by capacity.

Design a Grocery Store (POS & Checkout)

A **point-of-sale (POS) system** is the software behind a supermarket till: the cashier (or a self-checkout kiosk) scans items, the screen shows a running total, offers are applied, the customer pays in one or more ways, a receipt is printed, and stock goes down. Amazon (§19.1) was about an online cart that becomes an order; a grocery till is different in three ways that make it a good interview question:

- **Items are weighed as well as counted.** Loose produce is priced per kilogram; the scale sends a weight and the price is computed at the till.
- **Offers interact.** "Buy 2 get 1 free", "3 for ₹80", "10% off produce" and a basket coupon can all apply to one basket — and the rules for combining them decide what the customer pays, what tax is due, and how much a return refunds.
- **The till must never block a physical sale.** If the system says milk stock is 0 but a customer is holding a carton, the *count* is wrong, not the customer.

Money in this section is Indian rupees (₹; written `Rs` in the program output) and uses `BigDecimal`, following the chapter's four rules.

Problem & clarifying questions

Question	Assumed answer
Who uses it?	Cashiers at several registers (lanes) in one store; a supervisor for voids and refunds. Self-checkout uses the same register API.
How are items identified?	Packaged goods by **barcode** (EAN-13, the standard 13-digit product barcode); loose produce by a 4-digit **PLU** (price look-up) code plus the scale's weight.
Are shelf prices tax-inclusive?	Yes (as in India, the UK and the EU): the receipt shows how much tax the price *contains*. A US-style store adds sales tax at the till — the design must support both.
Which offers?	Buy X get Y free, multi-buy ("3 for ₹80"), percent off a department, and a basket coupon ("₹50 off when you spend ₹500").
Can offers stack?	Each product gets at most **one** item offer — the best for the customer. A basket coupon applies on top, to what is still owed.
How do people pay?	Cash (with change), card, UPI — and **split tender** (part UPI, part cash).
Can the customer change their mind?	Void a line while scanning; go back to scanning if nothing is paid yet; cancel the whole sale (card/UPI payments reversed).
Returns?	Yes, with the receipt: refund what the customer **actually paid** for that item, never more units than bought.
Stock?	Decrease on sale, increase on return; alert when low; never refuse a sale because of the stock count.

Requirements

Functional

1. Catalog lookup by barcode or PLU; weighed items priced by weight.
2. A **sale** collects line items; lines can be voided (kept on the receipt, marked VOID).
3. Item offers and basket coupons, with clear stacking rules.
4. Totals with tax per tax category (inclusive or exclusive policy).
5. Split payment: cash (with change), card, UPI; a declined card changes nothing.
6. Immutable **receipt** with lines, discounts, tax breakdown, tenders and change.
7. Returns against a receipt, refunding the net price paid, at most the quantity bought.
8. Stock updates and **low-stock / negative-stock alerts**.

Non-functional

- **Exact money**: `BigDecimal`, 2 decimal places, `HALF_UP` rounding (a 5 or more rounds up), and parts (per-product discounts, refunds) that always add up to the total.
- **Several registers at once** share the catalog, the stock and the receipts safely.
- **Deterministic pricing**: the same basket always prices the same way (a **pure function**: its result depends only on its inputs, and it changes nothing outside itself) — needed for audits and for returns.
- **Auditable**: voids stay on the receipt; prices are copied into lines at scan time.

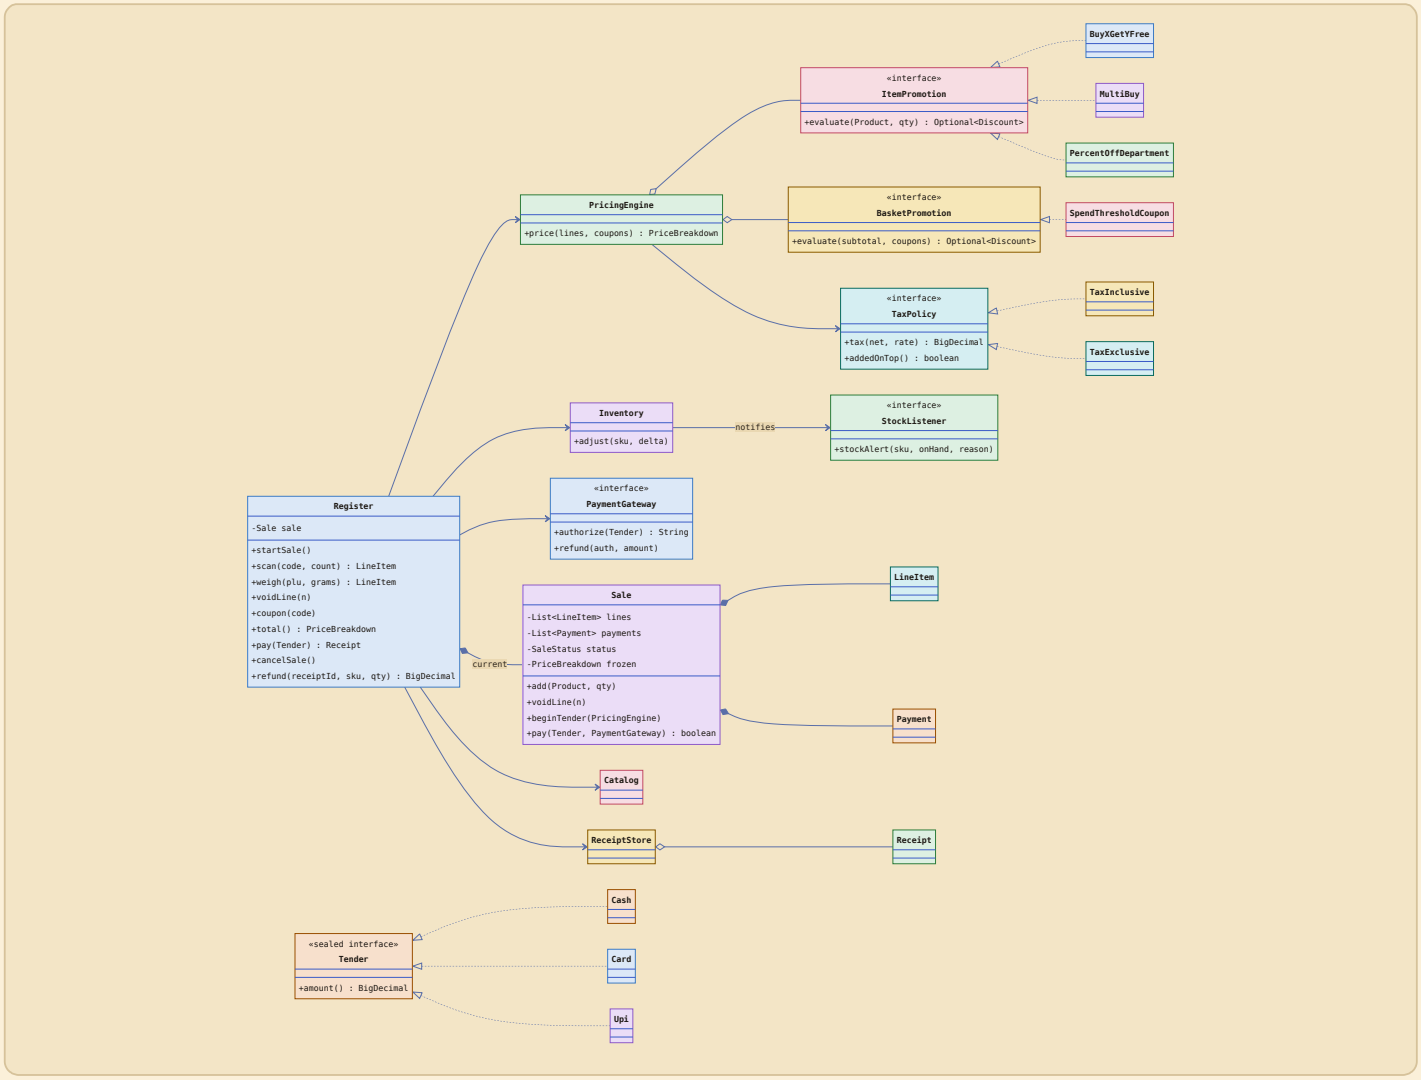
Use cases

Actor	Use cases
Cashier / self-checkout	start sale, scan, weigh, void line, add coupon, total, take payment, cancel sale
Customer	pay by cash / card / UPI, return items with the receipt
Supervisor	approve voids and returns (not modelled), reprice products
Payment network (system)	authorise and reverse card / UPI payments
Purchasing / store manager (subscriber)	receive low-stock and negative-stock alerts

Core entities

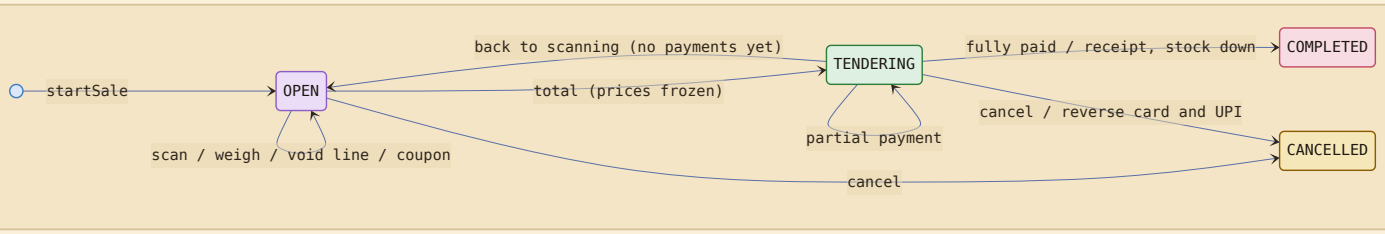
Class	Kind	Responsibility
`Product`	record	SKU (stock-keeping unit — the store's id for one distinct product), barcode/PLU, name, department, `PricingUnit` (EACH or PER_KG), unit price, `TaxCategory`.
`Catalog`	class	Lookup by code; `reprice` replaces the record (old sales keep old prices).
`LineItem`	record	One scan: product copy, quantity (count or kg), gross amount, voided flag.
`Sale` + `SaleStatus`	class + enum	OPEN → TENDERING → COMPLETED, or → CANCELLED; lines, coupons, payments, frozen price breakdown.
`ItemPromotion` + `BuyXGetYFree`, `MultiBuy`, `PercentOffDepartment`	interface + records	**Strategy** for item offers.
`BasketPromotion` + `SpendThresholdCoupon`	interface + record	**Strategy** for basket offers.
`TaxPolicy` + `TaxInclusive`, `TaxExclusive`	interface + classes	**Strategy** for how tax relates to the shelf price.
`PricingEngine` → `PriceBreakdown`	class → record	Pure function: lines + coupons → discounts, net per SKU, tax per category, total.
`Tender` (sealed) `Cash`, `Card`, `Upi`; `Payment`	records	How the customer pays; the part applied to the bill.
`PaymentGateway`	interface	Port (an interface through which the core code talks to an outside system) to the card / UPI networks (authorise, refund).
`Receipt`, `ReceiptStore`	record, class	Immutable proof of purchase; returns ledger per receipt and SKU.
`Inventory`, `StockListener`	class, interface	Shared stock; **Observer** for edge-triggered alerts (fired once when a line is crossed, not on every sale below it).
`Register`	class	**Facade** for one lane: the only API the till UI calls.

Class diagram

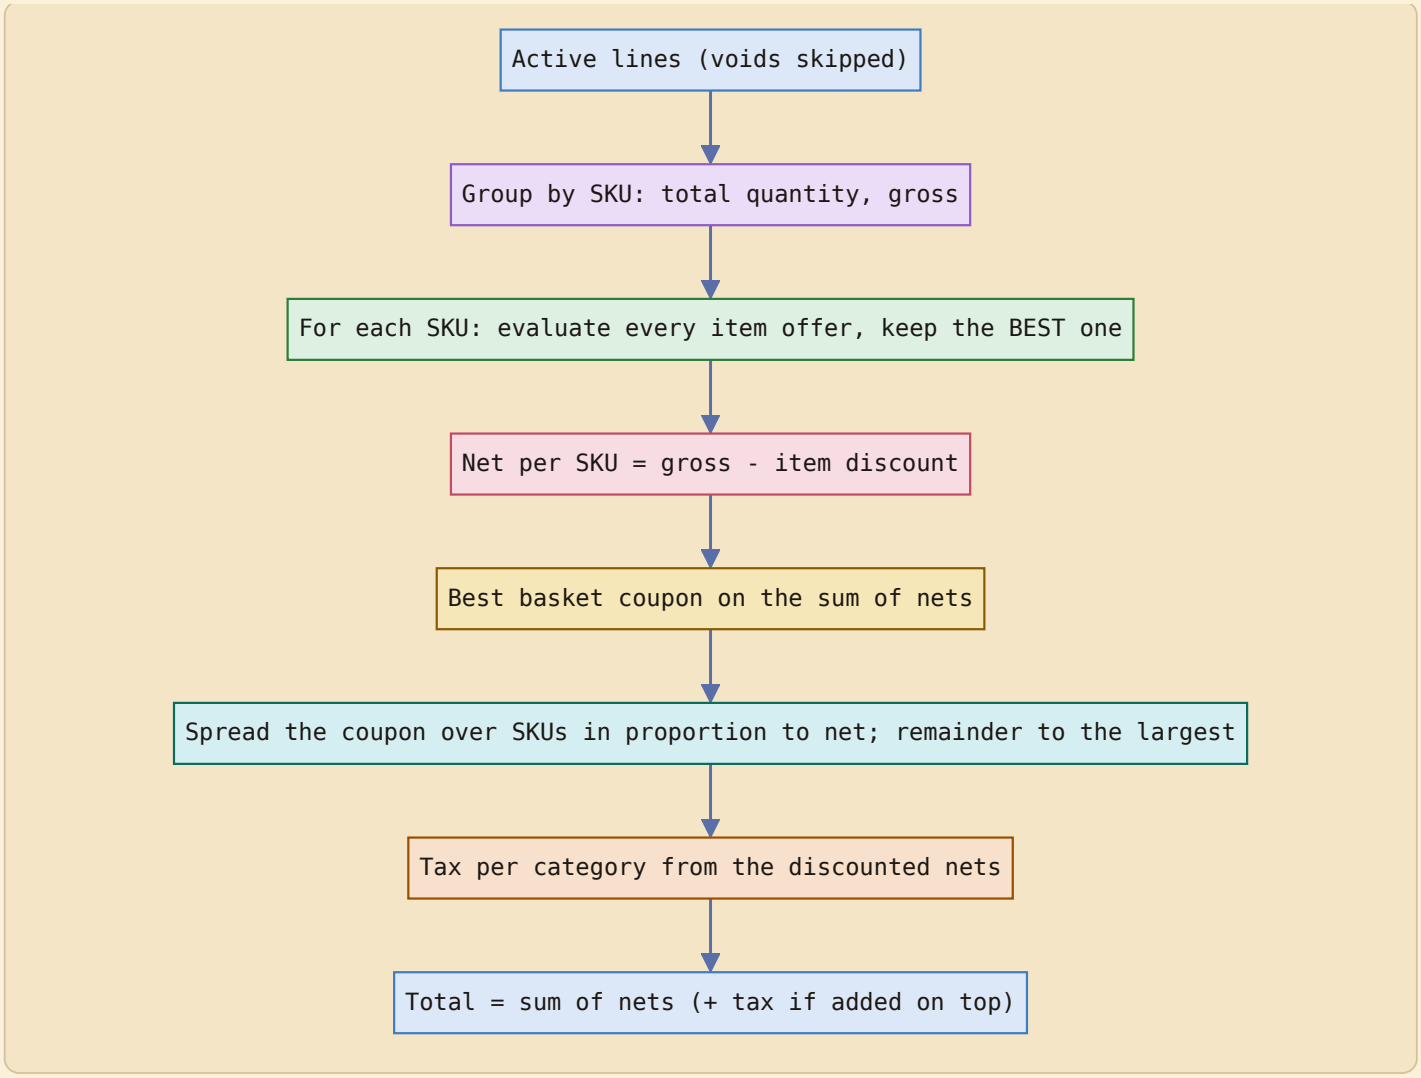


Key flows

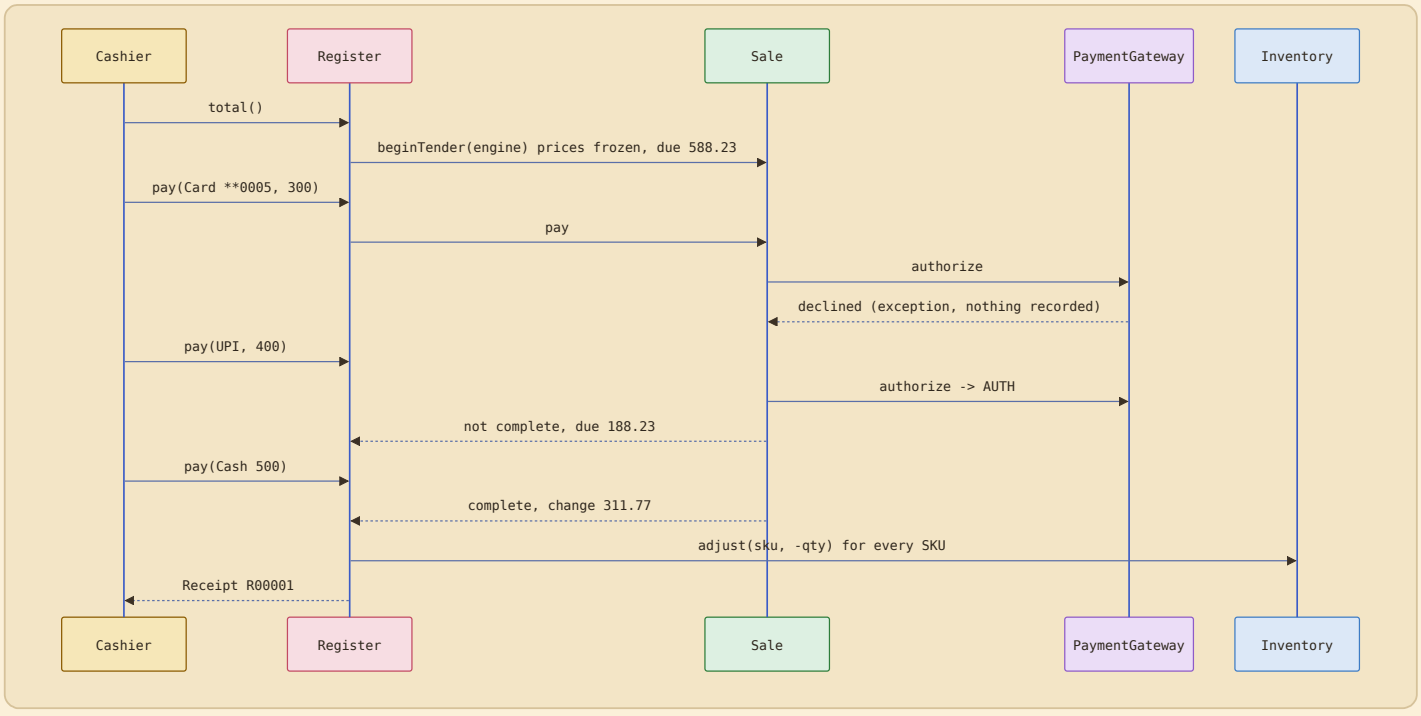
Sale lifecycle.



How one basket is priced (the hard method, `PricingEngine.price`):



Split payment.



Design decisions & patterns used

Decision	Pattern	Why	Alternative rejected
Each offer is a small class behind `ItemPromotion` / `BasketPromotion`	**Strategy**	Marketing adds offers weekly; a new offer is one new class, the engine does not change	A `switch` over offer types inside the pricing code
Best offer per SKU wins; basket coupon after item offers	Explicit stacking policy	Stacking rules are business decisions that must be written down once; "best for the customer" is simple to explain at the till	Applying every offer in list order (results depend on the order; can go below zero)
`PricingEngine` is a **pure function** of lines and coupons	Stateless service	Same basket → same price; one engine shared by all registers (stateless: it keeps no data between calls); easy to test	Mutating discounts into the line items as they are scanned
Prices **frozen** when payment starts	Snapshot	A price change or an offer expiring mid-payment must not change the amount due	Re-pricing on every payment
Coupon **spread over SKUs**, remainder to the largest	Allocation with exact rounding	Tax is per category and returns refund per item, so every rupee of discount must belong to some item — and the parts must add up exactly	Keeping the coupon as one unallocated number
Tax as a `TaxPolicy`	**Strategy**	Inclusive (India/EU) vs exclusive (US) is a store-level choice	Two versions of the engine
Tenders as a **sealed** interface	Sealed types	The receipt printer's `switch` is checked by the compiler	`String paymentType`
`Register` as the only API the UI calls	**Facade**	The UI does not need to know about engines, stores and gateways	UI code calling each part directly
Sale status in an enum with `canMoveTo`	Enum state machine	"Scan after payment started" and "pay a cancelled sale" fail loudly	Boolean flags (`isPaying`, `isDone`)
Stock may go **negative**, alerts are **edge-triggered**	**Observer**	The shelf is the truth; negative stock is a signal for a recount. Each crossing alerts once	Refusing the sale; alerting on every sale below the line
Voided lines are kept and printed	Audit trail (a permanent record of every action)	Voids are a common way to hide theft; supervisors review them	Deleting the line

}
```

How the code works, part by part

- **Scanning.** `Register.scan` checks the EAN-13 check digit (a last digit computed from the others, so a misread code fails the sum) first (a misread barcode is caught before lookup), then refuses weighed products; `weigh` converts grams to kilograms with `movePointLeft(3)` so 1245 g becomes exactly `1.245`. `Sale.add` copies the product — and therefore its price — into the new `LineItem`.
- **Pricing.** `PricingEngine.price` skips voided lines, groups by SKU, asks every item offer for a discount and keeps the largest (capped at the gross), applies the best basket coupon to what is left, spreads that coupon across SKUs, and computes tax per category on the discounted amounts. With `TaxInclusive`, tax = amount × r ÷ (100 + r); with `TaxExclusive`, tax = amount × r ÷ 100 and is added to the total.
- **Paying.** `beginTender` freezes the breakdown. `pay` treats cash specially: if it is more than the amount due, the extra becomes change. Card and UPI may not exceed the amount due and must be authorised; a declined authorisation throws before anything is recorded. When the amount due reaches zero, the sale completes and the register writes the receipt and reduces stock.
- **Returns.** `ReceiptStore.claimReturn` uses `ConcurrentHashMap.compute` so "check how many were already returned, then add" is atomic. The refund for a return is `share(after) − share(before)`, where `share(k)` is the net paid for the first *k* units; that way three separate one-item returns add up to exactly what was paid.
- **Stock.** `Inventory.adjust` uses `merge`, which is atomic per key; it compares the value before and after *this* change, so each crossing of the reorder point — the stock level at which more should be ordered — (or of zero) alerts exactly once, however many registers sell at the same time.

Output:

```
== 1. Scan a basket ==
   error: Unknown code 8901000000095: call a supervisor
   error: Bad barcode 8901000000018: check digit wrong, rescan

    incl. tax STANDARD @18%                        Rs 40.07
  Paid UPI asha@okbank                             Rs 400.00
  Paid cash                                        Rs 500.00
  Change                                           Rs 311.77

== 3. Returns refund what was really paid ==
   return 1 of 3 chips -> refund Rs 12.29
   return 2 more chips -> refund Rs 24.58  (all three add up to the Rs 36.87 paid)
   error: Only 0 of CHP left to return on R00001
   error: Only 1 of PNR left to return on R00001

== 4. Price change during a sale; going back to scanning; cancelling ==
   2 milk scanned around a reprice: gross Rs 140.00 = Rs 68 (old price kept) + Rs 72 (new)
   after adding paneer, due Rs 230.00
   error: Payments already taken; cancel them first
   gateway: reversed Rs 100.00 on AUTH1002
   error: Cannot pay when the sale is CANCELLED

== 5. Same basket, US-style tax added at the till ==
   inclusive total Rs 588.23 vs exclusive total Rs 644.73 (tax {EXEMPT=0.00, REDUCED=9.22, STANDARD=47.28})

== 6. Four registers sell 30 paneer each at once; stock was 100 ==
   paneer on hand: -21  (sold 120 + 1 earlier; the till never refuses a real item)
   alert: PNR LOW - reorder (on hand 20)
   alert: PNR NEGATIVE - recount the shelf (on hand -1)
```

Reading the output: the misread barcode (wrong check digit), an unknown code and scanning bananas without the scale are all refused. On the receipt, chips qualify for both "buy 2 get 1 free" (saves ₹20) and "3 for ₹50" (saves ₹10); only the better one is applied. The ₹50 coupon applied because the basket was still over ₹500 after item offers. The total ₹588.23 contains ₹8.78 + ₹40.07 of tax; the same basket under a US-style policy costs ₹644.73. The declined card and the over-large UPI amount changed nothing; UPI ₹400 plus cash ₹500 gave ₹311.77 change. Returning the chips one, then two, refunded ₹12.29 + ₹24.58 = ₹36.87 — exactly the net paid after the offer and the coupon share, not the shelf price of ₹60. The re-priced milk shows that a line keeps the price it was scanned at. Four registers selling 30 paneer each drove stock from 99 to −21 without refusing anyone, and the low and negative alerts each fired once.

Concurrency & edge cases

Case	Handling
Four registers sell the same product at once	`Inventory.adjust` uses `ConcurrentHashMap.merge` (atomic per key); no lost updates
Stock count says zero but the item is in hand	Sale goes through; stock goes negative; one "recount" alert
Alert spam when stock is low	Edge-triggered: alert only on the change that crosses the line
Two service desks refund the same receipt line at once	`ReceiptStore.claimReturn` uses `compute`: check-and-add is atomic; the second over-claim is refused
Price changes during a sale	Lines keep the price copied at scan; the frozen breakdown fixes the amount due
Offer changes during payment	Breakdown frozen at `total()`; going back to scanning re-prices
Card declined	Exception from the gateway before anything is recorded
Cancel after a card payment	`cancel` reverses every non-cash payment through the gateway
Rounding pennies in coupon allocation and refunds	Remainder to the largest SKU; refunds as differences of cumulative shares
One register used by one cashier	`Register` and `Sale` are single-threaded by design; shared objects (`Catalog`, `Inventory`, `ReceiptStore`) are the thread-safe ones

Real-world example

Supermarket tills identify loose produce by **PLU codes** — 4011 is the standard code for yellow bananas, and tomatoes have their own codes in the 4000 range — and read the weight from an integrated scale, exactly like `weigh(plu, grams)`. Packaged goods carry EAN-13 barcodes whose last digit is a check digit, which is why a smudged barcode is rejected rather than misread as another product. Receipts in tax-inclusive countries (for example GST — Goods and Services Tax — invoices in India or VAT — value-added tax — receipts in the UK) print how much tax the total *contains*, while US receipts add sales tax below the subtotal — our two `TaxPolicy` strategies. Retailers also run periodic "cycle counts" to fix the kind of negative stock our `Inventory` reports.

Extensions & follow-up questions

- **"Loyalty points and member prices."** A `CustomerContext` passed to the engine; member-only offers check it. Points are earned on the *net* paid (after discounts), from the receipt.
- **"Weighed items with a pre-packed label."** In-store printed barcodes that encode the price or weight in the digits (a variable-measure barcode); the scanner decodes them into a `LineItem` directly.
- **"Offers that span products (buy pasta + sauce, save ₹20)."** A `BundlePromotion` that looks at several SKUs; the "one offer per unit" rule then needs a small optimiser (try the combinations, keep the best) instead of best-per-SKU.
- **"Refund to the original payment method."** Store tender splits on the receipt; refund card/UPI parts through the gateway first, then cash.
- **"The network is down."** Offline mode: queue card authorisations (with a floor limit — a maximum amount accepted without online approval), keep selling, reconcile (match up the records) later; the catalog and offers are cached locally in each register.
- **"End-of-day."** A `Shift` per cashier: opening float (the cash put in the drawer at the start), cash counted at close, expected cash = float + cash sales − change − cash refunds.
- **"Self-checkout."** The same `Register` facade with a weight-check step at the bagging area (weight mismatch → assistance needed).

In the interview

Plan for 45 minutes: clarify offers, tax, tenders, returns (5) → entities and the Register facade (8) → sale state machine (5) → **pricing engine** with the stacking rules (12) → split payment and receipt (7) → returns, stock and concurrency (8).

> **30-second answer:** "A Register facade drives one Sale through OPEN, TENDERING, COMPLETED or CANCELLED. Lines copy the price at scan time; produce is priced by weight from the scale. A pure pricing engine groups lines

by SKU, gives each SKU its single best offer, applies a basket coupon, spreads it over SKUs so tax and refunds are exact, and computes tax through a pluggable inclusive or exclusive policy. The price is frozen at total; tenders are a sealed type, cash can give change, card and UPI go through a gateway. On completion an immutable receipt is stored and shared stock is reduced atomically, with edge-triggered alerts — and the till never refuses a real item."

Follow-ups with answers

- *Why not apply all offers that match?* Stacking can give away more than intended or even a negative price; the business has to choose a rule, and "best single offer per product, then one basket coupon" is simple and explainable.
- *Why spread the coupon over items?* Tax differs per category and returns must refund the price actually paid for that item.
- *Why is the pricing engine stateless?* So every register can share it and the same basket always gives the same answer — also what makes returns reproducible.

Self-check

1. **Q:** Three chips qualify for "buy 2 get 1 free" and "3 for ₹50". What is applied? **A:** Only the larger discount (₹20), because each SKU gets its single best item offer.
2. **Q:** Why does a return of one chip refund ₹12.29, not ₹20? **A:** The refund is the net price paid — after the offer and the item's share of the coupon.
3. **Q:** What stops two service desks refunding the same unit? **A:** `ConcurrentHashMap.compute` makes "check already returned, add" one atomic step.
4. **Q:** Why is stock allowed to go negative? **A:** The physical item is in the customer's hand; the count is wrong, so we sell and raise a recount alert.
5. **Q:** When are prices frozen, and why? **A:** At `total()`, so price or offer changes during payment cannot change the amount due.
6. **Q:** Which patterns appear? **A:** Strategy (offers, tax, payment gateway), Observer (stock alerts), Facade (Register), enum state machine (sale), sealed types (tenders).

TL;DR

- **Register facade** → one **Sale** state machine; lines copy prices; produce priced by **weight** (PLU + scale).
- **Pure pricing engine**: best item offer per SKU → basket coupon → spread over SKUs → tax per category via a **TaxPolicy** strategy.
- **Freeze** prices at total; **split tender** with a sealed `Tender`; declined cards change nothing; cancel reverses non-cash payments.
- Returns refund the **net paid**, claimed atomically; stock updates are atomic, may go negative, alerts are **edge-triggered**.

Chapter summary

Problem	Hard part	The move that solves it
Amazon	Guests vs members; last-item races; cancel rules	Ordering only on `Member` (LSP); atomic all-or-nothing stock reservation; order state machine
Brokerage	Four order types; tax lots; over-spending	Two abstract questions on `Order`; `StockLot` + FIFO `LotSale`; reserved funds
Stock exchange	Fair matching	Per-symbol `TreeMap<price, FIFO queue>`; price then time; one lock per symbol
Auction	Concurrent bids	All bid rules in one per-listing critical section; notify after unlocking
Music streaming	Shuffle/repeat without losing order	Play order as a strategy-produced permutation of indexes; plan rules in the enum
Food delivery / FoodKart	Capacity and riders under concurrency	Reserve kitchen slots atomically; CAS-claim riders; strategies for assignment and selection
Grocery POS	Weighed items, stacking offers, split tender, returns	Pure pricing engine (best offer per SKU, coupon spread, tax per category); frozen price; atomic return claims; edge-triggered stock alerts

Patterns that kept coming back: Strategy (payments, play order, rider assignment, restaurant selection, trade-price policy, grocery offers and tax), Observer (notifications, fills, plays), state machines in enums (orders, auctions, player), Template Method (statements), Facade (every `*Service`), and one concurrency rule — **make check-then-act atomic** (lock, or compare-and-set).

Sources combined in this chapter: the DesignGurus *Grokking the Object-Oriented Design Interview* lessons on Amazon and the stock brokerage (requirements, actors, staged class design and diagrams); the awesome-low-level-design problem statements for the auction system, music streaming service and food delivery service; and the kumaransg/LLD machine-coding statements for the Navi stock exchange and Flipkart's FoodKart. All Java code is original. The grocery point-of-sale case is designed from first principles, using public retail conventions (GS1 EAN-13 check digits, IFPS PLU codes for produce, tax-inclusive vs sales-tax receipts).

Chapter 20 — Case Studies: Pattern-Driven Components

> **Goal.** The problems in this chapter are not whole products. They are **building blocks** that almost every real system contains: a ledger that splits money, a service that sends notifications, a cache, a matcher that pairs riders with drivers, a logger, a message broker and a rate limiter. Each one is small enough to finish in an interview, and each one is **anchored on one or two design patterns**. If you can name the pattern and say what change it absorbs, you have already answered half of the question.

Why "components" deserve their own chapter. A component is a part that other parts of a system *use*. It has a small public surface (a few methods), and a lot of hidden rules behind it. That makes it the perfect interview question: the interviewer can keep asking "what if this rule changes?" and a good design answers with "one new class, nothing else touched".

#	Component	Anchor pattern(s)	The change the pattern absorbs
20.1	Splitwise (expense sharing)	**Strategy** (split rules)	A new way to split a bill
20.2	Notification service	**Template Method** (retry loop), **Strategy** (send rules), **Observer** (outcomes), Simple Factory (channels)	A new channel, a new reason not to send, a new thing that watches results
20.3	In-memory cache (+ LRU from scratch)	**Strategy** (eviction policy), **Observer** (removal listener), Builder	A new eviction rule
20.4	Ride sharing (Uber)	**Strategy** (matching, pricing, payment), **Decorator** (surge), State machine (trip)	A new matching rule, surge on/off, a new payment method
20.5	Logging framework	**Chain of Responsibility** (logger hierarchy), **Singleton** (LogManager), Strategy (formatter), Decorator (async appender)	A new sink, a new format, async writing
20.6	Pub-Sub system	**Observer / Publish-Subscribe**, append-only log with offsets	New subscribers, replay, slow consumers
20.7	Rate limiter	**Strategy** (algorithm), Simple Factory, Composite	A new algorithm, a new tier, combined limits

> **Key terms — the patterns named above.** A **design pattern** is a named, reusable shape for solving a design problem that keeps coming back. In one line each: **Strategy** puts each interchangeable rule in its own class behind one interface (a list of methods with no code, which several classes implement in their own way); **Template Method** writes the fixed steps of an algorithm once in a parent class and lets subclasses fill in one or two steps; **Observer** lets objects sign up to be told when something happens; **Simple Factory** is one place that decides which class to create; **Builder** assembles an object with many optional settings step by step; **Decorator** wraps an object in another object of the same type to add behaviour; a **state machine** is a fixed set of states plus the allowed moves between them; **Chain of Responsibility** passes a request along a line of handlers; **Singleton** guarantees exactly one instance of a class; **Composite** lets a group of objects be used as if it were one; **Publish-Subscribe** sends messages through a middleman so senders and receivers never know each other. An **append-only log with offsets** is a list that is only ever added to at the end, where each entry is found by its position number (its offset).

How every case is laid out (the case-study template used in Chapters 14–21): *Problem & clarifying questions → Requirements → Use cases → Core entities → Class diagram → Key flows → Design decisions & patterns used → Java implementation (+ real output) → Concurrency & edge cases → Extensions & follow-up questions → Real-world example → In the interview → Self-check → TL;DR.* (*Concurrency* means several threads running at the same time, which is where most subtle bugs hide.)

Running the code. All code is Java 21, standard library only (only the classes that ship with Java itself, no extra downloads), under `code/lld/ch20/<name>/`. Every package (Java's folder-like grouping of related classes) has a `Main` (a class with the `main` method the program starts from). From `chapters/20-case-components/code`:

```
javac --release 21 -d /tmp/lld_20 $(find . -name '*.java')
java -cp /tmp/lld_20 lld.ch20.splitwise.Main      # also: notification, cache, lrucache,
                                                  # ridesharing, carpool, logging, pubsub, ratelimiter
```

Money is always `BigDecimal`. A `double` (Java's standard binary floating-point number type, fast but approximate for decimals) cannot hold 0.1 exactly, so sums drift (`0.1 + 0.2` prints `0.30000000000000004`). `BigDecimal` stores decimal digits exactly. Two rules to remember: compare amounts with `compareTo` (not `equals`, because `equals` also compares the scale (the number of digits after the decimal point), so `2.0` and `2.00` are "different"), and always say how to round when you divide (`divide(x, 2, RoundingMode.HALF_EVEN)`), or Java throws an `ArithmeticException` for results like 1/3. (An **exception** is Java's way of signalling an error: normal execution stops and the error travels up to whoever catches it.)

Reading the course diagrams. The figures marked "(course diagram)" are UML diagrams (UML, the Unified Modeling Language, is the standard box-and-arrow notation for drawing classes and how they relate) and use one arrow legend throughout:

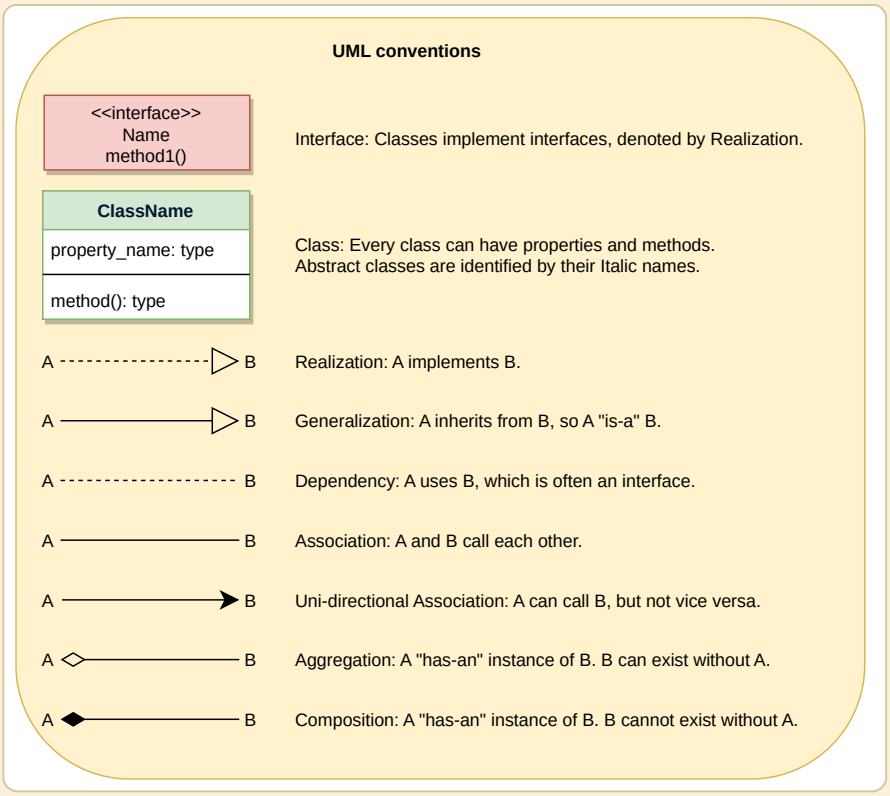

Figure — UML conventions used in the course class diagrams: interface, class, realization (implements), generalization (inherits), dependency, association, one-way association, aggregation and composition (course diagram)

The mermaid diagrams (Mermaid is a text format that a renderer turns into pictures) are drawn from **this chapter's Java code**, so they match the code line by line.

20.1 Design Splitwise

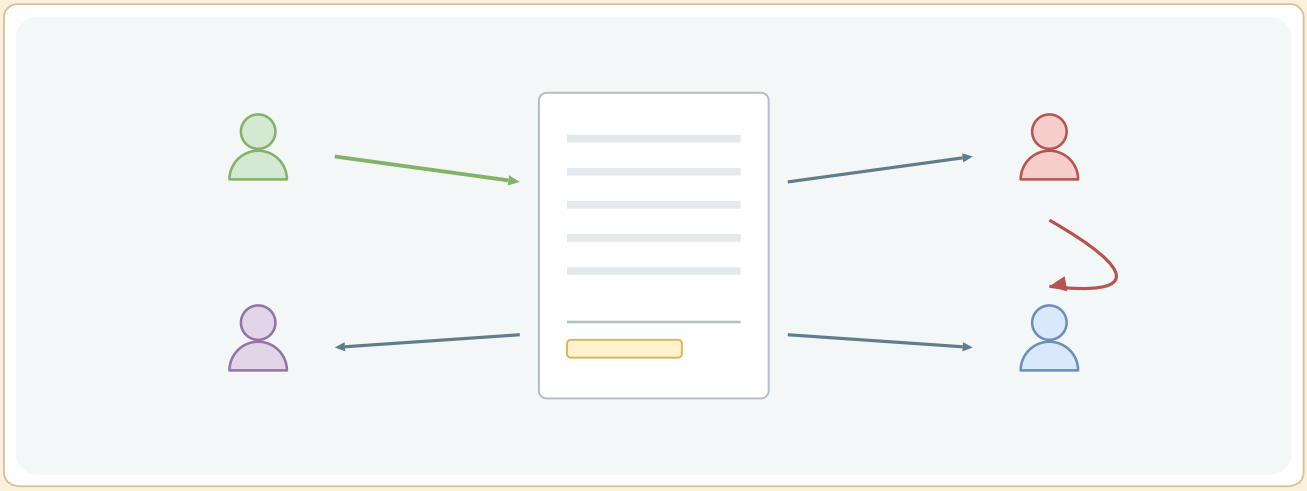

Figure — Splitwise in one picture: people send expenses into one shared record, and the record tells each person what they owe (course diagram)

Problem & clarifying questions

What it is. Splitwise is an app that remembers who paid for what when friends share costs, and tells everyone who owes whom. Everyday analogy: a weekend away with four friends. The hotel goes on Alice's card, Bob covers dinner, Carol gets the cab. By Sunday evening no one can reconstruct the totals. Splitwise is the shared notebook that does the maths.

The hard part is **not** the UI (user interface: the screens people tap). The real decision is *which class owns the money arithmetic*, so the books still balance after every single operation.

Questions to ask the interviewer (with the answers we assume):

Question	Assumed answer
Which split types?	Equal, exact amounts, percentage. More may come later.
Must shares add up to the total exactly?	Yes. If they don't, the whole expense is rejected and no balance changes.
Rounding?	Amounts are money with 2 decimal places. No cent may be lost.
Groups, or only one-to-one?	Both. A group is just a name plus a member list (a trip, a shared flat).
Can a person pay for only themselves?	No. That is not shared spending: at least two people (the payer counts) must be involved.
Settle up?	Yes: record a real payment that reduces a debt.
Simplify debts?	Yes: on request, replace many small debts with a shorter list of transfers.
Multiple currencies, receipts, comments, undo?	Out of scope (say so explicitly).

Requirements

Functional

1. Every user is identified by a name and an email.
2. Users form groups; a group has a name and members.
3. An expense records a description, total, who paid and who shares it.
4. Split types: equal, exact, percent.
5. Shares must add up to the total; otherwise the expense is refused and **nothing changes**.
6. At least two distinct people (the payer plus the sharers) must be involved in an expense.
7. Balances between every pair of people are tracked continuously.
8. A user can query their balance with one specific person, and their overall net balance.
9. Settle up: a real payment reduces a debt.
10. A group can request a simplified settlement plan with fewer transfers.

11. Rounding never loses or creates a cent.
12. Expenses are stored permanently, so a group's history can be listed.

Non-functional

- Correctness of money above everything (exact decimals, no drift).
- Adding a new split type must not change existing classes (Open/Closed Principle).
- Thread-safe: two people adding expenses at the same time must not corrupt the ledger. (A **thread** is one independent line of execution inside a running program; code is **thread-safe** when several threads can use it at the same moment without corrupting its data.)

Use cases

Actors:

- **Member** — adds expenses, settles up, asks what they owe.
- **Group creator** — sets up a group and invites its members.
- **System** — works out each share, checks shares add up, updates the ledger, simplifies debts.

Main use cases: *Add an expense* (which includes *Work out each share*, *Check the shares add up*, *Update the ledger*), *Settle up*, *See what I owe*, *Create a group / add people*, *Simplify the debts*.

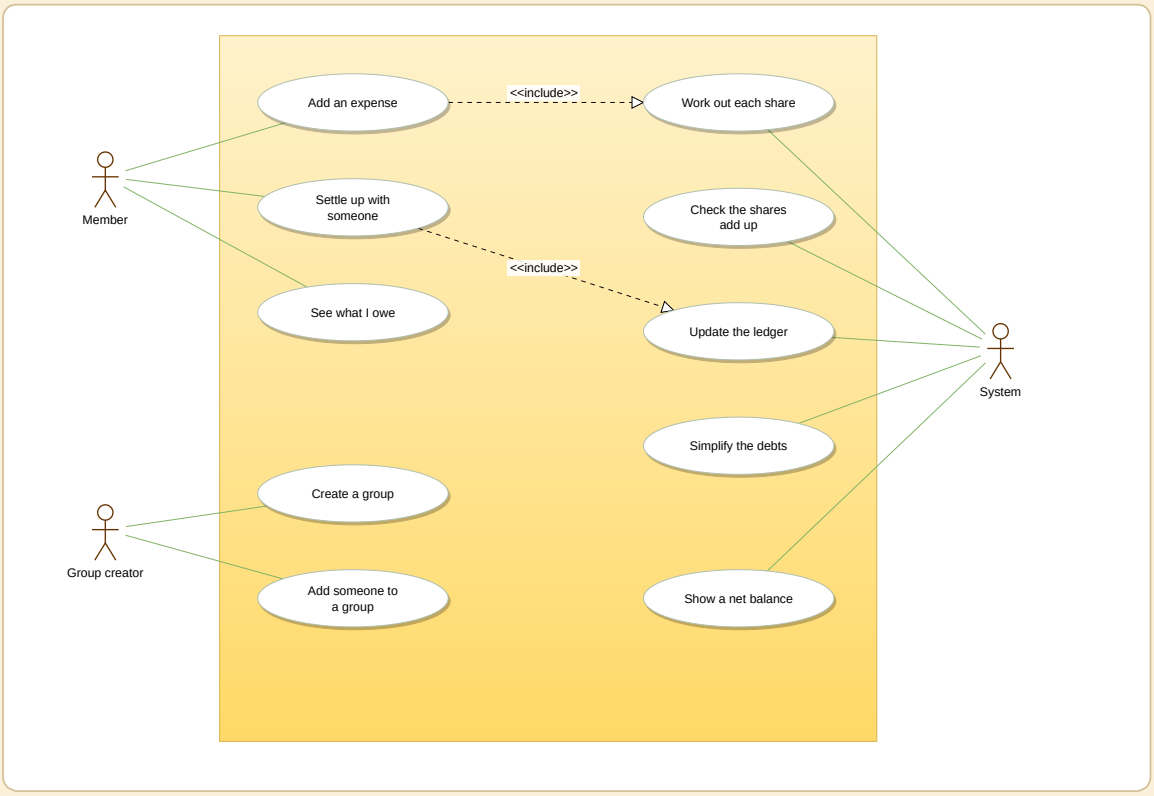

Figure — Splitwise use cases: members add expenses and settle up; the system computes shares, validates them, updates the ledger and simplifies debts (course diagram)

In the figure above, "Add an expense" *includes* the three system steps. "Include" in a use-case diagram means the step always happens as part of the bigger use case.

Core entities

Class	Responsibility
`User` (record)	Identity: id, name, email. No money.
`Group`	A named set of member ids + the list of its expense ids. **Holds no balances.**
`SplitStrategy` (interface)	Turns a total into one `Share` per person.
`EqualSplit`, `ExactSplit`, `PercentSplit`	The three rules.
`Share` (record)	A (person, amount) pair for a single expense (a value object).
`Expense`	Description, total, payer, shares. Validates itself once, when created.
`Ledger`	Who owes whom: exactly **one signed number per pair** of people. One mutator: `adjust`.
`DebtSimplifier`	Greedy minimum-cash-flow: turns net positions into a short list of payments.
`Payment` (record)	One suggested transfer (a suggestion, not a record of money moving).
`Splitwise`	Facade: the one class the app talks to. Orders the steps, contains no arithmetic.
`Money`	Tiny helper: 2-decimal `BigDecimal` values.

A few words from the table: a **record** is Java's short syntax for a class that only carries data, whose fields cannot change after creation; a **value object** is a small object defined only by its values (two shares with the same person and amount are interchangeable); a **mutator** is a method that changes an object's state; a **Facade** is one simple front class that hides several classes behind it; and a **greedy** algorithm makes the best-looking choice at each step without reconsidering earlier choices.

Why the group holds no money. If each group kept its own balances, a person in two groups would have "what Bob owes Alice" stored in two places. Sooner or later the two copies disagree. One ledger, one number per pair, is the single source of truth.

Why `Group → User` is association, not composition. Association = one object refers to another that lives independently. Composition = the part is owned and dies with the whole. Deleting a group must not delete its people, so it is association.

Class diagram

The course builds the model in five stages, and the order is worth copying in an interview because every stage leaves a slice that already works (run out of time and you still have something that runs, not half a diagram):

Stage	Adds	Works afterwards
1	`User`, `Group`	You can say who shares costs
2	`SplitStrategy` + three rules, `Share`	A total becomes one amount per person
3	`Expense` (self-checking)	A bill that does not add up is rejected
4	`Ledger`	Pairwise balances are tracked
5	`Splitwise` facade + `DebtSimplifier`	A whole trip can be recorded, settled and simplified

Here is the finished course diagram:

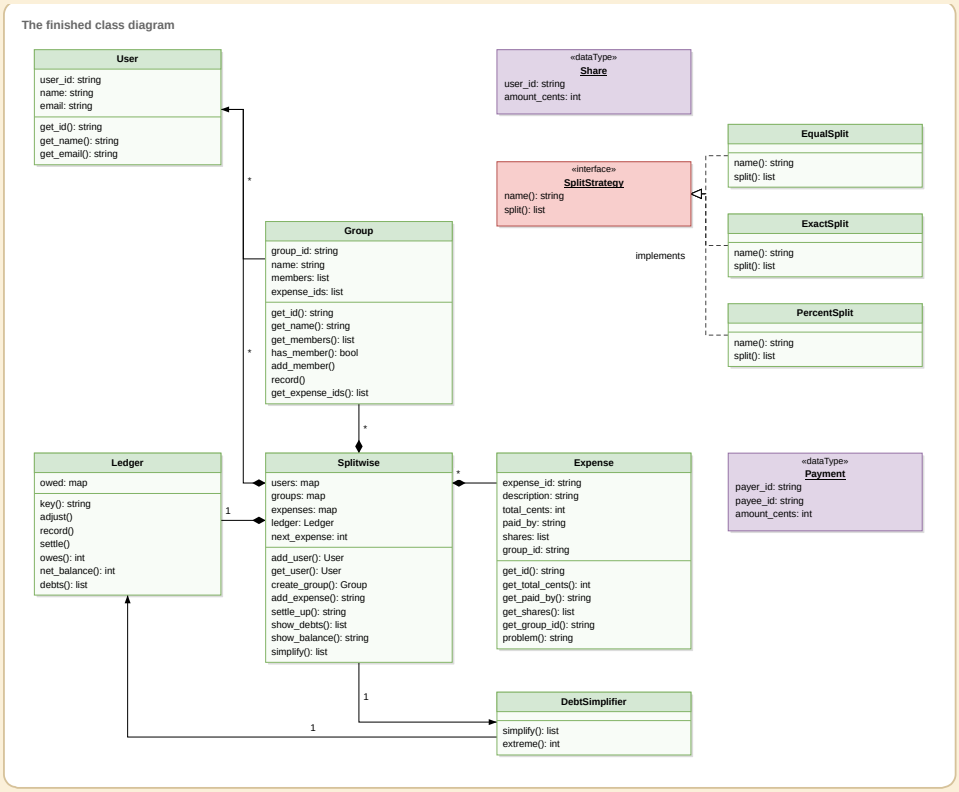

Figure — The finished Splitwise class diagram: service owning users, groups, expenses and the ledger, with the split strategies and the simplifier (course diagram)

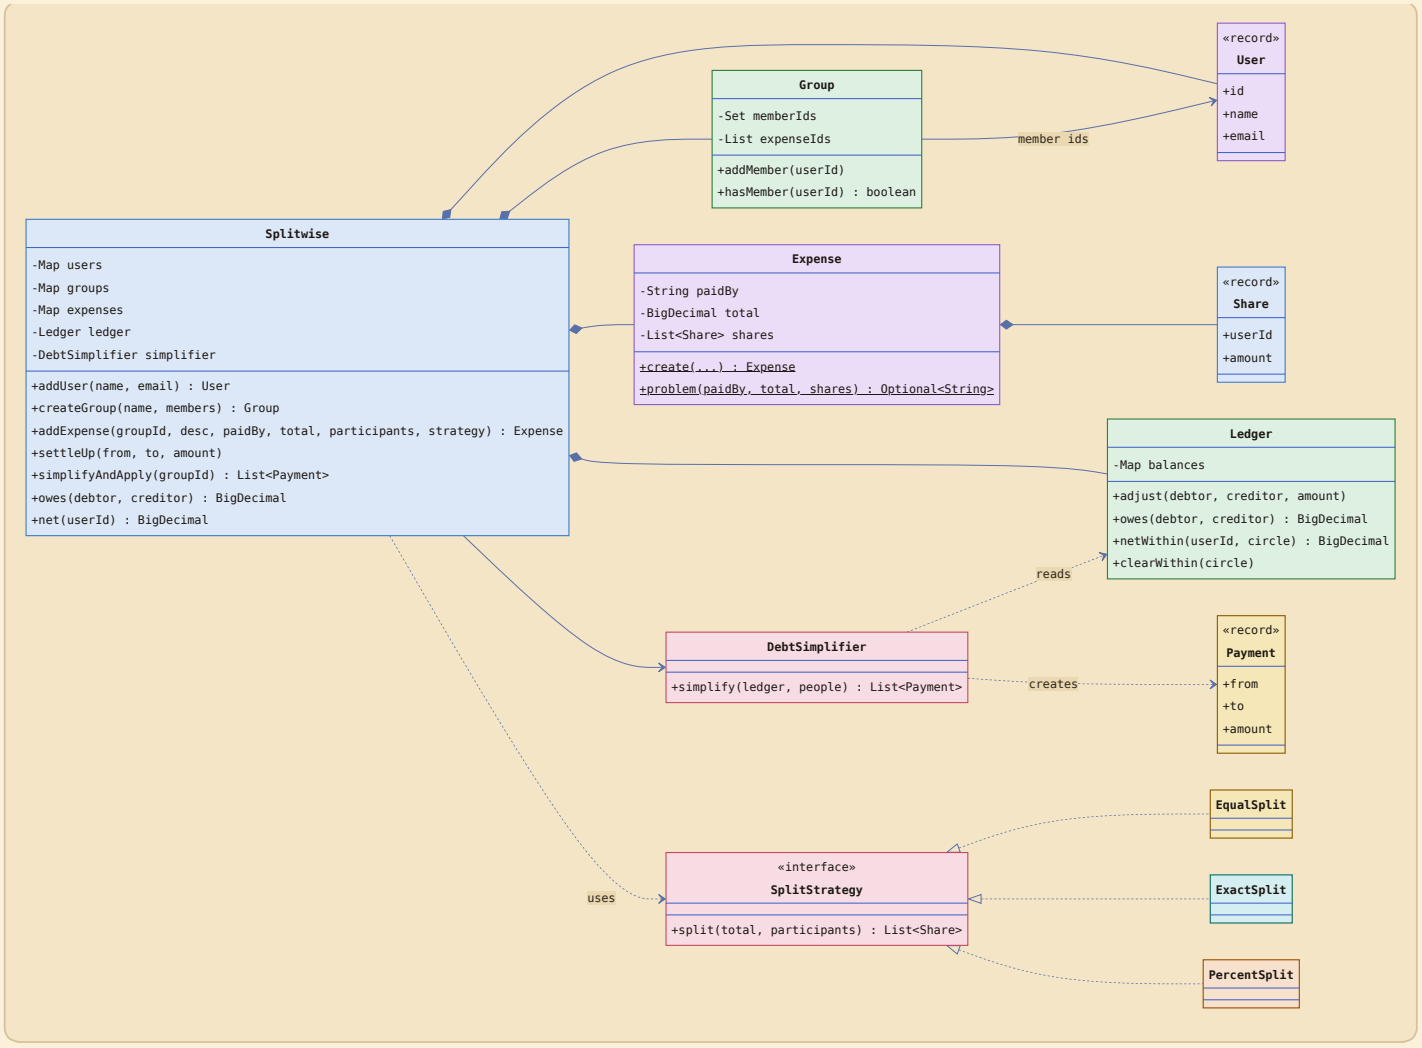
In the figure above, the three split rules meet in one hollow triangle: they all realize the same interface. The service's filled diamonds are composition: it owns users, groups, expenses and the ledger.

Our Java code, as a class diagram:



Key flows

Adding an expense. Nothing touches the ledger until both checks pass.

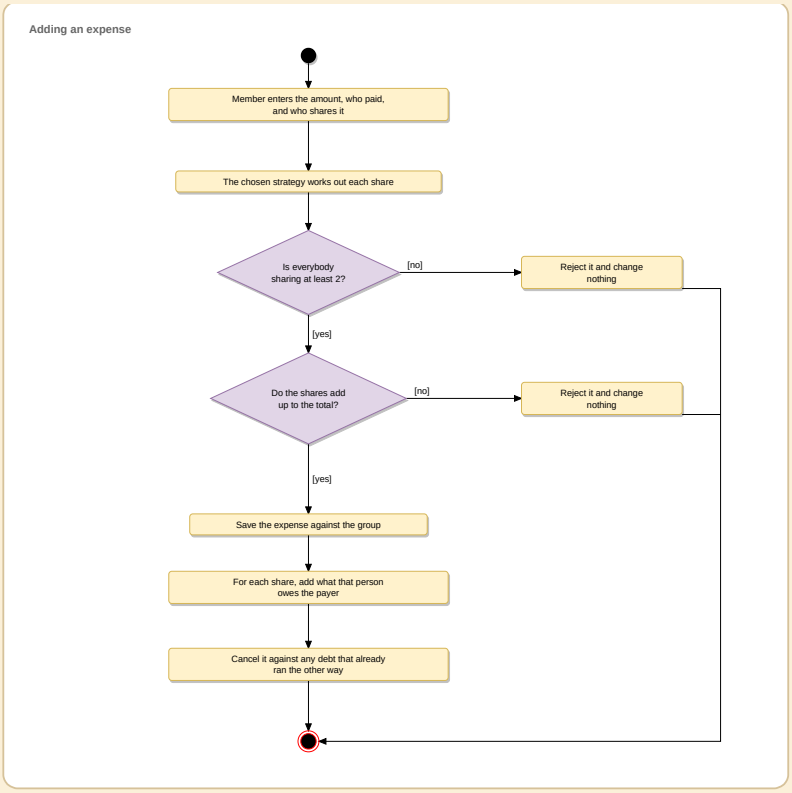


Figure — Adding an expense: the strategy computes shares, the expense checks itself, and only then is the ledger updated (course diagram)

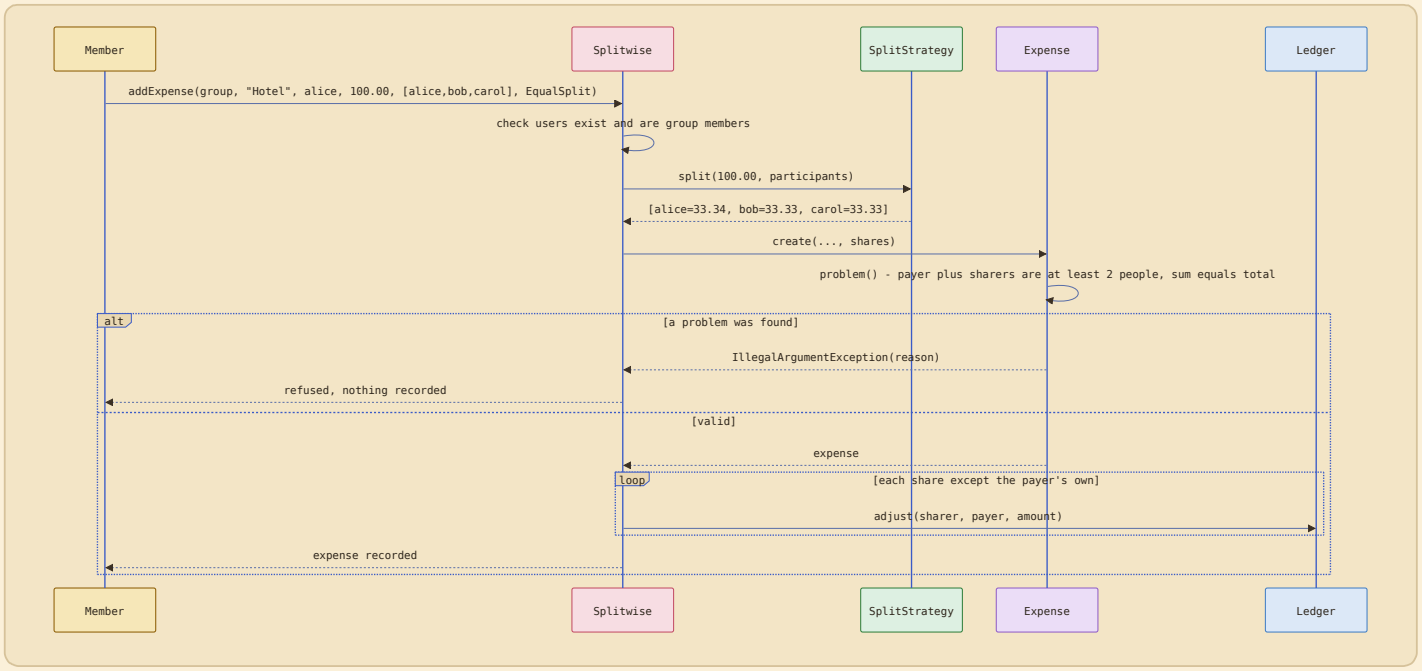

Simplifying a group's debts (minimum cash flow, greedy).

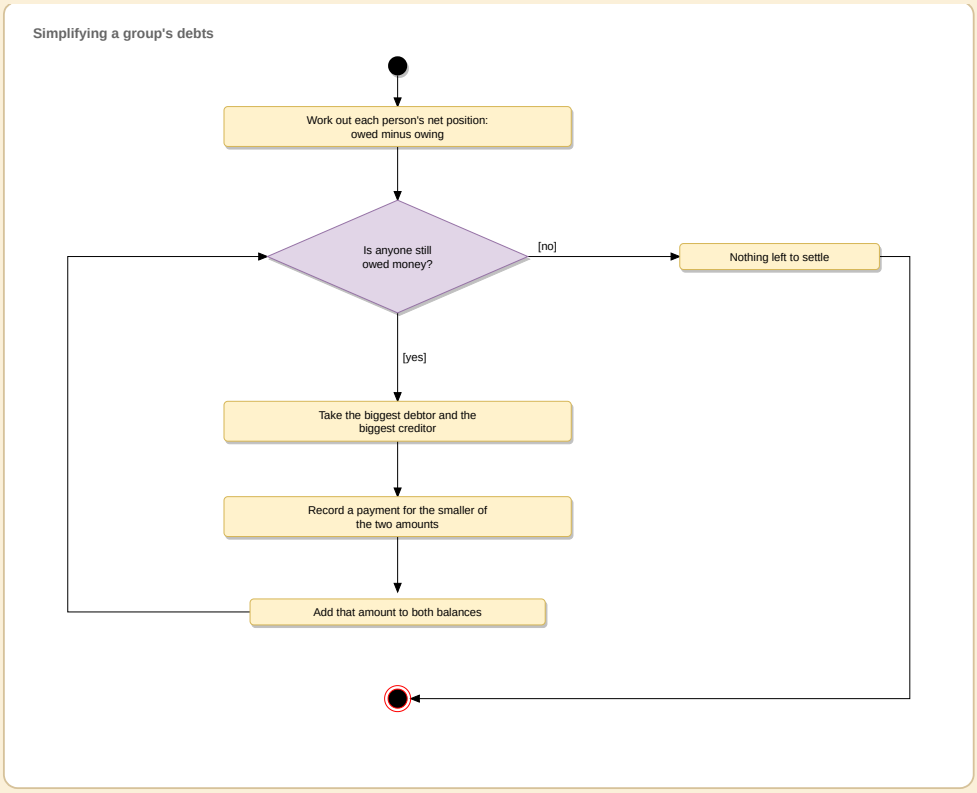

Figure — Simplifying debts: compute net positions, then the largest debtor repeatedly pays the largest creditor until every balance is zero (course diagram)

How it works, step by step:

1. For each member, compute the **net position** = (what others owe them) − (what they owe others). Positive = creditor, negative = debtor. The nets always sum to zero.
2. Put creditors in one max-heap and debtors in another (by amount; ties by name, so the output is deterministic). A **max-heap** is a priority queue that always hands back its largest item first; **deterministic** means the same input always gives the same output.
3. Pop the biggest creditor C and biggest debtor D. Let x = min(C, D). Suggest "D pays C x".
4. Push back whichever side still has a remainder.
5. Stop when a heap is empty (everyone is at zero).

Each round brings at least one person to zero, and the final round brings two to zero, so there are **at most n − 1 payments** for n people. It is **not always the true minimum**: finding the minimum number of transfers is NP-hard (no fast algorithm for it is known: the work needed explodes as the number of people grows; it is related to splitting people into as many zero-sum subgroups as possible). Say that before you are asked.

Design decisions & patterns used

Decision	Why	Alternative rejected
Strategy for split rules (`SplitStrategy`)	The rule arrives from outside and is interchangeable. A fourth rule (by shares, by adjustment) is a new class. Every rule returns the same `List<Share>`, so nothing downstream knows which rule ran.	`if (type == EQUAL) ... else if (type == EXACT)` in the service: every new type edits old, tested code.
Expense validates itself in a **static factory** (a static method that builds the object instead of `new`; here `Expense.create`)	Checked once, when created; after that every class can trust its shares. An invalid expense can never exist.	Checking in the ledger: re-checks on every read and still lets bad objects exist.
`problem()` returns the **reason**, not a boolean	The user sees *why* ("shares add up to 15.00 but the total is 30.00").	`boolean isValid()`: loses the reason.
Ledger stores **one signed number per unordered pair**	A debt is never stored twice, so it can never disagree with itself. Money moving the other way cancels automatically.	Two maps "A owes B" and "B owes A": two places for the truth.
Ledger has **one mutator** (`adjust`)	Expenses, settle-ups and simplification all go through it, so the cancel rule exists in exactly one place.	Separate `addDebt`, `settle`, `reduce` methods each with their own arithmetic.
`DebtSimplifier` separate from `Ledger`	Single Responsibility (each class has one reason to change): *keeping* balances and *planning* settlements change for different reasons.	Putting the algorithm inside the ledger.
`BigDecimal` with explicit rounding; spare cents handed out one at a time	100.00 / 3 = 33.33 × 3 = 99.99 would lose a cent. Equal split gives the extra cent to the first people; percent split lets the last person absorb the remainder.	`double`: 0.1 + 0.2 ≠ 0.3. (The course keeps whole cents in a `long`; that is equally correct. We use `BigDecimal` as this book's standard.)
`Splitwise` is a **Facade**	One entry point; it orders the steps and decides nothing.	UI code calling ledger and strategies directly.

Only one named GoF pattern here (Strategy). (GoF, the "Gang of Four", are the four authors of the 1994 book that catalogued 23 classic design patterns.) That is fine. Good designs do not collect patterns; they use the one that absorbs the change that is likely.

Java implementation

```java
// File: code/lld/ch20/splitwise/Model.java

        app.history(trip.id()).forEach(h -> System.out.println("  " + h));
    }

    private static void tryIt(Runnable r) {
        try {
            r.run();
            System.out.println("  accepted");
        } catch (IllegalArgumentException e) {
```

```
            System.out.println("  refused: " + e.getMessage());
        }
    }
}
```

Walking through the code.

- `Money.of("10.005")` throws, because `RoundingMode.UNNECESSARY` refuses to silently round. Inputs with more than 2 decimals are a bug, not something to hide.
- `EqualSplit` divides with `RoundingMode.DOWN` (33.33), computes the leftover (0.01), and gives one extra cent to the first participant(s). The shares always add up exactly.
- `PercentSplit` rejects percentages that do not total 100, rounds each share with `HALF_EVEN` (banker's rounding: halves go to the even neighbour, which avoids a systematic upward bias), and lets the **last** person absorb whatever remains.
- `Ledger.Pair.of(a, b)` sorts the two ids so (alice, bob) and (bob, alice) are the same key. The sign of the stored value says who owes whom.
- `Splitwise.addExpense` builds shares, then the expense (which validates), and **only then** updates the ledger. That order is requirement 5.
- `settleUp` refuses to pay more than is owed, then calls `adjust(to, from, amount)`: a debt in the reverse direction that cancels the existing one.
- `simplifyAndApply` replaces all debts between the group's members with the simplified plan. Every net position stays the same (the output proves it).

Output:

```
== 1. Equal split with a spare cent
Hotel shares: [alice=33.34, bob=33.33, carol=33.33]
== 2. Exact split
== 3. Percent split
Taxi shares: [alice=16.66, bob=16.66, dave=16.68]
== 4. Invalid expenses are refused, ledger untouched
  refused: shares add up to 15.00 but the total is 30.00
  refused: an expense needs at least two people
  refused: percentages add up to 90, not 100
== 5. Who owes whom
  bob owes alice 23.33
  carol owes alice 16.67
  carol owes bob 13.34
  dave owes carol 16.68
  net alice = 40.00
  net bob = -9.99
  net carol = -13.33
  net dave = -16.68
  bob owes alice: 23.33
== 6. Simplify the group's debts (min cash flow, greedy)
  suggested: dave pays alice 16.68
  suggested: carol pays alice 13.33
  suggested: bob pays alice 9.99
  bob owes alice 9.99
  carol owes alice 13.33
  dave owes alice 16.68
  net alice = 40.00
  net bob = -9.99
  net carol = -13.33
  net dave = -16.68
== 7. Settle up
  refused: dave owes alice only 16.68, cannot pay 999.00
  after a partial payment of 5.00, bob owes alice: 4.99
  (everyone is settled up)
== 8. Group history
  e2 Hotel 100.00 paid by alice [alice=33.34, bob=33.33, carol=33.33]
  e3 Dinner 60.00 paid by bob [alice=10.00, bob=20.00, carol=30.00]
  e4 Taxi 50.00 paid by carol [alice=16.66, bob=16.66, dave=16.68]
```

Look at step 5 and step 6: four pairwise debts became three payments, and every net (alice +40.00, bob −9.99, carol −13.33, dave −16.68) is identical before and after.

Related machine-coding problem: The Ledger Co. (Navi)

Splitwise is not the only "ledger" question you will meet. The Geektrust / Navi machine-coding round (an interview round where you write a complete, runnable program in one or two hours) **"Ledger Co."** also keeps money records, but for **bank loans** (simple interest — interest charged only on the original amount borrowed; a fixed monthly instalment; lump-sum prepayments — extra one-off payments made early) rather than bills shared between friends. It is fully designed, coded and run in **Chapter 21, §21.6**, so it is not repeated here. The comparison is the useful part: both keep **one authoritative record** and compute every answer from it (Splitwise: one signed balance per pair of people; Ledger Co.: one loan per bank and borrower, holding its lump-sum payments), and both use `BigDecimal` with an explicitly named rounding mode. What differs is the rule set: Splitwise's rules are about *who owes whom*, Ledger Co.'s are about *how much has been repaid by a given month*.

Concurrency & edge cases

- **Two expenses at once.** Every public method on `Splitwise` is `synchronized` (a Java keyword that lets only one thread at a time run such methods on the same object), so "build → validate → adjust ledger" is atomic (it happens as one indivisible step that no other thread can see half-done). Simple and correct for one process. At scale you would lock per group or per pair of users (a **lock** is an object only one thread can hold at a time; others wait for it), or store balances in a database and update them in one transaction (a group of database changes that either all succeed or all fail together).
- **Rounding.** Covered by spare-cent distribution and "last person absorbs". Test: 100.00 / 3 must give 33.34 + 33.33 + 33.33.
- **Payer not among the sharers** (Alice pays for Bob and Carol only, or for Bob alone): allowed. Every share becomes a debt to Alice. `Expense.problem` counts the payer as one of the "at least two people", so Alice buying Bob's lunch is a valid expense, while Dave paying only for Dave is refused.
- **Payer's own share:** `adjust(alice, alice, …)` is a no-op (does nothing) by design.
- **Overpaying on settle-up:** refused, so a debt can never flip direction by accident.
- **Unknown user / not a group member:** refused before any computation.
- **Duplicate person in the shares list, negative share, zero total:** refused by `Expense.problem`.
- **Simplify and other groups.** Because the ledger has one number per *pair*, simplifying a group rewrites all debts *between its members*, even ones that came from another group with the same two people. That is the price of the single source of truth. If per-group simplification must not touch other groups, keep the ledger per group *and* a global view derived from them.

Extensions & follow-up questions

- **"Add a split by shares (e.g. 2:1:1)."** A new `ShareRatioSplit implements SplitStrategy`. Nothing else changes.
- **"Delete or edit an expense."** Our ledger stores totals, not history, so undo means re-adding the inverse (`adjust(payer, sharer, amount)` for each share). Cleaner: make the ledger an **append-only list of entries** (like accounting journals / event sourcing — storing every change as an event and rebuilding the current state from them) and compute balances on demand or in a cache (a saved copy of computed results kept for quick reuse; see 20.3). Then delete = append a reversing entry.
- **"Multiple currencies."** Add a `Currency` to every amount (a `Money(amount, currency)` value object) and keep one ledger per currency, or convert at the time of the expense and store the rate used.
- **"Is the greedy always optimal?"** No. Counter-example: nets A −6, B −5, C +2, D +4, E +5. Greedy: A pays E 5, B pays D 4, then two more small payments to C = **4 payments**. Optimal: B pays E 5 (they cancel exactly), A pays D 4 and C 2 = **3 payments**. The optimum groups people into as many zero-sum subsets as possible, which needs an exponential search; greedy is the accepted interview answer.
- **"Isn't `Splitwise` doing too much?"** A fair criticism: it holds users, groups, expenses *and* the ledger. At larger scale, give each of the four its own repository (store) and let `Splitwise` shrink to the part that orders the steps. Say this before the interviewer does.
- **"Show a user's activity feed."** Keep expenses and settle-ups as events; the feed is a query over them.
- **"Notify people when an expense is added."** Publish an `ExpenseAdded` event to an Observer / the notification service in 20.2.

Real-world example

Splitwise really does offer a "simplify debts" option for groups: when it is on, the app shows each member a small number of payments to make instead of every pairwise debt, exactly the net-position idea above. Payment apps with "split the bill" features face the same rounding problem and solve it the same way: one person absorbs the leftover cent.

In the interview

30-second answer: "Users and groups hold no money. Each split rule is a `SplitStrategy` that returns shares. An `Expense` validates itself once: at least two people, shares add to the total. The `Ledger` keeps one signed number per pair of people and has a single `adjust` method, so debts cancel automatically. Settling up is just an adjust in the other direction. Simplification uses net positions and a greedy biggest-debtor-pays-biggest-creditor loop: at most n − 1 payments, not always the true minimum."

Tip: reach the split rules early and say the phrase "one class per split rule" while you draw them; that is the part of the question with a pattern name. Then invest your time in the ledger, because the one-number-per-pair decision is what keeps everything else short.

Suggested 40-minute plan: clarify (5) → entities + the "no money in groups" decision (5) → Strategy for splits and the cents problem (8) → Expense validation (5) → Ledger with one number per pair (7) → simplify algorithm (5) → concurrency and extensions (5).

Likely follow-ups (with answers):

- *"What if 100 does not divide by 3?"* → Hand out spare cents one by one; the total is always exact.
- *"How do you simplify debts?"* → Net positions + greedy; mention n − 1 bound and that optimal is NP-hard.
- *"Why not store balances in the group?"* → A person in two groups would have two copies of the truth.

Self-check

1. Why does `Group` hold no balances? → So each debt lives in exactly one place (the ledger); two copies would eventually disagree.
2. Split 10.00 equally among 3 people. → 3.34, 3.33, 3.33.
3. Why does `Expense.problem` return a `String` instead of a `boolean`? → So the caller can show the reason it was refused.
4. What is the maximum number of payments the greedy simplifier suggests for n people? → n − 1.
5. Why compare `BigDecimal` with `compareTo` rather than `equals`? → `equals` also compares scale, so `2.0` does not equal `2.00`.
6. Alice pays 20.00 for Bob's lunch and Bob owes the whole 20.00. Is that a valid expense? → Yes. Two people are involved (payer and sharer), even though only one of them has a share.

TL;DR

- **Strategy** for split rules; every rule returns shares.
- **Expense validates itself** once; invalid expenses never exist.
- **Ledger = one signed number per pair**, one mutator; settle-up is a reverse adjust.
- **Simplify** = net positions + greedy; ≤ n − 1 payments; optimal is NP-hard.
- **BigDecimal**, explicit rounding, no lost cents.

20.2 Design a Notification Service

Problem & clarifying questions

`What it is.` A notification service is the component of a product responsible for emails, text messages (SMS) and push alerts ("Your order has shipped", "Your login code is 482913"). Everyday analogy: a post office

counter. Many departments hand it letters; the counter picks the right delivery method, respects "do not disturb" notes, retries if the courier fails, and keeps a receipt for every letter.

Why it is a design question. Every product grows one. It starts as one `sendEmail()` function. Then someone adds SMS. Then "don't wake me at 3 a.m.". Then marketing wants "max 2 promos per hour". Six months later one method has fourteen `if`s and nobody dares touch it. The whole exercise is: **where should each of those additions have gone instead?**

Question	Assumed answer
Channels?	Email, SMS, push. More later (WhatsApp, Slack).
Who chooses the channel?	The user, **per kind** of notification (SMS for deliveries, email for newsletters), in order of preference.
Wording?	Templates with placeholders, e.g. `Hi {name}, it arrives {eta}.`
Quiet hours?	Yes, per user; they can wrap past midnight (22:00–07:00). Urgent messages (login codes) ignore them.
Rate limits?	At most N notifications of one kind per user per hour.
Failures?	Retry a channel up to a limit, then fall back to the next accepted channel; if all fail, record FAILED.
Audit?	Every attempt recorded: SENT, FAILED or SUPPRESSED, and why.
Sync or async? (synchronous = caller waits; asynchronous = caller moves on)	The caller should not wait for a slow SMS gateway (the provider service that actually sends texts).
Bulk sends / translations / open tracking / unsubscribe links?	Out of scope.

Requirements

Functional

1. A user has a name, email, phone number and device token (the address a push service uses for one phone).
2. Channels: email, SMS, push.
3. Each user chooses accepted channels **per kind** of notification, in order.
4. The text for each kind comes from a template with placeholders ("holes") filled in per request.
5. Users can set quiet hours; nothing normal is sent during them.
6. Urgent notifications ignore quiet hours.
7. A user receives no more than N notifications of a given kind in any hour.
8. A channel that fails is retried, but only a bounded number of times.
9. When a channel runs out of retries, the service falls back to the user's next accepted channel.
10. When no channel succeeds, the outcome is stored as FAILED.
11. Every attempt is recorded with its outcome and reason.
12. Adding a channel, **or** a new reason to hold a message back, requires no edit to the service class.

Non-functional: the caller is not blocked by slow providers (async option); thread-safe under concurrent sends; testable without waiting for real time (injected clock); a broken listener must never break delivery. An **injected** clock is one handed to the class from outside (instead of the class reading the system time itself), so a test can pass in a fake clock it moves by hand; a **listener** is an object that has asked to be told when something happens.

Use cases

Actors: **Product code** (asks for a notification), **Person** (chooses channels, sets quiet hours), **Operator** (adds channels, watches outcomes), **Service** (renders, checks rules, tries channels, retries, records).

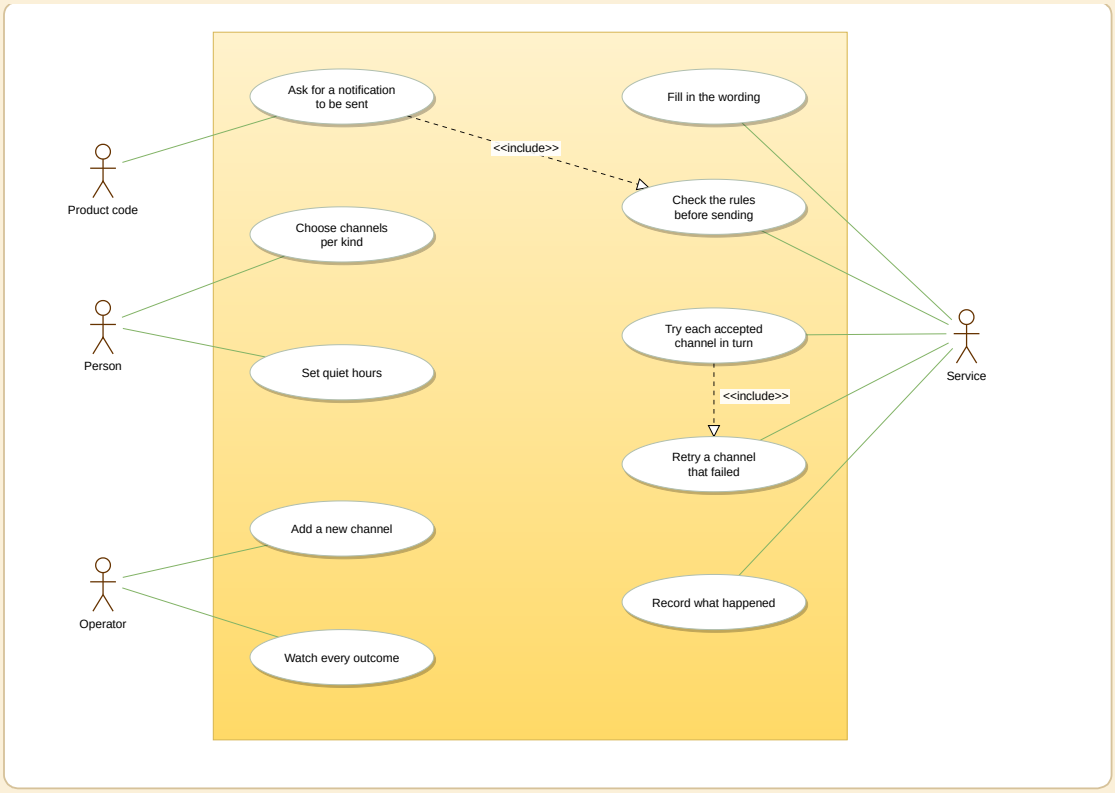

Figure — Notification service use cases: product code asks for a notification; the service checks rules, fills in the wording, tries each channel with retries and records the outcome (course diagram)

Core entities

Class	Responsibility
`User` (record)	Who someone is: id, name, email, phone, device token.
`Preferences`	What they accept: ordered channels per kind; quiet hours (with midnight wrap logic in **one** place).
`Template` (record)	Subject + body with `{holes}`; `render(values)` → `Message`.
`Message` (record)	The finished subject and body, identical on every channel.
`NotificationRequest` (record)	One ask: kind, user, values, priority (NORMAL / URGENT).
`Gateway` (interface)	The external provider (SMTP server, SMS gateway, push service). Swappable and fakeable.
`NotificationChannel` (abstract)	**Template Method**: the final `deliver()` holds the retry-with-backoff loop; subclasses supply only `addressOf(user)`.
`EmailChannel`, `SmsChannel`, `PushChannel`	Three tiny subclasses.
`ChannelFactory`	**Simple Factory**: channel type → channel object.
`RetryPolicy` (record)	Max attempts + initial backoff (doubles each time).
`SendRule` (interface)	**Strategy**: one reason not to send. Returns the reason text, or empty.
`QuietHoursRule`, `RateLimitRule`	Two rules. Quiet hours knows urgent bypasses it; rate limit counts only *successful* sends.
`DeliveryRecord` (record)	What happened: status, channel, attempts, reason.
`DeliveryListener` (interface)	**Observer**: told every outcome. `LoggingListener`, `MetricsListener`.
`TimeSource`	Where "now" comes from (a manual clock in tests).
`NotificationService`	Thin coordinator: rules → preferences → render → channels in order → `finish()`. Decides nothing itself.

Terms from the table: **SMTP** is the protocol mail servers use to pass email along; a **fake** is a pretend version of a real dependency used in tests; an **abstract** class cannot be created on its own and exists to be extended; a `final` method cannot be overridden by subclasses; **backoff** means waiting a little longer before each new retry, so a struggling provider gets time to recover.

Why `User` and `Preferences` are separate classes. Who you are rarely changes; what you are willing to receive changes often. Separate reasons to change → separate classes (Single Responsibility Principle).

Class diagram

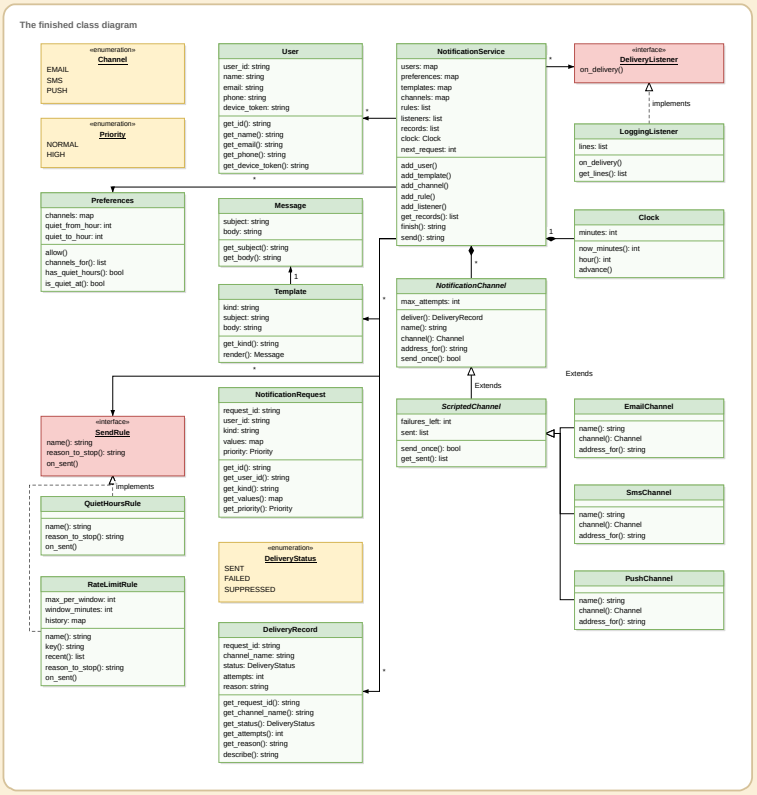

Figure — The finished notification service class diagram: the service in the middle, the channel hierarchy with the retry in the parent, the send rules, templates, preferences and the delivery listeners (course diagram)

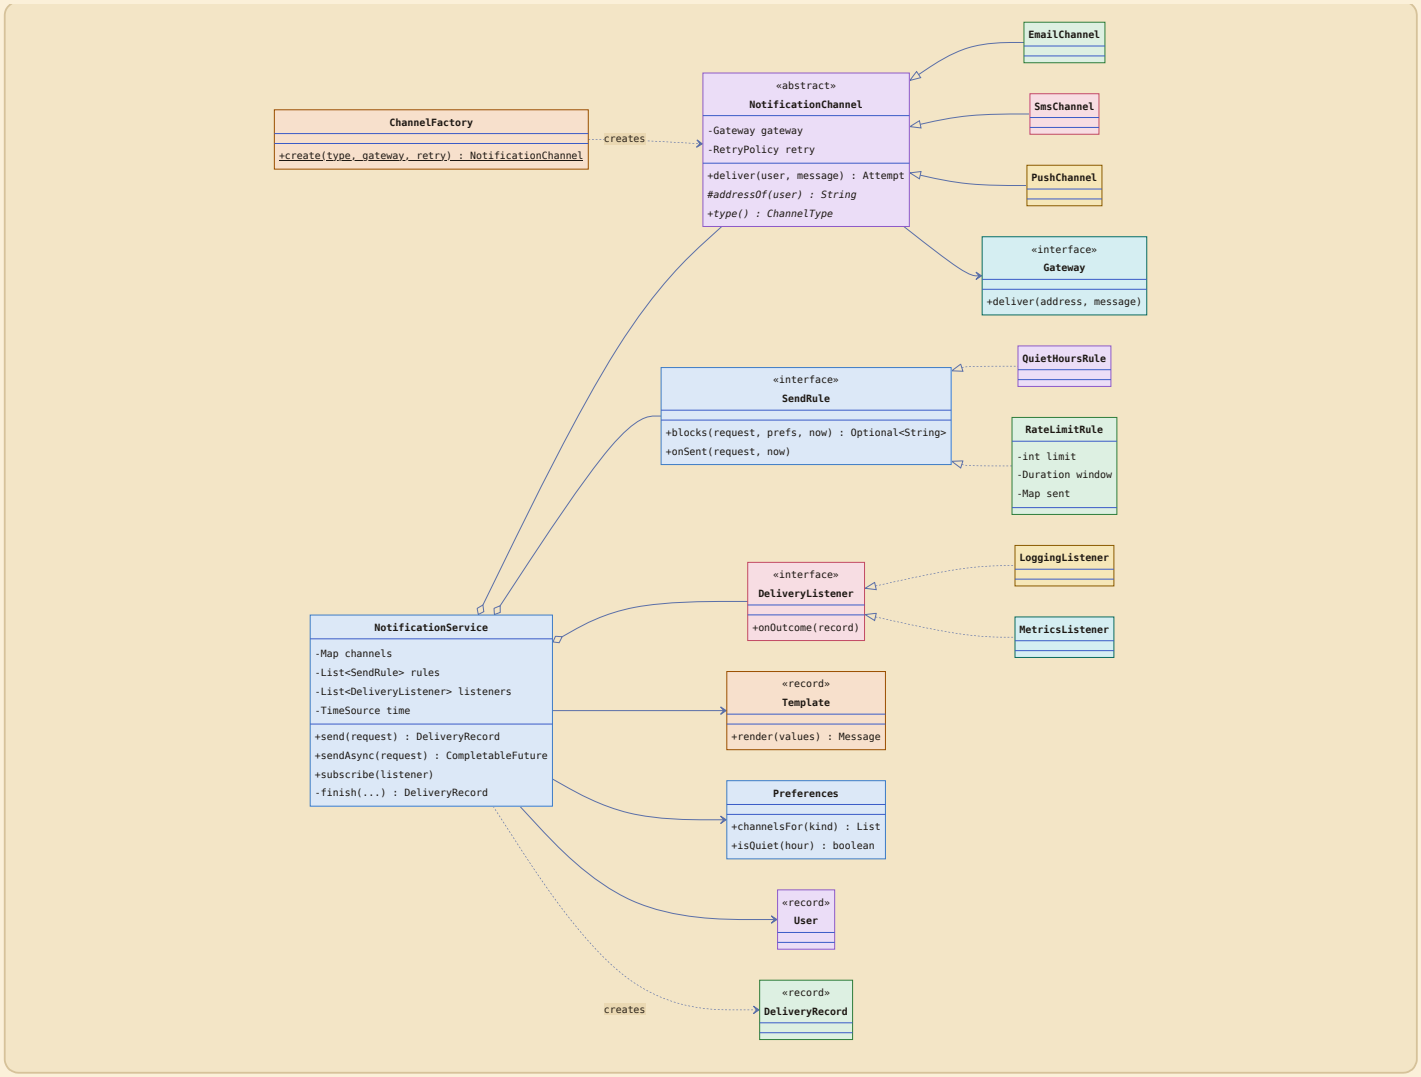
In the figure above, notice that the three channel classes are tiny: all the behaviour that makes sending reliable lives in the abstract parent.

The course reaches this diagram in five build stages, each leaving something that already works: (1) `User` + `Preferences` (you can ask what a person accepts, and when); (2) `Template` + `Message` + `NotificationRequest` (wording filled in once); (3) the channel hierarchy (delivery with retries and an outcome); (4) the `SendRule`s (a notification can be stopped before sending); (5) `NotificationService` + listeners (end-to-end sending, observable by any listener). Reuse this order when you interview.



Key flows

Sending one notification. A rule (or a missing channel preference) may stop it before any work is done; otherwise channels are tried in the user's order until one succeeds.

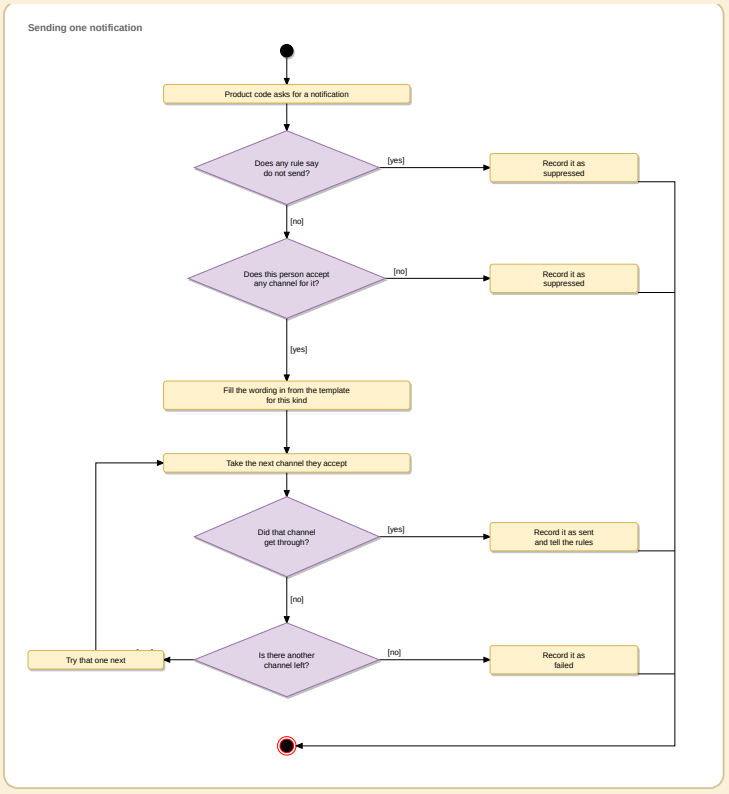


Figure — Sending one notification: ask every rule, render once, try each accepted channel in turn, and record sent / failed / suppressed (course diagram)

Inside one channel — the retry loop, which exists exactly once, in the abstract parent:

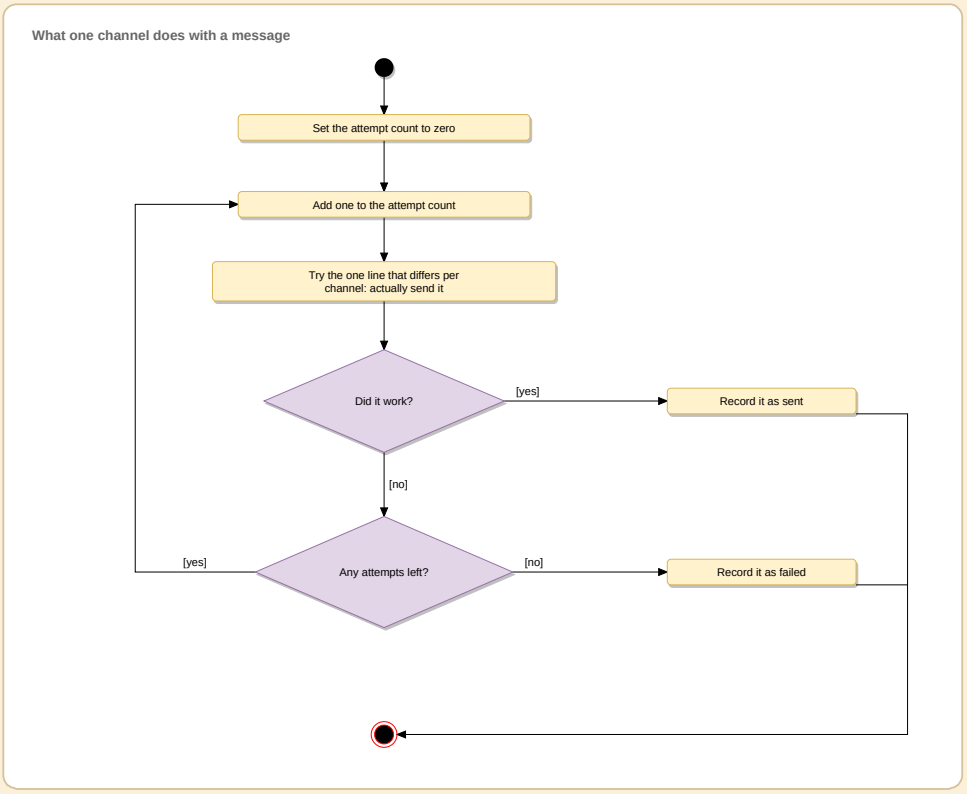

Figure — One channel's delivery loop: attempt, and on failure retry while attempts remain; then report success or give up (course diagram)

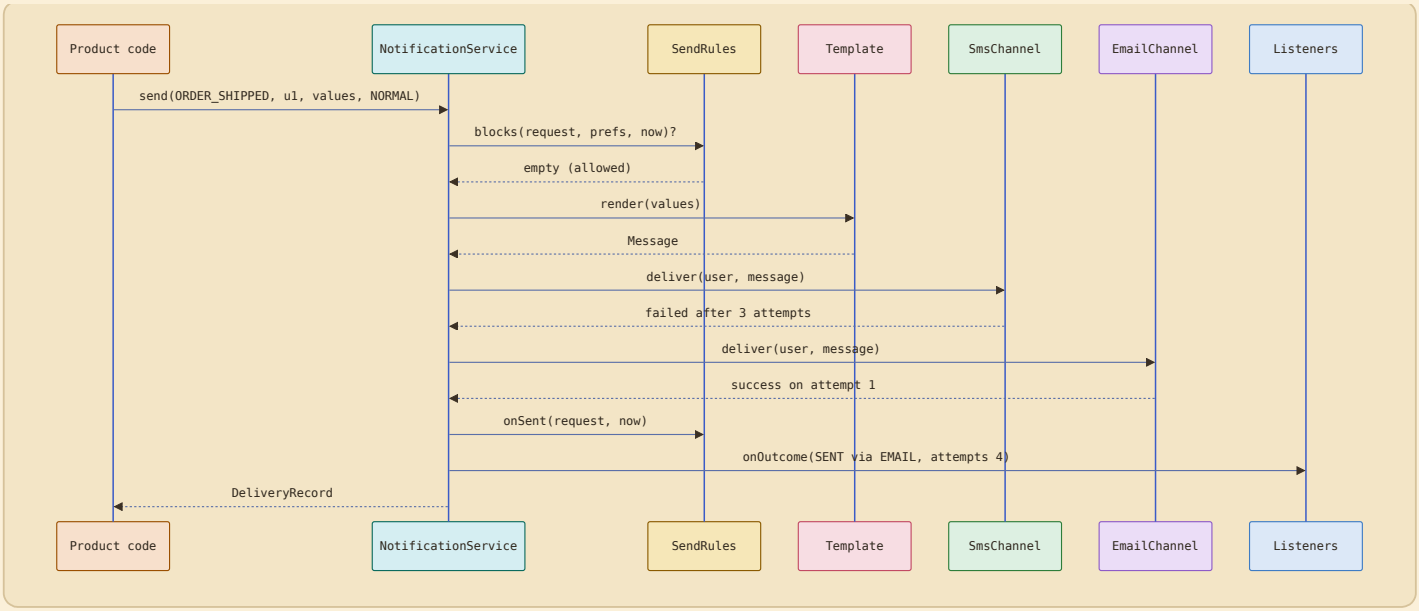

Product code
NotificationService
SendRules
Template
SmsChannel
EmailChannel
Listeners
send(ORDER_SHIPPED, u1, values, NORMAL)
blocks(request, prefs, now)?
empty (allowed)
render(values)
Message
deliver(user, message)
failed after 3 attempts
deliver(user, message)
success on attempt 1
onSent(request, now)
onOutcome(SENT via EMAIL, attempts 4)
DeliveryRecord
Product code
NotificationService
SendRules
Template
SmsChannel
EmailChannel
Listeners

Design decisions & patterns used

Pattern / decision	Where	Why	Alternative rejected
Template Method	`NotificationChannel.deliver()` is `final`; subclasses fill `addressOf()`	The retry loop is identical for all channels. Write it once; new channels inherit reliability. Only a *step* varies, not the whole algorithm.	Copying the loop into every channel (they drift apart), or Strategy (would replace the whole method, not one step).
Strategy	`SendRule`	Every "reason not to send" is its own class. A new rule (e.g. "user unsubscribed", "duplicate within 5 minutes") is a new class plus one line in the wiring code.	`if (quiet) … if (tooMany) …` inside `send`.
Observer	`DeliveryListener`	Logs, dashboards, alerts all want outcomes. The service announces; it doesn't know who listens.	Hard-coding logging/metrics in the service; it grows forever.
Simple Factory	`ChannelFactory`	One place maps `ChannelType` → class; config can list channel names.	`new SmsChannel(...)` scattered through wiring code.
Adapter (target interface; an adapter converts one API into the shape your code expects)	`Gateway`	Each real provider SDK (the vendor's client library) has its own API (the set of calls a library or service offers to programs); an adapter per provider implements `Gateway`. Also lets tests use a fake.	Channels calling vendor SDKs directly.
Rule returns **reason text**, not boolean	`SendRule.blocks`	The reason is recorded (requirement 11).	`boolean allowed()` loses why.
Urgency handled **inside** the rule	`QuietHoursRule`	The service doesn't need to know which rules urgent messages ignore.	A special case in the service.
Rate limit counts only **successful** sends	`onSent` hook	A suppressed/failed message shouldn't use up the user's hourly allowance.	Counting at check time.
Single exit `finish()`	Service	Every path stores a record and notifies listeners. A second exit that forgot would leave invisible gaps.	Returning from many places.
Template rendered **once**	Service	Every channel gets the same text; a wording change is one edit.	Wording inside each channel.

Using three patterns here is not decoration: each one soaks up a *separate* axis of change — another channel (Template Method + Factory), another reason to hold a message back (Strategy), another party interested in outcomes (Observer).

                            .quietHours(22, 7));
            svc.register(new User("u2", "Ben", "ben@mail.com", null, "tok-ben"),
                    new Preferences().accept("ORDER_SHIPPED", ChannelType.PUSH));

            Map<String, String> order = Map.of("orderId", "A-17", "name", "Asha", "eta", "Tuesday");

            System.out.println("== 1. Normal send over the first accepted channel (SMS)");
            svc.send(new NotificationRequest("ORDER_SHIPPED", "u1", order, Priority.NORMAL));

            System.out.println("== 2. SMS fails 3 times -> retried, then falls back to EMAIL");
            twilio.failNext(3);
            svc.send(new NotificationRequest("ORDER_SHIPPED", "u1", order, Priority.NORMAL));

            System.out.println("== 3. Quiet hours at 23:00: normal is suppressed, urgent goes through");
            clock.set(LocalDateTime.of(2026, 9, 28, 23, 0));
            svc.send(new NotificationRequest("PROMO", "u1", Map.of("name", "Asha", "pct", "20"), Priority.NORMAL));
            svc.send(new NotificationRequest("OTP", "u1", Map.of("code", "482913"), Priority.URGENT));
```

```
            System.out.println("== 4. Rate limit: 2 PROMO per hour, the 3rd is suppressed");
            clock.set(LocalDateTime.of(2026, 9, 29, 10, 0));
            for (int i = 0; i < 3; i++)
                svc.send(new NotificationRequest("PROMO", "u1", Map.of("name", "Asha", "pct", "" + (10 + i)),
Priority.NORMAL));
            clock.set(LocalDateTime.of(2026, 9, 29, 11, 1));
            System.out.println("  ...61 minutes later the window has moved:");
            svc.send(new NotificationRequest("PROMO", "u1", Map.of("name", "Asha", "pct", "50"), Priority.NORMAL));

            System.out.println("== 5. Every channel gives up -> FAILED");
            fcm.failNext(3);
            svc.send(new NotificationRequest("ORDER_SHIPPED", "u2",
                    Map.of("orderId", "B-2", "name", "Ben", "eta", "Friday"), Priority.NORMAL));

            System.out.println("== 6. No accepted channel for this kind -> SUPPRESSED");
            svc.send(new NotificationRequest("PROMO", "u2", Map.of("name", "Ben", "pct", "5"), Priority.NORMAL));

            System.out.println("== 7. Template value missing -> FAILED, still recorded through finish()");
            svc.send(new NotificationRequest("OTP", "u1", Map.of(), Priority.URGENT));

            System.out.println("== 8. Async send (caller not blocked)");
            DeliveryRecord r = svc.sendAsync(new NotificationRequest("ORDER_SHIPPED", "u2",
                    Map.of("orderId", "B-3", "name", "Ben", "eta", "Monday"), Priority.NORMAL)).get();
            System.out.println("  future completed with " + r.status() + " via " + r.channel());

            System.out.println("== Metrics: " + metrics.counts() + ", history size = " + svc.history().size());
        }
    }
}
```

Walking through the code.

- `Preferences.isQuiet` handles the midnight wrap: if start ≤ end (09–17) it is a simple range; otherwise (22–07) it is "after start **or** before end".
- `Template.render` uses a regex (regular expression: a small pattern language for finding text) `\{(\w+)}` and `Matcher.appendReplacement` with `Matcher.quoteReplacement`, so a value containing `$` or `\` is inserted literally. A missing value is an error, not a silent `{name}` in a customer's inbox.
- `NotificationChannel.deliver` is `final`: subclasses cannot break the retry loop. Backoff doubles after each failure (exponential backoff). The course's version retries immediately and names that as a weakness (three back-to-back tries against a server that is down are three quick failures); the waiting belongs in this one parent loop, which is exactly where we put it.
- `RateLimitRule` keeps a deque (double-ended queue: items can be added or removed at either end) of send times per (user, kind) and **prunes** old ones on every check, so one key's deque never holds more than `limit` entries (the course's version never discarded old timestamps and flagged that as a known leak — a **memory leak** is memory a program keeps holding although it no longer needs it). The *map of keys* still grows with every (user, kind) pair ever seen; a production version adds a periodic sweep that drops empty or stale deques, or uses a fixed-size window counter per key.
- `NotificationService.send` has one exit, `finish()`. Even a template with a missing value is caught and recorded as FAILED (step 7 of the output) instead of escaping as an exception that no listener would ever hear about. A listener that throws is caught so it cannot break delivery.
- `NotificationRequest` copies its values into a `TreeMap` (a map that keeps its keys sorted), so the values are always in the same order and the same request always renders the same text: handy when comparing test output.
- `sendAsync` runs `send` on a worker pool (a fixed set of threads that pick up tasks as they arrive) and returns a `CompletableFuture` (a handle to a result that will be ready later); in production a durable queue (Kafka, SQS) would sit here instead.

> **Key term — message queue:** a queue is a waiting line for work. Producers put messages in at one end; workers take them out at the other, at their own pace. A **durable** queue stores its messages on disk, so they survive a crash or restart. **Kafka** (an open-source log-based messaging system) and **Amazon SQS** (a managed queue service in AWS, Amazon's cloud) are two widely used examples. See System Design Fundamentals for queues in larger systems.

Output:

```
== 1. Normal send over the first accepted channel (SMS)
    SMS-GW -> +91-98450 : Order A-17 shipped | Hi Asha, it arrives Tuesday.
  [log] SENT       ORDER_SHIPPED user=u1 channel=SMS attempts=1
== 2. SMS fails 3 times -> retried, then falls back to EMAIL
    SMTP -> asha@mail.com : Order A-17 shipped | Hi Asha, it arrives Tuesday.
  [log] SENT       ORDER_SHIPPED user=u1 channel=EMAIL attempts=4
== 3. Quiet hours at 23:00: normal is suppressed, urgent goes through
  [log] SUPPRESSED PROMO         user=u1 channel=- attempts=0 reason=quiet hours
    FCM -> tok-asha : Your code | 482913 is your login code.
  [log] SENT       OTP           user=u1 channel=PUSH attempts=1
== 4. Rate limit: 2 PROMO per hour, the 3rd is suppressed
    SMTP -> asha@mail.com : Sale! | Asha, 10% off today.
  [log] SENT       PROMO         user=u1 channel=EMAIL attempts=1
    SMTP -> asha@mail.com : Sale! | Asha, 11% off today.
  [log] SENT       PROMO         user=u1 channel=EMAIL attempts=1
  [log] SUPPRESSED PROMO         user=u1 channel=- attempts=0 reason=rate limit 2 per 60 min
  ...61 minutes later the window has moved:
    SMTP -> asha@mail.com : Sale! | Asha, 50% off today.
  [log] SENT       PROMO         user=u1 channel=EMAIL attempts=1
== 5. Every channel gives up -> FAILED
  [log] FAILED     ORDER_SHIPPED user=u2 channel=- attempts=3 reason=all channels failed, last PUSH: FCM timeout
== 6. No accepted channel for this kind -> SUPPRESSED
  [log] SUPPRESSED PROMO         user=u2 channel=- attempts=0 reason=user accepts no channel
== 7. Template value missing -> FAILED, still recorded through finish()
  [log] FAILED     OTP           user=u1 channel=- attempts=0 reason=template: missing value for {code}
== 8. Async send (caller not blocked)
    FCM -> tok-ben : Order B-3 shipped | Hi Ben, it arrives Monday.
  [log] SENT       ORDER_SHIPPED user=u2 channel=PUSH attempts=1
  future completed with SENT via PUSH
== Metrics: {SENT=7, FAILED=2, SUPPRESSED=3}, history size = 12
```

Step 2 shows Template Method + fallback: 3 failed SMS attempts + 1 successful email = 4 attempts. Step 4 shows that the suppressed third promo did not count: an hour later the window has moved and sending works again.

Concurrency & edge cases

- **Shared state is thread-safe:** users/preferences/templates in `ConcurrentHashMap` (a map built for many threads to read and write at once); listeners and history in `CopyOnWriteArrayList` (a list that copies itself on every write, so reads need no lock: cheap reads, rare writes); the rate-limit deque is locked per key.
- **Check-then-act gap in rate limiting.** (Check-then-act: code first checks a condition, then acts on it, and another thread can change things in between.) Two concurrent (running at the same time) sends for the same user and kind can both pass `blocks()` before either calls `onSent()`, so the limit can be exceeded by the number of concurrent sends. Fixes: reserve a slot atomically at check time and release it if the send fails, or serialize sends per user (run them strictly one after another, e.g. a per-user queue, which also keeps their order).
- **Retries block a worker thread.** With `Thread.sleep` backoff, a slow provider ties up threads. Real systems re-enqueue the message with a delay instead (a "retry topic" — a topic is a named channel that messages are published to — or delayed queue, which hands a message out only after a set delay).
- **Idempotency.** A retry after a timeout (giving up on waiting for a reply after a set time) may deliver twice (the provider may have sent it but the reply was lost). Pass an idempotency key / message id to providers that support it, and make receivers tolerate duplicates.

> **Key term — idempotency:** an operation is **idempotent** when doing it twice has the same effect as doing it once ("set the balance to 10" is; "add 10 to the balance" is not). Retries are only safe on idempotent operations. An **idempotency key** is a unique id sent with a request, so the receiver can recognise a repeat and skip it. More in System Design Fundamentals.

- **Missing address** (user has no phone): the channel returns a failed attempt with 0 tries and the next channel is used.
- **Unknown kind / no template:** FAILED with a reason; **no accepted channel:** SUPPRESSED.

- **Time zones:** quiet hours should use the *user's* time zone; store a `ZoneId` (Java's type for a time zone) in preferences and convert `Instant` (an exact moment on the global timeline) → local hour.

Extensions & follow-up questions

- **"Add WhatsApp."** One `WhatsAppChannel extends NotificationChannel` (3 small methods), one enum value (an enum is a type with a fixed list of named values), one `Gateway` adapter. Nothing else changes.
- **"Someone is getting too many messages."** A new `SendRule` (e.g. a global daily cap, or "dedupe identical messages within 10 minutes"), not a new `if`.
- **"Send to a million users (a campaign)."** Split into a fan-out stage (fan-out: one input turned into many copies or tasks) that expands the audience into individual requests on a queue, and many workers that each run this `send`. Rate-limit per provider too (SMS gateways have throughput limits — **throughput** is how much work gets done per unit of time, e.g. messages per second).
- **"Priorities."** Separate queues per priority (OTP — one-time password, the login-code kind — queue drained first), or a `PriorityBlockingQueue` (a thread-safe queue that always hands out the highest-priority item next).
- **"Localization."** (Localization: adapting text to a user's language and region.) Key templates by (kind, locale — a language-plus-region code such as `fr-CA`) and store the user's locale in preferences.
- **"Delivery receipts / opened tracking."** Providers call back via webhooks (an HTTP request — HTTP being the protocol web clients and servers talk — that the provider sends to a URL you registered, when something happens on their side); record them as further events on the `DeliveryRecord`.
- **"Circuit breaker."** If a provider fails repeatedly, stop calling it for a while (Resilience4j-style; Resilience4j is a Java library of such fault-tolerance tools) and go straight to the next channel. Like an electrical breaker, it "trips" after too many failures and lets calls through again after a pause.

Real-world example

Push notifications on phones go through platform services: **Firebase Cloud Messaging (FCM)** for Android and **Apple Push Notification service (APNs)** for iOS; the app's server sends to a *device token*, exactly the `deviceToken` field above. Email is usually sent through providers such as Amazon SES or SendGrid, and SMS through gateways such as Twilio; each has its own API, which is why the `Gateway` adapter exists. **AWS SNS** is a managed (run for you by the cloud provider) pub-sub that fans one message out to email, SMS, mobile push and queues. LinkedIn's engineering blog describes **Air Traffic Controller (ATC)**, a central service that almost all LinkedIn notifications now pass through and that decides whether, when and how to notify each member, to stop excessive, repetitive notifications: the `SendRule` idea at company scale. And phone "Focus" / "Do Not Disturb" modes are quiet hours with an urgent-bypass list.

In the interview

> **30-second answer:** "Channels sit behind one abstract class whose final `deliver` method holds the retry-with-backoff loop (Template Method); each channel only supplies its address. Each "do not send" condition is its own `SendRule` (Strategy) returning a reason string, so we can record why. The user's preferences give an ordered channel list per kind; we render the template once and try channels in order, falling back on failure. Every outcome goes through one `finish` method that stores a record and notifies listeners (Observer). For scale, a queue sits in front and workers call `send`."

Plan (35–45 min): clarify (5) → entities, User vs Preferences (5) → Template + Message (3) → channel hierarchy + retry (8) → rules (7) → service flow + single exit + listeners (7) → async/queue, idempotency, follow-ups (5).

Follow-ups with answers:

- *"Add a new channel."* → One subclass + gateway adapter.
- *"What about duplicate messages on retry?"* → Idempotency keys; at-least-once delivery (every message arrives, but some may arrive more than once) means receivers must tolerate duplicates.
- *"Why not Strategy for channels?"* → Channels share an algorithm and vary in one step; that is Template Method. (Composition-based alternative: inject a `RetryPolicy` object and a `Sender` Strategy; also valid, mention it.)

Self-check

1. Which pattern puts the retry loop in one place? → Template Method (`final deliver()` in the abstract channel).
2. Why does `SendRule.blocks` return `Optional<String>` (Java's box that holds either one value or nothing)? → So the reason for suppression is recorded.

3. Why should a suppressed notification not count against the rate limit? → The user never received it; counting it would block legitimate later messages.
4. Quiet hours 22–07: is 06:00 quiet? Is 12:00? → Yes; no.
5. Where would you put a queue to avoid blocking checkout? → Between product code and `NotificationService.send` (our `sendAsync` is the in-process version).
6. What must every exit path of `send` do? → Go through `finish()`: store the record and notify listeners.

TL;DR

- **Template Method** for channels: retry/backoff once in the parent; subclasses give the address.
- **Strategy** for send rules (quiet hours, rate limit); rules return the *reason*.
- **Observer** for outcomes; **Simple Factory** for channels; **Adapter** for providers.
- Render once, try channels in the user's order, fall back, single `finish()` exit.
- Scale with a queue in front; watch for idempotency and the rate-limit check-then-act gap.

20.3 Design an In-Memory Cache (and an LRU Cache from scratch)

Problem & clarifying questions

`What it is.` A cache is a small, fast store that keeps recently used values close at hand, so you don't have to fetch them again from a slow place (a database, another service, the disk). (For where caches sit in bigger systems, see System Design Fundamentals.) Everyday analogy: the few books on your desk. The library (database) has everything, but the desk (cache) holds the ones you are using. When the desk is full and you need a new book, one must go back to the shelf. **Which one goes back** is the eviction policy, and it is the rule most likely to change.

Because the question is about **one component**, vague answers are exposed quickly. The interviewer will ask: *which data structure gives O(1) get and put?* (O(1), "constant time", means the time does not grow with the number of entries.)

Question	Assumed answer
Capacity measured in?	Number of entries (not bytes).
Eviction rule?	LRU (least recently used) by default; must be swappable for FIFO or LFU without changing the cache.
Time limits?	Optional TTL (time to live) per entry. Reading an expired entry is a miss and removes it.
Stats?	Hits, misses, evictions, expirations.
Notifications?	Interested code can subscribe to removals and learn the cause.
Thread-safe?	Yes (the course version left it out; we add it).
Load from DB (database) on miss / write-back (save changes to the DB later)?	Out of scope; discussed in extensions.

Requirements

Functional

1. Holds key → value pairs, never more than a fixed number.
2. `get` returns the value or reports a miss.
3. `put` inserts a new key or overwrites the value of an existing one.
4. Inserting a new key into a full cache first evicts one entry.
5. Default rule: **LRU** (least recently used — the entry whose last access is the oldest).
6. Swapping in another rule (FIFO — first in, first out; LFU — least frequently used) needs no change to the cache class.
7. `get` and `put` are O(1).

8. An entry may carry a TTL; once it has passed, a read returns a miss and deletes the entry.
9. Counts hits, misses, evictions, expirations.
10. Registered listeners hear about every removal together with its cause.
11. Callers can invalidate a single key or empty the whole cache.
12. Every entry leaves through **one** code path, whatever the reason.

Non-functional: O(1) operations; thread-safe; testable TTL (injected clock); listeners must not slow down or deadlock the cache (a **deadlock** is when two threads each wait forever for something the other one holds).

Use cases

Actors: **Application** (reads, stores, removes keys), **Operator** (chooses the eviction rule, reads stats), **Cache** (evicts, expires, counts, notifies).

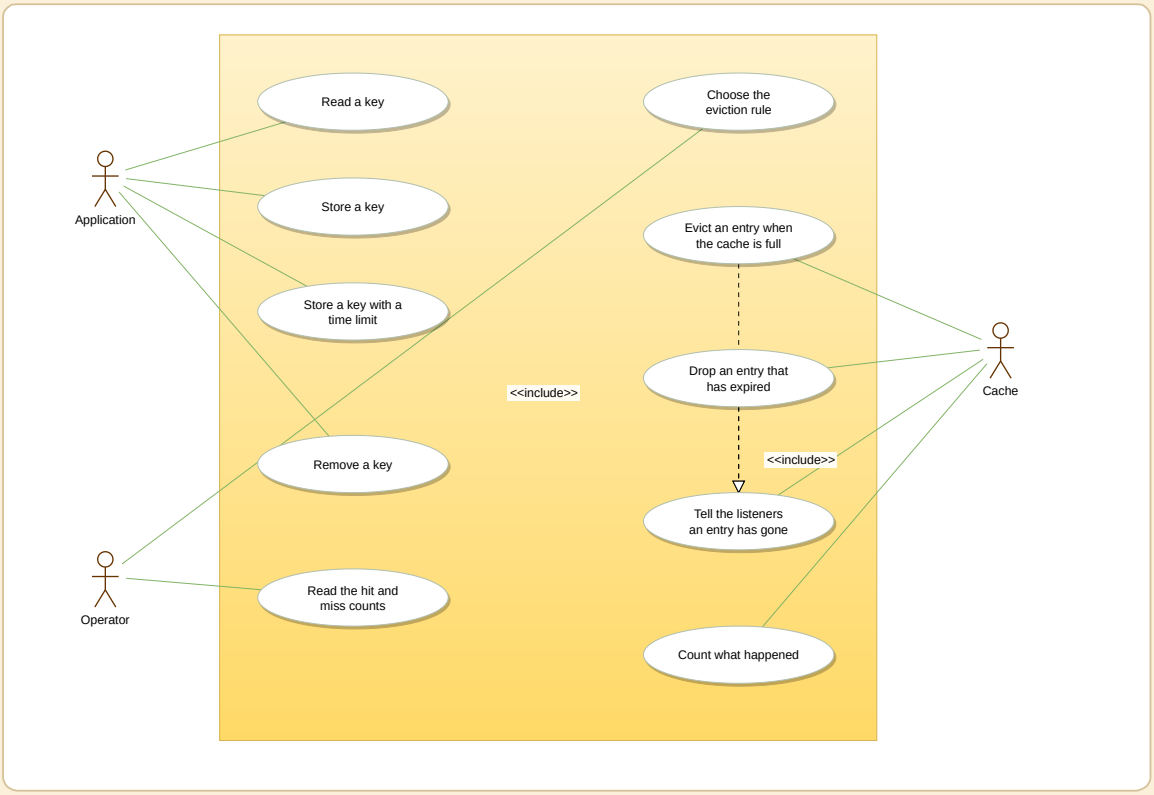

Figure — Cache use cases: read, store (with optional time limit), remove; the cache evicts, drops expired entries and tells listeners (course diagram)

Core entities

Class	Responsibility
`Node<K,V>`	One entry: key, value, `expiresAtMillis`, `frequency`, and its own `prev`/`next` links.
`DoublyLinkedList<K,V>`	Order of entries, newest at the front, with two **sentinel** (dummy) nodes so add/remove never need null checks.
`EvictionPolicy<K,V>` (interface)	**Strategy**: three events (`onInsert`, `onAccess`, `onRemove`) and one question (`victim()`). Owns the *order*.
`LruPolicy`, `FifoPolicy`, `LfuPolicy`	The three rules. LFU is O(1) using a chain of frequency buckets.
`EvictionPolicies` + `PolicyType`	**Simple Factory**: enum → policy.
`Cache<K,V>`	The map + policy + clock + stats + listeners. One lock. **One removal method.**
`Cache.Builder`	**Builder**: capacity, policy, clock with defaults, validated once.
`CacheStats`	Counters (`LongAdder`, a thread-safe counter).
`RemovalReason`	EVICTED, EXPIRED, REMOVED, CLEARED.
`EvictionListener<K,V>`	**Observer**: told key, value and reason.
`ShardedCache<K,V>`	N independent caches picked by key hash, to reduce lock contention.

Key terms — hash map, linked list, hashing, contention. A **hash map** (`HashMap`) stores key → value pairs; it turns each key into a number (its **hash**) that says which slot to look in, so finding a key takes about the same time however many entries there are. A **linked list** is a chain of nodes where each node points to the next one (a **doubly** linked list also points back to the previous one); inserting or unlinking a node you already hold is just a few pointer changes. **Lock contention** is threads queueing for the same lock; splitting data into **shards** (independent pieces, here chosen by key hash), each with its own lock, reduces it.

The core idea: two structures, each answering one question.

Question	Structure	Cost
"Where is key k?"	`HashMap<K, Node>`	O(1)
"Who should leave next?"	Doubly linked list ordered by recency	O(1) at the ends
"Move this entry to the front"	Node has its own `prev`/`next`, and the map hands us the node	O(1) — no search

A map alone cannot tell you the oldest entry. A list alone cannot find a key without walking it. Together they give O(1) for everything. A **doubly** linked list is needed because removing a node from the middle requires its predecessor, and a singly linked list would have to walk to find it.

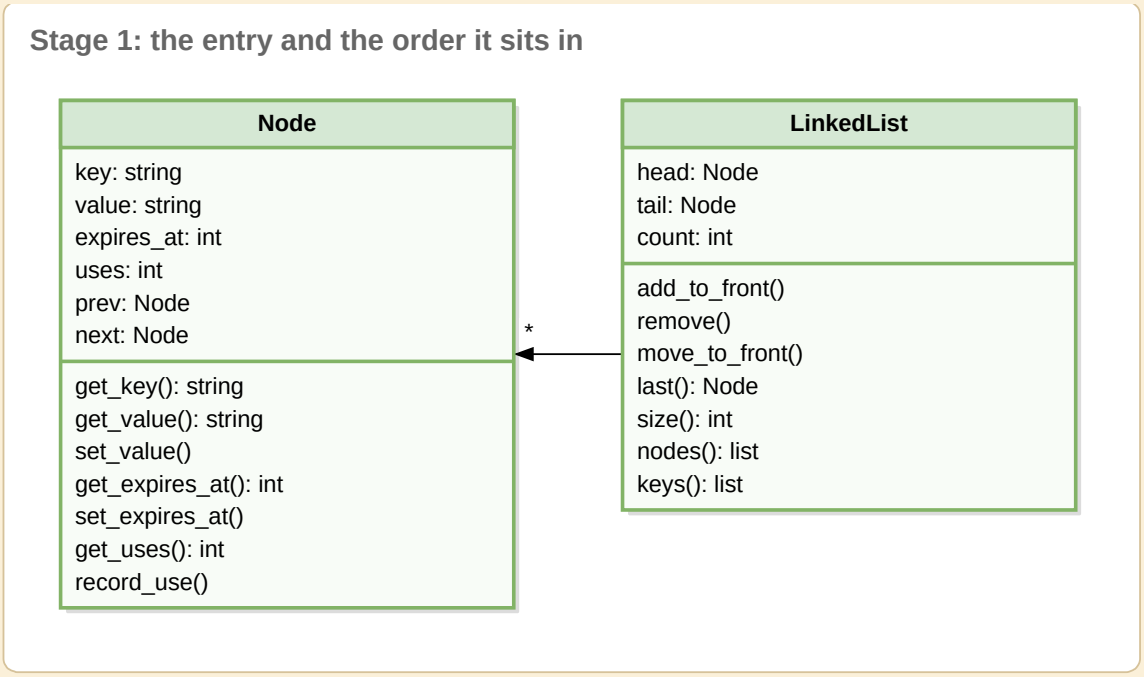

Figure — Stage 1 of the course build: the Node (key, value, expiry, use count, prev and next links) and the linked list that orders the nodes (course diagram)

Class diagram

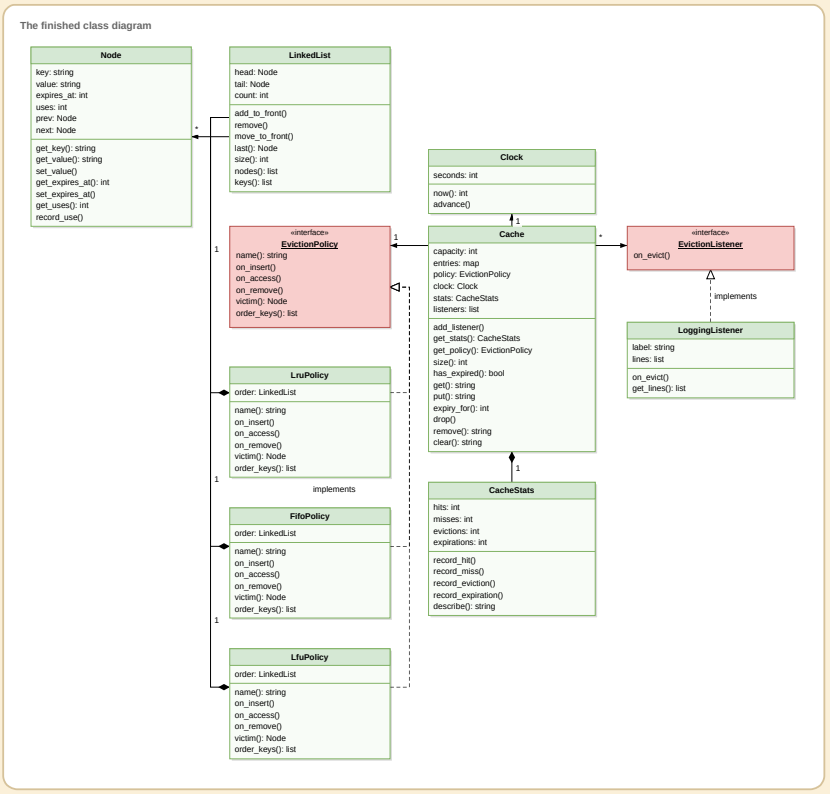

Figure — The finished cache class diagram: Cache with its map, policy, clock, stats and listeners; the three eviction policies behind one interface (course diagram)

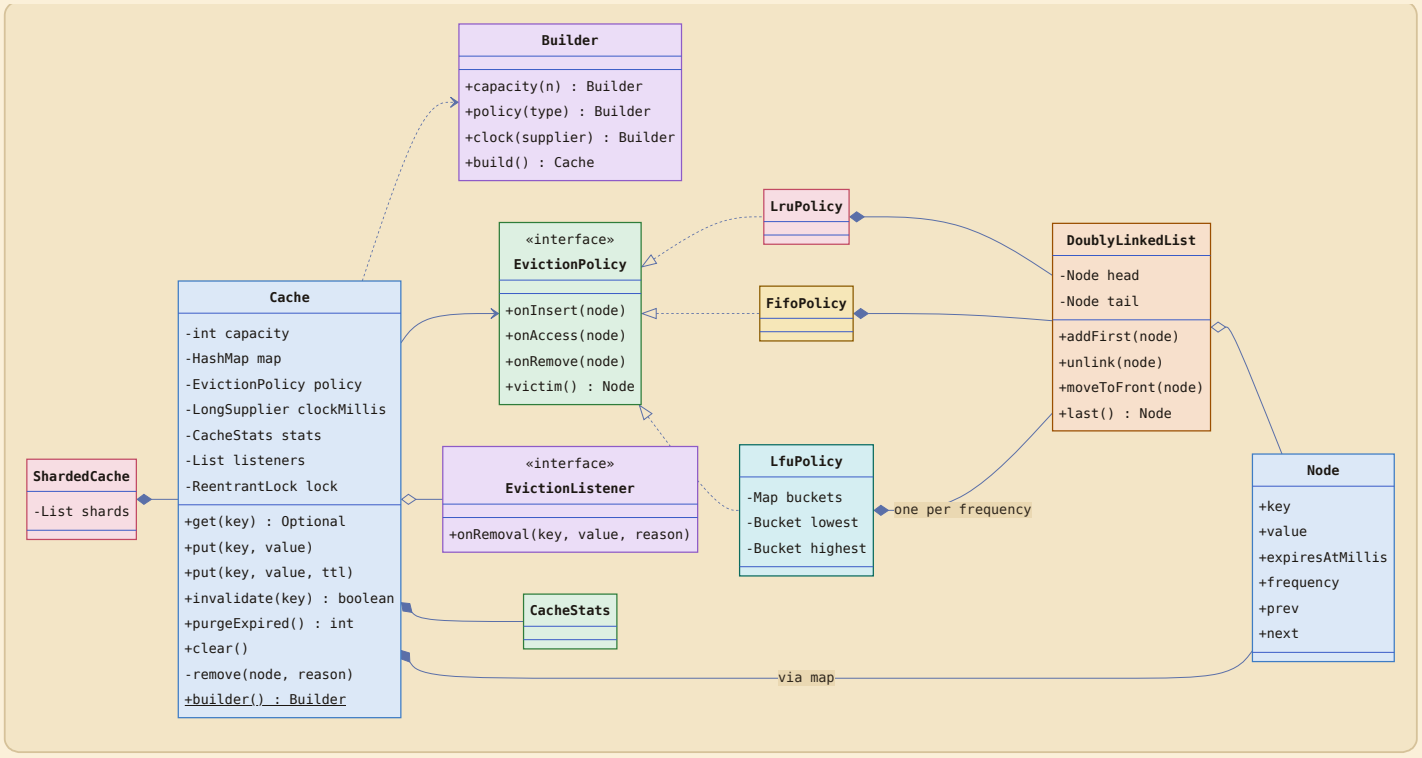

Build order (from the course). (1) `Node` + `DoublyLinkedList`: entries can be ordered and moved to the front; (2) `EvictionPolicy` + `LruPolicy`: you can ask who should leave; (3) `FifoPolicy` + `LfuPolicy`: the same question gets three answers with no change to the cache; (4) `Cache` with clock, stats and TTL: reads and writes work; (5) `EvictionListener`: other code can react when an entry goes. Each stage leaves something runnable; reuse this order when you interview.

Who owns what. The cache owns the map (and so the nodes). The policy owns the *order* of those nodes. Neither reaches into the other's structure. That split is exactly what lets us add FIFO and LFU without touching `Cache`.

Key flows

Reading a key — three ways out, only one returns a value:

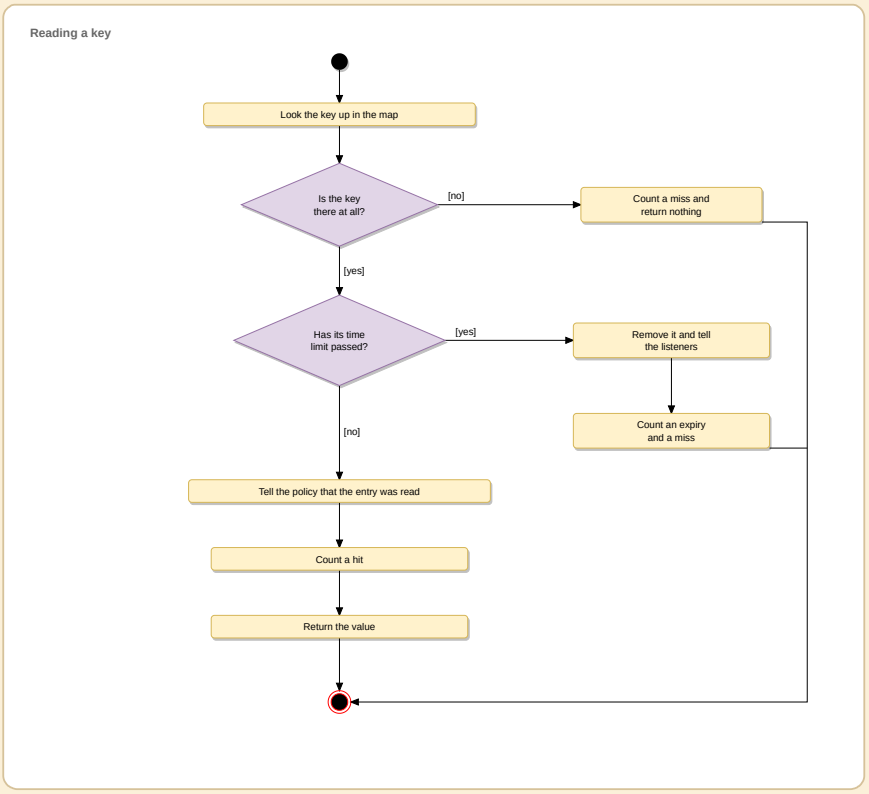

Figure — Reading a key: not present means a miss; present but expired means a miss plus an expiry removal; otherwise a hit, the policy is told, and the value is returned (course diagram)

Storing a key — eviction work happens only when the cache is already full, so a cache with free room pays nothing extra:

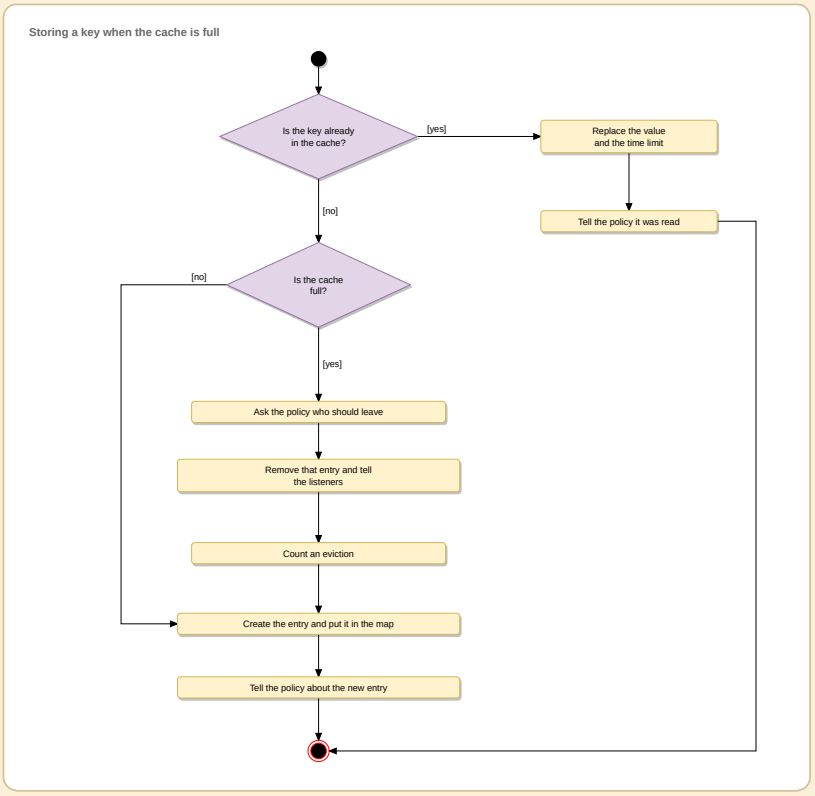

Figure — Storing a key: replace if present; otherwise, if full, ask the policy for a victim and remove it through the single removal path, then insert (course diagram)

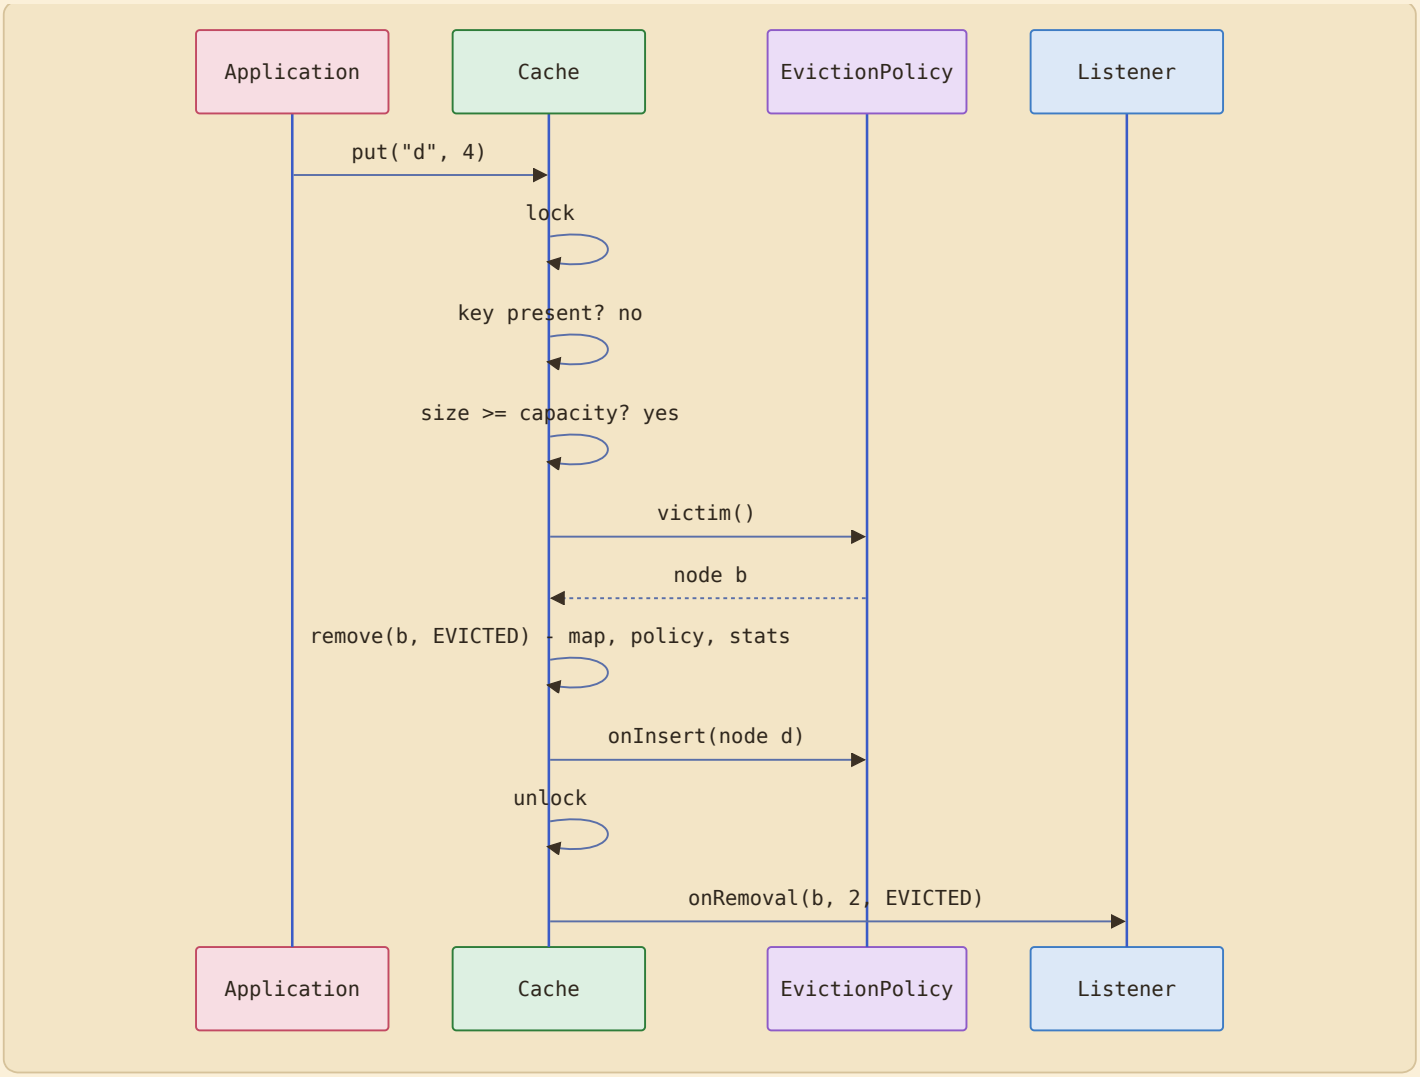

How the three policies differ (the only difference is what they do on each event):

Event	LRU	FIFO	LFU (O(1) buckets)
`onInsert`	add to front	add to front	frequency = 1, add to bucket 1 (always first in the chain)
`onAccess`	move to front	**nothing**	move from bucket f to bucket f+1 (created right after f if missing); drop bucket f from the chain if it emptied
`onRemove`	unlink	unlink	unlink; drop the bucket if it emptied
`victim()`	back of the list	back of the list	back of the **first** bucket in the chain (least recently used among the least frequent)

The FIFO policy is LRU with one empty method, which is good evidence that the interface boundaries are well chosen. The course's LFU scanned all entries (O(n): the time grows in step with the number of entries) and named a structure grouping entries by count as the fix; our `LfuPolicy` implements that fix. The buckets are themselves kept in a **doubly linked chain in increasing frequency order**, and a new bucket f+1 is always created right after bucket f, so the chain never needs sorting and the lowest bucket is always the first one. That makes `onInsert`, `onAccess`, `onRemove` and `victim()` all O(1), even after a manual removal or an expiry empties the lowest bucket (this is the O(1) LFU scheme of Shah, Mitra and Matani, 2010). Ties inside the lowest bucket are broken by recency (the back of the bucket), so two runs of the same test always evict the same key.

Design decisions & patterns used

Decision	Why	Alternative rejected
Strategy for eviction	"Who leaves" is the rule most likely to change.	A `switch (policyType)` inside `get` / `put`.
Observer for removals	Logging, metrics, deleting a temp file on eviction — none belong inside the cache. The reason is passed so one listener can handle all cases.	Callbacks (methods handed over to be called later) hard-coded per reason.
One removal method (`remove(node, reason)`)	Eviction, expiry, manual removal and clear all update map, policy, stats and listeners the same way; nothing can be forgotten on one path.	Four copies of the clean-up code.
Sentinel nodes	Add and unlink are always the same four pointer writes (a **pointer** here is a reference from one node to another); no special cases for empty list or ends.	Null checks everywhere (a classic source of bugs).
Injected clock (`LongSupplier`, a function that returns a `long`)	TTL tests run instantly by moving a fake clock forward.	`System.currentTimeMillis()` inside the cache: tests must `sleep`.
Lazy expiry + optional sweeper	Lazy = checked only when needed: expired entries are dropped when read; `purgeExpired()` lets a background task reclaim memory.	Only lazy (memory held by dead entries) or a timer per entry (expensive).
One `ReentrantLock` (Java's explicit lock object), listeners called **after unlock**	In LRU even `get` writes (moves a node), so a read-write lock (one that lets many readers in together but a writer only alone) would not help. Calling listeners outside the lock means a slow or re-entrant listener cannot block or deadlock the cache.	`synchronized` around listener calls.
Builder	Optional settings with defaults; validation once in `build()`.	Telescoping constructors (many constructors, each taking one more parameter).
Sharding (splitting data into independent pieces; `ShardedCache`)	N locks instead of one: threads touching different shards never wait for each other.	One global lock (every reader waits for every writer).

Java implementation

```java
// File: code/lld/ch20/cache/Structures.java
package lld.ch20.cache;

/** One cache entry. It carries its own links, so it can be unlinked in O(1). */
final class Node<K, V> {
    final K key;
    V value;
    long expiresAtMillis;  // 0 = never expires
    int frequency;         // used by LFU
    Node<K, V> prev, next;

    Node(K key, V value, long expiresAtMillis) {
        this.key = key;
        this.value = value;
        this.expiresAtMillis = expiresAtMillis;
    }

    boolean isExpired(long now) { return expiresAtMillis != 0 && now >= expiresAtMillis; }
}

/** Doubly linked list with two sentinel nodes: no null checks at the ends. Newest at the front. */
final class DoublyLinkedList<K, V> {
    private final Node<K, V> head = new Node<>(null, null, 0); // sentinel before the front
    private final Node<K, V> tail = new Node<>(null, null, 0); // sentinel after the back
    private int size;

    DoublyLinkedList() {
        head.next = tail;
        tail.prev = head;
    }

    void addFirst(Node<K, V> n) {
        n.prev = head;
        n.next = head.next;
        head.next.prev = n;
        head.next = n;
        size++;
    }

    void unlink(Node<K, V> n) {
        n.prev.next = n.next;
        n.next.prev = n.prev;
        n.prev = n.next = null;
        size--;
    }

    void moveToFront(Node<K, V> n) {
        unlink(n);
        addFirst(n);
    }

    /** The oldest node (at the back), or null if empty. */
    Node<K, V> last() { return size == 0 ? null : tail.prev; }

    boolean isEmpty() { return size == 0; }
}
```

```java
// File: code/lld/ch20/cache/EvictionPolicy.java
package lld.ch20.cache;

    }
}
```

Walking through the code.

- `DoublyLinkedList` never touches `null` at the ends because `head` and `tail` are dummy nodes that are never removed.
- In `Cache.get`, an expired entry counts as a miss **and** an expiration, and is removed through `remove()` — all three in one place, so the counters always add up.

- Every public method collects `Removal` events while holding the lock and calls `notifyListeners` in `finally` (a block that always runs, even when an exception is thrown) **after** `unlock()`.
- `put` on an existing key replaces value and TTL and counts as an access (in LRU the key moves to the front).
- `CacheStats` uses `LongAdder`, which is faster than `AtomicLong` (a `long` that threads can update safely without a lock) when many threads increment.

Output:

```
== LRU (capacity 3): put a,b,c; get b,b,b,c,a,a; put d
  listener: b=2 left, EVICTED
  still cached: [a, c, d]
== FIFO (capacity 3): put a,b,c; get b,b,b,c,a,a; put d
  listener: a=1 left, EVICTED
  still cached: [b, c, d]
== LFU (capacity 3): put a,b,c; get b,b,b,c,a,a; put d
  listener: c=3 left, EVICTED
  still cached: [a, b, d]
== TTL with a manual clock
  t=0s  get session:42 -> alice
  listener: session:42 left, EXPIRED
  t=6s  get session:42 -> MISS
  listener: session:43 left, EXPIRED
  sweeper purged 1 more expired entry
  config (no TTL) -> v1
  listener: config left, REMOVED
  stats: hits=2 misses=1 evictions=0 expirations=2 hitRate=67%
== Sharded cache under 8 threads
  finished: true, size <= 8000: true
```

With the same access pattern (b read 3 times, then c once, then a twice), the three policies evict three **different** keys: LRU evicts b (least recently touched), FIFO evicts a (inserted first), LFU evicts c (read only once).

LRU Cache from scratch (the classic interview question)

Very often the interviewer skips the pluggable design and asks for exactly this: **"Implement an LRU cache with O(1) `get` and `put`"** (LeetCode 146; LeetCode is a popular website of coding interview problems). The answer is the same two structures, written inline:

1. A `HashMap<K, Node>` for lookup.
2. A doubly linked list with `head`/`tail` sentinels; most recent right after `head`, least recent right before `tail`.
3. `get(k)`: look up the node; if found, unlink it and add it at the front; return the value.
4. `put(k, v)`: if present, update and move to front. Otherwise, if full, remove `tail.prev` from the list **and** from the map (that is why the node stores its key); then add the new node at the front and to the map.

Java also has a shortcut: `LinkedHashMap` with `accessOrder = true` keeps entries in access order, and overriding `removeEldestEntry` evicts automatically. Mention it, but write the manual version when asked "from scratch" — that is what is being tested.

```java
// File: code/lld/ch20/lrucache/Main.java
package lld.ch20.lrucache;

        }

        private void unlink(Node n) {
            n.prev.next = n.next;
            n.next.prev = n.prev;
        }
```

```
        @Override
        public synchronized String toString() {
            StringBuilder sb = new StringBuilder("[");
            for (Node n = head.next; n != tail; n = n.next) sb.append(n.key).append(n.next == tail ? "" : ", ");
            return sb.append("] (most -> least recent)").toString();
        }
    }

    /** The JDK shortcut: LinkedHashMap in access order + removeEldestEntry. Not thread-safe. */
    static <K, V> Map<K, V> jdkLru(int capacity) {
        return new LinkedHashMap<>(16, 0.75f, true) {
            @Override
            protected boolean removeEldestEntry(Map.Entry<K, V> eldest) { return size() > capacity; }
        };
    }

    public static void main(String[] args) {
        System.out.println("== Hand-written LRU (LeetCode 146 sequence, capacity 2)");
        LRUCache<Integer, Integer> c = new LRUCache<>(2);
        c.put(1, 1);
        c.put(2, 2);
        System.out.println("get(1) = " + c.get(1) + "   order " + c);
        c.put(3, 3);
        System.out.println("put(3) evicts 2        order " + c);
        System.out.println("get(2) = " + c.get(2));
        c.put(4, 4);
        System.out.println("put(4) evicts 1        order " + c);
        System.out.println("get(1) = " + c.get(1) + ", get(3) = " + c.get(3) + ", get(4) = " + c.get(4));

        System.out.println("== Same sequence with LinkedHashMap(accessOrder=true)");
        Map<Integer, Integer> j = jdkLru(2);
        j.put(1, 1);
        j.put(2, 2);
        j.get(1);
        j.put(3, 3);
        j.put(4, 4);
        System.out.println("keys (least -> most recent) = " + j.keySet());
    }
}
```

Output:

```
== Hand-written LRU (LeetCode 146 sequence, capacity 2)
get(1) = 1   order [1, 2] (most -> least recent)
put(3) evicts 2        order [3, 1] (most -> least recent)
get(2) = null
put(4) evicts 1        order [4, 3] (most -> least recent)
get(1) = null, get(3) = 3, get(4) = 4
== Same sequence with LinkedHashMap(accessOrder=true)
keys (least -> most recent) = [3, 4]
```

The printed values match LeetCode 146's expected answers for this sequence (1, miss, miss, 3, 4); LeetCode's `int` version returns `-1` for a miss, while this generic version returns `null`.

Approach	get / put	Thread-safe	When to use
HashMap + own doubly linked list	O(1) / O(1)	Only with a lock (`synchronized` here)	Interviews; when you need custom behaviour
`LinkedHashMap(accessOrder=true)` + `removeEldestEntry`	O(1) / O(1)	No (wrap with a lock)	Quick, small, single-threaded caches
Caffeine / Guava cache (widely used Java caching libraries)	amortized O(1) (O(1) on average over many calls)	Yes, highly concurrent	Production Java

Concurrency & edge cases

- **Why a plain read lock is not enough:** an LRU `get` moves the node (several pointer writes). Two threads doing that at once corrupt the list. So `get` needs the exclusive lock.
- **Contention:** one lock serializes everything. `ShardedCache` splits keys over 8 caches (8 locks); the demo hammers it from 8 threads and the size never exceeds the total capacity. Trade-off: eviction is per shard, so the global LRU order is approximate.
- **Listeners:** called outside the lock; a listener that calls back into the cache cannot deadlock.
- **Cache stampede** (many threads miss the same key at once and all hit the database): use a "loading" cache where the first thread computes and the others wait for its result (`ConcurrentHashMap.compute` / `computeIfAbsent` — `computeIfAbsent` creates and stores a value only if the key is missing, as one atomic step — or a `CompletableFuture` stored per key). Chapter 13 (§13.6) builds a TTL cache whose `getOrLoad` does this with `ConcurrentHashMap.compute`.
- **TTL semantics, precisely.** An entry expires *at* its deadline (`now >= expiresAt`), so a 5-second TTL written at t=0 is already a miss at t=5.000 s. Expiry is **lazy**: a dead entry still occupies a slot until it is read, swept by `purgeExpired()`, or picked as the eviction victim (in which case it is reported as `EVICTED`, not `EXPIRED`, because it left to make room). `put(key, value)` without a TTL on an existing key **clears** the old TTL (the entry becomes permanent); pass the TTL again to keep one. A production cache would also let the sweeper run on a `ScheduledExecutorService` (Java's tool for running tasks on a timer).
- **Capacity 0 or negative:** refused by the builder.
- **Null keys/values:** not supported here; say so (Caffeine forbids nulls too).
- **Clock going backwards:** use a monotonic clock (one that only ever moves forward, unlike wall-clock time that can be adjusted; `System.nanoTime`) for TTL in production.

Extensions & follow-up questions

- **"Make it LFU."** One new policy class (done). Volunteer that the naive LFU (scan for the lowest count) is O(n) and the chained-bucket version is O(1).
- **"Size in bytes, not entries."** Add a `Weigher<K,V>` strategy; evict until `totalWeight <= maxWeight`.
- **"Load from the database on a miss."** *Read-through*: `get(key, loader)` calls the loader on a miss and stores the result. *Write-through*: writes go to cache and DB together. *Write-back (write-behind)*: writes go to cache and are flushed to DB later (faster, risk of loss). *Cache-aside*: the application does "check cache → on miss read DB → put in cache" itself.
- **"Distributed cache."** Consistent hashing (a way to assign keys to servers so that adding or removing a server moves only a small share of the keys) to spread keys over nodes (Redis Cluster, Memcached clients — Redis and Memcached are in-memory key-value stores that run as separate servers); that is high-level design (HLD: designing services, databases and networks, as opposed to the classes inside one program).
- **"Which policy is best?"** Depends on access patterns. Modern caches (Caffeine's *Window TinyLFU*) combine recency and frequency and beat pure LRU on many workloads (patterns of real requests).

Real-world example

`java.util.LinkedHashMap` with access order is the JDK's (Java Development Kit: Java's compiler plus standard library) built-in LRU. **Guava's** `CacheBuilder` and **Caffeine** expose exactly this chapter's knobs: `maximumSize` (capacity), `expireAfterWrite` / `expireAfterAccess` (TTL), `removalListener` (Observer, with a cause such as `EXPIRED`, `SIZE`, `EXPLICIT`, `REPLACED`), and `recordStats()` (hit rate: the share of reads answered from the cache). **Redis** supports eviction policies selected by configuration (`maxmemory-policy`: `allkeys-lru`, `allkeys-lfu`, `volatile-ttl`, `noeviction` and others) — a Strategy chosen by config — and approximates LRU by sampling a few keys rather than keeping a full list, to save memory. Browsers, CDNs (content delivery networks: servers spread around the world that keep copies of files close to users) and operating-system page caches (recently read disk data kept in memory) all use variants of LRU.

In the interview

30-second answer: "A HashMap from key to node for O(1) lookup, and a doubly linked list with sentinels for O(1) ordering; the node carries its own links so the map hands us something we can unlink directly. The eviction rule goes behind an `EvictionPolicy` interface — LRU moves on access, FIFO doesn't, LFU uses frequency buckets for O(1). Every exit goes through one `remove` method that updates stats and notifies

> listeners after the lock is released. For concurrency, one lock is correct; sharding by key hash reduces contention."

Plan: sketch the map and the list together straight away and explain what each one lacks on its own → write LRU get/put → pull the rule behind an interface unprompted → TTL + stats + listeners → thread safety and sharding → follow-ups.

Follow-ups with answers:

- *"Why doubly and not singly linked?"* → Removing a node needs its predecessor; with `prev` we have it in O(1).
- *"Why does the node store the key?"* → When evicting the tail we must also delete it from the map.
- *"Make it thread-safe."* → Lock around each operation; better, shard by key; production: Caffeine.

Self-check

1. Which two structures give O(1) LRU? → HashMap (key → node) + doubly linked list (recency order).
2. What do sentinel nodes buy you? → No null checks; add/remove are always the same pointer writes.
3. How does FIFO differ from LRU in code? → `onAccess` does nothing.
4. Why call listeners after releasing the lock? → A slow or re-entrant listener cannot block or deadlock the cache.
5. Why can't a read-write lock speed up an LRU cache's `get`? → `get` modifies the list, so it is a write.
6. What is a cache stampede and one fix? → Many concurrent misses for one key hitting the DB; let one thread load while others wait on the same future.

TL;DR

- **HashMap + doubly linked list (with sentinels)** = O(1) get/put.
- **Strategy** for eviction (LRU / FIFO / O(1) LFU); **Observer** for removals; **Builder** for config.
- **One removal path** keeps stats and listeners correct; TTL is lazy + optional sweeper; clock injected.
- Thread safety: one lock (gets are writes), listeners outside the lock, **shard** to scale.
- Know `LinkedHashMap(accessOrder=true)` + `removeEldestEntry`, and Caffeine/Guava/Redis policies.

20.4 Design a Ride Sharing Service (Uber)

Problem & clarifying questions

What it is. A ride sharing service connects a rider who wants a car with a nearby driver. Everyday analogy: a taxi dispatcher with a radio. A call comes in, the dispatcher looks at the map, radios the nearest free cab; if that driver says no, the next one. At the end the meter shows the fare.

Two decisions are the whole question: **which driver is asked** (matching) and **what the trip costs** (pricing). The rest is bookkeeping. A good design lets either rule change with no edits anywhere else.

Question	Assumed answer
Vehicle types?	Economy, premium, van. Rider asks for one type.
Who can get a request?	Drivers who are online, not on a trip, with the right car type, within range.
Offer to one driver or broadcast?	One at a time, nearest first; decline → next; nobody left → cancel.
Trip states?	Requested → accepted → started → ended; canceled from requested/accepted only. Illegal actions do nothing.
Fare?	Base + per km + per minute, never below a minimum; per vehicle type.
Surge?	A multiplier when the city is busy, applied to the same fare.
Ratings?	Rider and driver rate each other once after a finished trip; accounts show the average.
Payments?	Charge the rider's payment method (cash, wallet, card) at the end.
Map?	A grid; distance measured along streets (Manhattan distance), which keeps all distances integral (whole numbers). Production systems query a routing engine (a service that works out the road route between two points) that gives back road distance plus an estimated duration, and pricing would take both from it.
Pool/shared rides, scheduled rides, live tracking, payouts?	Out of scope.

Requirements

Functional

1. Riders and drivers have a name and phone number.
2. A driver has one vehicle: plate, seats, type.
3. Drivers go online/offline; only online, free drivers get requests.
4. A rider requests a trip with pickup, drop and car type.
5. Free drivers with a matching car type are ordered by distance to the pickup, and the closest one is offered the trip first.
6. A driver accepts or declines; a decline goes to the next driver; if none are left, the request is canceled.
7. A trip moves through fixed states; an action that doesn't fit the current state does nothing.
8. Fare = base + per-km + per-minute, never below a minimum.
9. During peak demand, a surge multiplier scales that same fare.
10. Riders may cancel until the trip starts; after that, the only way out is ending it.
11. After a finished trip, rider and driver rate each other; accounts show the average.
12. Riders and drivers can see their finished trips.
13. (Added) The rider is charged through their payment method.

Non-functional: a driver can never be assigned to two trips at once (even with concurrent requests); rules swappable without editing the service; deterministic behaviour for tests (tie-breaks).

Use cases

Actors: **Rider** (request, cancel, rate), **Driver** (go online, accept/decline, start/end, rate), **System** (find nearby drivers, offer, price, surge, history).

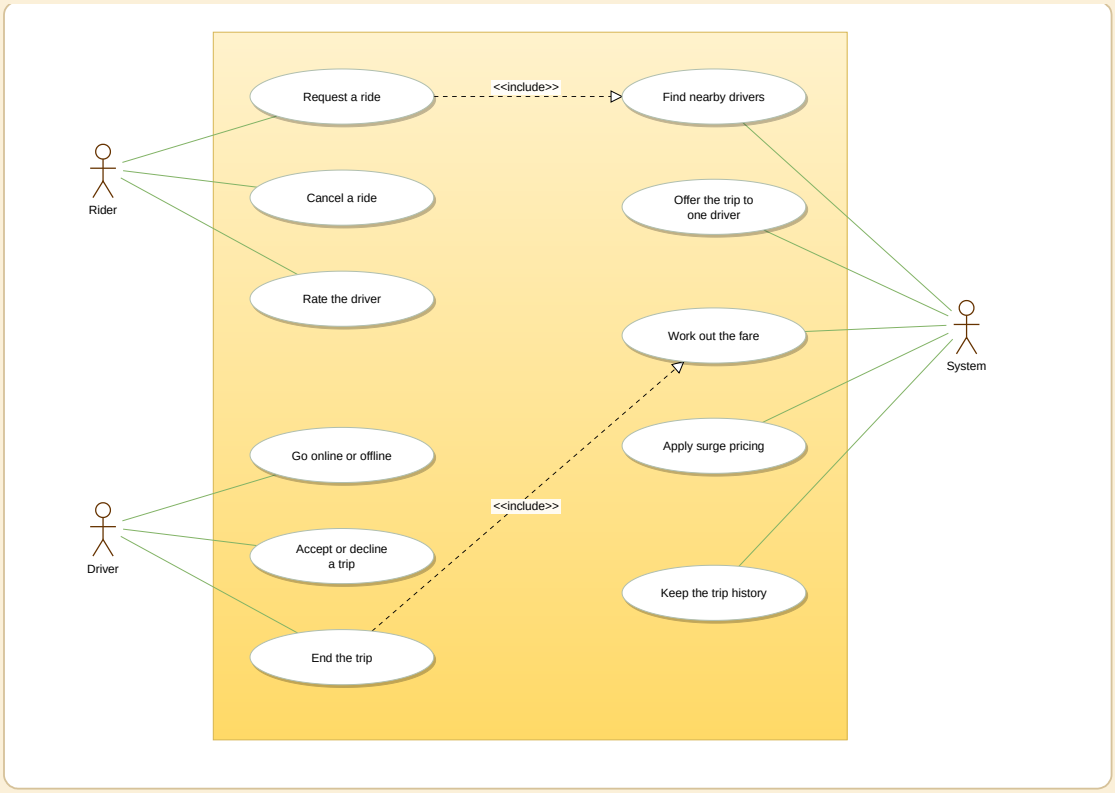

Figure — Ride sharing use cases: rider requests, cancels and rates; driver goes online, accepts or declines and ends the trip; the system matches, offers, prices and applies surge (course diagram)

Core entities

Class	Responsibility
`Location` (record)	Grid point; `distanceTo` = Manhattan distance in km.
`VehicleType` (enum), `Vehicle` (record)	Car type and details.
`Account` (abstract)	What riders and drivers share: id, name, phone, **rating as running total + count**, finished trips.
`Rider`	+ payment method.
`Driver`	+ vehicle, location, online flag, **atomic busy flag** (`tryClaim`).
`TripStatus` (enum)	The state machine: legal next states per state.
`Trip`	One journey: rider, pickup, drop, type, **ranked candidate list + cursor** (a marker for the current position in the list), status, driver, minutes, fare. Every action checks state first.
`PricingStrategy`	**Strategy**: fare for (type, km, minutes).
`StandardPricing` + `RateCard`	Base + per km + per minute, with a floor (a minimum fare), per vehicle type.
`SurgePricing`	**Decorator**: wraps any `PricingStrategy` and multiplies its answer.
`MatchingStrategy`	**Strategy**: ranks drivers. `NearestDriverMatcher`, `BestRatedMatcher`.
`PaymentMethod`	**Strategy**: `CashPayment`, `WalletPayment`.
`TripListener`	**Observer**: apps are told about trip events.
`RideSharingService`	Facade: owns accounts and trips; holds one pricing and one matching rule; knows only the order of steps.

Why the rating is a total and a count. Only the average is ever displayed, so a sum and a count suffice, and recording a new rating is O(1) whether the account has 10 trips or 10,000.

Why `Rider` and `Driver` extend `Account`. They pass the "is-a" substitution test (Liskov Substitution Principle): wherever the code reads a name or records a rating, a `Rider` or a `Driver` can be passed.

Class diagram

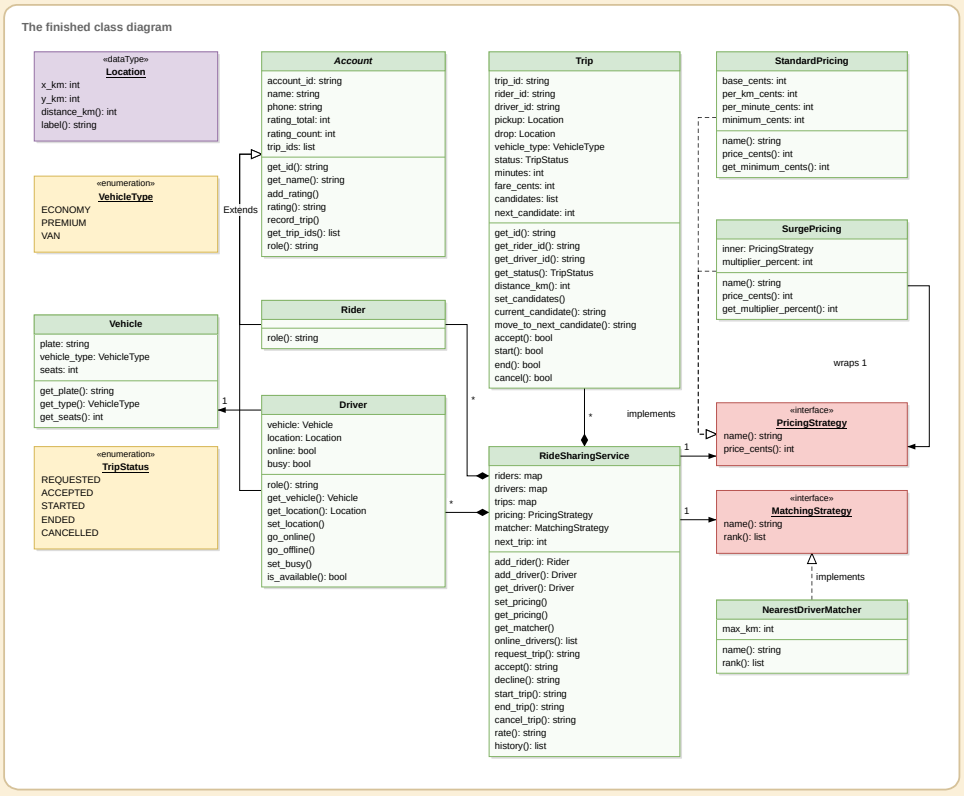

Figure — The finished ride sharing class diagram: the service owning riders, drivers and trips; PricingStrategy with StandardPricing and the SurgePricing wrapper; MatchingStrategy with the nearest-driver matcher (course diagram)

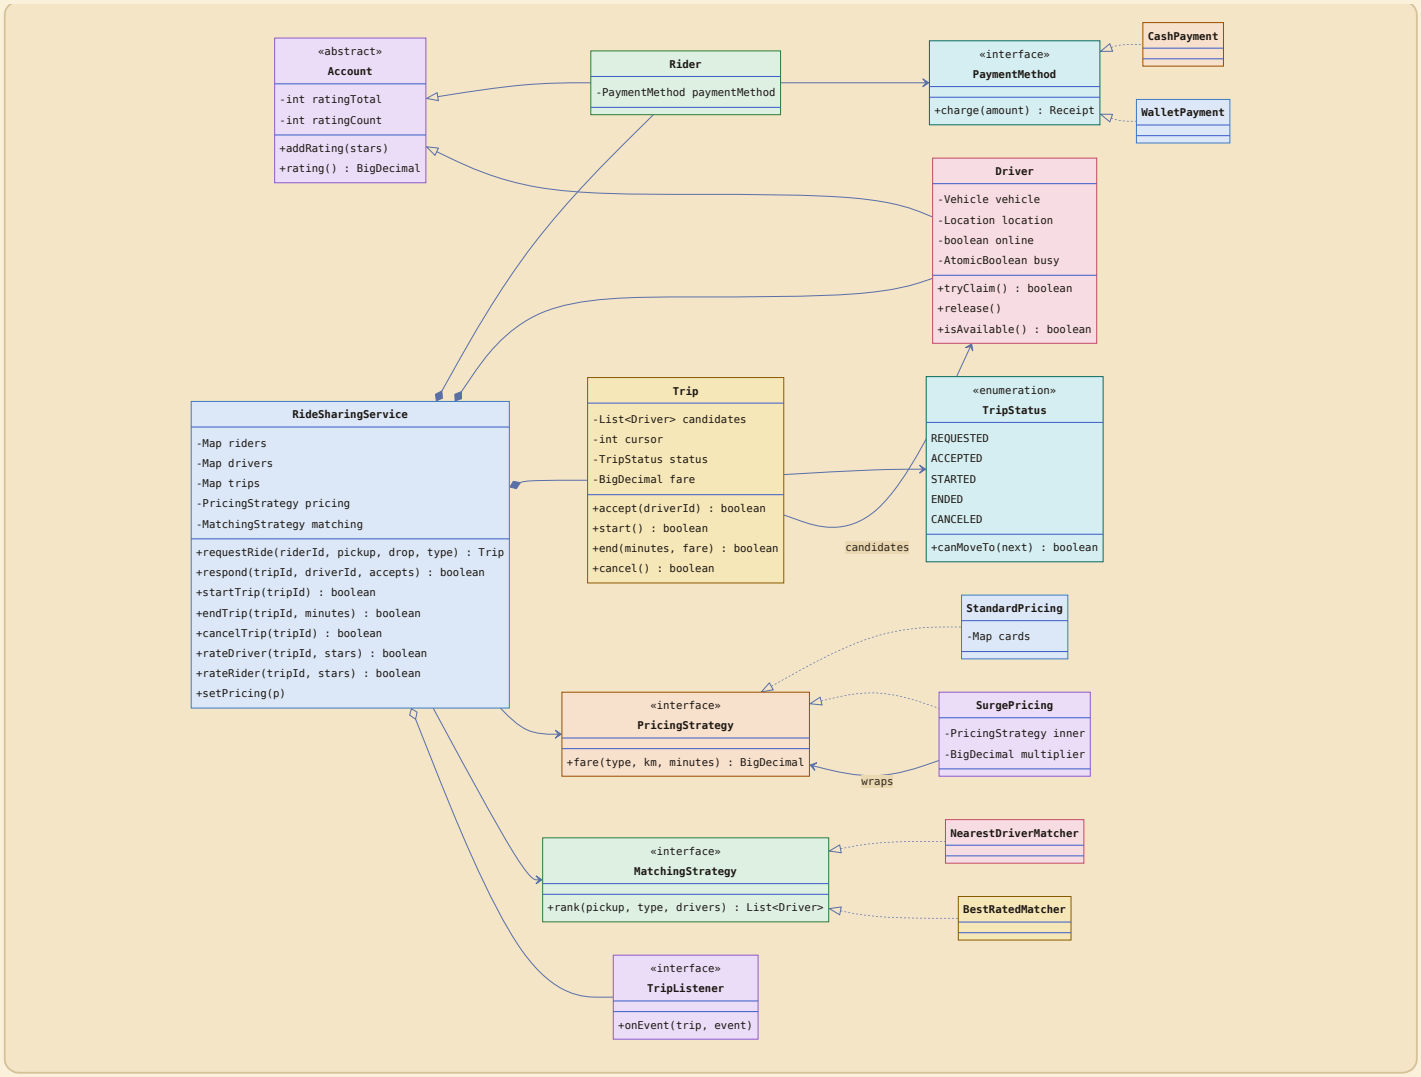
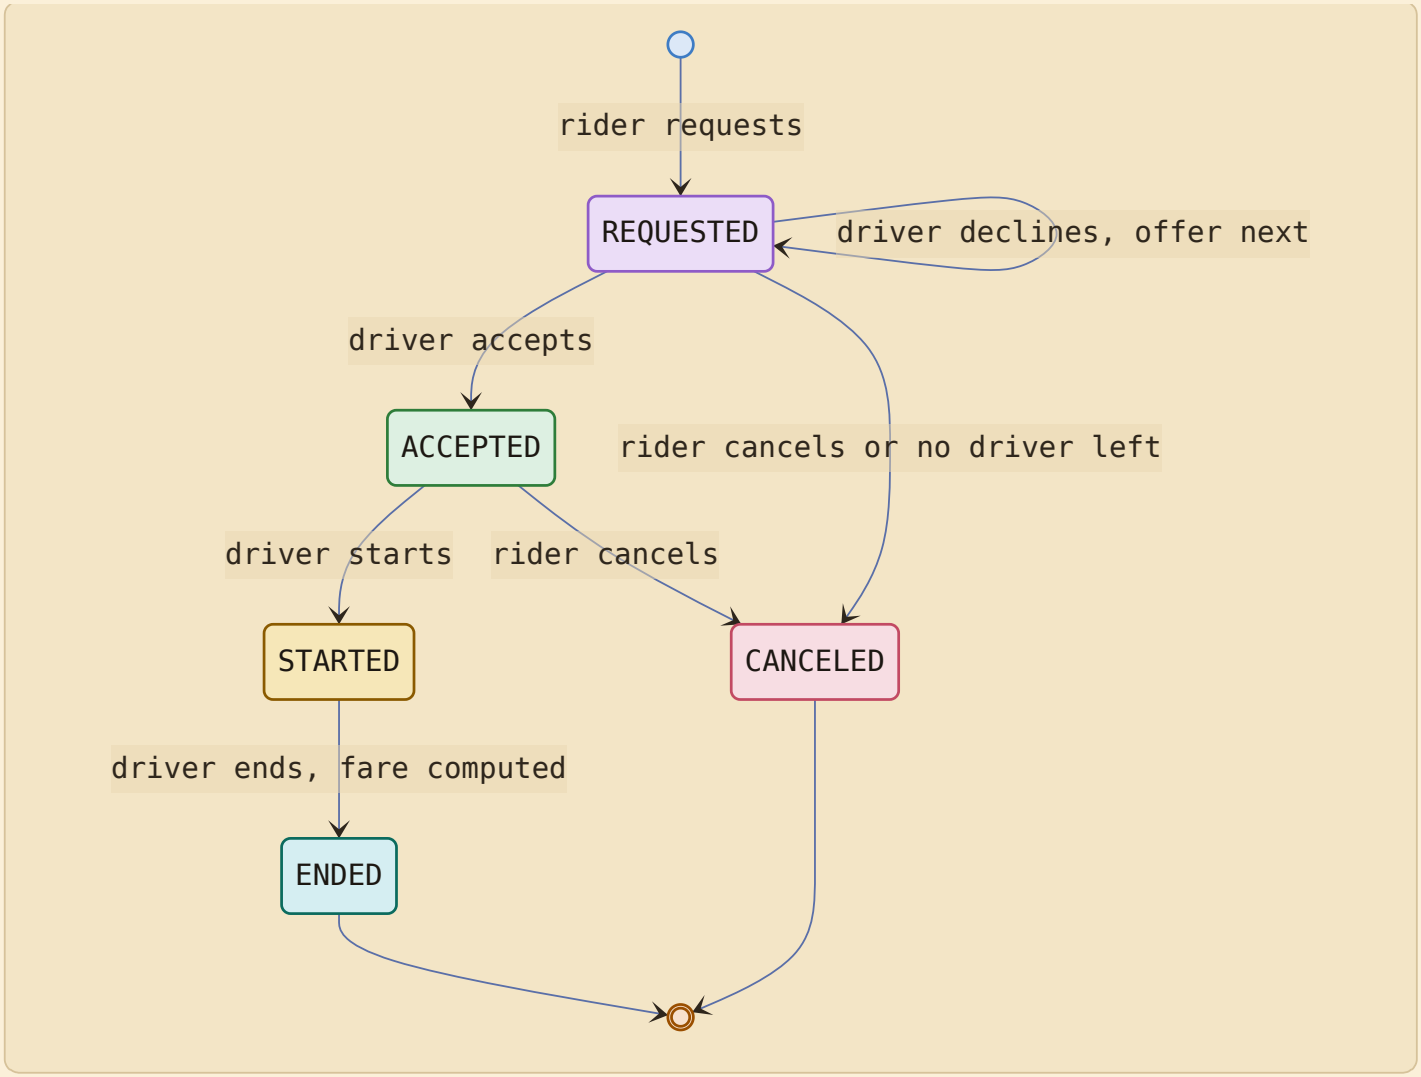
The course builds it in five stages, each leaving something runnable: (1) `Account` / `Rider` / `Driver`, `Vehicle`, `Location` (who is free and where); (2) `Trip` + `TripStatus` (the lifecycle, with illegal moves refused); (3) pricing with the surge wrapper (a finished trip has a fare); (4) matching (drivers who could take a request can be ranked); (5) `RideSharingService` (the complete flow, request through rating).

In the figure above, look for the extra arrow from `SurgePricing` back to the `PricingStrategy` interface: that "has-a of my own type" arrow is what turns it into a Decorator instead of one more Strategy.



Key flows

Trip lifecycle (state machine). A *state machine* is a fixed set of states plus the only moves allowed between them.



Finding a driver — including the case where every candidate declines:

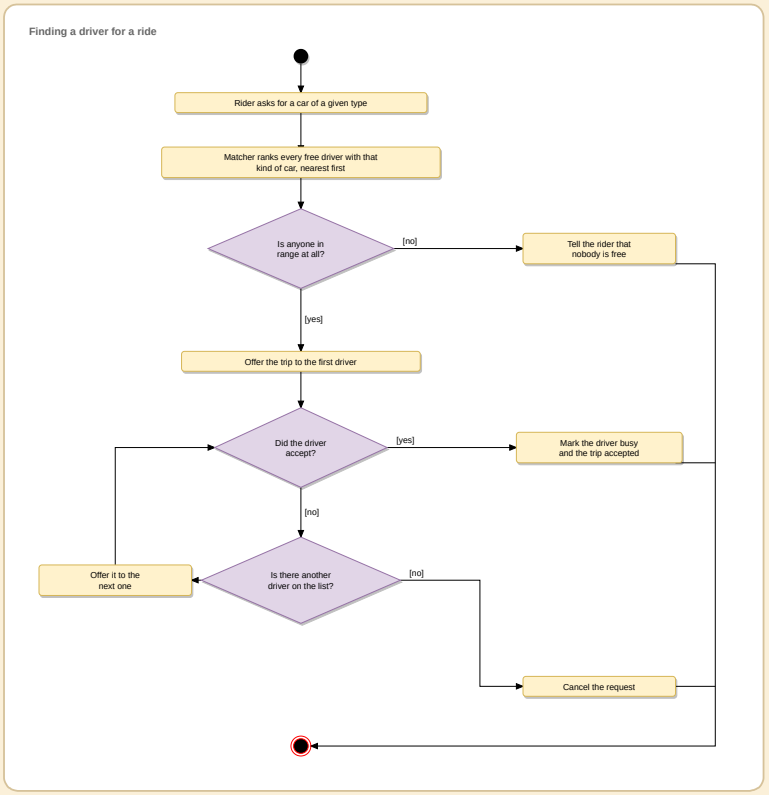


Figure — Finding a driver: rank free drivers of the right type nearest first; offer to the first; on decline move to the next; cancel when nobody is left (course diagram)

Ending and charging a trip — pricing is a single call no matter how many decorators wrap the rule:

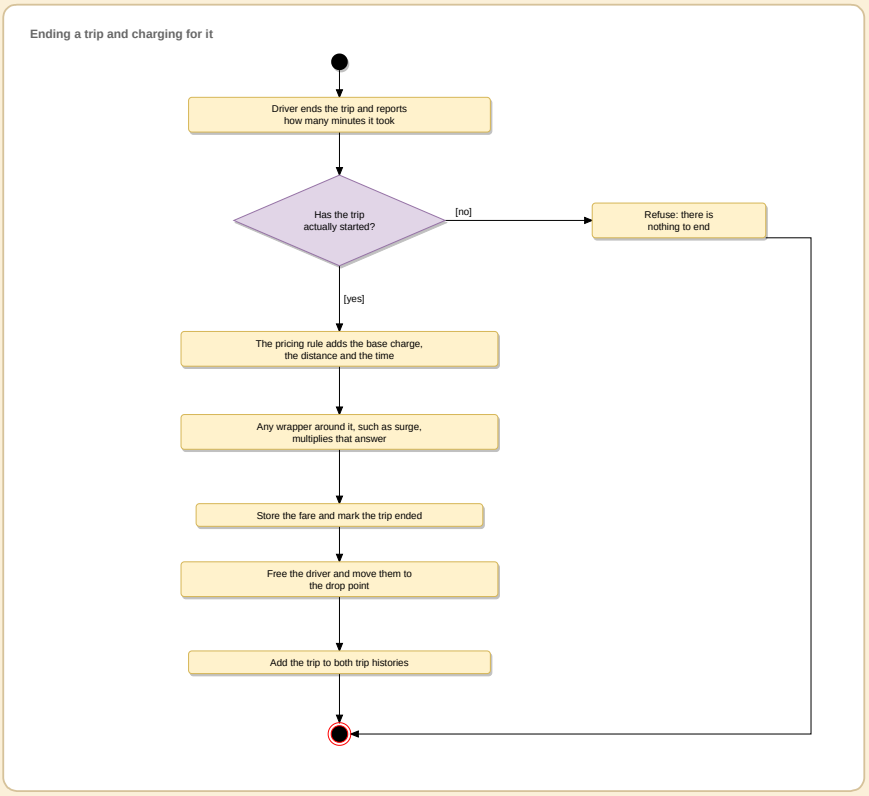

Figure — Ending a trip: refuse if not started; otherwise the pricing rule computes base plus distance plus time, any surge wrapper multiplies it, and the trip is recorded (course diagram)

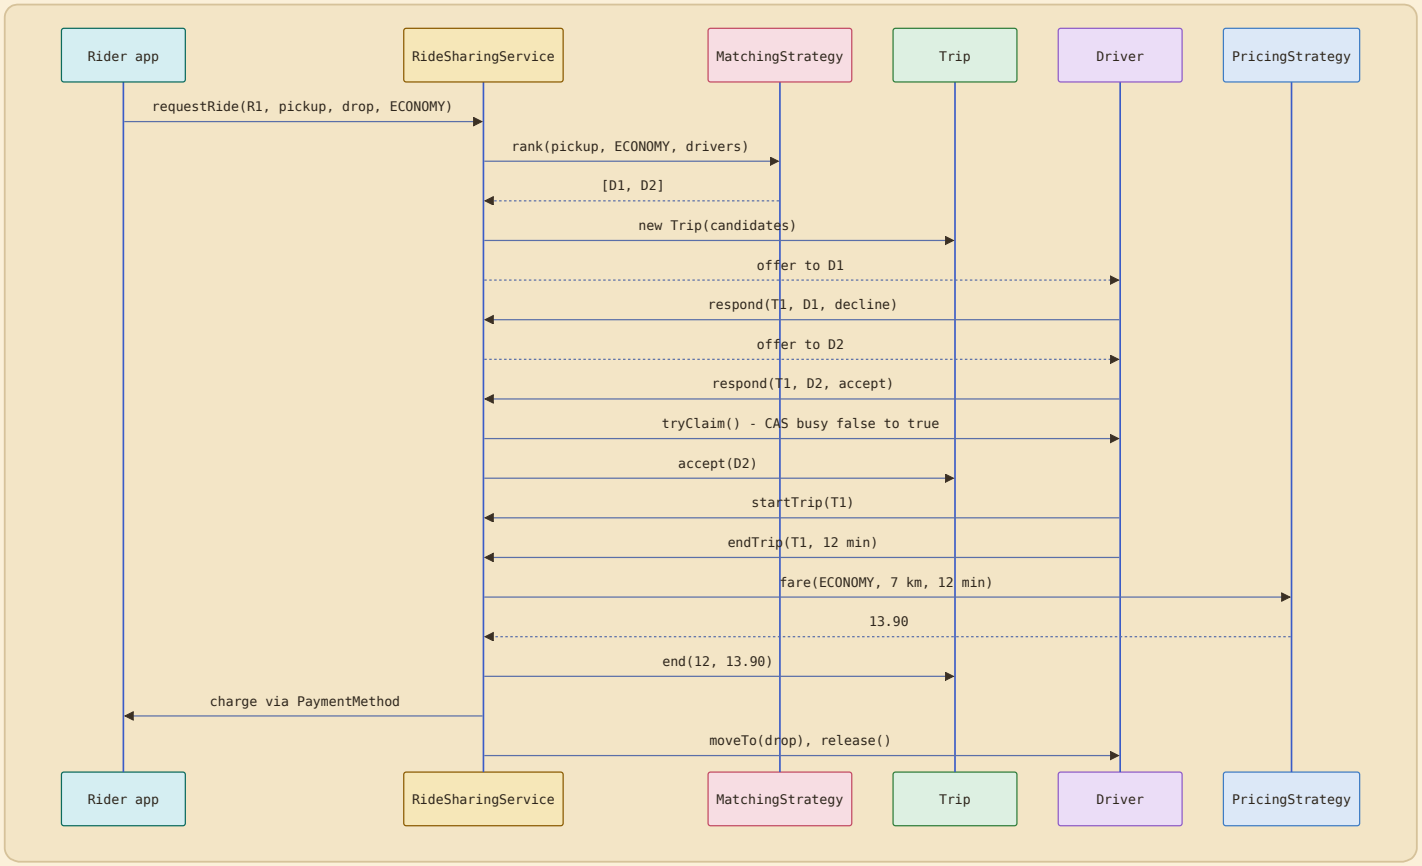

Design decisions & patterns used

Decision	Why	Alternative rejected
Strategy for matching	Cities rank differently (nearest, best-rated, least-earned-today). One class each.	Sorting logic inside the service.
Matcher returns a **ranked list**, stored on the trip	A decline just moves the cursor; no new city-wide search, and the system remembers who refused.	Returning one driver: every decline re-searches from scratch.
Strategy for pricing, **Decorator** for surge	Surge wraps *any* pricing rule (even future ones). Turning it off = removing the wrapper, not editing an `if`. Decorators stack (surge + airport fee + discount).	A `surgeMultiplier` field and `if (surge)` in the pricing code.
State machine via `TripStatus.canMoveTo`	One table says what is legal; every method checks it and returns `false` on an illegal move. No exceptions for normal refusals.	Scattered `if (status == …)` checks; or the full State pattern (one class per state). The State pattern is worth it when behaviour per state is large; here a transition table is enough.
Atomic claim of a driver (`AtomicBoolean.compareAndSet`: "set to true only if it is still false", in one indivisible step)	Two trips racing for the same driver: exactly one wins, the other treats it as a decline.	Checking `isAvailable()` then setting busy: a check-then-act race (a race condition: the result depends on which thread happens to run first).
Driver **moved to the drop point** at trip end	Otherwise the next match uses where they were this morning.	Forgetting (a real bug class).
Observer for trip events	Rider/driver apps, push notifications, analytics (code that collects usage data for reports) listen; the service doesn't know them.	Service calling the notification code directly.
Deterministic tie-breaks (by driver id)	Same input → same ranking → reproducible tests.	Unordered ties: flaky tests (tests that sometimes pass and sometimes fail with no code change).
Money in **`BigDecimal`**, rounded `HALF_UP` (halves round up: 2.345 → 2.35) to 2 places	Exact fares. (The course keeps money as whole cents and the surge multiplier as a whole-number percentage, 150 = ×1.5, so no floating point (binary fractional numbers such as `double`) appears; `BigDecimal` is this book's equivalent.)	`double`.

Java implementation

```java
// File: code/lld/ch20/ridesharing/Model.java
package lld.ch20.ridesharing;

import java.math.BigDecimal;
import java.math.RoundingMode;
import java.util.ArrayList;
import java.util.Collections;
import java.util.List;
import java.util.concurrent.atomic.AtomicBoolean;

/** A point on a city grid. Distance is measured along streets (Manhattan distance), in km. */
record Location(int x, int y) {
    int distanceTo(Location o) { return Math.abs(x - o.x) + Math.abs(y - o.y); }
    @Override public String toString() { return "(" + x + "," + y + ")"; }
}

enum VehicleType { ECONOMY, PREMIUM, VAN }

    private static BigDecimal bd(String s) { return new BigDecimal(s); }
}
```

Walking through the code.

- `TripStatus.NEXT` is the whole lifecycle in five lines; `Trip.move` refuses any move not in the table.
- `Trip` methods are `synchronized`: rider cancel and driver accept on the same trip cannot interleave (have their steps mixed together).
- `RideSharingService.respond`: only the *current* candidate may answer. Accept first **claims the driver atomically**; if the claim fails (another trip got them), it's treated as a decline and the next candidate is offered.
- `endTrip` works in a fixed order: price, store the fare on the trip, charge the rider, relocate the driver to the drop-off point, and only then release them (so no matcher can see a free driver at the old position) — then it records history for both sides. The course lists the same steps; relocating the driver is the step most often skipped, and skipping it makes the next match use the driver's morning position.
- Ratings are allowed once per side and only for ENDED trips (`markDriverRated` / `markRiderRated`).

Output:

```
== 1. Request, first driver declines, second accepts, full ride
  [T1] requested by R1, candidates [D1, D2]
  [T1] offered to D1
  [T1] declined by D1
  [T1] offered to D2
  [T1] accepted by D2
  D2 available while on trip? false
  [T1] started
  [T1] start refused in state STARTED
  [T1] ended: 7 km, 12 min, fare 13.90 (wallet debited 13.90, left 36.10)
  D2 now at (5,3), available? true
  rate driver twice allowed? false; D2 rating 5.00, R1 rating 4.00
== 2. Surge: wrap the same rule in a decorator (x1.5)
  [T2] requested by R2, candidates [D1, D2]
  [T2] offered to D1
  [T2] accepted by D1
  [T2] started
  [T2] ended: 1 km, 3 min, fare 7.50 (collect 7.50 in cash)
== 3. Rider cancels after accept; cancel after start is refused
  [T3] requested by R1, candidates [D3]
  [T3] offered to D3
  [T3] accepted by D3
  [T3] canceled by rider
  D3 released? true
  [T4] requested by R1, candidates [D3]
  [T4] offered to D3
  [T4] accepted by D3
  [T4] started
  [T4] cancel refused in state STARTED
  [T4] ended: 4 km, 10 min, fare 17.00 (wallet debited 17.00, left 19.10)
== 4. Nobody available for a VAN
  [T5] requested by R2, candidates []
  [T5] no driver left - canceled
== 5. Race: 40 riders, 10 drivers, all accept at once
  trips accepted = 10 (never more than 10 drivers)
```

Check the fares: trip 1 is 7 km and 12 min → 2.50 + 7 × 1.20 + 12 × 0.25 = **13.90**. Trip 2 is 1 km, 3 min → 4.45, below the 5.00 minimum → 5.00, then the surge decorator × 1.5 → **7.50**. The race test shows 40 concurrent requests against 10 drivers produce exactly 10 accepted trips — no driver is ever double-booked.

Machine-coding variant: carpool / "offer and select a ride"

A different ride-sharing problem is popular in machine-coding rounds (it appears in the kumaransg/LLD collection — a public GitHub repository of low-level design (LLD: designing the classes inside one program) problems — as a Flipkart-style round). Here there is **no dispatcher**: users *offer* spare seats in their own vehicle on a route, and other users *select* a ride using a **selection strategy**.

Requirements (from the problem statement, in brief):

- `add_user`, `add_vehicle` (a user may own several vehicles).
- `offer_ride(user, origin, seats, vehicle, destination)` — **fails if that vehicle already has an active offered ride**.
- `select_ride(user, origin, destination, seats, strategy)` — seats is 1 or 2; strategy is **Most Vacant** (most free seats) or **Preferred Vehicle** (e.g. "Activa", a scooter model).
- `end_ride(ride)` and `print_ride_stats()` — rides *taken* and *offered* per user, counting only **ended** rides (an offered ride counts even if nobody took it).

Design: `Ride` with an atomic `book(user, seats)`; `RideSelectionStrategy` (Strategy) with `MostVacant` and `PreferredVehicle`; one `RideService` that filters active rides by route and seats, excludes the user's own offers, and lets the strategy choose. The demo replays the problem's sample test case and prints the expected answers (2(c), 2(b), none, 2(d), none; then the stats).

```

	Uber-style (20.4 main design)	Carpool variant
Who supplies the ride	Professional drivers, online/offline	Any user, per offered ride
Who chooses	The system (matching strategy) offers to drivers	The rider picks with a selection strategy
Key pattern	Strategy + Decorator + state machine	Strategy (selection)
Key invariant	A driver is on at most one trip	A vehicle has at most one active offer; seats never go negative

Concurrency & edge cases

- **Double booking a driver:** prevented by `Driver.tryClaim()` (compare-and-set). Proven by the 40-riders/10-drivers race in the output.

- **Cancel vs accept race:** both go through `synchronized` `Trip` methods; if the rider cancels after the claim but before `accept`, `accept` fails and the driver is released.
- **Stale candidate list:** the list is computed once. A driver may go offline or be claimed later; `tryClaim` fails and we move on. A nearer driver who becomes free later is not noticed (real systems re-match periodically).
- **Offer timeouts:** a driver who never answers should be treated as a decline after N seconds (a `ScheduledExecutorService` task per offer).
- **No drivers at all:** trip canceled immediately (see trip T5).
- **Illegal transitions** (start twice, cancel after start, end before start): return `false`; state unchanged.
- **Wallet with insufficient balance:** `Receipt(paid=false)`; a real system would retry another method or record a debt on the rider's account.
- **Rating abuse:** one rating per side per trip; stars validated 1–5.

Extensions & follow-up questions

- **"Rank by rating instead."** Swap `MatchingStrategy` (`BestRatedMatcher` is included) — one line at startup.
- **"Airport fee, promo code, tolls."** More decorators around the pricing rule: `new PromoDiscount(new AirportFee(new SurgePricing(standard, 1.5)))`.
- **"How is surge computed?"** From demand (open requests) vs supply (free drivers) per area and time window; the result feeds the multiplier. The pricing design doesn't change.
- **"Find nearby drivers fast in a real city."** A geospatial index (a lookup structure for finding things by location): split the map into cells (geohash, Google S2 or Uber's H3 hexagons — three standard ways of dividing the globe into numbered cells) and keep a map cell → drivers; search the pickup cell and its neighbours instead of all drivers.
- **"Shared rides (pool)."** Honest answer: this design assumes one rider per trip. The change starts at `Trip` (many riders, many stops) and a matcher that considers detours.
- **"Live tracking."** Drivers send location updates every few seconds; store the latest per driver and publish to the rider (pub-sub, see 20.6).
- **"Scheduled rides."** A request with a future time; a scheduler (a component that runs jobs at chosen times) starts matching shortly before.

Real-world example

Uber really does show riders a surge ("dynamic pricing") multiplier when demand exceeds supply in an area, and it sends a request to a nearby driver who has a short time to accept before it goes to someone else — the ranked-list-with-cursor idea. Uber open-sourced (published free for anyone to use) **H3**, a hierarchical (cells nest inside bigger cells) hexagonal grid that its engineering blog describes as built for optimizing ride pricing and dispatch (for example, bucketing supply and demand per hexagon); the same cell idea answers "which drivers are near this point" without scanning the whole city. Ola, Lyft and Grab follow the same request → match → accept → trip → rate lifecycle.

In the interview

> **30-second answer:** "Two rules behind interfaces: `MatchingStrategy` returns a ranked list of free drivers with the right car, and `PricingStrategy` computes base + distance + time with a floor. Surge is a Decorator that wraps any pricing rule and multiplies it. The trip is a small state machine; every action checks the transition table and returns false if illegal. A decline moves a cursor along the stored ranking. Drivers are claimed with a compare-and-set so one driver can never get two trips."

Tip: name the two rules (matching and pricing) in your first minutes and say both go behind interfaces; that one sentence pre-answers most follow-ups. Then spend real time on surge: *wrapping* the pricing rule instead of adding a flag to it is what separates strong answers from weak ones.

Plan (40 min): clarify (5) → accounts, vehicle, location (5) → trip + state machine (8) → pricing + surge decorator (7) → matching list + decline flow (7) → concurrency (claim) (4) → extensions (4).

Follow-ups with answers:

- *"What happens when a driver declines?"* → Next driver in the stored ranked list; none left → cancel.
- *"Strategy vs Decorator here?"* → Strategy replaces the rule; Decorator wraps it and remains in the call path (it holds an `inner` of the same interface).
- *"Two riders get the same driver?"* → Impossible: atomic claim; the loser moves to its next candidate.

Self-check

1. Why does the matcher return a list instead of one driver? → So a decline just moves to the next candidate without re-searching and remembers who refused.
2. What makes `SurgePricing` a Decorator? → It is a `PricingStrategy` that also wraps a second `PricingStrategy` and adjusts that one's result.
3. Can a rider cancel a STARTED trip? → No; `STARTED` can only move to `ENDED`.
4. Why update the driver's location to the drop-off when the trip ends? → Later matches must use their real position.
5. Which Java class makes the driver claim atomic? → `AtomicBoolean` (`compareAndSet(false, true)`).
6. In the carpool variant, when does `offer_ride` fail? → When the same vehicle already has an active offered ride.

TL;DR

- **Strategy** ×3 (matching, pricing, payment) + **Decorator** (surge) + **state machine** (trip).
- Matcher returns a **ranked list**; the trip keeps a cursor; decline = next.
- **Atomic claim** of drivers prevents double booking; relocate the driver to the drop-off at trip end.
- Ratings = running total + count; `BigDecimal` fares with a minimum.
- Carpool variant: users offer seats; riders select with Most Vacant / Preferred Vehicle strategies.

20.5 Design a Logging Framework

Problem & clarifying questions

What it is. A logging framework lets code write messages like "payment 991 authorised" with a **level** (how serious it is) and sends them to one or more **destinations** (console, file, a log server), in a chosen **format**. Everyday analogy: a company's internal mail room. Every department drops notes in; each note has an urgency stamp; the mail room decides, by department and urgency, which notes get copied to which inboxes and in what envelope.

Think Log4j 2, Logback or `java.util.logging` (the most widely used Java logging libraries): this question asks you to design a small version of them.

Question	Assumed answer
Levels?	TRACE < DEBUG < INFO < WARN < ERROR < FATAL (and OFF).
Per-module configuration?	Yes: loggers are named `app.payment`, `app.orders`… and form a **hierarchy** by dots. A child inherits its level from the nearest ancestor that sets one.
Destinations?	Console, file, in-memory (tests); pluggable. Each can have its own minimum level.
Formats?	Plain pattern and JSON (a text format of nested key-value pairs); pluggable.
Propagation?	An event goes to the logger's own destinations and then **up** to its ancestors' destinations, unless that logger turns propagation (additivity) off.
Async?	Yes, optional: the application thread must not wait for disk I/O (input/output: reading or writing the disk).
Thread-safe?	Yes: many threads log at once.
Config files, rolling files (a log file is closed and a new one started at a size or date limit), remote shipping (sending logs to another server)?	Out of scope (extensions).

Requirements

Functional

1. Log a message at a level; messages below the logger's effective level are dropped cheaply.
2. Loggers are obtained by name; the same name returns the same logger.
3. Loggers form a dot-separated hierarchy under a root; level is inherited when not set.
4. A logger has zero or more appenders (destinations). Each appender has a minimum level and a formatter.
5. Events propagate up to parent appenders unless additivity is off.
6. Formatters are pluggable (pattern, JSON).
7. Asynchronous appending is available without changing the appenders.
8. Exceptions can be attached to an event.
9. Expensive messages can be built lazily (only if the level is enabled).

Non-functional: very cheap when disabled; thread-safe; logging must never crash the application; testable (inject a clock).

Use cases

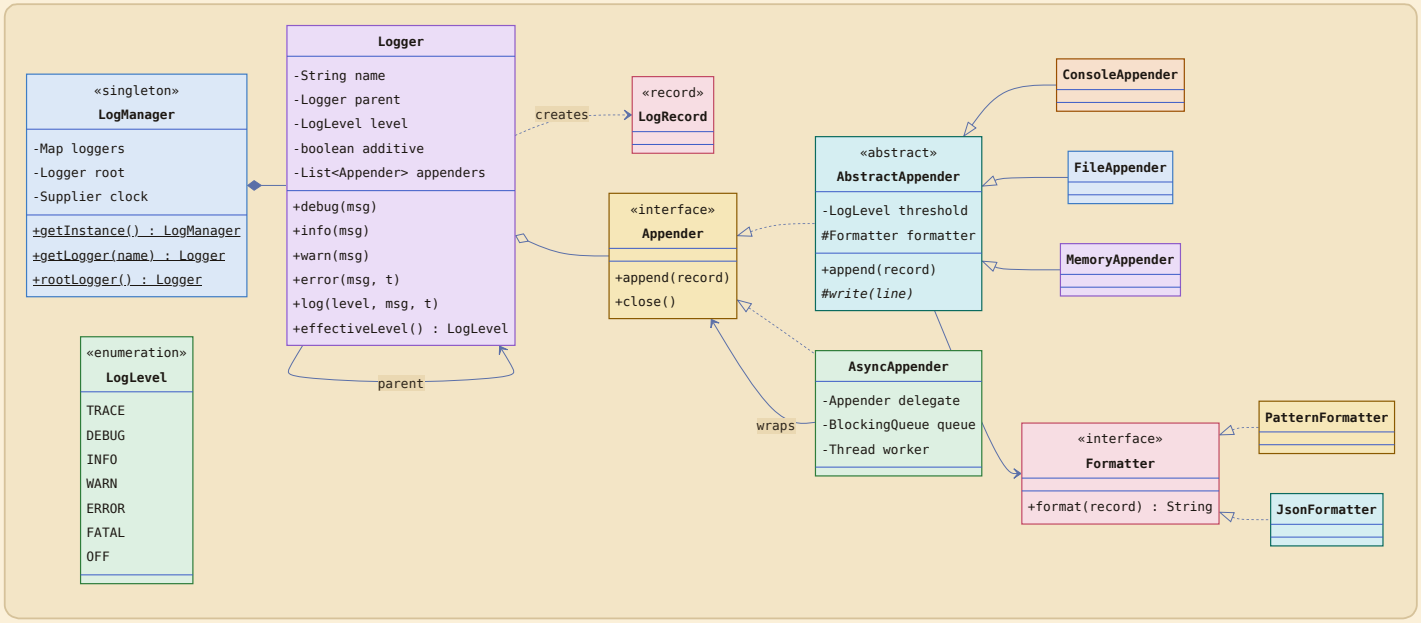
Actors: **Developer code** (logs messages), **Operator** (configures levels, appenders, formats at startup or runtime — while the program is running), **Framework** (filters, formats, routes, writes).

Main use cases: *Log a message*, *Get a logger by name*, *Set a level for a subtree*, *Add a destination*, *Choose a format*, *Switch to async writing*, *Stop propagation for a subtree*.

Core entities

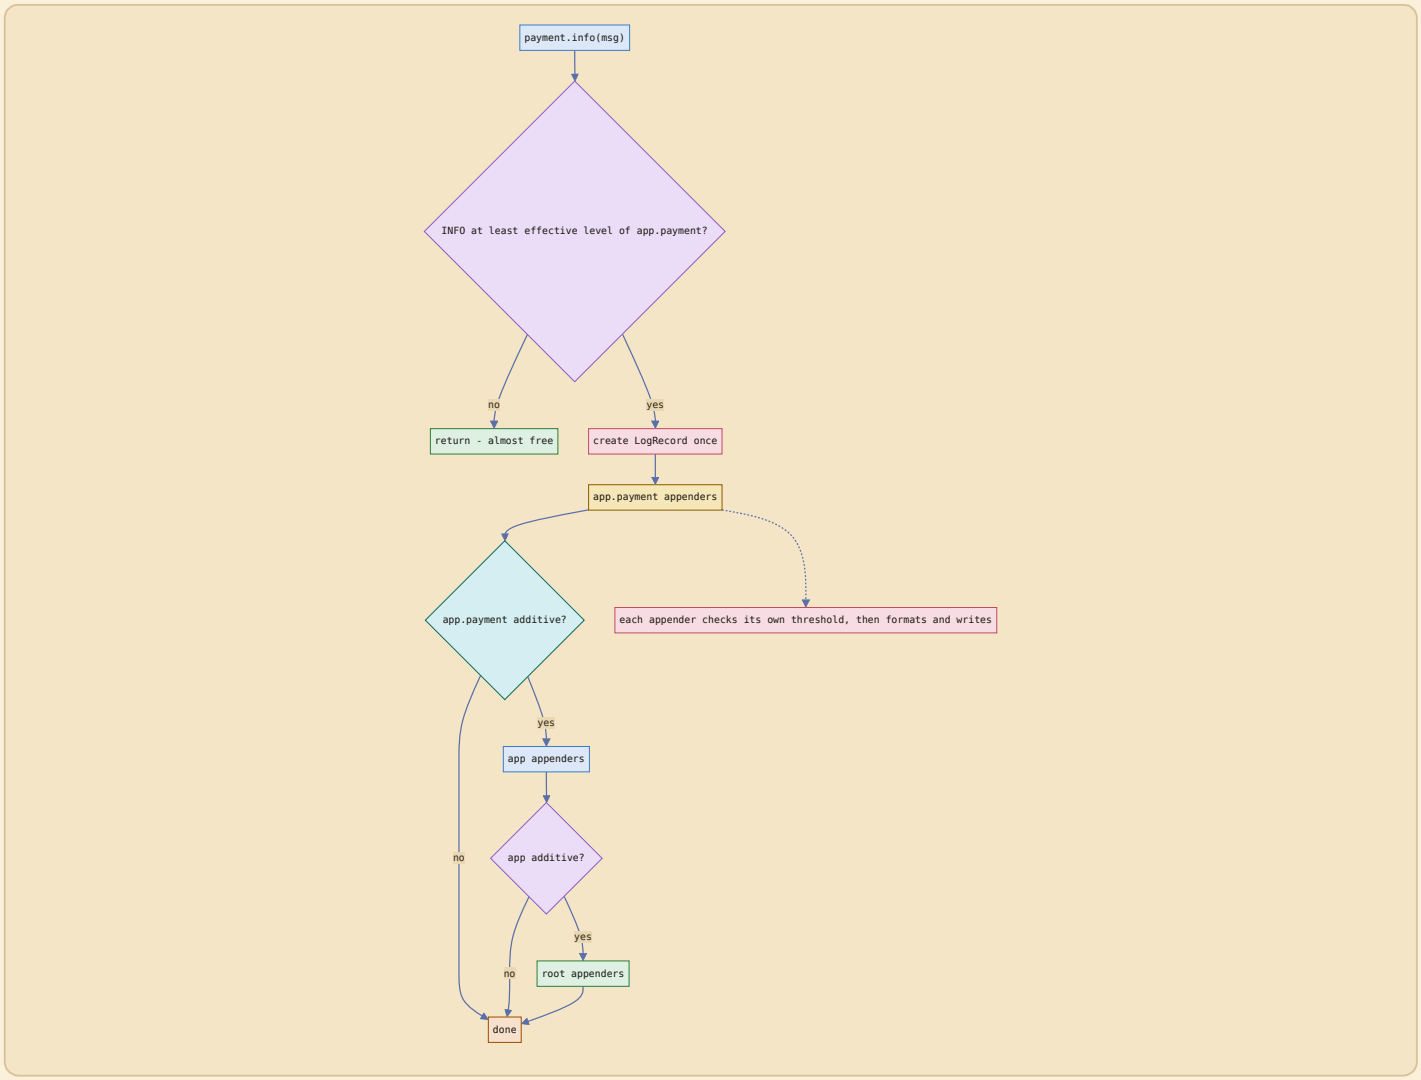
Class	Responsibility
`LogLevel` (enum)	Ordered severities; `isAtLeast(threshold)`.
`LogRecord` (record)	One immutable (cannot change after creation) event: time, level, logger name, thread, message, error.
`Logger`	Named node in the hierarchy: parent, optional level, appenders, additivity; `log()` walks the chain upward.
`LogManager`	**Singleton** registry; `getLogger(name)` creates parents first and returns one instance per name; holds the clock.
`Appender` (interface)	A destination (sink).
`AbstractAppender`	**Template Method**: `append()` checks the appender's threshold and formats; subclasses only `write(line)`.
`ConsoleAppender`, `FileAppender`, `MemoryAppender`	Concrete sinks.
`AsyncAppender`	**Decorator**: wraps any appender with a bounded queue + one writer thread.
`Formatter` (interface)	**Strategy**: record → text. `PatternFormatter`, `JsonFormatter`.

Class diagram



Key flows

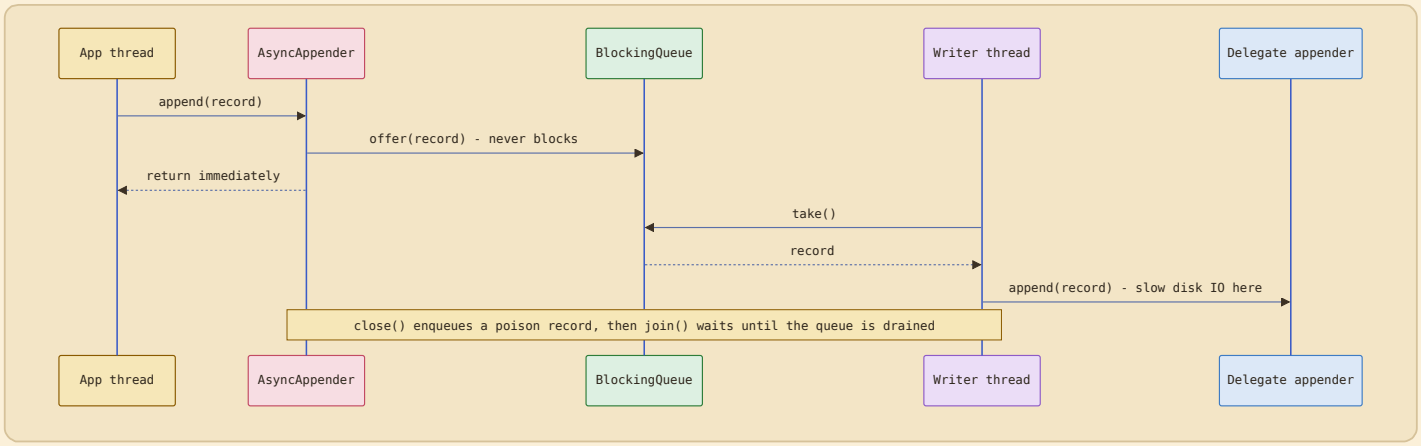
Logging one event (Chain of Responsibility up the hierarchy). *Chain of Responsibility* = a request is passed along a chain of handlers; each may handle it and/or pass it on. Here every logger in the chain hands the record to its own appenders and passes it to its parent, unless additivity is off.



Note the Log4j/Logback rule we copy: the **level check happens once, at the logger where the call was made.** Parents' *levels* are not re-checked during propagation; only each **appender's own threshold** filters. That is why,

in the demo, a DEBUG event from `app.payment` (set to DEBUG) still reaches the root console appender even though root is at INFO.

Async appending.



Design decisions & patterns used

Pattern / decision	Where	Why	Alternative rejected
Chain of Responsibility	`Logger.log` walks `this → parent → … → root`, stopping when `additive == false`	Configure destinations once near the root; subtrees can add or stop.	Every logger listing all its appenders explicitly.
Singleton	`LogManager` (initialization-on-demand holder)	One registry per process, so `getLogger("x")` always returns the same object. Holder idiom (a standard coding recipe) = lazy + thread-safe with no locking (the JVM — Java Virtual Machine, the program that runs Java code — initializes the nested class once).	Public static mutable (changeable) map; double-checked locking (check, lock, check again; easy to get wrong).
Static factory method	`LogManager.getLogger(name)`	Hides creation, caches instances, creates parents first.	`new Logger(...)` by users (breaks the hierarchy).
Strategy	`Formatter`	Format is independent of destination: any sink × any format.	`JsonFileAppender`, `PatternFileAppender`, … (class explosion).
Template Method	`AbstractAppender.append` (final) → `write`	Threshold + formatting done once; sinks only write text.	Each sink re-implementing filtering.
Decorator	`AsyncAppender` wraps any `Appender`	Async becomes an add-on, not a rewrite of every sink.	`AsyncFileAppender`, `AsyncConsoleAppender`, …
Level check first; **lazy** `Supplier<String>` (a function that builds the string only when called)	`isEnabled`, `debug(Supplier)`	Disabled logging costs one comparison; expensive strings are never built.	Always building the message (a real performance bug).
Appender failures caught	`Logger.log`	Logging must never crash the app.	Letting exceptions escape.
Parent resolved **outside** `computeIfAbsent`	`LogManager.loggerFor`	A `ConcurrentHashMap` mapping function must not modify the same map (the JDK may throw `IllegalStateException: Recursive update`).	Recursive `computeIfAbsent`.

A note on another common "CoR logger" answer. Many LLD write-ups model Chain of Responsibility as a chain of *level handlers* (`ErrorHandler → WarnHandler → InfoHandler → DebugHandler`), each writing messages of "its" level and passing others along. It works for a toy, but real frameworks put the chain on the **logger hierarchy** (as here) because that is what operators actually configure. If an interviewer expects the level-handler version, explain both and why the hierarchy is the one Log4j/Logback use.

Java implementation

```java
// File: code/lld/ch20/logging/Core.java
package lld.ch20.logging;

import java.time.Instant;
import java.time.ZoneOffset;
import java.time.format.DateTimeFormatter;

/** Severity, lowest to highest. A logger set to WARN drops TRACE, DEBUG and INFO. */
enum LogLevel {
    TRACE, DEBUG, INFO, WARN, ERROR, FATAL, OFF;

    boolean isAtLeast(LogLevel threshold) { return this.ordinal() >= threshold.ordinal(); }
}

/** One immutable log event. Created once, passed along the chain, formatted by each appender. */
record LogRecord(Instant time, LogLevel level, String loggerName, String thread, String message, Throwable error)
{}

/** Strategy: how a record becomes text. */
interface Formatter {
    String format(LogRecord r);
}

final class PatternFormatter implements Formatter {
    private static final DateTimeFormatter TIME =
            DateTimeFormatter.ofPattern("yyyy-MM-dd HH:mm:ss.SSS").withZone(ZoneOffset.UTC);

    @Override
    public String format(LogRecord r) {
        String line = String.format("%s %-5s [%s] %s - %s", TIME.format(r.time()), r.level(), r.thread(),
                r.loggerName(), r.message());
        return r.error() == null ? line : line + " | " + r.error();
    }
}

final class JsonFormatter implements Formatter {
    @Override
    public String format(LogRecord r) {
        return "{\"ts\":\"" + r.time() + "\",\"level\":\"" + r.level() + "\",\"logger\":\"" + r.loggerName()
                + "\",\"msg\":\"" + r.message().replace("\"", "\\\"") + "\"}";
    }
}
```

            }));
        }
        for (Thread t : threads) t.join();
```

```
        async.close();
        System.out.println("  written=" + counter.count.get() + " dropped=" + async.dropped()
                + " total=" + (counter.count.get() + async.dropped()));
    }

    static final class CountingAppender implements Appender {
        final AtomicInteger count = new AtomicInteger();
        public void append(LogRecord r) { count.incrementAndGet(); }
    }
}
```

Walking through the code.

- `Logger.effectiveLevel` walks up until a logger has a level; root always has one.
- `Logger.log` creates the `LogRecord` **once** and hands the same immutable object to every appender in the chain (safe to share across threads because it is a record with final fields).
- `AbstractAppender.append` is `final`; `ConsoleAppender` and `FileAppender` synchronize `write` so lines from different threads never interleave mid-line.
- `AsyncAppender` uses a bounded `ArrayBlockingQueue` (a fixed-size, thread-safe queue) and `offer` (non-blocking: returns at once instead of waiting): when full, it drops and counts instead of stalling the application. `close()` puts a "poison pill" record (a special marker that means "stop after this") so the writer drains everything before stopping. The no-loss promise is precise: every record appended **before** `close()` is either written or counted in `dropped` (queue full); a record appended after `close()` is counted as dropped too, so `written + dropped` always equals the number of `append` calls. A delegate that throws is caught inside the writer loop, so one bad write cannot kill the writer thread (which would otherwise leave `close()` waiting forever on a full queue).
- `LogManager` uses the holder idiom: `Holder.INSTANCE` is created the first time `getInstance()` runs, and the JVM guarantees that happens once.

Output:

```
== 1. Same name -> same instance: true
== 2. Levels: 'app.payment' inherits INFO from root
2026-09-28 10:15:30.123 INFO  [main] app.payment - payment 991 authorised
2026-09-28 10:15:30.123 WARN  [main] app.payment - retrying gateway call
== 3. Raise one subtree to DEBUG; extra JSON sink only for payments
2026-09-28 10:15:30.123 DEBUG [main] app.payment - card token=tok_42 (built lazily)
  audit sink got: [{"ts":"2026-09-28T10:15:30.123Z","level":"DEBUG","logger":"app.payment","msg":"card token=tok_42
(built lazily)"}]
== 4. Additivity off: 'app.payment' events stop at its own appenders
  (nothing printed on console above) audit sink now has 2 lines
== 5. File sink with its own threshold (WARN+)
2026-09-28 10:15:30.123 INFO  [main] app - info goes to console only
2026-09-28 10:15:30.123 WARN  [main] app - disk 91% full
  file contains: [2026-09-28 10:15:30.123 WARN  [main] app - disk 91% full]
== 6. Async appender: 4 threads x 1000 events, then close() flushes
  written=4000 dropped=0 total=4000
```

Step 4: with additivity off, the ERROR went only to the JSON audit sink (2 lines now) and not to the console. Step 6: 4 threads × 1000 events all arrived (4000 written, 0 dropped), and `close()` flushed the queue.

Concurrency & edge cases

- **Many threads logging:** appenders list is `CopyOnWriteArrayList` (reads without locking, rare writes); level and additivity are `volatile` (a Java keyword that makes every thread see the latest written value) so a runtime change is seen by all threads.
- **Interleaved output:** each sink's `write` is synchronized.
- **Async queue full:** drop-and-count (never block). Alternatives: block (back-pressure — slowing the producer down when the consumer cannot keep up — can stall the app) or drop only low levels. Logback's `AsyncAppender`, by default, starts discarding TRACE/DEBUG/INFO events when the queue is 80% full.
- **Shutdown:** without `close()`, queued events are lost; register a JVM shutdown hook (code the JVM runs just before the program exits) that closes appenders.

- **Recursive logging** (an appender that logs while appending) can loop forever; guard with a thread-local (each thread gets its own separate copy) "already inside" flag.
- **Security:** never let log messages trigger lookups or code; Log4Shell (CVE-2021-44228, December 2021; a CVE is a public id for a known security flaw) came from Log4j 2 interpreting `${jndi:...}` (a lookup that could load code from a remote server) inside logged strings. Treat messages as plain data.
- **Sensitive data:** mask card numbers, tokens and passwords before formatting.

Extensions & follow-up questions

- **"Rolling files."** A `RollingFileAppender` with a `RollingPolicy` (size- or time-based) Strategy: when triggered, close, rename to `app-2026-09-28.log`, open a new file.
- **"Config file."** Parse XML/YAML/properties (common configuration-file text formats) into calls on `LogManager` (set levels, attach appenders). Watching the file lets levels change at runtime.
- **"Filters."** A `Filter` chain per appender (e.g. only `app.payment`, only messages containing "refund") — another Chain of Responsibility.
- **"MDC / request id."** A thread-local map (Mapped Diagnostic Context) copied into each `LogRecord`, so every line of one request carries the same id.
- **"Ship logs to a server."** A network appender behind `AsyncAppender`, batching records.
- **"Structured logging."** Key-value fields in `LogRecord` rendered by `JsonFormatter` for tools like Elasticsearch/Kibana (a search engine and its dashboard, often used to store and browse logs).

Real-world example

SLF4J (Simple Logging Facade for Java) is a facade (the API your code calls); **Logback** and **Log4j 2** are implementations with exactly this model: dot-named loggers in a hierarchy, inherited levels, appenders with layouts/encoders, and *additivity*. Log4j 2's async loggers use the LMAX Disruptor (a lock-free ring buffer: a fixed-size circular array that threads share without taking locks) to hand events to a background thread. `java.util.logging` has the same shape with different names: `Logger`, `Handler` (appender), `Formatter`, `Level`, and `setUseParentHandlers(false)` (additivity off).

In the interview

> **30-second answer:** "Loggers are named and form a dot hierarchy under a root managed by a singleton `LogManager`. A log call first checks the effective level (inherited), builds one immutable record, and passes it up the chain of loggers to their appenders — Chain of Responsibility — until additivity stops it. Each appender has its own threshold and a pluggable formatter (Strategy). `AsyncAppender` is a Decorator with a bounded queue and a writer thread, so the app never waits for disk."

Plan (35 min): clarify (5) → levels + record (4) → logger hierarchy + effective level (6) → appenders + formatters (6) → propagation/additivity (5) → singleton + thread safety (4) → async (5).

Follow-ups with answers:

- *"Why is a disabled debug call cheap?"* → One level comparison before any string is built; use `Supplier` for expensive messages.
- *"How do you make it thread-safe?"* → Immutable records, `CopyOnWriteArrayList` appenders, synchronized sinks, `ConcurrentHashMap` registry, volatile config.
- *"What happens to queued logs on crash?"* → They're lost unless flushed; close on shutdown, or accept the trade-off for speed.

Self-check

1. `app.payment` has no level; `app` is WARN; root is INFO. What is `app.payment`'s effective level? → WARN (nearest ancestor that sets one).
2. What does additivity=false do? → Stops the event from reaching ancestor loggers' appenders.
3. Which pattern lets any appender become async? → Decorator (`AsyncAppender`).
4. Why is `Formatter` separate from `Appender`? → So formats and destinations combine freely (Strategy) without a class per combination.
5. Why resolve the parent before `computeIfAbsent`? → Modifying the same `ConcurrentHashMap` inside its mapping function is not allowed.

6. How does `close()` guarantee nothing queued is lost? → It enqueues a poison pill and joins the writer thread, which drains every record queued before the pill. (Records refused because the queue was full, or appended after `close()`, are not lost silently: they are counted as dropped.)

TL;DR

- Named **logger hierarchy**; effective level inherited; one cheap level check up front.
- **Chain of Responsibility** up to the root, stopped by additivity; **Singleton** `LogManager`.
- **Strategy** formatters, **Template Method** appender base, **Decorator** async appender.
- Immutable `LogRecord`, thread-safe sinks, never crash the app, never block on a full queue.

20.6 Design a Pub-Sub System

Problem & clarifying questions

What it is. Publish-subscribe (pub-sub) is a way for parts of a system to talk **without knowing each other**. A *publisher* sends a message to a named *topic* ("orders"); every *subscriber* of that topic receives it. Everyday analogy: a newspaper. The newspaper prints once; every subscriber gets a copy; the newspaper doesn't know or care who reads it, and new readers can sign up any time.

It is the **Observer pattern** turned into infrastructure: in Observer the subject calls its observers directly; in pub-sub a **broker** in the middle decouples them further (makes each side depend less on the other: by topic, by time, and often by machine). We design a simplified, Kafka-like, in-process (living inside one running program) broker.

Question	Assumed answer
Delivery to how many?	Every subscription gets every message (fan-out).
Order?	Messages are delivered in publish order per subscription.
Guarantee?	**At-least-once**: a message is only acknowledged after the subscriber processes it; failures are retried; duplicates are possible.
Slow subscriber?	Must not slow down the others or the publisher.
Keep messages after delivery?	Yes: an append-only log with **offsets**, so late subscribers can start from the beginning and anyone can replay.
Poison message (always fails)?	After N attempts, send to a dead-letter topic (a side topic that holds messages that could not be processed) and move on.
Push or pull?	Push to a callback, driven by one dispatcher (the loop that hands out messages) per subscription.
Partitions, consumer groups sharing work, persistence to disk, retention?	Out of scope (extensions; each is explained there).

Requirements

Functional

1. Create topics; publish a message (key, payload) to a topic; the broker assigns an **offset** (its position in the topic's log).
2. Subscribe to a topic with a subscription id and a callback, starting from EARLIEST (offset 0) or LATEST (only new messages).
3. Each subscription receives every message in order.
4. A message is acknowledged (offset committed) only after the callback returns normally.
5. Failures are retried with backoff; after `maxAttempts` the message goes to a dead-letter topic.
6. A subscription can **seek** to an offset to replay.
7. Unsubscribe; shut down cleanly.

Non-functional: thread-safe publish from many threads; subscribers isolated from each other; no busy-waiting (a thread spinning in a loop checking "anything yet?" and burning CPU (processor) time; here threads sleep until data arrives); ordering preserved.

Use cases

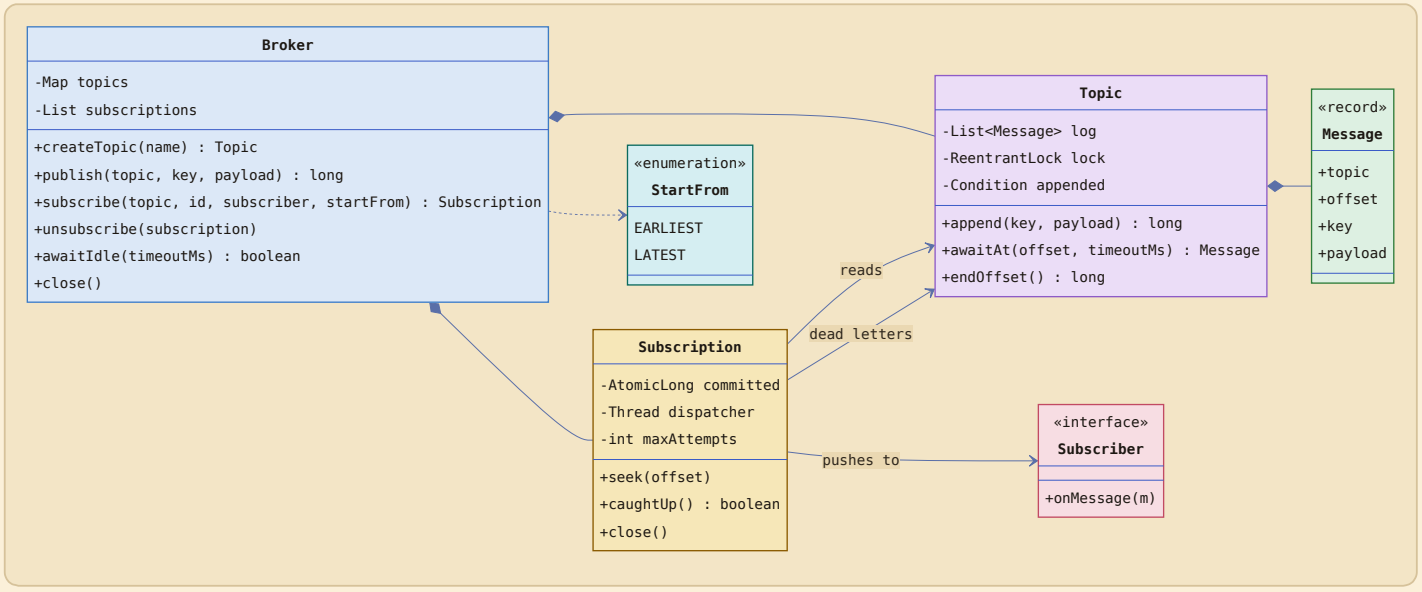
Actors: **Publisher** (publishes), **Subscriber** (subscribes, processes, fails sometimes), **Operator** (creates topics, replays, inspects dead letters), **Broker** (stores, dispatches, retries).

Core entities

Class	Responsibility
`Message` (record)	topic, offset, key, payload. Immutable.
`Topic`	Append-only log (`List<Message>`), guarded by a `ReentrantLock` with a `Condition` (an object a thread can wait on until another thread signals it) "appended" to wake waiting dispatchers.
`Subscriber` (interface)	Callback `onMessage(Message)`; throwing = negative acknowledgement ("I could not process this").
`Subscription`	One subscriber on one topic: committed offset (`AtomicLong`), its **own dispatcher thread**, retry and dead-letter logic, `seek`.
`StartFrom` (enum)	EARLIEST / LATEST.
`Broker`	Topic registry, `publish`, `subscribe`, `unsubscribe`, dead-letter topic, `awaitIdle` (tests), `close`.

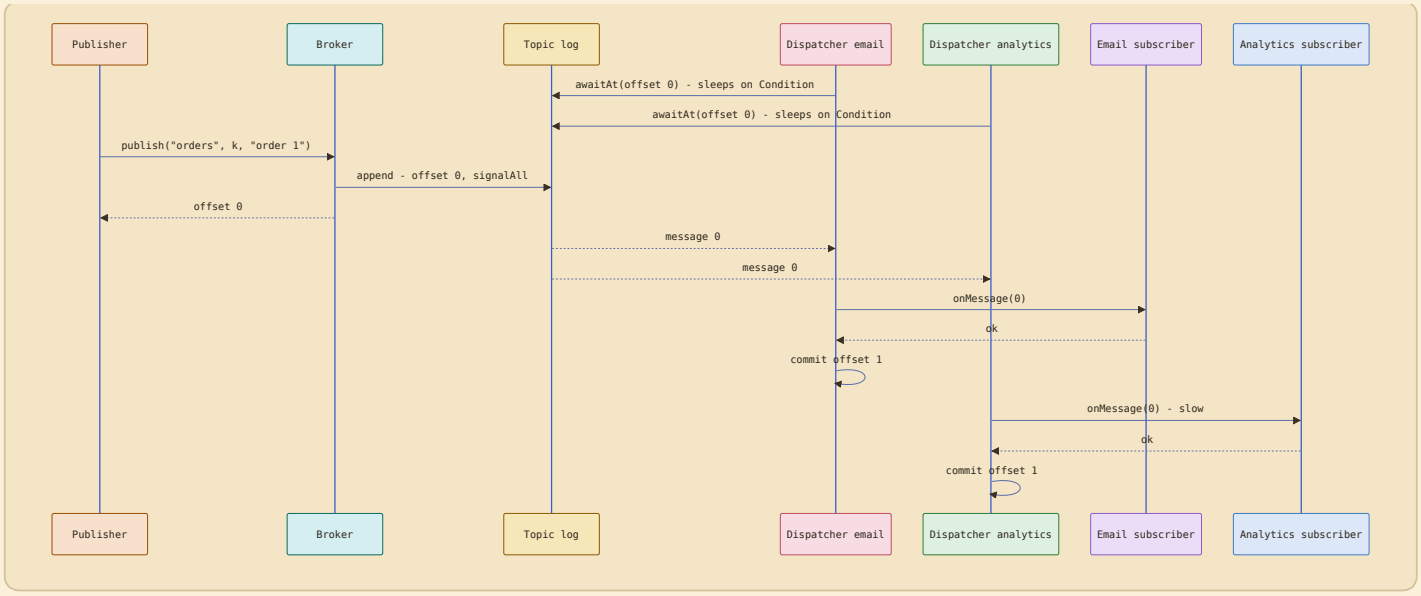
The key idea: messages are not removed when consumed. Each subscription only remembers *how far it has read* (its offset). That gives, almost for free: late subscribers from the beginning, replay (`seek`), and independent progress per subscriber. This is Kafka's model. (Classic queues such as RabbitMQ, a popular open-source message broker, instead delete a message once it is acknowledged.)

Class diagram

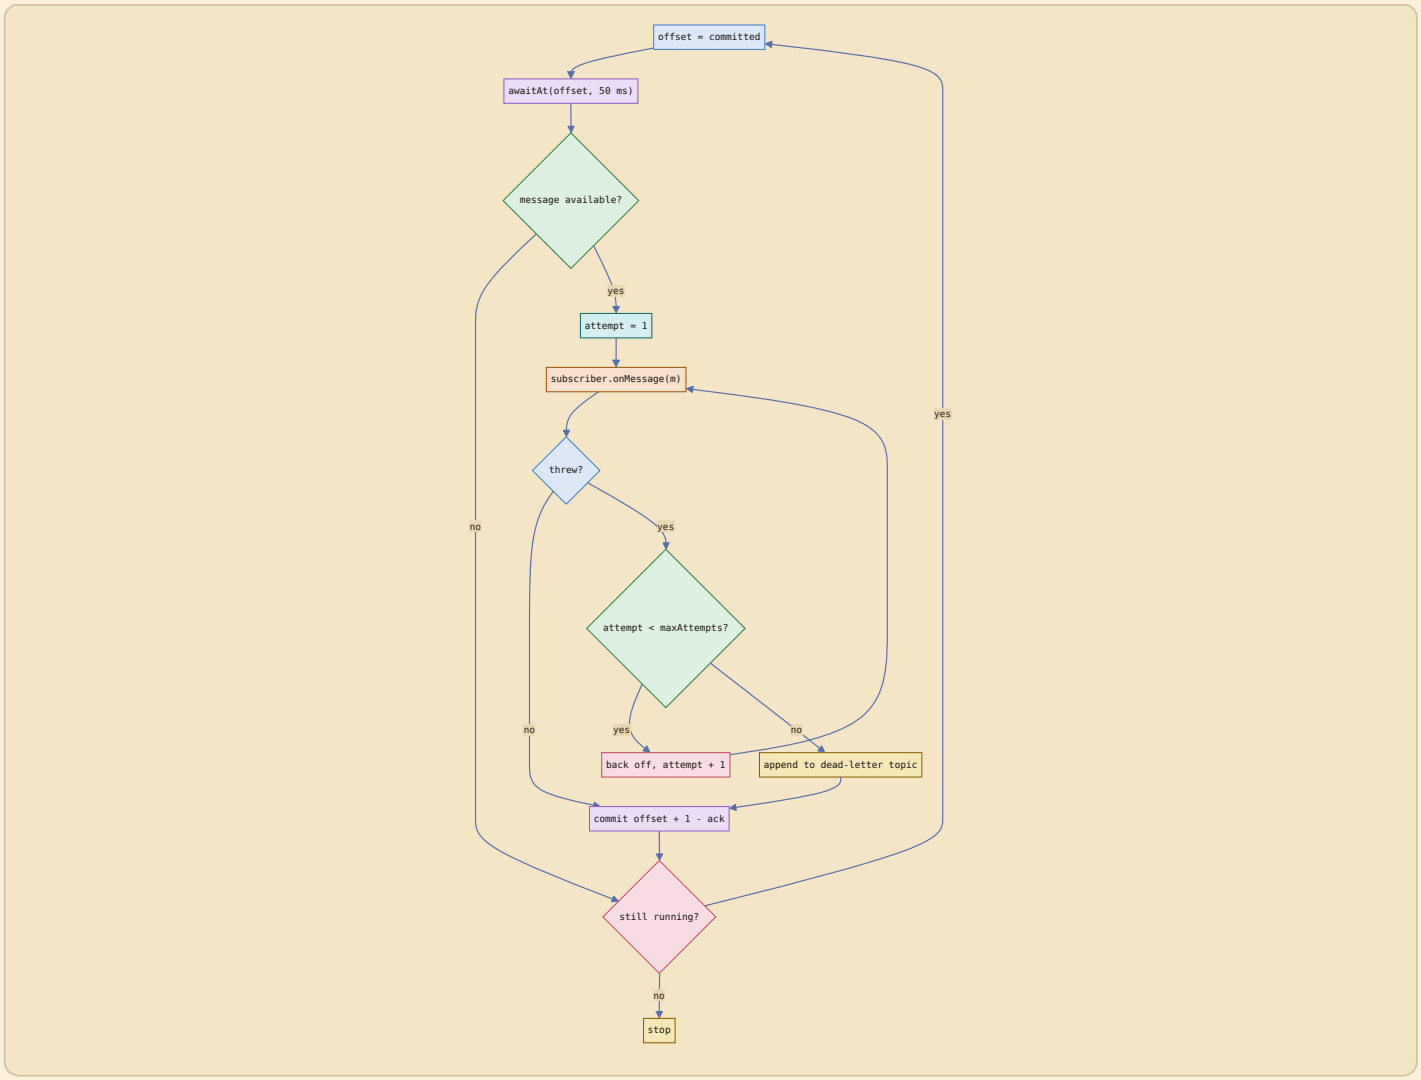


Key flows

Publish and fan-out.



One subscription's dispatcher loop (at-least-once with dead letters).



Design decisions & patterns used

Decision	Why	Alternative rejected
Publish-Subscribe (Observer via a broker)	Publishers and subscribers never reference each other; add a subscriber with zero publisher changes.	Publisher calling each consumer directly (tight coupling).
Append-only log + offsets	Replay, late joiners and independent progress. Ordering is the log order.	Deleting on delivery: no replay; per-subscriber copies: wasteful.
One dispatcher thread per subscription (virtual threads: Java 21's very cheap threads managed by the JVM rather than the operating system)	A slow subscriber only delays itself (see "analytics" in the output). Order within a subscription is kept because only one thread delivers for it. Virtual threads make one-thread-per-subscription cheap.	One shared thread delivering to all subscribers in turn (the slowest blocks everyone); a thread pool (a fixed set of reusable threads) per message (loses ordering).
`Lock` + `Condition` wait, with timeout	No busy-waiting; the timeout lets the loop notice `close()` and `seek()`. `while` loop guards against spurious wake-ups (a waiting thread may wake up although nobody signalled it).	`Thread.sleep` polling (repeatedly checking; wastes CPU and adds latency — the delay before something is handled).
Ack after processing (commit after `onMessage`)	At-least-once: a crash mid-processing re-delivers.	Commit before processing = at-most-once (each message is delivered once or not at all; can lose messages).
Dead-letter topic	One poison message cannot block the subscription forever; operators can inspect and re-publish.	Infinite retries (the subscription is stuck).
`compareAndSet` when committing	If `seek()` ran during delivery, the seek wins instead of being overwritten.	Plain `set`.

Delivery guarantees in one table:

Guarantee	How	Risk
At-most-once	Commit offset, then process	A crash loses the message
At-least-once (ours)	Process, then commit	A crash or retry duplicates the message → make subscribers **idempotent**
Exactly-once	At-least-once + deduplication (spotting and dropping repeats) / transactions that commit output and offset together	Complex; Kafka offers it within its own transactions

Java implementation

```java
// File: code/lld/ch20/pubsub/Topic.java

            System.out.println("== 4. 4 publisher threads x 250 messages on a new topic");
            broker.createTopic("clicks");
            RecordingSubscriber clicks = new RecordingSubscriber(0, null);
            broker.subscribe("clicks", "counter", clicks, StartFrom.EARLIEST);
            List<Thread> pubs = new ArrayList<>();
            for (int t = 0; t < 4; t++) {
                int id = t;
                pubs.add(Thread.ofPlatform().start(() -> {
                    for (int i = 0; i < 250; i++) broker.publish("clicks", "user" + id, "c" + id + "-" + i);
                }));
            }
            for (Thread t : pubs) t.join();
            broker.awaitIdle(5_000);
            boolean inOrder = true;
            for (int i = 0; i < clicks.received.size(); i++)
                inOrder &= clicks.received.get(i).startsWith(i + ":");
            System.out.println("  received " + clicks.received.size() + " messages, offsets strictly in order: " +
inOrder);
        }
    }
}
```

Walking through the code.

- `Topic.append` adds to the list and calls `signalAll()` under the lock, waking every dispatcher waiting for new data.
- `Topic.awaitAt` waits on the `Condition` in a `while` loop with `awaitNanos` (correct handling of spurious wake-ups and timeouts), then returns the message at that offset.
- `Subscription.loop` delivers one message at a time and only then commits `offset + 1` with `compareAndSet`, so a concurrent `seek()` wins.
- `deliver` retries with a small backoff and, after `maxAttempts`, writes a description to the `__dead_letters` topic and moves on.
- `Broker.awaitIdle` is a test helper: it waits until every subscription's committed offset has reached its topic's end.

Output:

```
== 1. Fan-out: every subscriber gets every message, in order
  all acknowledged: true
  email     [0:order#1, 1:order#2, 2:BAD-JSON, 3:order#3]
  analytics [0:order#1, 1:order#2, 2:BAD-JSON, 3:order#3]  (slow, but did not slow the others)
  inventory [0:order#1, 1:order#2, 3:order#3]  (offset 1 retried, offset 2 dead-lettered)
  dead letter: orders@2 BAD-JSON -> cannot parse
== 2. A late subscriber chooses where to start
  audit (EARLIEST) [0:order#1, 1:order#2, 2:BAD-JSON, 3:order#3, 4:order#4]
  live  (LATEST)   [4:order#4]
== 3. Replay: seek the 'live' subscription back to offset 3
  live after replay [4:order#4, 3:order#3, 4:order#4] (order#4 seen twice: at-least-once)
== 4. 4 publisher threads x 250 messages on a new topic
  received 1000 messages, offsets strictly in order: true
```

Points to notice: the slow "analytics" subscriber still got everything, and the other subscribers were not delayed; "inventory" retried offset 1 (a transient — temporary — failure) and dead-lettered offset 2 (the poison message) while still receiving offset 3; after `seek(3)`, "live" saw order#4 twice — that is what at-least-once means. The 1000 messages from 4 concurrent publishers got unique offsets and arrived strictly in order.

Concurrency & edge cases

- **Concurrent publishers:** `append` is under a lock, so offsets are unique and gap-free.
- **Readers vs writers:** dispatchers only read under the same lock; messages are immutable records, safe to share.
- **Unbounded memory:** the log grows forever; real brokers apply **retention** (delete segments — the chunks the log is stored in — older than N days or beyond N bytes).

- **Slow subscriber falling far behind:** it is fine here (it just reads older offsets); with retention it may fall off the end — detect "offset out of range" and reset.
- **Subscriber that blocks forever:** add a processing timeout. It stalls only its own subscription, because every subscription has its own dispatcher thread. (One Java 21 caveat: a virtual thread that blocks while inside a `synchronized` block *pins* its carrier platform thread (the real operating-system thread it runs on); many such subscribers could exhaust the carriers. Prefer `ReentrantLock` in subscriber code, or use platform threads.)
- **Duplicates:** at-least-once means subscribers must be idempotent (e.g. remember processed order ids).
- **Shutdown:** `close()` flips `running` and joins each dispatcher (waits for its thread to finish); the 50 ms wait timeout bounds how long that takes.

Extensions & follow-up questions

- **"Consumer groups (share the work)."** Split a topic into **partitions** (several logs); messages with the same key go to the same partition (`hash(key) % n`), keeping per-key order. A **consumer group** is a set of consumers that split one topic's work between them; a group's members each own some partitions; the committed offset is per (group, partition). That is how Kafka scales consumers.
- **"Persist to disk."** Append to segment files; keep an index (a lookup table) from offset to file position; store committed offsets in a special topic (Kafka uses `__consumer_offsets`).
- **"Pull instead of push."** Expose `poll(subscriptionId, maxMessages)` returning messages from the committed offset and a `commit(offset)` call; the client controls its pace (back-pressure for free).
- **"Message filtering."** Subscribe with a predicate (a yes/no test, e.g. only `region = EU`); dispatcher skips non-matching messages but still commits them.
- **"Wildcard topics."** Subscribe to `orders.*` (`*` is a wildcard that matches any name part); the broker matches topic names on creation.
- **"Delayed messages / retry topics."** Re-publish failed messages to `orders.retry.5s` consumed after a delay, instead of blocking the dispatcher with sleeps.

Real-world example

Apache Kafka is exactly this model at scale: topics split into partitions, each an append-only log; consumers track offsets; consumer groups share partitions; ordering is per partition; messages are retained by time/size rather than deleted on read, so services can replay history. **Google Cloud Pub/Sub** and **AWS SNS + SQS** (Amazon's notification and queue services) offer managed fan-out with acknowledgements and **dead-letter** topics/queues. In Java, Spring Kafka's (Spring is the most popular Java application framework) `DeadLetterPublishingRecoverer` publishes a record that keeps failing to a dead-letter topic after the retries are used up — the same idea as our `__dead_letters`. Inside one JVM, Guava's `EventBus` and Spring's `ApplicationEventPublisher` are simple in-process pub-sub.

In the interview

> **30-second answer:** "Each topic is an append-only log; publishing appends and returns an offset. Each subscription keeps a committed offset and has its own dispatcher thread that waits on a condition for new data, calls the subscriber, and commits only after success — at-least-once and in order. Failures retry with backoff, then go to a dead-letter topic. Because messages aren't deleted on read, late subscribers can start at the beginning and anyone can replay by seeking. To scale, split topics into partitions by key and let consumer groups share partitions."

Plan (35–40 min): clarify guarantees (5) → topic log + offsets (6) → subscription + dispatcher + ack (8) → retries + DLQ (dead-letter queue) (5) → thread safety and ordering (6) → partitions / consumer groups / persistence (5).

Follow-ups with answers:

- *"How do you keep a slow consumer from slowing others?"* → One dispatcher per subscription; the log is shared, progress is not.
- *"Exactly-once?"* → Hard; at-least-once + idempotent consumers is the practical answer.
- *"How is order guaranteed?"* → One writer (the lock) assigns offsets; one dispatcher per subscription delivers in offset order. With partitions, order is per partition (per key).

Self-check

1. What is an offset? → A message's position in a topic's log; subscribers remember the next one to read.

2. Commit before or after processing for at-least-once? → After.
3. Why a dead-letter topic? → So one poison message cannot block a subscription forever.
4. Why does replay work here but not in a delete-on-ack queue? → Messages stay in the log; seeking just moves the offset.
5. Why `while` around `Condition.await`? → Spurious wake-ups; re-check the condition every time.
6. How does Kafka let several consumers share one topic's work while keeping order per key? → Partitions by key hash; each partition consumed by one group member.

TL;DR

- **Pub-sub = Observer through a broker**; publishers and subscribers are decoupled.
- **Append-only log + per-subscription offsets** → fan-out, late joiners, replay.
- **One dispatcher per subscription**: isolation + order; **ack after processing** = at-least-once.
- Retries with backoff, then **dead-letter**; subscribers must be **idempotent**.
- Scale: partitions by key, consumer groups, retention, persisted offsets (Kafka).

20.7 Design a Rate Limiter

Problem & clarifying questions

`What it is.` A rate limiter decides whether a request is allowed right now, so one client can't overwhelm a service (by accident or on purpose). Everyday analogy: a turnstile that lets through at most 10 people per minute per ticket type. Over the limit, the answer is "come back in 6 seconds" — in HTTP, status **429 Too Many Requests** with a `Retry-After` header (a header is a named line of metadata sent with an HTTP response).

Chapter 13 (§13.11) already built the concurrency core: a thread-safe token bucket (a bucket of tokens refilled at a steady rate; each request spends one, and an empty bucket means "wait") with `synchronized` and a lock-free CAS version (CAS = compare-and-set: update a value only if it still holds what you last read, as one hardware-level step, so no lock is needed), and compared the algorithms. This section is about the **object-oriented design around it**: pluggable algorithms, rules per API and per user tier (a plan level such as free or paid), a factory, combined limits, and a clean decision object.

Question	Assumed answer
Limit by what?	Per (user, API). Could also be IP (the caller's network address) or API key (a secret string that identifies the calling app) — same design, different key.
Different limits?	Yes: per API and per tier (FREE vs PREMIUM); a default for everything else.
Algorithms?	Token bucket, fixed window, sliding window log, sliding window counter (all compared in the table under Key flows) — swappable per rule.
Several limits at once?	Yes, e.g. "2 per 10 s **and** 3 per minute" on `/login`.
Response?	Allowed / denied + remaining + retry-after.
Single process or distributed (spread over several machines)?	Single process here; distributed in extensions.

Requirements

Functional

1. `check(userId, api)` → `Decision(allowed, remaining, retryAfter)`.
2. Rules configured per API and tier; fallback default rule.
3. Each (user, api) gets its **own** limiter instance, created on first use.
4. Algorithms pluggable per rule.
5. Several rules can apply together (all must allow).

Non-functional: O(1) (or close) per check; thread-safe (exactly N allowed under any concurrency); injectable clock for tests; memory bounded (discussed).

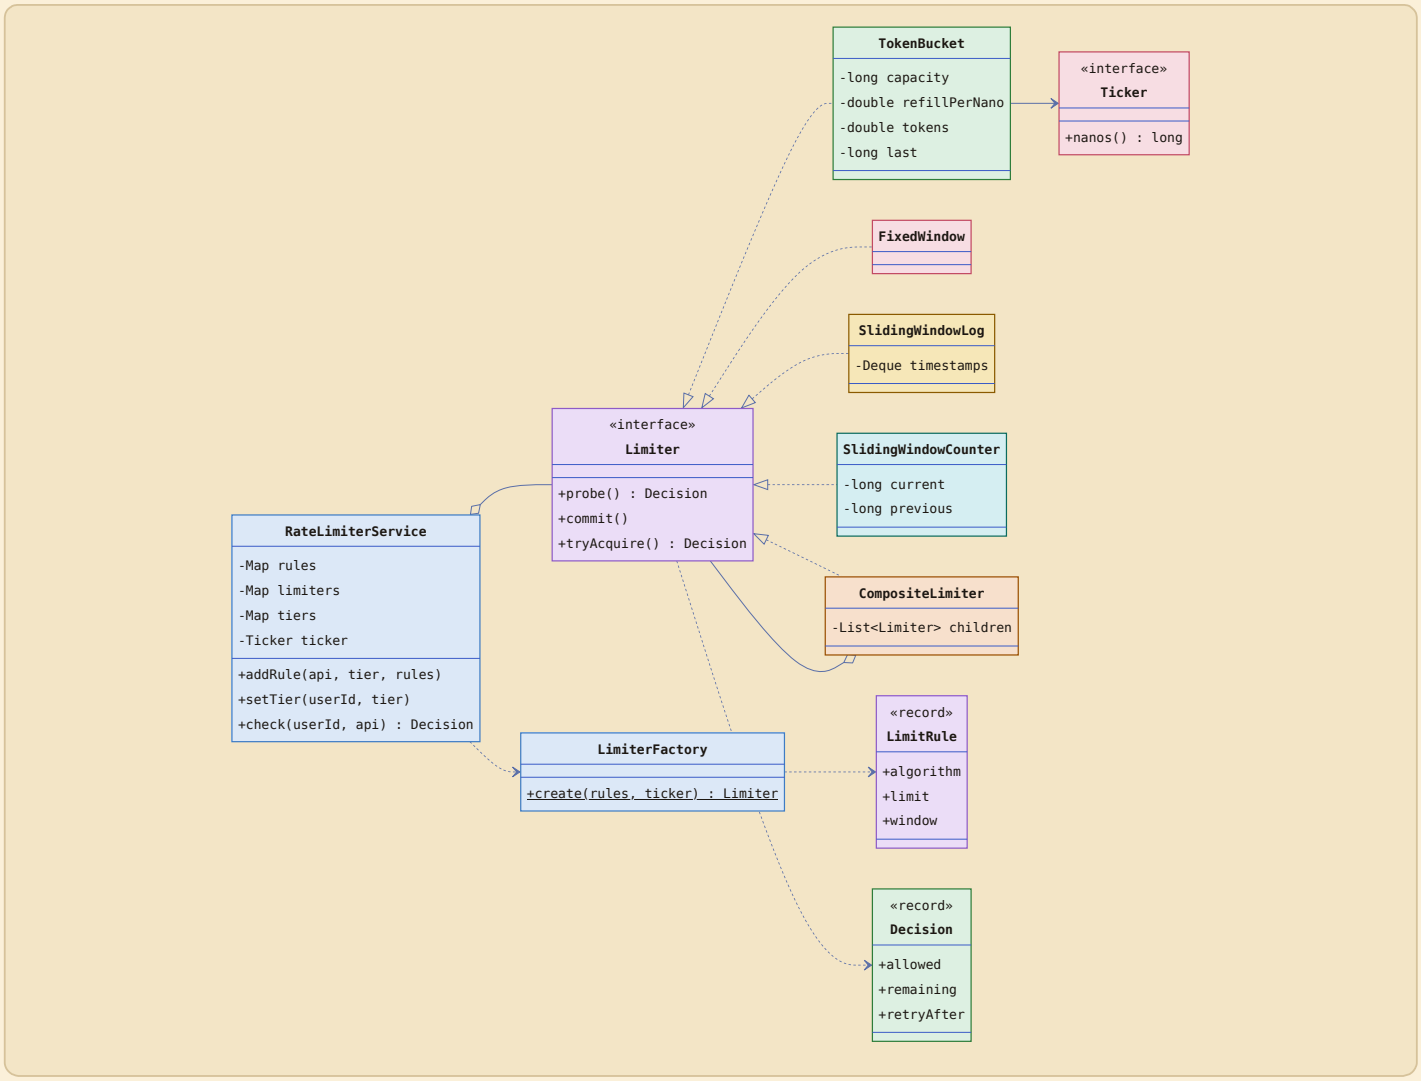
Use cases

Actors: **Client** (sends requests), **API gateway / filter** (the front door that every request passes through; calls `check` before the handler — the code that does the real work), **Operator** (configures rules and tiers).

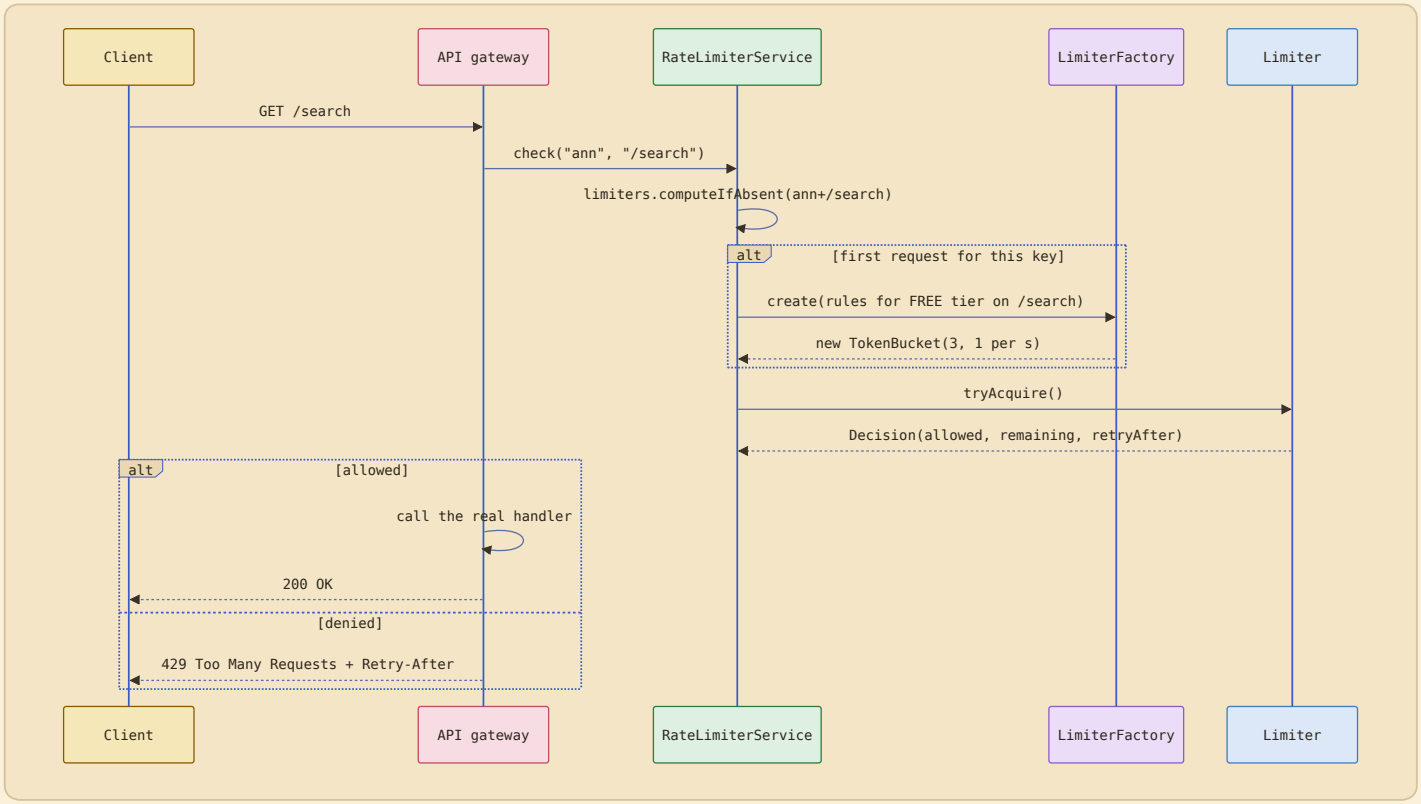
Core entities

Class	Responsibility
`Limiter` (interface)	**Strategy**: `probe()` (would one more request pass? consumes nothing), `commit()` (record it), and `tryAcquire()` = both in one atomic step → `Decision`. One instance per key.
`TokenBucket`, `FixedWindow`, `SlidingWindowLog`, `SlidingWindowCounter`	The algorithms (each `synchronized`).
`CompositeLimiter`	**Composite**: allowed only if every child allows; probes all children, then commits to all, under one lock, so a denied request consumes nothing.
`Decision` (record)	allowed, remaining, retryAfter.
`LimitRule` (record)	algorithm, limit, window.
`Algorithm`, `Tier` (enums)	Configuration values.
`LimiterFactory`	**Simple Factory**: rule(s) → `Limiter` (single or composite).
`RateLimiterService`	**Facade**: resolves the user's tier and the API's rules, keeps one limiter per (user, api) in a `ConcurrentHashMap`.
`Ticker`	Injected time source (nanoseconds).

Class diagram



Key flows



The four algorithms side by side (limit N per window W):

Algorithm	State per key	Bursts	Accuracy	Notes
Token bucket	tokens, last refill time	Up to capacity	Good	Most common for APIs; smooth refill
Fixed window counter	window start, count	**Up to 2N across a boundary**	Poor at edges	Simplest
Sliding window log	one timestamp per allowed request	None beyond N	Exact	Memory O(N) per key
Sliding window counter	2 counters	Approximate	Good	Estimate = previous × overlap + current
(Leaky bucket)	a queue	Smooths output to a constant rate	—	Traffic shaping (evening out the flow); not implemented here

Design decisions & patterns used

Decision	Why	Alternative rejected
Strategy (`Limiter`)	Algorithms differ in accuracy/memory; pick per rule. New algorithm = new class.	`switch` on algorithm inside `check`.
Simple Factory (`LimiterFactory`)	One place turns config into objects; service never names concrete classes.	`new TokenBucket(...)` in the service.
Composite (`CompositeLimiter`)	"10/s and 1000/day" is just a limiter made of limiters; callers don't know. **Check all, then commit all**, so a request denied by one child never uses up a slot in another.	Special-casing multiple rules in the service; or calling each child's `tryAcquire` in turn (a later denial would leave earlier children charged for a request that never ran).
Facade (`RateLimiterService`)	Gateway code asks one question.	Gateway juggling tiers, rules and limiters.
One limiter per key via `computeIfAbsent`	Exactly one limiter per (user, api), even when the first two requests race.	`get` then `put` (two limiters could be created and one's counts lost).
`Decision` with `remaining` and `retryAfter`	Maps directly to HTTP headers (`X-RateLimit-Remaining`, `Retry-After`).	`boolean`.
Injected `Ticker`	Tests move time instantly (the demo never sleeps).	`System.nanoTime()` inside algorithms.
Each algorithm `synchronized`; `tryAcquire` = `probe` + `commit` under the limiter's lock	Refill + check + take must be one atomic step (see §13.11 for the lock-free version).	Unsynchronized fields (two threads take the last token).

Java implementation

```java
// File: code/lld/ch20/ratelimiter/Limiters.java
package lld.ch20.ratelimiter;

import java.time.Duration;
import java.util.ArrayDeque;
import java.util.Deque;
import java.util.List;

/** Where time comes from (nanoseconds). Injected so tests do not sleep. */
interface Ticker { long nanos(); }

/** The answer to one request: allowed or not, what is left, and when to retry (HTTP 429 Retry-After). */
record Decision(boolean allowed, long remaining, Duration retryAfter) {
    static Decision allow(long remaining) { return new Decision(true, remaining, Duration.ZERO); }
    static Decision deny(Duration retryAfter) { return new Decision(false, 0, retryAfter); }
}

/**
 * Strategy: one algorithm, one instance per key (user, API key, IP...). Must be thread-safe.
 * Two-phase so that limits can be combined without side effects:
 * probe() answers "would one more request be allowed now?" WITHOUT using up anything,
 * commit() records the request. Both must be called while holding this object's lock.
 */
interface Limiter {
    Decision probe();

    private static String show(Decision d) {
        return d.allowed() ? "200 OK (remaining " + d.remaining() + ")"
                : "429 Too Many Requests (retry after " + d.retryAfter().toMillis() + " ms)";
    }
}
```

Walking through the code.

- `TokenBucket` refills **lazily**: on each call it adds `elapsed × rate` tokens (capped at capacity). No background thread. When empty, `retryAfter` is the time until one whole token exists.
- `FixedWindow` computes the current window start with `now − (now mod W)` and resets the count when the window changes.
- `SlidingWindowLog` drops timestamps older than `now − W` and allows if fewer than N remain.
- `SlidingWindowCounter` estimates the count in the sliding window as `previous × (portion of previous window still inside) + current`.
- `Limiter` is split into `probe()` (answer only) and `commit()` (record); the default `tryAcquire()` runs both inside `synchronized (this)`, and every algorithm's own methods are `synchronized` on the same object, so check-and-take stays one atomic step.
- `CompositeLimiter` probes **every** child first and returns the first denial without committing anything; only if all allow does it commit to all of them. Its children are created for it alone by the factory and never shared, so the composite's lock makes the whole probe-then-commit atomic. `remaining` is the smallest of the children's.
- `RateLimiterService.check` builds the limiter inside `computeIfAbsent`, so the tier and rule are resolved once per key.

Output:

```
== 1. Per-user, per-API token bucket (FREE: burst 3, 1 token/s)
  t=0.0 ann /search #1 -> 200 OK (remaining 2)
  t=0.0 ann /search #2 -> 200 OK (remaining 1)
  t=0.0 ann /search #3 -> 200 OK (remaining 0)
  t=0.0 ann /search #4 -> 429 Too Many Requests (retry after 1000 ms)
  t=0.0 ann /search #5 -> 429 Too Many Requests (retry after 1000 ms)
  t=1.0 ann /search    -> 200 OK (remaining 0)
  t=1.0 bob /search    -> 200 OK (remaining 2)  (own bucket)
  t=1.0 pat (PREMIUM) 12 calls -> 10 allowed
  t=1.0 ann /orders (default rule) -> 200 OK (remaining 99)
== 2. Composite rule on /login: 2 per 10 s AND 3 per minute
  t=+0s ann /login -> 200 OK (remaining 1)
  t=+1s ann /login -> 200 OK (remaining 0)
  t=+2s ann /login -> 429 Too Many Requests (retry after 8000 ms)
  t=+11s ann /login -> 200 OK (remaining 0)
  t=+12s ann /login -> 429 Too Many Requests (retry after 48000 ms)
  t=+61s ann /login -> 200 OK (remaining 1)
== 3. A denied request uses up nothing: 3 per minute AND 2 per 10 s (minute rule first)
  t=+0s -> 200 OK (remaining 1)
  t=+1s -> 200 OK (remaining 0)
  t=+2s -> 429 Too Many Requests (retry after 8000 ms)
  t=+11s -> 200 OK (remaining 0)
== 4. Boundary burst: limit 5 per 10 s, 5 calls at t=9.9 and 5 at t=10.1
  FIXED_WINDOW     allowed 10 of 10 within 0.2 s
  SLIDING_LOG      allowed 5 of 10 within 0.2 s
  SLIDING_COUNTER  allowed 5 of 10 within 0.2 s
== 5. 64 threads x 10 calls on one bucket (capacity 50, no refill)
  allowed = 50 (exactly 50, never more)
```

Step 1: ann's burst of 3 is allowed, then 429 with "retry after 1000 ms"; a second later exactly one more is allowed; bob and the PREMIUM user have their own buckets. Step 2: the /login composite denies at +2s (10-second rule) and at +12s (1-minute rule, retry when the +0s call leaves the minute window). Step 3: the denied +2s call consumed nothing, so the +11s call passes both rules. Step 4 is the classic interview point: **fixed window lets 10 requests through in 0.2 seconds** across the boundary, while both sliding algorithms hold the line at 5. Step 5 proves thread safety: 640 concurrent attempts, exactly 50 allowed.

Concurrency & edge cases

- **Atomicity:** each limiter's `tryAcquire` is `synchronized`; the service map is a `ConcurrentHashMap`. Contention is per key, so different users never block each other.
- **Composite and denied requests.** The naive composite calls each child's `tryAcquire()` in turn. If child 1 allows (and consumes) and child 2 then denies, the request never runs but child 1 has been charged for it. Step 3 of the demo is built to expose that: with "3 per minute" first, the denied call at +2s would have used up the third per-minute slot, and the legitimate call at +11s would be refused for about 49 s. Our composite probes all children and commits only if all allow, so +11s is correctly allowed. (An alternative is *acquire, and refund on denial*, which needs a `release()` in every algorithm and is easy to get wrong when a window rolls over in between.)
- **Memory growth:** one limiter per (user, api) forever. Evict idle limiters (e.g. store them in a cache with expire-after-access, like 20.3). Set the idle timeout to at least the longest window (or the full-refill time of a bucket): after that much idle time the old limiter would allow a full burst anyway, so replacing it with a fresh one changes nothing.
- **Clock:** use a monotonic clock (`System.nanoTime`) — wall-clock time (the calendar time a person reads) can jump backwards.
- **Rule changes at runtime:** existing limiters keep old settings; clear the map (or version the rules) when config changes.

Extensions & follow-up questions

- **"Distributed (many gateway servers)."** Keep counters in a shared store: Redis with an atomic Lua script (Redis can run small Lua programs as one uninterrupted step) (or `INCR` + `EXPIRE` for fixed windows: Redis commands for "add one" and "delete after N seconds"). Trade-off: a network hop (one extra round trip to another machine) per request; mitigate with local pre-allocation of tokens. Or use sticky routing (the load balancer

— the component that spreads requests over servers — always sends one user to the same server) so each user always hits the same node.

- **"Leaky bucket."** A bounded queue drained at a constant rate by a worker: smooths bursts into a steady output (good for protecting a fragile downstream — a service that this one calls).
- **"Different cost per request."** `tryAcquire(permits)`: an expensive export costs 10 tokens.
- **"Soft limits / warnings."** Return `remaining` and warn the client at 80%.
- **"Rate limit by IP when not logged in."** The key is just a string; the rule resolver decides which key to use.
- **"Where does the limiter run?"** In an API gateway or a servlet filter / Spring `HandlerInterceptor` (Java web hooks that run before every request) before the controller (the class that handles a given URL).

Real-world example

Stripe has written publicly about using several limiters together ("Scaling your API with rate limiters": a request-rate limiter based on the token bucket, a concurrent-requests limiter, and load shedders — components that deliberately drop low-priority work when overloaded — implemented with Redis) — several independent checks on one request, the composite idea. **GitHub's API** returns `X-RateLimit-Limit`, `X-RateLimit-Remaining` and `X-RateLimit-Reset` headers, which is our `Decision`. HTTP 429 is defined in RFC 6585 (RFCs are the official documents that define internet standards). **NGINX** (a widely used web server and reverse proxy) `limit_req` uses the leaky-bucket method. In Java, **Guava's** `RateLimiter`, **Resilience4j's** `RateLimiter` and **Bucket4j** (token bucket) are common libraries. Cloudflare has described using the sliding-window-counter approximation (weighting the previous window) to rate limit at the edge (its servers closest to users) cheaply.

In the interview

> **30-second answer:** "A `Limiter` interface with interchangeable algorithms — token bucket by default, sliding window when exactness matters. A factory builds limiters from rules; rules are chosen by API and user tier; a composite limiter combines rules like '10 per second and 1000 per day'. The service keeps one limiter per (user, api) in a `ConcurrentHashMap` via `computeIfAbsent`, and returns a decision with remaining and retry-after for the 429 response. Each limiter makes refill-check-take atomic; for multiple servers, move the state into Redis with an atomic script."

Plan (30–40 min): clarify key/limits (4) → algorithms table and choice (8) → OO design: interface, factory, service, composite (10) → thread safety (5, point to §13.11) → distributed + memory (5).

Follow-ups with answers:

- *"Why is fixed window risky?"* → Up to 2N requests across a window boundary (shown in the output).
- *"Token bucket vs sliding log?"* → Bucket allows bursts, O(1) memory; log is exact but stores every timestamp.
- *"How do you avoid creating two limiters for the same user?"* → `ConcurrentHashMap.computeIfAbsent`.

Self-check

1. Which algorithm allows a burst up to its capacity and then a steady rate? → Token bucket.
2. How many requests can a fixed window of limit 5 let through in 0.2 s across a boundary? → Up to 10.
3. Which pattern lets "2 per 10 s AND 3 per minute" look like one limiter? → Composite.
4. What HTTP status and header go with a denial? → 429 and `Retry-After`.
5. Why must refill + check + take be atomic? → Otherwise two threads can both see the last token and both take it.
6. How do you keep memory bounded with millions of users? → Evict limiters idle for at least the longest window (expire-after-access cache); by then a fresh limiter behaves exactly like the old one.
7. Why does `CompositeLimiter` probe every child before committing to any? → So a request denied by one rule does not use up a slot in another rule.

TL;DR

- **Strategy** for algorithms, **Simple Factory** from rules, **Composite** for combined limits (probe all, then commit all), **Facade** service.
- One limiter per (user, api) via `computeIfAbsent`; `Decision` → 200 (HTTP "OK") or 429 + Retry-After.
- Token bucket (bursty, O(1)), fixed window (2× edge burst), sliding log (exact, O(N)), sliding counter (approximate, O(1)).

- Atomic refill-check-take (§13.11); Redis + Lua for distributed limits.

20.8 Chapter summary

Component	Anchor pattern(s)	The one sentence to remember
Splitwise	Strategy	Split rules return shares; the ledger stores one signed number per pair; simplify with net positions + greedy (≤ n − 1 payments).
Ledger Co. (full case in Ch 21 §21.6)	—	A loan ledger, not a bill-splitting ledger: same "one authoritative record + `BigDecimal`" idea, different rules.
Notification service	Template Method + Strategy + Observer	Retry once in the parent, one class per reason not to send, one exit that tells the listeners.
In-memory cache	Strategy + Observer	HashMap + doubly linked list; eviction policy owns the order; one removal path.
LRU cache	— (data structure)	Map to node, move to front on use, evict before tail; or `LinkedHashMap(accessOrder=true)`.
Ride sharing	Strategy + Decorator + state machine	Ranked list for declines, surge wraps pricing, atomic driver claim.
Carpool variant	Strategy	Offer seats per vehicle; select with Most Vacant / Preferred Vehicle.
Logging framework	Chain of Responsibility + Singleton + Decorator	Hierarchy with inherited levels; propagate up until additivity stops; async is a wrapper.
Pub-sub	Observer via broker	Append-only log + per-subscription offsets; ack after processing; dead letters.
Rate limiter	Strategy + Factory + Composite	One limiter per key; algorithms swappable; 429 with Retry-After.

The common thread. In every design, the part most likely to change sits behind an interface, and the "service" class only orders the steps. When the interviewer says "now add X", the best answer is a new class and a one-line change where objects are wired together.

20.9 Chapter self-check

1. Which two patterns appear in more than half of this chapter's designs? → Strategy and Observer.
2. Strategy vs Decorator in one line each? → Strategy *replaces* a rule; Decorator *wraps* one and adds to its result.
3. Strategy vs Template Method? → Strategy swaps the whole algorithm (composition); Template Method fixes the algorithm and lets subclasses fill steps (inheritance).
4. Which designs used a "single exit" method, and why? → Notification (`finish`) and cache (`remove`): so records, stats and listeners can never be skipped on one path.
5. Where did we call listeners outside a lock, and why? → The cache: a slow or re-entrant listener must not block or deadlock it.
6. What does at-least-once delivery require from consumers? → Idempotency.
7. Name three places this chapter used compare-and-set or `computeIfAbsent` for correctness. → Driver claim (`AtomicBoolean`), subscription commit (`AtomicLong.compareAndSet`), limiter creation (`computeIfAbsent`).

20.10 Chapter TL;DR

- Components are small, so interviews probe the **rule most likely to change** — put it behind an interface.
- **Strategy** everywhere (splits, eviction, matching, pricing, send rules, formatters, rate-limit algorithms); **Observer** for "tell someone when it happens"; **Decorator** to add behaviour without editing (surge, async);

Template Method for a shared algorithm with one varying step; **Chain of Responsibility** for the logger hierarchy; **Composite** for combined limits.

- Money in `BigDecimal`; time from an injected clock; thread safety with the smallest correct tool (one lock, CAS, `computeIfAbsent`, per-key locks, sharding).
- Always volunteer the honest limits: greedy is not optimal, LRU needs a write lock, at-least-once duplicates, fixed windows burst at edges.

Chapter 21 — Case Studies: Machine-Coding Round Problems

> **Goal.** Chapters 14–20 taught you to *design* a system on a whiteboard. This chapter trains the harder cousin of that interview: the **machine-coding round**, where you get a written problem statement, 90–120 minutes, and must hand over **running code** that the interviewer will feed their own inputs into. You will learn how the round is scored, a project skeleton you can type from memory, a minute-by-minute time plan, and then eight real problems — each solved end to end with a working, demo-able (ready to run in front of the interviewer) Java program.

How each problem is laid out: *Problem & clarifying questions → Requirements → Use cases → Core entities → Class diagram → Key flows → Design decisions & patterns → Java implementation (+ real output) → Concurrency & edge cases → Extensions → In the interview → Self-check → TL;DR.*

All code is Java 21, standard library only (only the classes that ship with Java, no extra downloads), one package (Java's folder-like grouping of related classes) per problem under `code/lld/ch21/<name>/`. Run from `chapters/21-case-machine-coding/code`:

```
javac --release 21 -d /tmp/lld_21 $(find . -name '*.java')
java -cp /tmp/lld_21 lld.ch21.taskmgmt.Main       # or wallet, calendar, codingblox, propertyhunt, ledger, inventory, filesearch
```

Every demo uses a fixed clock, a seeded random generator (a random-number generator started from a fixed "seed" number, so it produces the same sequence on every run), or sorted output, so what you see below is exactly what you get on every run.

Problem map

#	Problem	Where it is asked (source)	The one idea that makes it work	Patterns
21.1	Task Management System	awesome-low-level-design	Status *state machine* + composable filters	State (enum), Specification, Strategy, Observer
21.2	Digital Wallet Service	awesome-low-level-design	`BigDecimal` money, idempotency keys, lock ordering	Strategy (offers), Facade
21.3	Event Calendar	Flipkart (kumaransg/LLD)	Half-open intervals + a boundary *sweep* to find free slots	Strategy (representative choice), Repository
21.4	Coding Blox (LeetCode-like platform)	Flipkart (kumaransg/LLD)	Command dispatcher + level-based scoring rule	Command, Strategy, Repository
21.5	PropertyHunt	ClearTrip (kumaransg/LLD)	Optional search criteria → list of predicates; unit normalisation	Builder, Specification, Strategy
21.6	Ledger Co (loans & EMIs)	Navi (kumaransg/LLD, Geektrust)	Derive balances from facts instead of storing them	Strategy (interest), Command
21.7	Inventory Management System	Common (Amazon/Flipkart-style)	Append-only movement ledger + per-SKU lock	Strategy (allocation), Observer (reorder)
21.8	Unix File Search (`find`)	Common OOD/machine-coding question	Filters as Specifications combined by Composite AND/OR/NOT; Builder for criteria; a parser for `find` syntax	Specification, Composite (×2), Builder, Interpreter-style parser

(Food ordering "FoodKart", another kumaransg/LLD problem, is solved in Chapter 19.)

> **Key terms — the sources and patterns in the map.** *awesome-low-level-design* and *kumaransg/LLD* are public GitHub repositories that collect low-level design (LLD) problems; Geektrust is a hiring platform that sets such coding challenges. The patterns, one line each: a **state machine** is a fixed set of states plus the moves allowed between them (here kept in an enum, a Java type with a fixed list of named values); **Specification**

wraps one yes/no rule in an object so rules can be combined with AND / OR / NOT; **Strategy** puts each interchangeable rule in its own class behind one interface (a list of methods with no code, which several classes implement in their own way); **Observer** lets objects sign up to be told when something happens; **Facade** is one simple front class over several others; **Repository** hides how objects are stored behind save / find methods; **Command** turns each action into an object or handler that can be looked up by name; **Builder** assembles an object with many optional settings step by step; **Composite** lets a group of objects be treated like a single one. A few other words from the table: **idempotency keys** are explained in 21.2; **lock ordering** means always taking several locks in the same fixed order, so two threads can never block each other forever (a **thread** is one independent line of execution inside a running program; a **lock** is an object only one thread can hold at a time, while others wait); a **half-open interval** `[start, end)` includes its start but not its end; a **sweep** walks through sorted time points one by one; **unit normalisation** converts every input to one unit (e.g. square feet) as soon as it is read; an **SKU** (stock keeping unit) is the id of one sellable item; **OOD** is object-oriented design; an **Interpreter-style parser** turns text written in a small language into a tree of objects.

21.0 How the machine-coding round works

What it is

A **machine-coding round** (also called an *LLD coding round*) is an object-oriented design (designing a program as classes of objects that hold data and behaviour together) interview in which **working code is the answer**. The same round is called *object-oriented design* or *low-level design* at other companies; machine coding simply adds the rule that the code must compile and run at the end. You get a one- or two-page problem statement (usually a PDF), a laptop with your own IDE (integrated development environment: the code editor plus compiler and debugger, such as IntelliJ IDEA), and 90–120 minutes. Internet use is limited to looking up syntax. There is **no database, no UI (user interface: screens) and no web framework (a library for building websites and web APIs — an API is the set of calls a program or service offers to other programs)**: all data lives in memory (maps and lists), and the program is driven by a `main` method, a list of commands, a file, or unit tests (small automated checks that call one piece of code and compare the result with what is expected).

Do not confuse it with the **system design** interview. That round is about keeping a product alive under millions of users, so the conversation is about servers, databases, caches and message queues (see System Design Fundamentals if those words are new). This round never leaves a single program: its vocabulary is **classes** (a *class* is a named code type that bundles some data with the methods that act on that data), their fields and methods, and how the classes relate. Same product, very different zoom level — and practising for one leaves you unready for the other.

Everyday analogy: a whiteboard design interview is an architect *describing* a house. A machine-coding round is being asked to *build a small shed* while the inspector watches — then the inspector leans on every wall.

The format is especially common at Indian product companies such as Flipkart, Swiggy, PhonePe, Navi, Razorpay, CRED, Meesho and Cleartrip; several of this chapter's problems are statements candidates have shared from those rounds.

How it is judged

Interviewers use a rubric (a scoring checklist). The exact wording differs by company, but it always covers the same things. Read the "Expectations" section of any statement in this chapter (Coding Blox, PropertyHunt and Event Calendar all have one) and you will see these repeated almost word for word.

#	Criterion	What the interviewer checks	How to score well
1	**Working, demo-able code**	Does it compile? Does the driver (the small piece of code that feeds input into the program and prints the results) run the sample input and print the expected output? Does it survive *their* inputs?	Get a thin end-to-end path working in the first hour. Never finish with code that does not compile.
2	**Functional completeness**	Every *mandatory* requirement done; bonus only after that.	Implement requirements in the statement's order; tick them off.
3	**Clean models**	Entities have one job, fields are private, invariants (rules that must always be true, such as "balance is never negative") live inside the entity (for example a task refuses an illegal status change).	Use enums for fixed sets, records (Java's compact, unchangeable data classes) for values, classes for things that change.
4	**Service interfaces / separation of concerns** (each class handles one kind of work)	Parsing, business logic (the product's actual rules) and storage are in different classes. No `System.out` inside services.	Driver → Service → Repository layers (skeleton below).
5	**Extensibility**	"Add a new offer / sort order / scoring rule" should mean *adding a class*, not editing `if` chains.	Strategy and Specification for things the statement says "can be X or Y".
6	**Edge cases & failure handling**	Unknown IDs, duplicates, invalid input, wrong user, double-run. The program prints a clear error and **keeps going**.	Custom exceptions (your own error classes; an exception is how Java signals an error) with good messages; the driver catches them per command.
7	**Readability**	Intuitive names, small methods, no copy-paste.	Name classes after nouns in the statement; name methods after verbs in it.
8	**Concurrency (when asked)**	Wallets, inventory, booking: can two threads corrupt state?	Say where the lock is and why; demo it with a thread pool (a fixed set of reusable threads) if time allows.
9	**Tests (bonus)**	Some companies give extra credit for unit tests.	A tiny `assert`-style self-check in `main` is enough if there is no JUnit (Java's standard unit-testing library).

The five-step method, and how the clock changes it

The whiteboard version of this round (Chapter 1) always follows five steps in a fixed order:

1. **Requirements** — turn the one-line prompt into a short written list of what the system must do.
2. **Actors and use cases** — name *who* uses the system (actors) and *what* each of them does with it (use cases).
3. **Classes** — derive classes from the requirements and give each one responsibility.
4. **Relationships** — decide how each pair of classes is connected and draw it as a class diagram.
5. **Code** — implement the key classes, plus the two or three methods that make the main flows work.

Getting the order right beats going fast: each step is the input of the next, so if you skip requirements, you end up inventing classes nobody asked for. Every problem in this chapter is laid out in that same order.

A whiteboard round usually lasts 45 minutes to an hour. A budget for the 45-minute version:

Step	Minutes	Finished artefact
Requirements	5–8	8–12 written requirements
Actors & use cases	3–5	2–4 actors, 6–10 use cases
Classes	8–10	Class list, one responsibility each
Relationships	8–10	Class diagram with relationships and multiplicity (how many objects sit on each side, e.g. one-to-many)
Code	12–15	2–3 methods for the main flows

Two things in that table catch people off guard. The first two steps — which name no class at all — may take as much as a quarter of the time. And coding gets the biggest single slot yet still covers only two or three methods: nobody finishes the whole product, and you are graded on the slice you chose to build well, not on how much ground you covered. **Machine coding keeps the five steps but flips the proportions:** steps 1–4 shrink to about 20 minutes (see the time plan below) and code fills the rest, because now every mandatory feature must actually run.

How big is a complete answer? For a parking lot, roughly twelve requirements lead to about twelve classes joined by some fifteen relationships. Only three of them carry the main flows — issuing a ticket, holding a vehicle, pricing the stay. On a whiteboard you write those three properly and describe each of the other nine in one sentence. The costliest mistake is detailing all twelve equally: it looks thorough but leaves no time to demonstrate one complete flow. In machine coding the same instinct applies — make one thin path run end to end first, then widen.

Beyond "does it run", the interviewer is watching five things:

- **Scope** — did you pin down a bounded list of what you will build? A well-bounded design outranks a sprawling, open-ended one.
- **One job per class** — can you describe every class in a single sentence? A class that needs two sentences is usually two classes.
- **Relationships** — does a class *hold* another, *own* it, or *extend* it? These are different designs, and picking the wrong one is spotted immediately.
- **Code and model agree** — if the code contains a method your model has no place for, either the model or the code needs fixing.
- **A trade-off** — the option you took *and* the one you turned down, both said out loud.

Notice what is missing: nobody grades your UML notation (UML: the standard box-and-arrow notation for class diagrams) or counts how many diagram types you drew. The model is what gets marked; a diagram is just one way of displaying it.

The single most common failure is **running out of time with nothing that runs**. The second is a "god class" (a class that does everything): one `Manager` with every map and every method. Both are avoidable with the skeleton and time plan below.

A reusable project skeleton

Type this structure from memory in the first five minutes. It is the same for every problem, which is exactly why it saves time.

```
src/
  model/          entities & value objects      (Task, Wallet, Loan, Property ...)   - enums, records, small
classes
  repository/     storage contracts + in-memory (TaskRepository, InMemoryTaskRepository)
  service/        business rules, one per area  (TaskService, WalletService)          - no printing, no parsing
  strategy/       pluggable rules               (Offer, AllocationStrategy, SortBy)
  exception/      domain exceptions             (NotFoundException, InsufficientFundsException)
  driver/         Main + CommandProcessor       (parses input, calls services, prints output)
```

Layer	Knows about	Must NOT know about	Why
model	nothing but itself (and other models)	services, storage, console	Entities guard their own invariants (e.g. `Task.changeStatus` rejects `TODO → DONE`).
repository	model	services, console	Swapping `HashMap` for a DB (database) later touches only this layer (Dependency Inversion — services depend on interfaces, not on concrete classes; Chapter 4).
service	model, repository *interfaces*, strategy *interfaces*	concrete repositories (injected — handed in from outside rather than created inside), console	This is the part the interviewer reads most carefully.
strategy	model	services	Each "X or Y" rule in the statement becomes one interface + small classes (Open/Closed).
exception	—	—	One class per failure *kind*, with a message a user could read.
driver	services	repositories' internals	Parsing and printing are replaceable; business logic is not.

In this book each problem lives in **one Java package** (for example `lld.ch21.wallet`) so the full listing stays short and readable. In the real round, create the sub-packages above — it costs nothing and the interviewer notices. Three reusable building blocks appear again and again:

1. **A generic in-memory repository** — a `ConcurrentHashMap<K, V>` (a map that many threads can use at once; `K, V` are type parameters, so the same class works for any key and value type — that is what *generic* means) behind an interface with `save / findById / findAll / delete` (see `Repository<K,V>` in Coding Blox, 21.4).
2. **An ID generator** — an `AtomicInteger` (an integer threads can increment safely without a lock) per entity type (`"T" + seq.incrementAndGet()`), thread-safe and predictable, which matches statements that say "auto-increment id starting with 1".
3. **A command processor** — a `Map<String, Consumer<String[]>>` from command name to handler (`Consumer` is a function that takes an argument and returns nothing; a *handler* is the code that deals with one command), fed by a built-in `List<String>` of sample commands (Coding Blox, PropertyHunt, Ledger). Adding a command = adding one map entry (Command pattern, Chapter 10).

The 90-minute time plan

Minutes	Activity	Output you should have
0–10	Read the statement twice. Ask clarifying questions. Mark mandatory vs bonus. Write the sample input as your driver's input list.	A numbered requirement list, a list of questions answered.
10–20	Nouns → entities, verbs → service methods. Pick the 1–2 patterns the statement is begging for ("can be sorted by X or Y" → Strategy).	Skeleton packages created, enums and records typed.
20–60	Implement mandatory requirements **in order**, running the driver after each one.	Sample input produces the sample output.
60–75	Edge cases and validation: unknown ids, duplicates, wrong owner, invalid numbers. Custom exceptions.	Driver prints errors and continues.
75–85	Bonus features (only if all mandatory ones work). Thread-safety where money or stock is involved.	Bonus commands in the driver.
85–90	Clean up names, delete dead code (code that is never run), run everything one last time. Prepare a 2-minute walkthrough.	Code that compiles, a demo, a story.

A good rule: **run the program at least every 15 minutes**. A compile error found at minute 88 is a disaster; the same error found at minute 30 is a 20-second fix.

What to say in the first two minutes

1. "I'll keep everything in memory with a repository interface, so a DB can be added later without touching services."
2. "I'll drive it from `main` with the sample commands from the statement, and print errors without crashing."

3. "The mandatory list is A, B, C; the bonus is D, E. I'll do A–C first."
4. "Where does it need to be thread-safe?" (Ask. For wallets and inventory the answer is always yes.)

Common mistakes in this round

Mistake	Why it hurts	Do this instead
Starting with a perfect class diagram for 20 minutes	No time left for code	Enums/records first; the diagram lives in your head and in names
One `Manager` class with 15 maps	Fails "separation of concerns"	One service per area + repositories
`System.out.println` inside the service	Service cannot be reused or tested	Services return data; the driver prints
`double` for money	`0.1 + 0.2 != 0.3` — interviewers test this	`BigDecimal` (Java's exact decimal number type) with a fixed scale (number of digits after the decimal point; 21.2) or whole units (`long` paise; a paisa is 1/100 of a rupee)
Crashing on the first bad command	"Fails gracefully" is an explicit criterion	Catch domain exceptions (errors that describe a broken business rule) in the driver loop, print, continue
Implementing bonus before mandatory	Partial credit on the mandatory part	Mandatory in order; bonus last
Writing every class in full detail	Nothing works end to end when time runs out	Make the core flow run first; stub (write an empty placeholder for) or name the rest
`Random` without a seed	Output changes every run; hard to demo	Seed it, or put randomness behind a Strategy (21.4)
Hard-coding "today" with `LocalDate.now()`	Demo changes daily	Inject a `java.time.Clock` (Java's replaceable source of the current time; 21.1, 21.2)

Real-world examples

The skeleton above is the standard layering of real Java back ends (the server-side part of an application): in a Spring Boot (the most popular Java framework for building services) service, controllers (classes that receive web requests) play the "driver" role, `@Service` classes hold business rules, and `@Repository` interfaces (Spring Data) hide storage. (The `@Something` markers are annotations: labels a framework reads to know what a class is for.) The in-memory repository you write in the round is exactly the kind of fake that teams use in unit tests for those services.

In the interview

> **30-second answer — "How do you approach a machine-coding problem?"** "I read the statement twice, list mandatory and bonus requirements and ask about anything ambiguous. I set up model / repository / service / strategy / exception / driver packages, put the sample input into the driver, and implement requirements one by one, running after each. Services return data and throw domain exceptions; the driver prints and keeps going. I finish with edge cases, thread-safety where state is shared, and bonus features if time allows."

Follow-ups

- *"Why an interface for an in-memory repository?"* — So services depend on an abstraction (an interface rather than a concrete class); a JDBC (Java's standard API for SQL databases) or Redis (a fast in-memory key-value store) implementation can replace it with no change to business code, and tests can use the in-memory one.
- *"How do you make random behaviour testable?"* — Put it behind an interface (a Strategy) and inject a seeded or scripted implementation for demos and tests.
- *"How much do you test?"* — At minimum, the driver replays the statement's samples and prints results I can compare with the expected output. With time, a few JUnit tests on the service layer.

Self-check

- **Q:** Name the six packages of the skeleton. → **A:** model, repository, service, strategy, exception, driver.

- **Q:** Where should `System.out.println` live? → **A:** Only in the driver (command processor / `Main`).
- **Q:** What do you do at minute 60 if the bonus is tempting but one mandatory requirement is missing? → **A:** Finish the mandatory one; bonus only after all mandatory ones run.
- **Q:** Why inject a `Clock`? → **A:** So time-based logic (due dates, reminders) gives the same output on every run and can be tested.

> **TL;DR**

Working code first, clean layering second, patterns where the statement asks for variation, graceful errors everywhere. Skeleton: **model** → **repository** → **service** → **strategy** → **exception** → **driver**. Run often.

21.1 Design a Task Management System

Problem & clarifying questions

Build the core of a tool like Jira, Asana or Trello (popular team task-tracking apps): users create tasks, assign them to people, move them through statuses, comment on them, and search/filter them; the system reminds people about tasks that are due. The awesome-low-level-design version asks for create / update / delete, title + description + due date + priority + status, assignment, reminders, search and filtering (by priority, due date, assignee), marking tasks complete, task history, and safe concurrent access (several users acting at the same moment without corrupting data).

Questions to ask (with the answers this solution assumes):

Question	Assumed answer
Which statuses exist, and can any status go to any other?	TODO, IN_PROGRESS, BLOCKED, DONE, CANCELLED. Only listed transitions are legal (e.g. TODO cannot jump straight to DONE; CANCELLED is final; DONE can be re-opened).
One assignee or many?	One assignee (nullable: the field may be `null`, Java's "no value"). A list is an easy extension.
What does "reminder" mean in a console app?	A method a scheduler would call: "notify owners of open tasks due within N days or overdue".
Should due dates in the past be allowed?	No, not on creation.
How are notifications delivered?	Through a listener interface; the demo prints them.
"View task history" — history of what?	Two readings: each task's audit log (a permanent record of who changed what, when) — built here — and a user's list of finished tasks, which is just a search: `assignedTo(u).and(withStatus(DONE))`.
"Set reminders" — per task, or a sweep?	A sweep over due dates is built here; a per-task reminder time is an extension (below).

> **Requirements**

Functional

1. Register users.
2. Create a task (title, description, priority, due date); update title / priority / due date; delete a task.
3. Assign / reassign a task to a user.
4. Change status following the allowed transitions; mark done.
5. Comment on a task.
6. Search with any combination of filters (assignee, status, minimum priority, due before, open only, title contains) and a sort order (due date, priority, id).
7. Reminders for open tasks due soon or overdue.
8. Per-task activity history.

Non-functional

- Thread-safe: two people editing the same task must not corrupt it.
- Extensible: new filters, sort orders and notification channels without editing existing code.
- Deterministic demo (injected `Clock`).

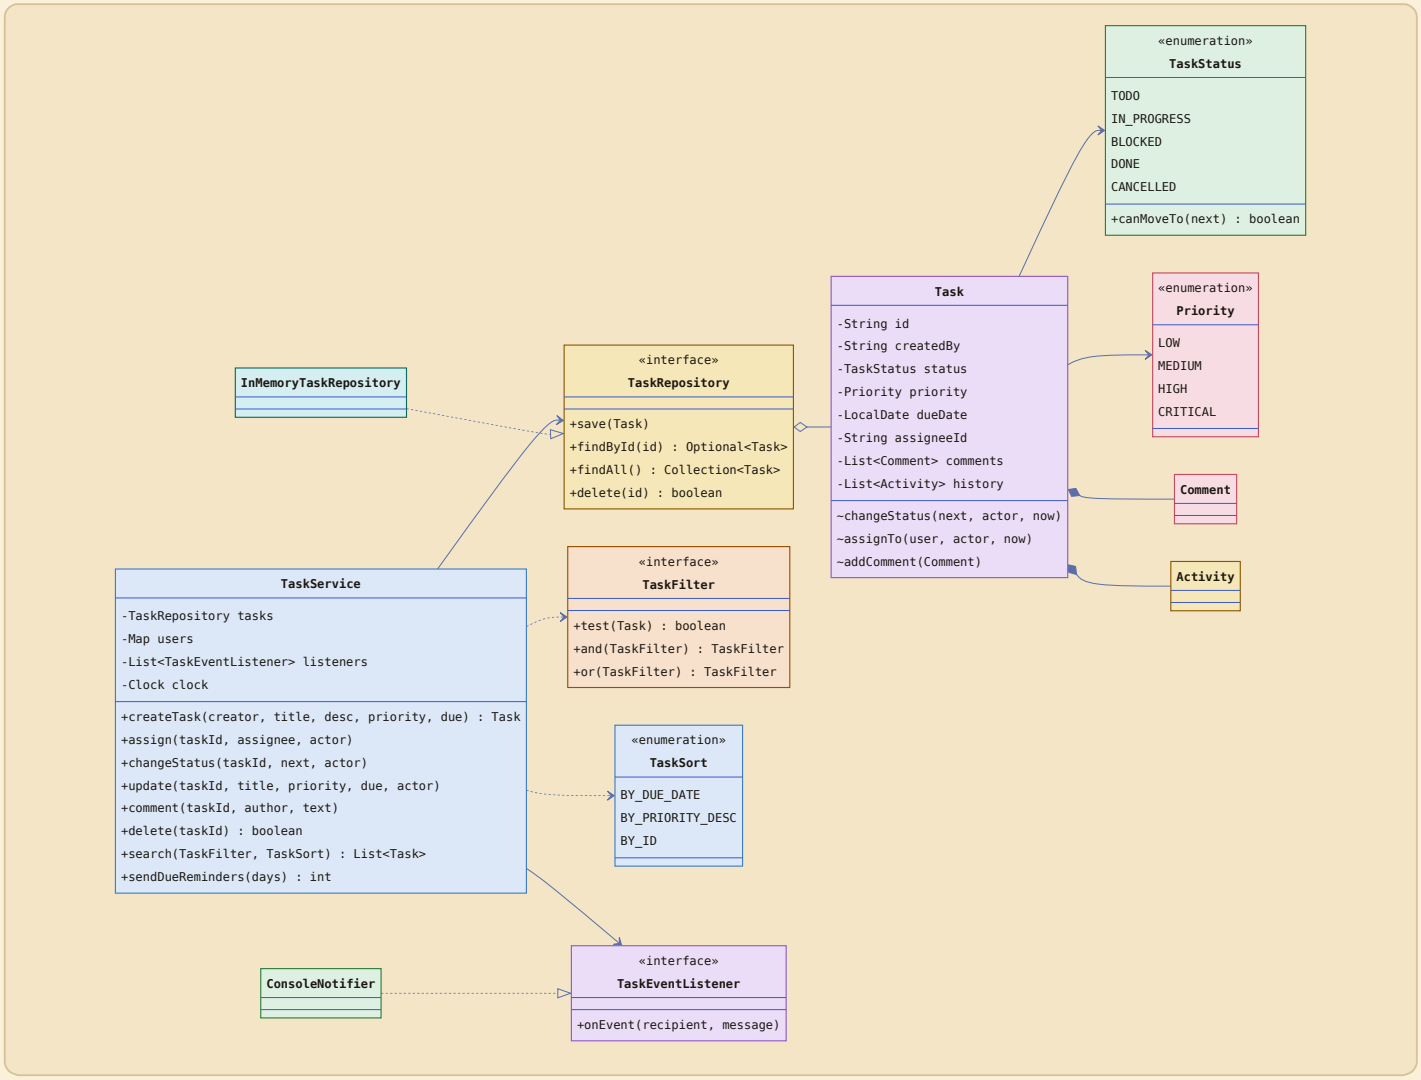
Use cases

Actor	Use cases
Task creator (any user)	create task, update, delete, assign, comment, search
Assignee	change status, comment, see own tasks
Scheduler (system actor)	send due-date reminders
Notification channel (external)	receives events (assigned, status changed, commented, reminder)

Core entities

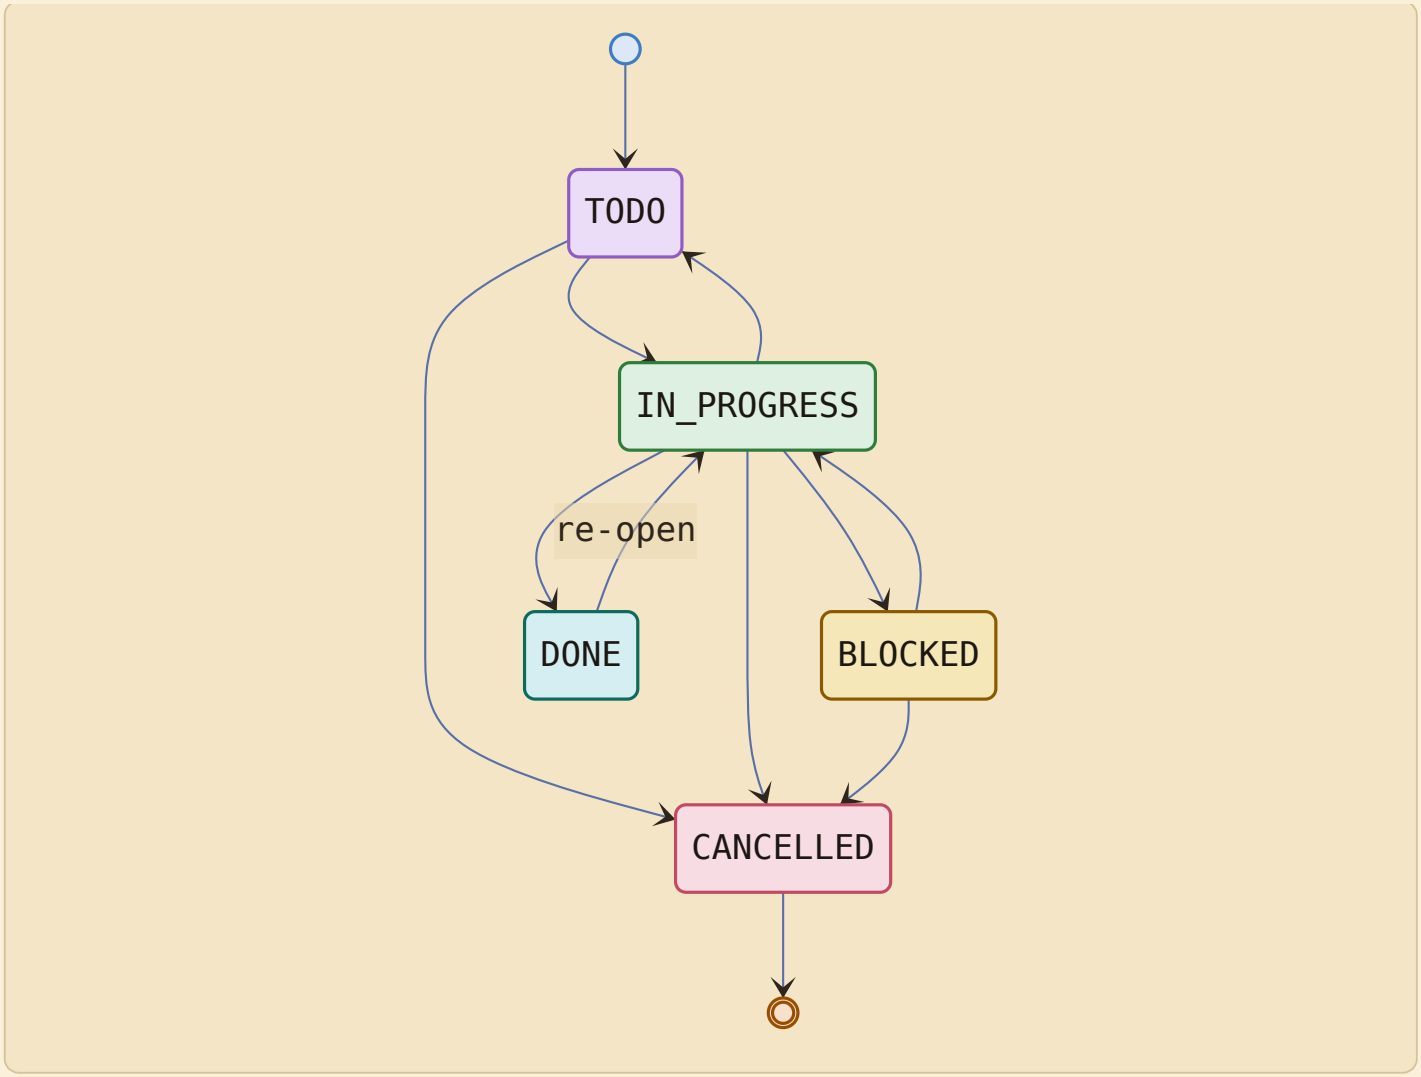
Class	Kind	Responsibility
`Task`	class	Holds task data; enforces legal status changes; records its own history. All mutators (methods that change state) `synchronized` (only one thread at a time may run them on the same object).
`TaskStatus`	enum	Lists statuses and, for each, which statuses it may move to (a tiny state machine).
`Priority`	enum	LOW < MEDIUM < HIGH < CRITICAL (enum order is used for comparison).
`User`, `Comment`, `Activity`	records	Immutable (cannot change after creation) values.
`TaskRepository` / `InMemoryTaskRepository`	interface / class	Storage contract and a `ConcurrentHashMap` implementation.
`TaskFilter`	functional interface (an interface with one method, so a short lambda function can implement it)	Composable predicate (a yes/no test; Specification pattern) with factory methods (static methods that create objects) and `and` / `or`.
`TaskSort`	enum	Named comparators (objects that decide which of two items sorts first; Strategy). `BY_ID` compares the number inside the id, so `T2` sorts before `T10`.
`TaskEventListener` / `ConsoleNotifier`	interface / class	Observer for notifications.
`TaskService`	class	Facade with every use case; validates input, uses the clock, fires events.
`NotFoundException`, `InvalidTransitionException`	exceptions	Clear failure messages.

Class diagram

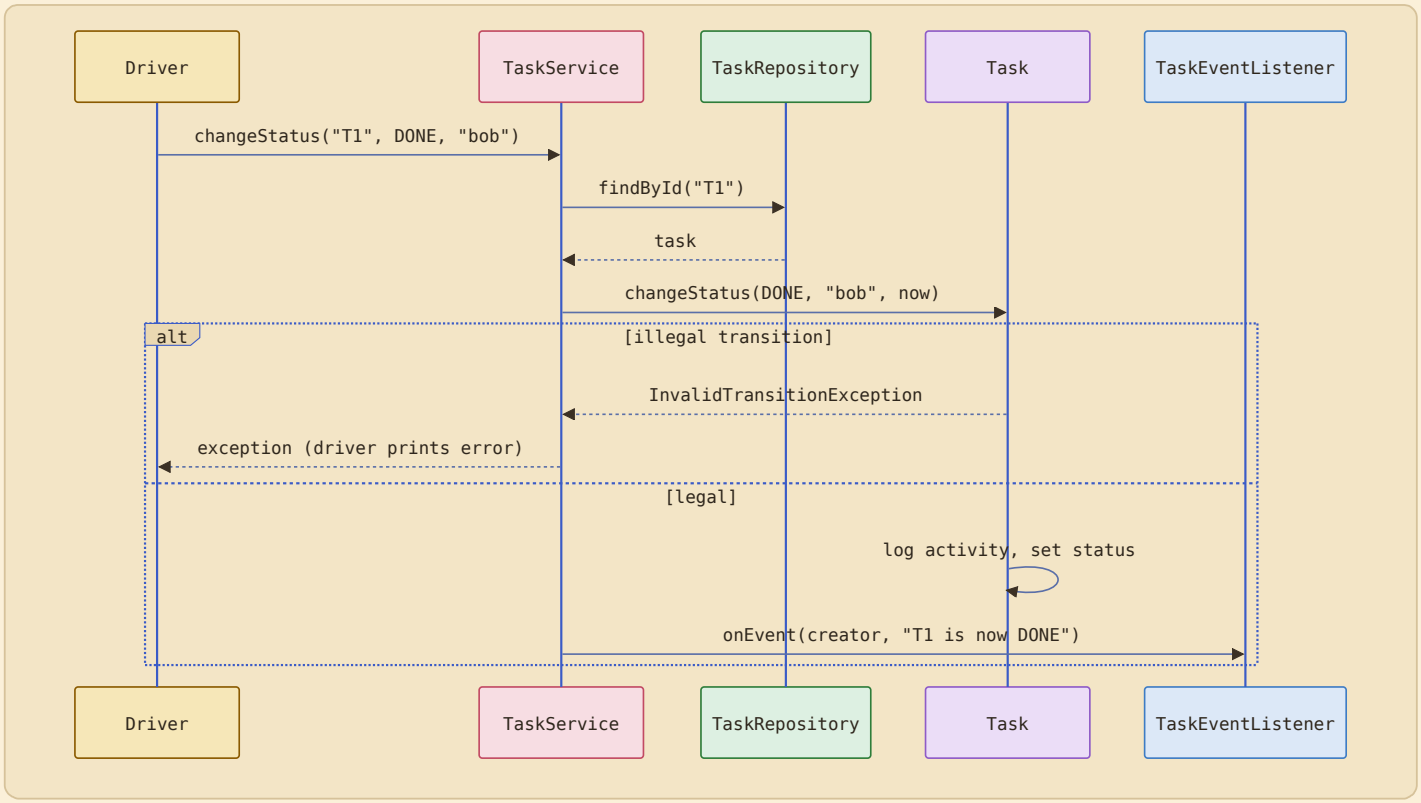


Key flows

Task status life cycle — the rules live in `TaskStatus.allowedNext()`:



Change status and notify:



Design decisions & patterns used

Decision	Pattern	Why	Alternative rejected
Transitions stored in the `TaskStatus` enum	State (enum-based)	All rules in one place; `Task` just asks `canMoveTo`.	Full State pattern (one class per state, each holding that state's behaviour) with one class per status — overkill when states carry no behaviour besides transitions.
`TaskFilter extends Predicate<Task>` with `and/or`	Specification	Any combination of filters without a method per combination; a new filter is one factory method.	`search(String assignee, Status s, Priority p, ...)` with many nullable parameters — grows forever.
`TaskSort` enum of comparators	Strategy	Sort order is data the caller picks.	`switch` on a sort string inside the service.
`TaskEventListener` list	Observer	Email/Slack/push can be added without touching the service.	Calling `System.out` from the service.
`TaskService` as the only entry point	Facade	Driver sees one simple API.	Driver talking to repositories directly.
`Clock` injected	Dependency injection (a class receives the objects it needs from outside instead of creating them)	Deterministic reminders and tests.	`LocalDate.now()` scattered in code.
`synchronized` on `Task` mutators	Monitor per entity (each object's own lock guards its methods)	Fine-grained (many small locks instead of one big one): two different tasks never block each other.	One global lock on the service — simpler but serialises everything (forces all work to run one at a time).

Java implementation

```java
// File: lld/ch21/taskmgmt/Priority.java
package lld.ch21.taskmgmt;

/** Ordered from least to most urgent, so natural enum order can be used for sorting. */
public enum Priority { LOW, MEDIUM, HIGH, CRITICAL }
```

```java
// File: lld/ch21/taskmgmt/TaskStatus.java
package lld.ch21.taskmgmt;

import java.util.EnumSet;
import java.util.Set;

/** Task lifecycle. Each status knows which statuses it may move to (a tiny state machine). */
public enum TaskStatus {
    TODO, IN_PROGRESS, BLOCKED, DONE, CANCELLED;

    public Set<TaskStatus> allowedNext() {
        return switch (this) {
            case TODO -> EnumSet.of(IN_PROGRESS, CANCELLED);
            case IN_PROGRESS -> EnumSet.of(BLOCKED, DONE, TODO, CANCELLED);
            case BLOCKED -> EnumSet.of(IN_PROGRESS, CANCELLED);
            case DONE -> EnumSet.of(IN_PROGRESS);          // re-open
            case CANCELLED -> EnumSet.noneOf(TaskStatus.class);
        };
    }

    public boolean canMoveTo(TaskStatus next) { return allowedNext().contains(next); }

    public boolean isOpen() { return this != DONE && this != CANCELLED; }
}
```

```java
// File: lld/ch21/taskmgmt/User.java
package lld.ch21.taskmgmt;

public record User(String id, String name) { }
```

```java
// File: lld/ch21/taskmgmt/Comment.java
package lld.ch21.taskmgmt;

import java.time.LocalDateTime;

public record Comment(String authorId, String text, LocalDateTime at) { }
```

```java
// File: lld/ch21/taskmgmt/Activity.java
package lld.ch21.taskmgmt;

import java.time.LocalDateTime;

/** One line of a task's audit history ("who did what, when"). */
public record Activity(LocalDateTime at, String actorId, String description) {
    @Override public String toString() { return at.toLocalTime() + " " + actorId + ": " + description; }
}
```

```java
// File: lld/ch21/taskmgmt/Task.java
package lld.ch21.taskmgmt;

import java.time.LocalDate;
import java.time.LocalDateTime;
import java.util.ArrayList;
import java.util.List;

/**
 * The central entity. All mutators are synchronized so two threads editing
 * the same task cannot interleave (e.g. a status change racing a reassignment).
 */
public class Task {
    private final String id;
    private final String createdBy;
    private String title;
    private String description;

TaskSort.BY_ID).size());
    }

    private static void attempt(Runnable r) {
        try { r.run(); System.out.println("  ok"); }
        catch (RuntimeException e) { System.out.println("  error: " + e.getMessage()); }
    }
}
```

Output:

```
== create & assign
  [notify bob] alice assigned you T1 'Fix login bug'
  [notify carol] alice assigned you T2 'Write release notes'
== work on tasks
  [notify alice] T1 is now IN_PROGRESS
  [notify alice] bob commented on T1
  [notify alice] T1 is now DONE
== search: bob's open tasks, by priority
  T3 Upgrade to Java 21     CRITICAL TODO        due=2026-10-01 assignee=bob
== search: priority >= MEDIUM due within 3 days, by due date
  T4 Review PR #42          MEDIUM   TODO        due=2026-09-28 assignee=-
  T1 Fix login bug          CRITICAL DONE        due=2026-09-29 assignee=bob
  T3 Upgrade to Java 21     CRITICAL TODO        due=2026-10-01 assignee=bob
== reminders (due within 3 days)
  [notify carol] Reminder: T4 'Review PR #42' is due 2026-09-28
  [notify bob] Reminder: T3 'Upgrade to Java 21' is due 2026-10-01
  reminders sent: 2
== history of T1
  09:00 alice: assigned to bob
  09:00 bob: status TODO -> IN_PROGRESS
  09:00 bob: commented "Root cause found in PasswordValidator"
  09:00 bob: status IN_PROGRESS -> DONE
== edge cases
  error: Task T2 cannot move from TODO to DONE
  error: Task not found: T99
  error: User not found: dave
  error: Due date is in the past: 2026-09-27
  error: Cannot assign a CANCELLED task T4
  deleted T2? true, remaining=3
```

What to notice in the output: self-assignment (`bob` assigning T3 to himself) sends no notification; `T1` shows up in the priority/due search even though it is DONE (that search did not ask for `open()`), but it is **not** in the reminders, which only consider open tasks; the illegal `TODO → DONE` jump is rejected with a clear message; and the history of T1 is a complete audit trail.

Concurrency & edge cases

- **Two users update the same task at once.** Each mutator of `Task` is `synchronized`, so a status change and a reassignment cannot interleave (have their steps mixed together); getters (methods that only read a field) are synchronized too so readers see a consistent value.
- **Storage.** `ConcurrentHashMap` for tasks and users; `findAll()` returns a copy so a search is never disturbed by a concurrent insert.
- **Listeners** (objects that asked to be told about events) are in a `CopyOnWriteArrayList` (a list that copies itself on each write, so reading needs no lock) — registering a listener while events fire is safe.
- **IDs** from an `AtomicInteger` — no duplicates under concurrency.
- **Edge cases handled:** unknown task / user / actor, blank title, past due date (on create and on update), illegal transition, assigning a closed (DONE/CANCELLED) task, self-assignment (no noise), comment notifications go to "the other party".
- **Not handled (say so):** lost updates between two *editors of the text fields* (last writer wins). Fix: optimistic locking with a `version` field — reject an update whose version is stale (out of date). Optimistic locking takes no lock up front; it only checks, at save time, that nobody else changed the record in the meantime.

Extensions & follow-up questions

- **Sub-tasks / dependencies?** Add `parentId` and a `Set<String> blockedBy`; forbid DONE while a blocker is open (a check inside `changeStatus`).
- **Multiple assignees or watchers?** Replace `assigneeId` with `Set<String>`; notify all watchers through the same listener.
- **Recurring tasks?** A `RecurrenceRule` (daily/weekly) that creates the next task when one is marked DONE.
- **Custom workflows per project (like Jira)?** Move the transition table from the enum into a `Workflow` object (a `Map<Status, Set<Status>>`) injected per project.
- **A reminder time chosen by the user?** Store `remindAt` on the task; the scheduler's sweep fires every reminder whose time has passed and clears it.

- **Real reminders?** A `ScheduledExecutorService` (Java's tool for running tasks on a timer) calling `sendDueReminders(1)` every hour; store "already reminded" per task to avoid spam.
- **Search at scale?** Secondary indexes (extra lookup maps keyed by a field other than the id: `Map<String, Set<Task>>` by assignee, `TreeMap<LocalDate, Set<Task>>` by due date; a `TreeMap` keeps its keys sorted) or a search engine such as Elasticsearch (a popular open-source search server).

Real-world example

In Jira, each project has a *workflow*: a set of statuses and the transitions allowed between them, and a transition can fire notifications to watchers. Search is done with JQL, a query language that combines conditions like `assignee = currentUser() AND status != Done ORDER BY priority DESC` (DESC = descending) — the same "compose filters, then sort" idea as `TaskFilter` + `TaskSort`, just with a text syntax on top.

In the interview

Present in this order (30–45 min version): (1) statuses and transitions on the whiteboard — it shows you think about invariants; (2) `Task` and `TaskService` API; (3) filters as composable predicates — the pattern interviewers love here; (4) the observer for notifications; (5) run the demo. If asked "why not the full State pattern?", answer: statuses have no behaviour except which transitions are legal, so an enum with a transition table is simpler and still closed to illegal moves.

Self-check

- **Q:** Where is the rule "TODO cannot go to DONE" coded? → **A:** In `TaskStatus.allowedNext()`; `Task.changeStatus` enforces it.
- **Q:** How do you add a "created by user X" filter? → **A:** Add `static TaskFilter createdBy(String u) { return t -> u.equals(t.createdBy()); }` — nothing else changes.
- **Q:** Why does the service take a `Clock`? → **A:** So "today" is controllable in demos and tests.
- **Q:** Why is `Task` synchronized per instance instead of a lock in the service? → **A:** Finer-grained: edits to different tasks never contend.

TL;DR

Task = entity that guards its own state machine and history. Service = facade. Filters = Specification, sorts = Strategy, notifications = Observer. Thread-safety per task.

21.2 Design a Digital Wallet Service

Problem & clarifying questions

Build the core of a wallet (an app account that stores money for payments) like Paytm, PhonePe or PayPal balance: users hold wallets, add money, transfer to other users and see a statement. The awesome-low-level-design statement also lists account and personal-info management, adding and removing payment methods (cards, bank accounts), transfers to *external* accounts, multiple currencies with conversion, security, **concurrent transactions with data consistency**, and scale. Promotional **cashback** (money given back to the customer after a payment, as a reward) is not in that statement; it is added here because wallet machine-coding variants often ask for it, and it is a clean place to show the Strategy pattern and double-entry thinking (the accounting rule that every amount added somewhere is taken from somewhere else, so the books always balance). In a machine-coding round the interviewer focuses on three things: **money arithmetic**, **no double-spending under concurrency** (spending the same money twice because two requests ran at the same time), and **no double-charging on retries** (idempotency).

> **Key term — idempotency:** an operation is **idempotent** if running it twice has the same effect as running it once. Networks fail in the middle of requests, so clients retry; if "transfer 100" is not idempotent, a retry moves another 100. The usual fix is an **idempotency key**: the client sends a unique id with the request, and the server remembers the result for each id and returns it again for a repeat instead of re-running the work. More in System Design Fundamentals.

Question	Assumed answer
Money type?	`BigDecimal` with scale 2 (paise/cents). Inputs with more than 2 decimals are rejected, not silently rounded.
Can a balance go negative?	No.
What if a client retries a request (network timeout — it gave up waiting for the reply)?	Each request carries an **idempotency key**; a repeated key returns the original result and moves no money.
Offers?	Cashback strategies: "10% on first transfer, max 50" and "flat 25 on transfers ≥ 1000". Offers do not stack — the best one wins.
Where does cashback money come from?	From a **promotions wallet** (`PROMO`) that marketing tops up. Cashback is an ordinary transfer PROMO → sender, so money is never created from nothing. If the budget is used up, no cashback is paid and the transfer still stands.
Top-up source?	An external bank/card; modelled as a credit (money added to the wallet) with a reference.
Multi-currency?	Out of scope for the 90-minute version; discussed in extensions.

Requirements

Functional

1. Create a wallet for a user.
2. Top up a wallet.
3. Transfer between two wallets (atomic: both sides or neither).
4. Transaction history (statement) per wallet, with running balance.
5. Apply the best eligible cashback offer after a transfer, paid out of the funded promotions wallet.
6. Idempotent top-up and transfer.

Non-functional

- **Correctness under concurrency:** no lost updates (one thread's change silently overwritten by another's), no negative balances, no deadlocks (two threads each waiting forever for a lock the other holds), total money conserved (only top-ups add money; transfers and cashback only move it).
- Exact decimal arithmetic.
- New offers added without touching the transfer code.

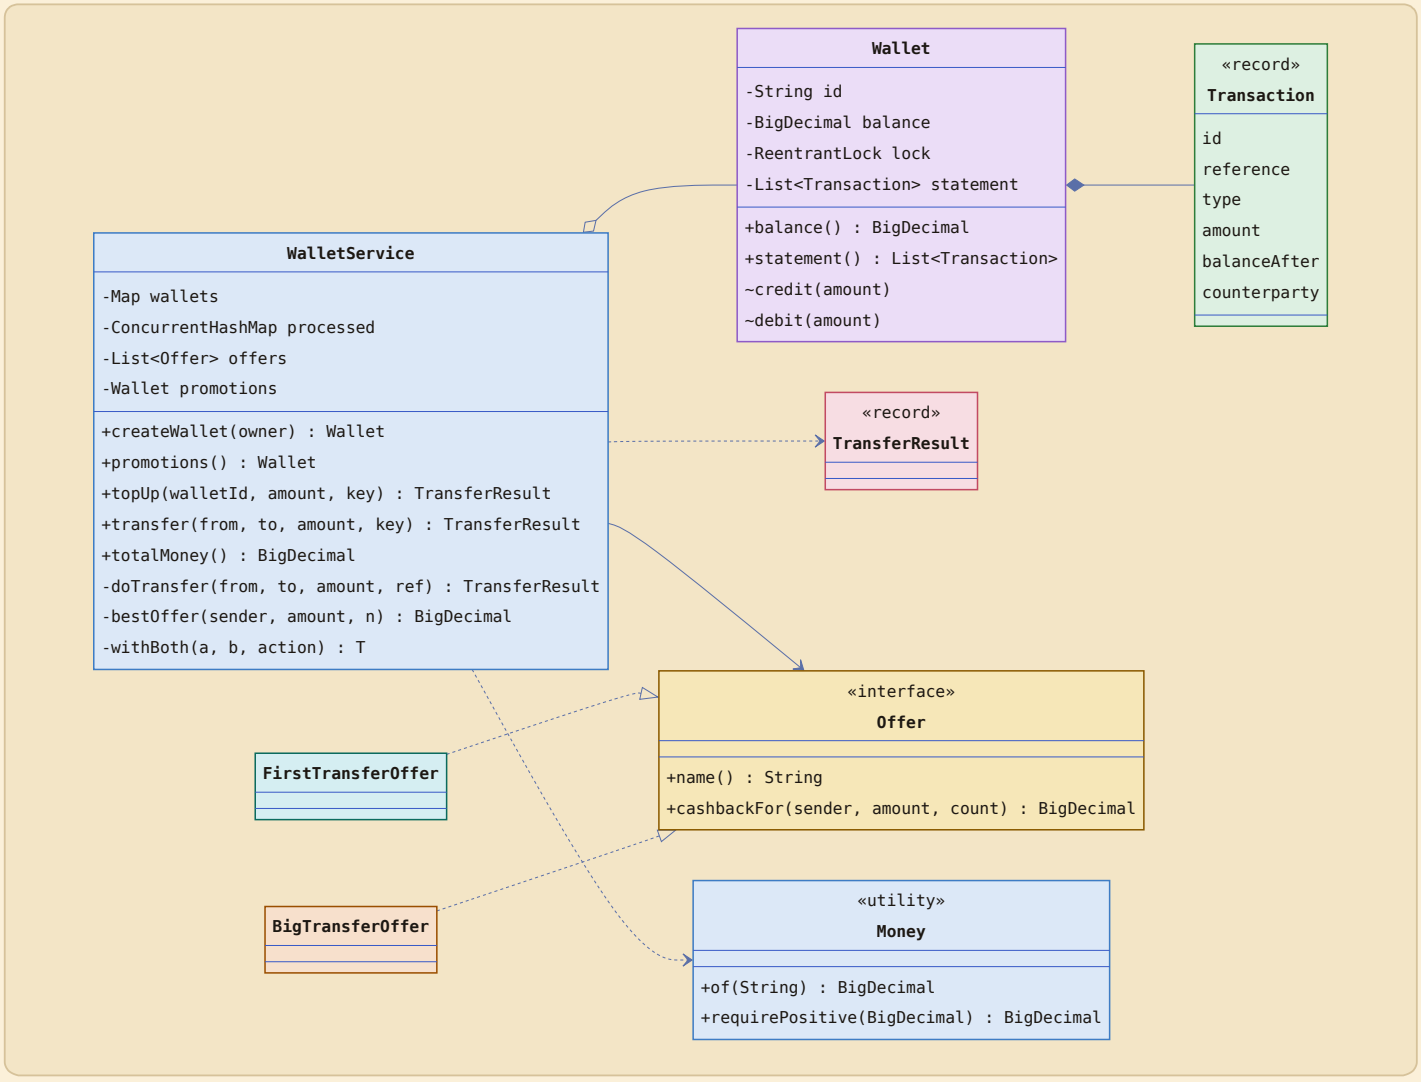
Use cases

Actor	Use cases
User	create wallet, top up, transfer, view statement
Bank / card gateway (external)	source of top-ups
Marketing (configures)	defines offers, funds the promotions wallet
Client app (retrying)	re-sends the same request with the same idempotency key

Core entities

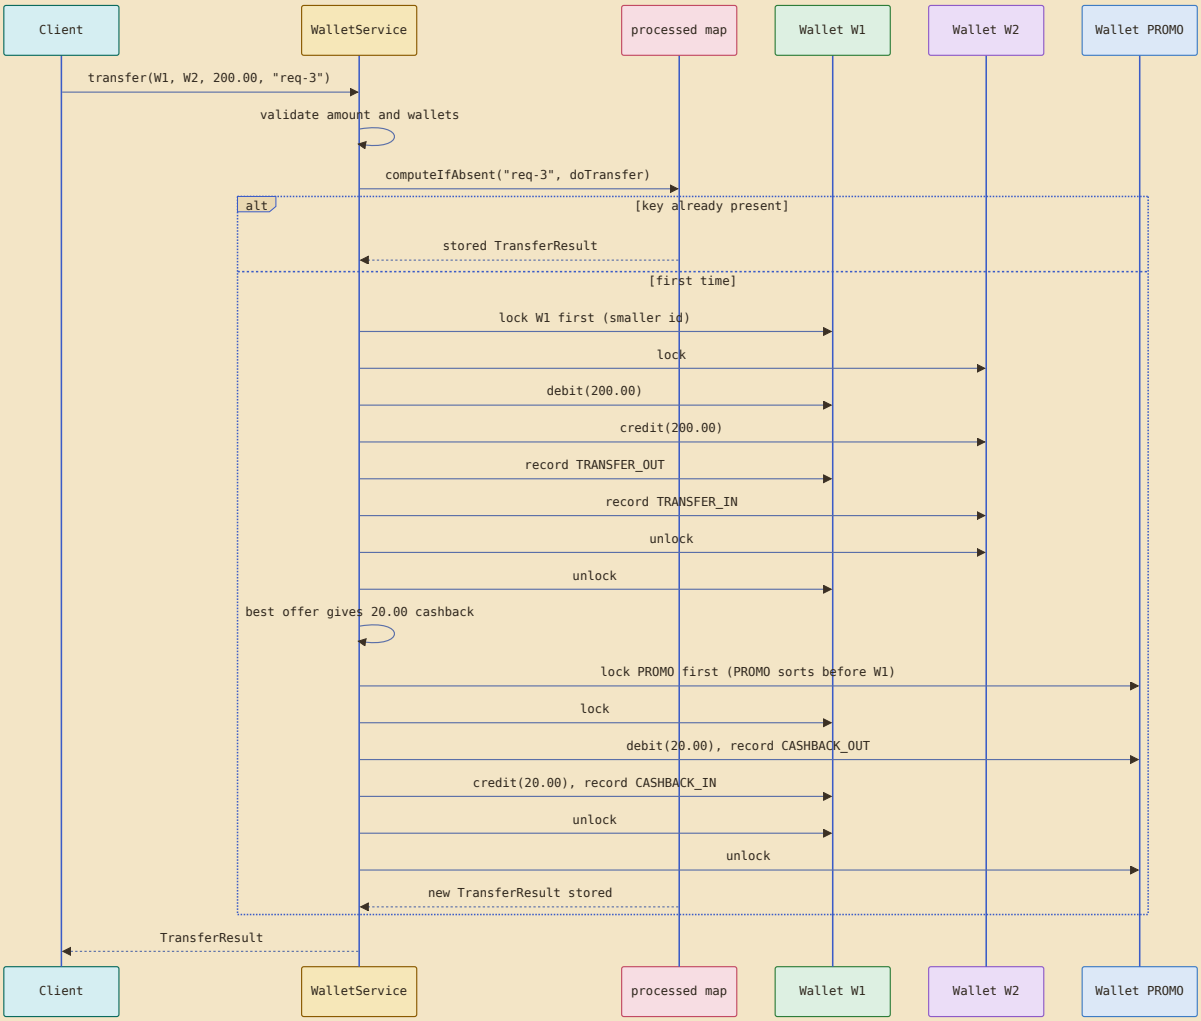
Class	Kind	Responsibility
`Wallet`	class	Balance + own statement + its `ReentrantLock` (Java's explicit lock object). `debit` refuses to go below zero. The service owns one special wallet, `PROMO`, that funds cashback.
`Transaction`	record	Immutable ledger line: type, amount, balance after, counterparty (the other wallet involved), reference.
`TxnType`	enum	TOP_UP, TRANSFER_OUT, TRANSFER_IN, CASHBACK_OUT (on PROMO), CASHBACK_IN (on the user).
`TransferResult`	record	What the caller gets (stored for idempotent replays).
`Money`	utility	Normalises and validates `BigDecimal` amounts.
`Offer` + `FirstTransferOffer`, `BigTransferOffer`	interface + strategies	Compute cashback for a completed transfer.
`WalletService`	class	Facade: creates wallets, orchestrates (calls in the right order) locking, idempotency, offers.
`InsufficientFundsException`, `WalletNotFoundException`	exceptions	Failure reasons.

Class diagram



Key flows

Transfer with idempotency and lock ordering:



Client
WalletService
processed map
Wallet W1
Wallet W2
Wallet PROMO
transfer(W1, W2, 200.00, "req-3")
validate amount and wallets
computeIfAbsent("req-3", doTransfer)
alt
[key already present]
stored TransferResult
[first time]
lock W1 first (smaller id)
lock
debit(200.00)
credit(200.00)
record TRANSFER_OUT
record TRANSFER_IN
unlock
unlock
best offer gives 20.00 cashback
lock PROMO first (PROMO sorts before W1)
lock
debit(20.00), record CASHBACK_OUT
credit(20.00), record CASHBACK_IN
unlock
unlock
new TransferResult stored
TransferResult
Client
WalletService
processed map
Wallet W1
Wallet W2
Wallet PROMO

Design decisions & patterns used

Decision	Why	Alternative rejected
`BigDecimal`, scale 2, reject > 2 decimals	`double` cannot represent 0.1 exactly; money must be exact. Rejecting `1.005` avoids silent rounding surprises.	`double` (wrong), `long` paise (also correct, and a fine choice — say so).
Lock per wallet, acquired in id order	Two opposite transfers (A→B and B→A) would deadlock if each locked its own source first. A global order (smaller id first) makes a cycle impossible.	One global lock — correct but every transfer in the system serialises.
Debit before credit, both under both locks	`debit` throws before any state changes, so a failed transfer leaves both wallets untouched (atomicity).	Credit then debit — would need a compensating action (a new step that undoes an earlier one) on failure.
Idempotency via `ConcurrentHashMap.computeIfAbsent` (creates and stores a value only if the key is missing, as one atomic step)	The check "seen this key?" and the execution are one atomic step per key, so two concurrent retries cannot both run. If the transfer throws, nothing is stored and the client can retry.	`if (!map.containsKey(k)) { run; put }` — check-then-act race (another thread can act between the check and the action).
Cashback paid from a funded `PROMO` wallet	Double-entry: every credit has a matching debit, so the sum of all wallets changes only on top-ups — which is exactly what the demo checks. A campaign cannot overspend its budget.	Crediting the user out of thin air — the books no longer balance and nobody can say what a campaign cost.
Cashback as a second step, after the transfer locks are released	Only two wallets are ever locked at once, and ordinary transfers never wait on the busy `PROMO` lock.	Locking sender, receiver and PROMO together for every transfer — correct, but every transfer in the system would queue on PROMO.
`Offer` interface, best one wins	Strategy: new promotions are new classes; the "no stacking" policy lives in one method.	`if/else` on promotion codes inside `transfer`.
Statement stored in the wallet	Reading a wallet's history needs no global scan.	One global transaction list filtered on read — fine for small data, slow at scale.

`computeIfAbsent` detail worth knowing: the JDK (Java Development Kit: Java's compiler and standard library) documents that the whole call is atomic, that the mapping function runs only when the key is absent, that an exception from the function is rethrown with no mapping recorded, and that other threads updating the *same map* may block while it runs — so the function should be short and must not update the map itself. Our function only touches wallets, never `processed`, so it is safe. At higher scale, store a `CompletableFuture` (a handle to a result that will be ready later) with `putIfAbsent` and run the transfer outside the map (extension below).

Java implementation

```java
// File: lld/ch21/wallet/Money.java
package lld.ch21.wallet;

import java.math.BigDecimal;
import java.math.RoundingMode;

/** Helpers that keep every amount at 2 decimal places. Never use double for money. */
public final class Money {
    public static final int SCALE = 2;
    private Money() { }

    public static BigDecimal of(String amount) { return normalize(new BigDecimal(amount)); }

    public static BigDecimal normalize(BigDecimal amount) { return amount.setScale(SCALE, RoundingMode.HALF_EVEN);
}

    public static BigDecimal requirePositive(BigDecimal amount) {
        if (amount == null || amount.signum() <= 0) throw new IllegalArgumentException("Amount must be positive: "
+ amount);
        if (amount.stripTrailingZeros().scale() > SCALE)
            throw new IllegalArgumentException("At most " + SCALE + " decimal places: " + amount);
        return normalize(amount);
    }
}
```

```java
// File: lld/ch21/wallet/TxnType.java

  Alice=655.00  Bob=1691.50  PROMO=54.00
```

Reading the output: marketing first funds `PROMO` with 100.00; the retried top-up `req-1` did not add another 2000; the retried transfer `req-3` returned the *same object* and moved no money; Alice's first transfer earned 10% (20.00), her 1200.00 transfer earned the flat 25.00 (the first-transfer offer no longer applies); the failed `req-5` stored nothing, so re-using that key later succeeded (and, being Bob's first successful transfer, earned him 1.00). Every cashback appears twice — `CASHBACK_OUT` on PROMO (100.00 → 80.00 → 55.00 → 54.00) and `CASHBACK_IN` on the receiver. Finally 1000 concurrent opposite transfers kept the total (PROMO included) exactly constant — no lost updates, no deadlock. (Each side starts with more than 500.00, so no transfer in that race can fail, and the final balances are the same on every run.)

Concurrency & edge cases

- **Race on one wallet:** every read-modify-write (read a value, compute a new one, write it back — three steps another thread can slip between) of `balance` happens with the wallet's lock held.
- **Deadlock:** avoided by a global lock order (lexicographic — dictionary order — wallet id; `"PROMO"` sorts before `"W1"`). Every two-lock path goes through one helper, `withBoth`, so the order cannot be forgotten. The program never holds more than two wallet locks at a time.
- **Double submit:** idempotency key → at most one execution per key.
- **Same key, different body** (client bug): today the stored result is returned. Production systems also store a hash (a short fingerprint computed from the data) of the request and reject a mismatch with an error.
- **Validation:** non-positive amounts, more than 2 decimals, same source and target, unknown wallet, insufficient funds.
- **Cashback money source:** a transfer from the `PROMO` wallet, so the books balance (double-entry: every credit has a matching debit). The cashback step runs after the transfer's locks are released, so for a moment the

transfer is visible without its cashback — fine for a reward. If the budget cannot cover the offer, the result reports a cashback of zero and the transfer is kept.

Extensions & follow-up questions

- **Multi-currency?** Each wallet has a `Currency`; transfers across currencies go through a `FxRateProvider` (FX = foreign exchange) interface; store both amounts and the rate used in the transaction. Use `java.util.Currency` for codes and decimal places.
- **Payment methods (card, bank, UPI — India's instant bank-to-bank payment system)?** A `PaymentMethod` interface with `charge(amount)`; top-up calls it first, and only credits the wallet on success (or uses a pending → confirmed state if the gateway is asynchronous). Users add and remove methods on their account.
- **Transfers to external accounts (withdraw to bank)?** Debit the wallet into a `PENDING_PAYOUT` state, call the bank through a `PayoutGateway` interface, and either confirm, or post a compensating credit if the bank rejects it.
- **Reversal / refund?** Never edit a past transaction; post a new compensating transaction referencing the original.
- **Distributed system?** Wallet balances in a database with row locks (`SELECT ... FOR UPDATE` locks the rows it reads until the transaction ends) or optimistic versioning; idempotency keys in a table with a unique constraint (a database rule that refuses a second row with the same value); ledgers as double-entry journals.
- **Long transfers blocking the idempotency map?** Use `putIfAbsent(key, new CompletableFuture<>())`: the winner runs the transfer outside the map and completes the future; duplicates just wait on `future.join()` (blocks until the result is ready). On failure, remove the key so a retry can run.
- **Limits (daily cap, KYC tier — KYC, "know your customer", is the identity check that sets how much a user may move)?** A chain of validators (Chain of Responsibility) run before `doTransfer`.
- **Why not `AtomicReference<BigDecimal>` + CAS (compare-and-set: replace a value only if it still equals what you last read, in one indivisible step)?** Works for a single wallet, but a transfer touches two balances that must change together; CAS on two variables is not atomic, so locks are simpler.

Real-world example

Stripe's (a large online-payments company) API accepts an `Idempotency-Key` header (a named piece of metadata sent along with an HTTP request): if a request times out and the client retries with the same key, Stripe returns the saved result of the first attempt instead of charging twice. Wallets such as Paytm and PhonePe run cashback campaigns with rules like "X% up to a cap on your first transaction" — exactly the shape of `FirstTransferOffer`.

In the interview

Lead with the three risks: exact money, concurrency, retries (and, if offers come up, "cashback must come out of a budget wallet"). Show `Money`, then `doTransfer` with the lock ordering (draw the A→B / B→A deadlock and how ordering breaks the cycle), then idempotency. Run the concurrent demo and point at `conserved=true`. Offers are a 2-minute Strategy mention. If time is short, cut multi-currency and payment methods — say you would add them behind interfaces.

Self-check

- **Q:** Why is `new BigDecimal("0.1")` preferred over `new BigDecimal(0.1)`? → **A:** The double constructor captures the binary approximation of 0.1 (`double` stores numbers in base 2, where 0.1 has no exact form) (a long, inexact decimal); the String constructor is exact.
- **Q:** Two threads transfer W1→W2 and W2→W1 at once. Why no deadlock? → **A:** Both lock W1 first (smaller id), so one waits for the other instead of each holding what the other needs.
- **Q:** A transfer fails for insufficient funds. Can the same idempotency key be reused? → **A:** Yes — `computeIfAbsent` stores nothing when the function throws.
- **Q:** Where would a "max 3 transfers per minute" rule go? → **A:** A validator run before `doTransfer`, not inside the wallet.

TL;DR

`BigDecimal` money, lock both wallets in a global order, debit before credit, idempotency key → run at most once, offers as Strategies paid out of a funded promotions wallet. Prove it with a concurrent demo where the total is conserved.

21.3 Design an Event Calendar (Flipkart)

Problem & clarifying questions

This is a Flipkart machine-coding statement (kumaransg/LLD, `Event_calendar_flipkart`). In short: onboard users with **working hours**; group users into **teams** (a user belongs to at most one team); create **events** on one day with a start and end time, whose participants are users, teams, or both. A user can be in **only one event at a time**. For team participants the event creator says how many **representatives (N)** each team must send; the system blocks the event against N *available* members of each team, and if any team cannot supply N the event is not created. Required features: create user, create team, create event, **get a user's events in a time range** (including events they were blocked for as a team representative), and **suggest free slots** for a list of users/teams on a day. Bonus: **update event time** (report failure if impossible) and **recurring events** (time, start date, end date, frequency). The statement says: no DB, no UI, no CLI (command-line interface: a program you type commands into) needed — a `main` or tests is enough — and "do not make assumptions, ask".

Clarifying questions (and the answers this solution uses):

Question	Answer used
Is an event that ends at 15:00 in conflict with one that starts at 15:00?	No. Slots are **half-open** `[start, end)` (the start minute belongs to the slot, the end minute does not).
Must an event lie inside every attendee's working hours?	Yes (the statement's Event5 fails because F starts at 11:00).
Which team members become representatives?	The first N free members in team order (a pluggable strategy).
If a user is invited directly *and* is in an invited team, do they count as a representative?	No — a direct attendee is not picked again as a representative.
Free slots for a team with N representatives: what counts as "free"?	A moment is free for the team if at least N members are working and not busy then.
Recurring event: if one occurrence clashes?	Reject the whole series (all-or-nothing).

A note on the statement's sample. For "free slots for user A and team T1 with 1 representative today" the sample answer says *10AM to 3PM and 4PM to 7PM*. But T1 = {C, E} and neither works before 11:00 (C starts 11:30, E 11:00), so by the statement's own rules the first slot should start at **11:00**. Our program prints `11:00-15:00, 16:00-19:00`. Pointing out such an inconsistency politely ("I think the sample means 11AM; shall I go with the rules?") is exactly what "do not make assumptions, ask" is testing. (A smaller slip in the same sample: its step 1 says "Onboard 5 Users" but then lists six, A to F. The demo creates all six.)

Requirements

Functional

1. Create user with working hours.
2. Create team of existing users (one team per user).
3. Create event for users and/or teams with N representatives; reject if any attendee is outside working hours, already busy, or a team lacks N free members.
4. Events of a user between two date-times (direct + as representative).
5. Free slots for users/teams on a day.
6. Bonus: update event time (atomic: old booking kept on failure).
7. Bonus: recurring events (daily/weekly between two dates).

Non-functional

- The check "is everyone free?" and the booking must be **atomic**, or two concurrent creations could book the same person twice.
- Representative choice should be replaceable (fairness, least-busy, random).

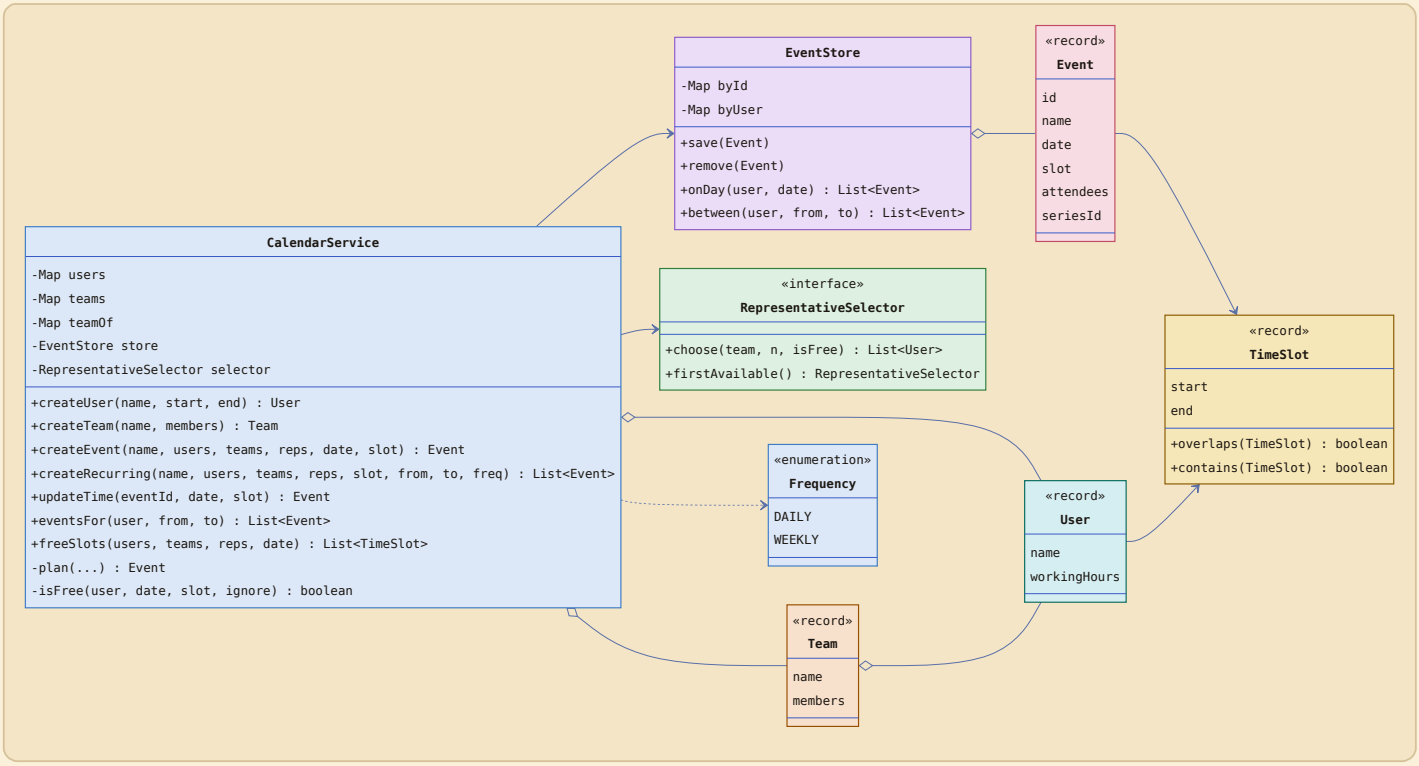
Use cases

Actor	Use cases
Admin	onboard user, create team
Organiser	create event, create recurring event, move event, find free slots
Attendee	view own events in a range

Core entities

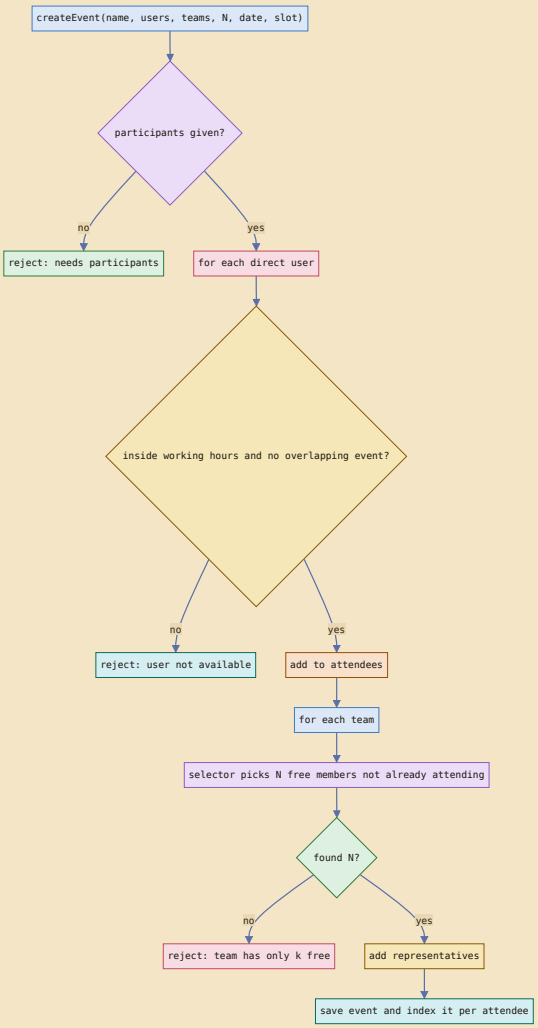
Class	Kind	Responsibility
`TimeSlot`	record	Half-open `[start, end)` on one day; `overlaps`, `contains`; validates start < end.
`User`	record	Name + working hours.
`Team`	record	Name + ordered members.
`Event`	record	One concrete occurrence: date, slot, what was requested (users, teams, N) and who is actually blocked (`attendees`), optional `seriesId`.
`Frequency`	enum	DAILY / WEEKLY — knows the next date.
`EventStore`	class	Repository + index `user → date → events` for fast conflict checks and range queries ("everything between X and Y"; `TreeMap.subMap` returns just that slice of a sorted map).
`RepresentativeSelector`	interface	Strategy: pick N free members of a team.
`CalendarService`	class	All use cases; planning (validation + representative choice) separated from saving.
`CalendarException`	exception	Readable reason for every rejection.

Class diagram

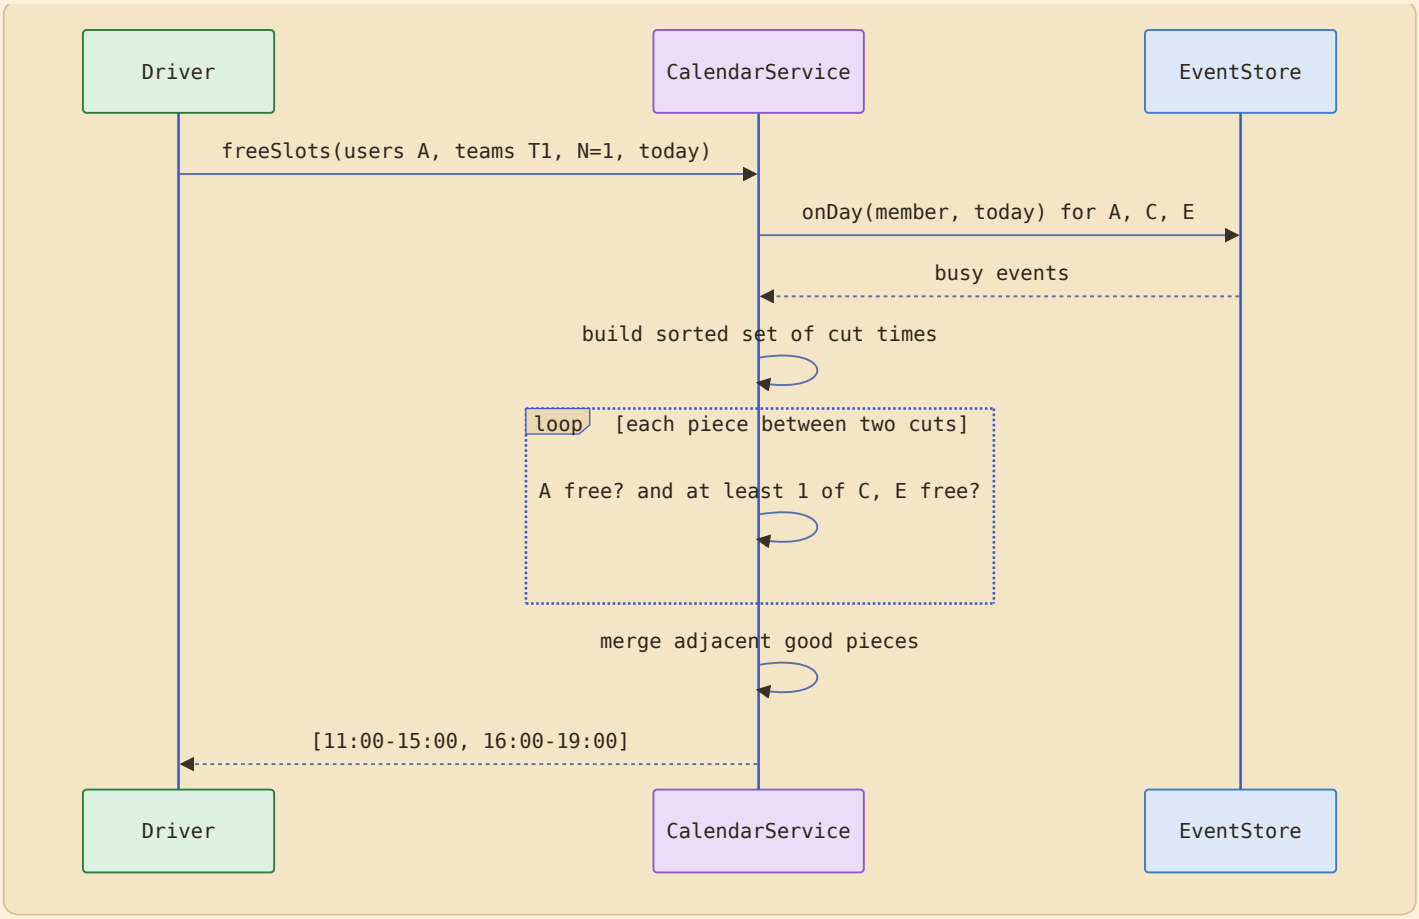


Key flows

Create an event (plan, then save):



Free-slot sweep. Collect every "interesting" time on that day: each involved person's working-hour start and end, and the start and end of each of their events. Sort them. Between two consecutive points nothing changes, so test each small piece once: all direct users free, and each team has at least N free members. Merge neighbouring good pieces. For the statement's example (A + T1, N = 1, today) the cut points are 10:00, 11:00, 11:30, 15:00, 16:00, 18:30, 19:00, 19:30, and the good pieces merge into 11:00–15:00 and 16:00–19:00.



Design decisions & patterns used

Decision	Why	Alternative rejected
Half-open intervals	Back-to-back meetings do not conflict; `overlaps` is one line: `a.start < b.end && b.start < a.end`.	Closed intervals — 14:00–15:00 would clash with 15:00–16:00.
`plan()` separate from `save()`	Validation + representative choice produce an `Event` without side effects (no change to any stored state). `createEvent`, `createRecurring` (plan all, then save all) and `updateTime` (plan while ignoring the old event, then swap) all reuse it — all-or-nothing for free.	Saving as you go and rolling back (undoing the saved steps) on failure.
`RepresentativeSelector` strategy	"Which N members?" is a policy; fairness or least-busy can be plugged in.	Hard-coded loop in the service.
Index `user → TreeMap<date, events>`	Conflict checks read only one user's one day; range queries use `subMap`.	Scanning all events each time.
Sweep over boundaries for free slots	Exact, simple, no minute-by-minute loops; works for any N.	Checking every 15 or 30 minutes — misses odd times like 11:30 and is slower.
Service methods `synchronized`	Check-then-book must be atomic; the store's lists are not thread-safe on their own.	Per-user locks — faster, but an event locks many users, so you need lock ordering; mention it as a scale-up.

Java implementation

```java
// File: lld/ch21/calendar/TimeSlot.java
package lld.ch21.calendar;

import java.time.LocalTime;

/** Half-open interval [start, end) inside one day. 14:00-15:00 and 15:00-16:00 do not overlap. */
public record TimeSlot(LocalTime start, LocalTime end) {
    public TimeSlot {
        if (!start.isBefore(end)) throw new IllegalArgumentException("start must be before end: " + start + "-" +
end);
    }
    public boolean overlaps(TimeSlot o) { return start.isBefore(o.end) && o.start.isBefore(end); }
    public boolean contains(TimeSlot o) { return !o.start.isBefore(start) && !o.end.isAfter(end); }
    @Override public String toString() { return start + "-" + end; }
}
```

```java
// File: lld/ch21/calendar/User.java
package lld.ch21.calendar;

public record User(String name, TimeSlot workingHours) { }
```

```java
// File: lld/ch21/calendar/Team.java
package lld.ch21.calendar;

import java.util.List;

```

```
        catch (RuntimeException e) { System.out.println("  FAILED: " + e.getMessage()); }
    }
}
```

Output:

```
== 1. onboard users
  6 users created
== 2. teams
  T1=[C,E] T2=[B,D,F]
  FAILED: C already belongs to team T1
== 3. events
  ok: Event1 2026-09-29 14:00-15:00 [A, C, E]
  FAILED: Event2: C is not available 2026-09-29 14:00-15:00
  ok: Event3 2026-09-28 15:00-16:00 [C, E, B, D]
  ok: Event4 2026-09-28 15:00-16:00 [A, F]
  FAILED: Event5: F is not available 2026-09-28 10:00-11:00
== 4. events in a time range (today 10:00 .. tomorrow 17:00)
  A: [Event4, Event1]
  B: [Event3]
  F: [Event4]
== 5. free slots today for A + T1 (1 representative)
  [11:00-15:00, 16:00-19:00]
  free slots today for B + D: [10:00-15:00, 16:00-17:30]
== bonus: update event time
  FAILED: Event1: team T1 has only 1 free member(s), needs 2
  ok: Event1 2026-09-29 16:00-17:00 [A, C, E]
== bonus: recurring daily stand-up (A + D), 3 days
  ok: [Standup@2026-09-28 2026-09-28 10:00-10:15 [A, D], Standup@2026-09-29 2026-09-29 10:00-10:15 [A, D],
Standup@2026-09-30 2026-09-30 10:00-10:15 [A, D]]
  FAILED: Sync@2026-09-28: A is not available 2026-09-28 15:30-16:30
  A today..+2: [Standup@2026-09-28, Event4, Standup@2026-09-29, Event1, Standup@2026-09-30]
```

Checking against the statement: Event2 fails (C is in Event1), Event5 fails (F starts at 11:00), user A sees Event4 and Event1, and user B sees Event3 — because T2's first two free members (B, D) represented it in Event3, which left F as the only free T2 member for Event4. The update to 18:30–19:00 is refused because Event1 needs both T1 members and C stops at 18:30; the old booking stays. The "Sync" series is rejected as a whole because its first day clashes with Event4.

Concurrency & edge cases

- **Double booking under concurrency:** all mutating and reading methods are `synchronized` on the service, so the "is free?" check and the save are one atomic step.
- **Edge cases handled:** start ≥ end, unknown user/team, user already in a team, empty participant list, N < 1 with teams, direct attendee also in an invited team (not double-counted), event outside working hours, recurring series with any clash (nothing saved), moving an event onto a slot where it would conflict with *itself* (we ignore the event being moved).
- **Time zones:** out of scope; everything is local time on one day. Real calendars store instants (exact moments, in UTC — the world reference time zone) plus the user's zone.
- **Multi-day events:** the statement fixes start and end on the same day; extension would split an event into per-day `TimeSlot`s.

Extensions & follow-up questions

- **Invites with accept/decline?** Add `InviteStatus {PENDING, ACCEPTED, DECLINED}` per attendee; a declined attendee no longer blocks the slot.
- **Fair representative choice?** A `LeastBusySelector` that sorts free members by number of events this week.
- **Recurring events at scale?** Store one *rule* (like the iCalendar RRULE — the standard text format for "repeats every Tuesday until June") and expand occurrences lazily (only when asked) for the queried range instead of materialising (creating and storing) every occurrence.
- **Rooms?** Treat a room like a user with "working hours" = building hours; the same availability logic applies.
- **Faster free-slot search for big teams?** For each team, a sweep counting free members per piece is O(members × events); with many members, use a count array or segment tree (a tree that answers "how many in this range?"

quickly) over minutes.

Real-world example

Google Calendar's "Find a time" and Outlook's Scheduling Assistant lay attendees' busy blocks side by side and highlight times when everyone is free — the same intersection this sweep computes. Both products store recurring meetings as a rule plus exceptions (following the iCalendar RRULE standard) instead of thousands of copies.

In the interview

Start by drawing a timeline with two users' working hours and events, and show that free time is "working time minus busy time, intersected". Explain half-open intervals in one sentence. Code `TimeSlot`, `plan()` and `createEvent` first — that satisfies the first three requirements. Then `eventsFor`, then the sweep. Mention the sample inconsistency. Bonus features fall out of `plan()` almost for free, which is the design win to point at.

Self-check

- **Q:** Why does `plan()` take an `ignore` event? → **A:** When moving an event, its current booking must not count as a conflict with its new time.
- **Q:** Why is the recurring series all-or-nothing easy here? → **A:** We plan every occurrence first (no side effects) and save only if all plans succeed.
- **Q:** What is the overlap test for half-open intervals? → **A:** `a.start < b.end && b.start < a.end`.
- **Q:** Why a `TreeMap` per user? → **A:** Dates are ordered, so a range query is `subMap(from, to)` instead of a full scan.

TL;DR

Half-open `TimeSlot`s, per-user day index, a side-effect-free `plan()` reused by create/recurring/update, a pluggable representative selector, and a boundary sweep for free slots. Ask about the sample that contradicts the rules.

21.4 Design a LeetCode-like Coding Platform — "Coding Blox" (Flipkart)

Problem & clarifying questions

A Flipkart SDE-2 (Software Development Engineer, level 2: a mid-level role) machine-coding statement (kumaransg/LLD, `leetcode-lld-flipkart-coding-blox`). Coding Blox lets users sign up, create contests, and take part in contests hosted by others. Questions and contests each have a level — LOW, MEDIUM or HIGH — and a contest of a level uses **all questions of that level** (the question list is independent of the contest). The platform is driven by commands:

Command	Meaning
`CreateUser <name>`	Register a user with a default score of **1500**.
`CreateQuestion <level> <score>`	Add a question; ids auto-increment from 1.
`ListQuestion [level]`	All questions, or only that level.
`CreateContest <name> <level> <creator>`	Creator automatically attends; contest ids auto-increment from 1.
`ListContest [level]`	All contests, or only that level.
`AttendContest <contestId> <user>`	Register for a contest.
`RunContest <contestId> <creator>`	Only the creator may run it. Simulate which questions each participant solved (random), sum their scores (`contestPoints`), then update ratings: LOW → `score + (points − 50)`, MEDIUM → `score + (points − 30)`, HIGH → `score + points`.
`LeaderBoard <asc/desc>`	Users with scores, sorted.
Bonus `ContestHistory <contestId>`	Per-contest leaderboard: user, points, solved question ids.
Bonus `WithdrawContest <contestId> <user>`	Leave before the contest runs; the creator cannot withdraw.

Expectations in the statement: create the sample data yourself, demo through a driver or tests, modular OO (object-oriented) design with interfaces, extensible, graceful edge-case handling, DRY ("don't repeat yourself": each piece of logic written once).

Question	Answer used
How many questions does a user "solve" in a run?	Random 1..all questions of the contest level. The randomness sits behind a `SolveSimulator` interface and is **seeded** for a reproducible demo.
Can a contest run twice?	No — second run is an error, so ratings are never applied twice.
Can someone attend after the run?	No.
Leaderboard tie-break?	By name.
Can a contest be created if no question of that level exists?	No (it would be empty).

Requirements

Functional: all commands above, including both bonus commands. **Non-functional:** commands from a built-in input list; errors printed, processing continues; scoring rule and solving logic replaceable; rating update safe if two contests finish at once.

Use cases

Actor	Use cases
User	sign up, attend/withdraw, view leaderboard, view contest history
Contest creator (a user)	create contest, run contest
Admin / problem setter	create and list questions
Judge (system actor, simulated)	decides which questions each participant solved

Core entities

Class	Kind	Responsibility
`Level`	enum	LOW/MEDIUM/HIGH, each with its penalty; `newScore(current, points)` implements the rating rule.
`User`	class	Name + score; `applyContest` updates the score atomically.
`Question`	record	id, level, score.
`Contest`	class	id, name, level, creator, participants, status, results; guards "open only" rules.
`ContestStatus`	enum	OPEN, COMPLETED.
`ContestResult`	record	user, points, solved ids.
`SolveSimulator` / `RandomSolveSimulator`	interface / class	Strategy for "who solved what".
`Repository<K,V>`	generic class	In-memory storage reused for users, questions and contests.
`CodingBloxService`	class	Business rules for every command.
`CommandProcessor`	class	Parses (splits and reads) a line, dispatches to (calls) a handler from a map, prints output/errors.
`BloxException`	exception	Readable failure.

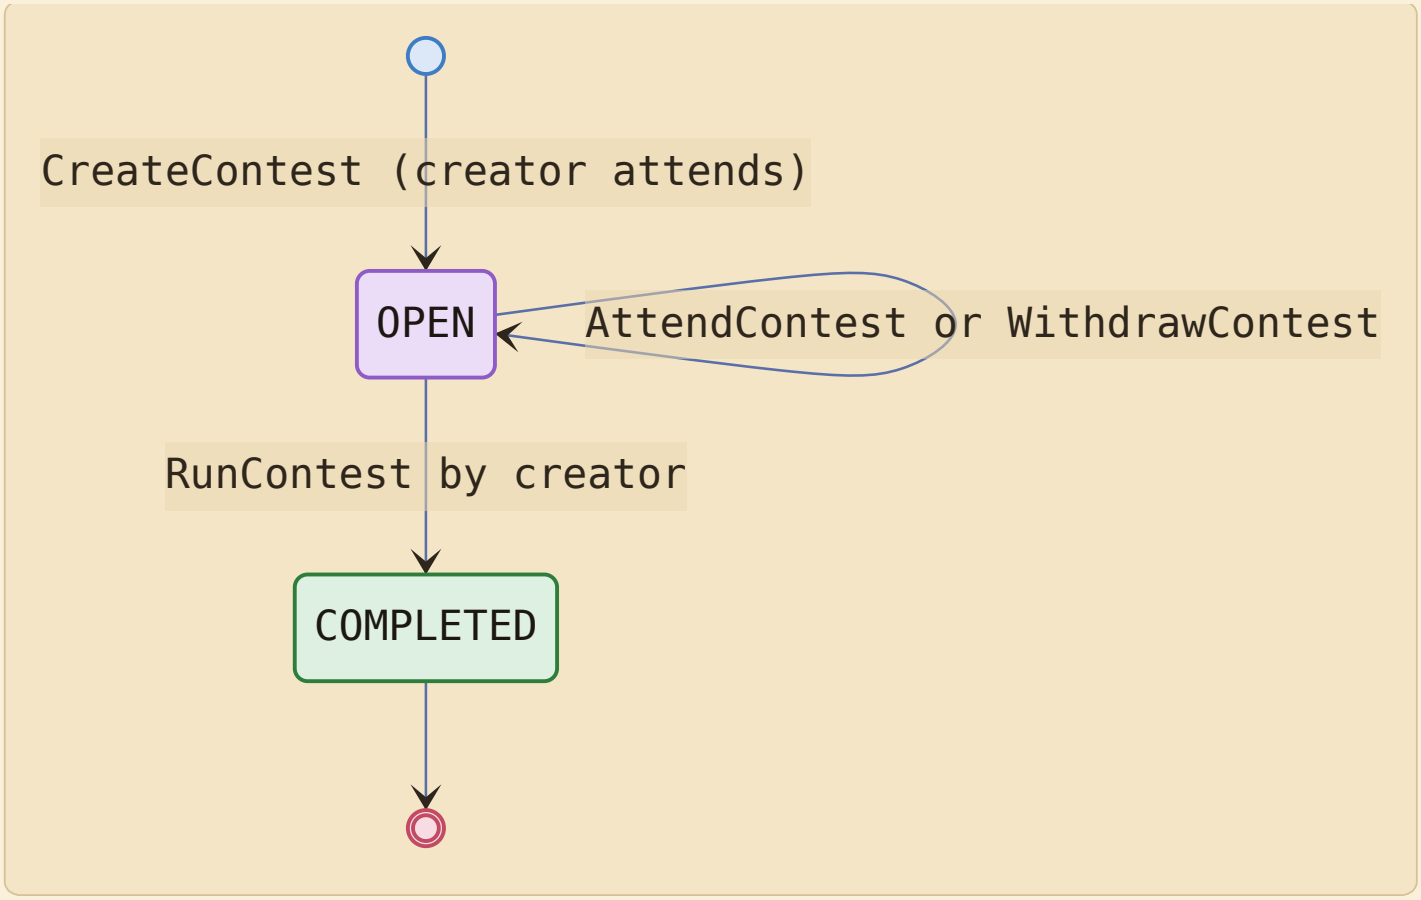
CodingBloxService
Contest
SolveSimulator
User
runContest(1, "Ross")
requester is creator?
pool = listQuestions(contest.level)
loop
[each participant]
solvedBy(user, pool)
solved questions
points = sum of scores
complete(results)
throws if already COMPLETED
loop
[each result]
applyContest(level, points)
results (driver prints)
CommandProcessor
CodingBloxService
Contest
SolveSimulator
User



Design decisions & patterns used

Decision	Pattern	Why	Alternative rejected
Command name → handler map	Command	Adding a command is one `put`; no giant `switch`. Parsing and printing stay out of the service.	Parsing inside the service.
Scoring rule inside `Level` enum	Strategy (each enum constant carries its own data)	The rule depends only on the level; a new level brings its own rule.	`if (level == LOW) ... else if ...` in `runContest`.
`SolveSimulator` interface	Strategy	Randomness is replaceable: seeded for demo, scripted for tests, a real judge later.	`new Random()` inside the service — untestable.
`Contest.complete` checks status	Entity guards invariant	"Run once" enforced where the state lives, so scores are never applied twice.	Checking in the driver.
Generic `Repository<K,V>`	Repository	Three stores, one class (DRY — the statement asks for it).	Three copy-pasted maps with lookup code.
Results computed, then `complete`, then ratings	Ordering for safety	If `complete` throws (already run), no rating has changed yet.	Updating ratings inside the loop.

Java implementation

```java
// File: lld/ch21/codingblox/Level.java
package lld.ch21.codingblox;

/** Difficulty of a question or a contest. Each contest level carries its own scoring rule. */
public enum Level {
    LOW(50), MEDIUM(30), HIGH(0);

    private final int penalty;
    Level(int penalty) { this.penalty = penalty; }

    /** newScore = currentScore + (contestPoints - penalty), exactly as the statement defines. */
    public int newScore(int current, int contestPoints) { return current + contestPoints - penalty; }

    public static Level parse(String s) {
        try { return valueOf(s.toUpperCase()); }
        catch (IllegalArgumentException e) { throw new BloxException("Unknown level: " + s); }
    }
}
```

```java
// File: lld/ch21/codingblox/User.java
package lld.ch21.codingblox;

public class User {
    public static final int DEFAULT_SCORE = 1500;
    private final String name;
    private int score = DEFAULT_SCORE;

    public User(String name) { this.name = name; }
    public String name() { return name; }
    public synchronized int score() { return score; }
    /** Read-modify-write under one lock, so two contests finishing together cannot lose an update. */
    synchronized void applyContest(Level level, int points) { score = level.newScore(score, points); }
}
```

```java
// File: lld/ch21/codingblox/Question.java
package lld.ch21.codingblox;

  Monica : 1540
> CreateContest x HIGH Rachel
ERROR: No such user: Rachel
> Dance 1
ERROR: Unknown command: Dance
```

Checking the arithmetic: contest 1 is LOW, so each participant gets `points − 50`: Ross 1500 + (20 − 50) = 1470, Joey and Monica 1500 + (30 − 50) = 1480. Contest 2 is MEDIUM (`points − 30`): Monica 1480 + (90 − 30) = 1540, Chandler 1500 + (40 − 30) = 1510. The leaderboard matches. (Which questions are "solved" comes from the seeded simulator — change the seed and you get different but equally valid results.)

Concurrency & edge cases

- **Concurrent commands:** repositories are `ConcurrentHashMap`s; `Contest` methods are `synchronized`; `User.applyContest` does its read-modify-write under the user's lock, so two contests finishing together cannot lose a rating update.
- **Double run:** `Contest.complete` throws if already completed; ratings are updated *after* it succeeds.
- **Known gap (say it):** `runContest` copies the participant list, simulates, then calls `complete`. A user who attends in that short window is registered but gets no result. Fix: add a `RUNNING` status and have `Contest` switch to it and hand back the participant list in one `synchronized` step, so no one can attend or withdraw once the run has started.
- **Edge cases handled:** duplicate user, unknown user/contest/level, non-positive question score, contest with no questions of its level, duplicate attend, attend/withdraw after the run, creator withdraw, non-creator run, missing arguments, non-numeric ids, unknown command.

Extensions & follow-up questions

- **Pick a fixed number of questions per contest?** A `QuestionSelectionStrategy` (random k of level, or by tags) called at contest creation; store the chosen ids in the contest.
- **Real submissions?** Replace `SolveSimulator` with a judge that returns verdicts per submission; add `Submission(user, question, verdict, time)` and score by time/penalty like ICPC (the International Collegiate Programming Contest).
- **Elo-style ratings?** (Elo is the chess rating system: beating a stronger player earns more points.) A `RatingStrategy` interface taking all participants' results (ratings depend on opponents), selected per contest type.
- **Scheduled contests?** Add `startTime/endTime`, a `SCHEDULED → RUNNING → COMPLETED` state machine, and a scheduler that triggers `run`.
- **Leaderboard at scale?** Keep a `TreeSet` (a set that keeps its items sorted) sorted by (score, name) or a Redis sorted set; update on each rating change instead of sorting on every query.

Real-world example

LeetCode's weekly contests publish a live ranking during the contest, and afterwards each participant's contest rating is recalculated from their rank relative to others — a more elaborate version of the per-level rule in this statement. HackerRank and Codeforces follow the same shape: contests reference a pool of problems, participants register, and ratings change only after the contest is finalised.

In the interview

Paste the sample commands into the driver list first. Build `CreateUser`, `CreateQuestion`, `CreateContest`, `AttendContest`, `RunContest`, `LeaderBoard` in that order, running after each. Point out the three design moves: command map, scoring rule on the enum, and randomness behind an interface (with a seed). Then bonus commands — both are tiny because `Contest` already stores results and guards its status.

Self-check

- **Q:** Why must `RunContest` update ratings only after marking the contest complete? → **A:** If the contest had already run, `complete` throws before any rating changes — no double application.
- **Q:** How would you add a `VERY_HIGH` level with bonus +20? → **A:** Add an enum constant with its own rule (e.g. a negative penalty); nothing else changes.

- **Q:** How do you make `RunContest` deterministic in tests? → **A:** Inject a scripted `SolveSimulator` (or a seeded random one).
- **Q:** Where is "creator always attends" enforced? → **A:** In the `Contest` constructor.

TL;DR

Command map in the driver, rules in the service, invariants in `Contest`, scoring on the `Level` enum, randomness behind a seeded `SolveSimulator`. Complete first, then update ratings.

21.5 Design a Property Listing Site — "PropertyHunt" (ClearTrip)

Problem & clarifying questions

A ClearTrip machine-coding statement (kumaransg/LLD, `PropertyHunt`). The folder holds two versions: a text `readme.md` and a longer version as screenshots in `Question Image/`; the summary below follows the longer one, which adds ViewSold, the range rules and the "shortlist *other users'* property" wording. Build a console application (a text-only program run in a terminal) for a property platform where users can: **register**; **list a property** they want to sell or rent; **view their own listings**; **shortlist** other users' properties; **view shortlisted** properties (sold ones still appear, with status SOLD); **search** available properties with any combination of **location** (case-insensitive — capital and small letters treated the same — exact match), **price range**, **listing type** (sell/rent), **size range**, **number of rooms** (1BHK/2BHK/3BHK — bedroom, hall, kitchen: 1BHK is one bedroom), and **sort by** price or size (ascending); **mark sold** (only the owner); and **view sold** properties. Ranges: `X-Y` inclusive; a single `X` means "at least X" for size and "at most X" for price. **Bonus:** sizes in sq ft / sq m / sq yd (buyer and seller may use different units); **nearby locations** on a listing, with nearby matches shown last; prices like `40000`, `40k`, `60L`, `2Cr` (k = thousand; L = lakh = 100,000; Cr = crore = 10,000,000 — the Indian number units); comma-separated values for location and rooms in search. The statement asks for in-memory storage, graceful errors ("Property does not exist"), and a clean, extensible OO design.

Question	Answer used
Input format?	One command per line, fields separated by `
Can I shortlist my own property?	No — the screenshot version says users shortlist *others'* properties. (The text readme's sample has Jack shortlisting his own listing; that is exactly the kind of conflict to ask about.)
Can I shortlist a sold property?	No; but a property sold *after* I shortlisted it stays in my list with status SOLD.
Units internally?	Price in whole rupees (`long`), size in square feet (`double`).
Sort with location?	Exact location matches first, nearby matches after, then the chosen sort.
Mark sold — record buyer and price?	The screenshot sample writes `marksold - 2, xyz, 50000` (property, buyer, price). We store only the status; keeping buyer and sale price is a small extension (a `Sale` record).

The sample search (`bellandur, 30000-50000, rent, ...`) returns a *sarjapur* property. In the screenshot version that is consistent: the sarjapur listing declares `nearby bellandur|kadubeesanahalli|marathahalli`, so it is a nearby match. The text readme's sample drops the `nearby` field, and there the result only makes sense if you know about the bonus. Our demo lists sarjapur with the same three nearby localities, and the search returns it.

Requirements

Functional: RegisterUser, ListProperty, Search, Shortlist, ViewShortlisted, ViewListed, MarkSold, ViewSold — plus all four bonus items. **Non-functional:** search filters combine freely; new filters or units without rewriting search; clear errors; safe under concurrent use.

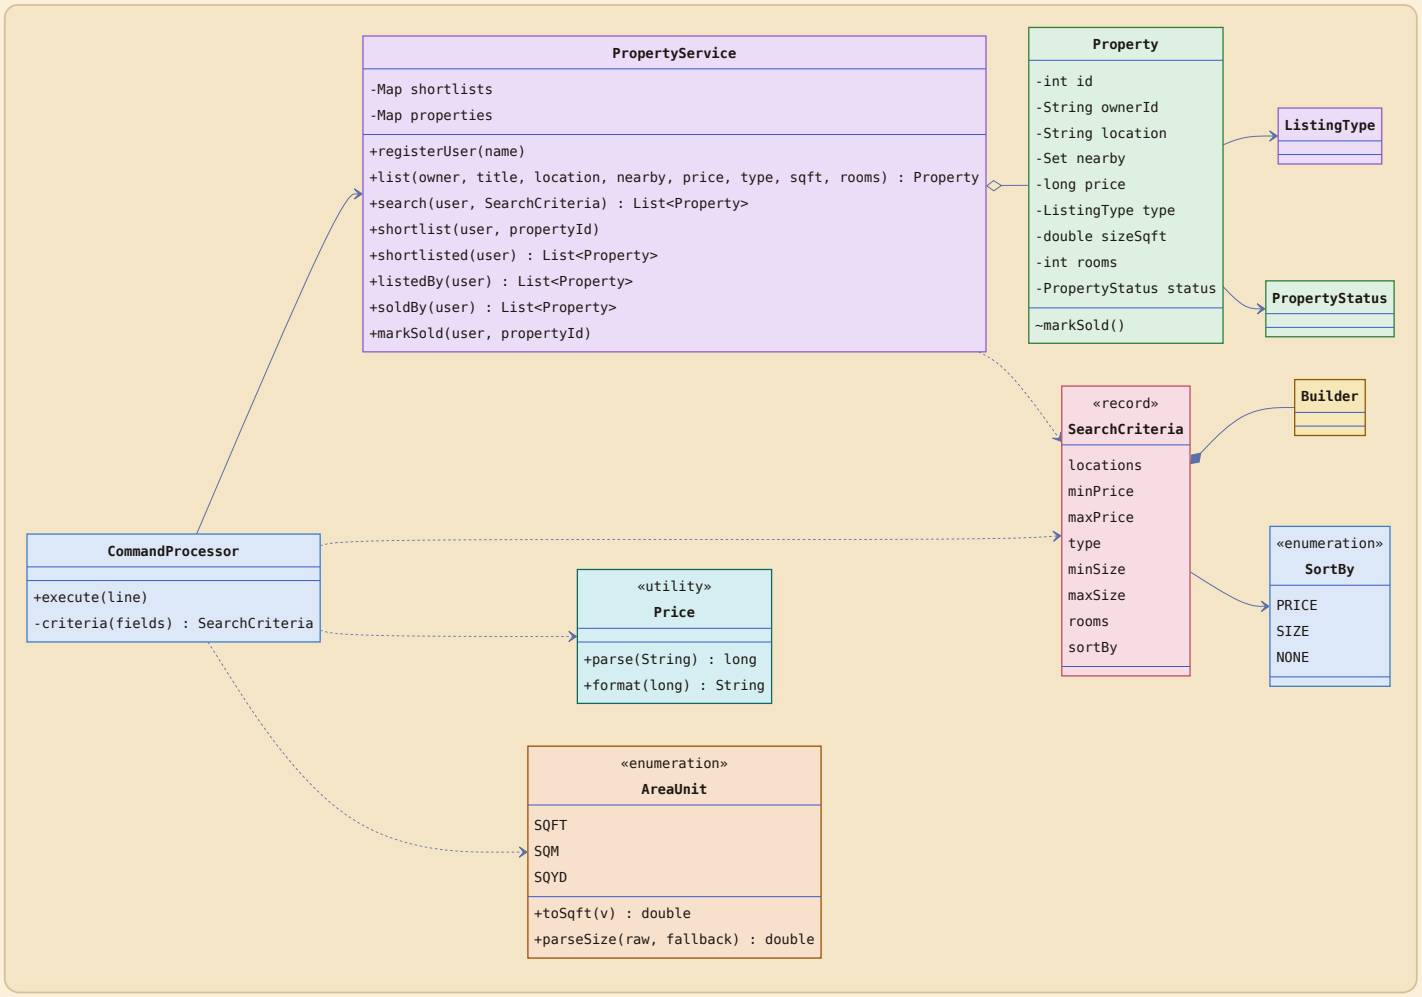
Use cases

Actor	Use cases
Seller / landlord	list property, view listed, mark sold, view sold
Buyer / tenant	search, shortlist, view shortlisted
(Any user can be both — roles are per property, not per account: the owner of a property is its seller.)	

Core entities

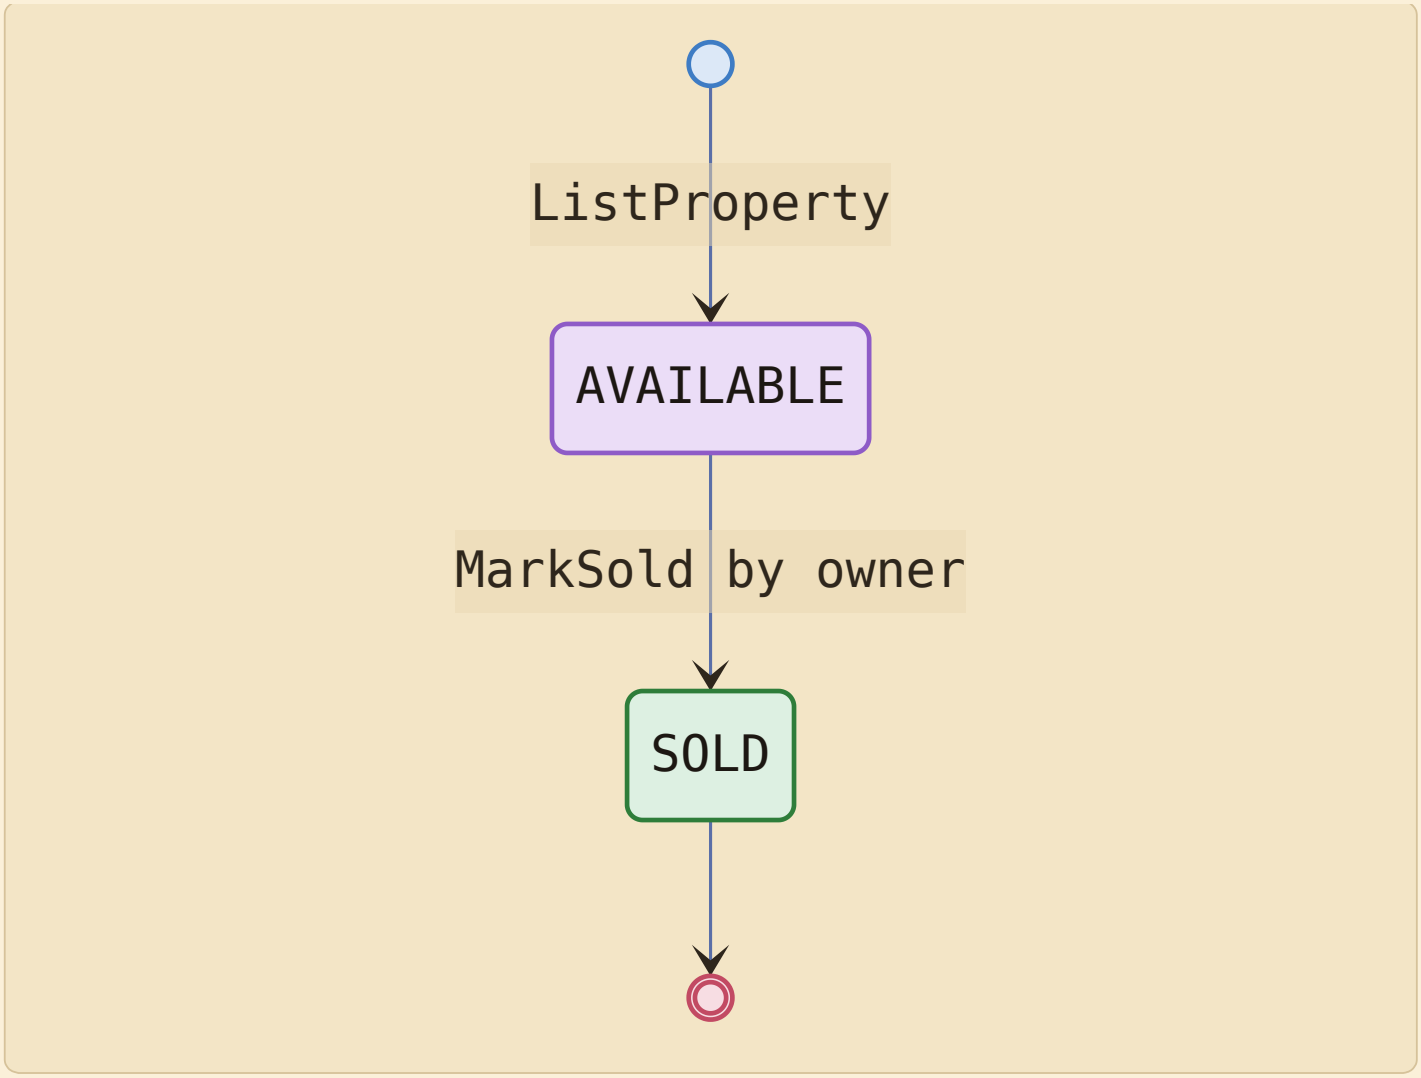
Class	Kind	Responsibility
`Property`	class	Listing data, owner, nearby locations, status; `markSold` guards double sale.
`ListingType`, `PropertyStatus`, `SortBy`	enums	SELL/RENT, AVAILABLE/SOLD, sort comparators.
`Price`	utility	Parse `40k/60L/2Cr/1.5Cr` → rupees; format back.
`AreaUnit`	enum	SQFT/SQM/SQYD with conversion to square feet; parses "1500 sq ft", "70 sqm".
`SearchCriteria` (+ `Builder`)	record	All-optional search parameters.
`PropertyService`	class	Register, list, search, shortlist, mark sold, views; owner-vs-buyer rules.
`CommandProcessor`	class	Parses `
`HuntException`	exception	Readable errors.

Class diagram



Key flows

Search = build criteria → list of predicates → one combined predicate → sort:



Design decisions & patterns used

Decision	Pattern	Why	Alternative rejected
All-optional `SearchCriteria` with a Builder	Builder	Eight optional fields; a constructor call with eight nulls is unreadable.	Telescoping constructors (a chain of constructors, each taking one more parameter) / overloads (several methods with the same name but different parameters).
Each criterion becomes a `Predicate<Property>`, reduced with `and`	Specification	Any combination works; a new filter is one line; no nested `if` pyramid.	One `if` per combination.
`SortBy` enum of comparators	Strategy	Adding "sort by rooms" is one constant.	`switch` inside search.
Normalise at the boundary (rupees, sq ft)	—	Business code compares plain numbers; units only matter while parsing.	Storing strings like "90L" and comparing them.
Location rank 0/1/2	—	Exact matches first, nearby second, others filtered out — one small function serves filtering *and* ordering.	Two separate searches merged.
Shortlist stored per user as a set of ids	—	View shortlisted shows current status (SOLD appears automatically).	Copying property objects into the shortlist — they would go stale.

Java implementation

```java
// File: lld/ch21/propertyhunt/Price.java
package lld.ch21.propertyhunt;

import java.math.BigDecimal;
import java.util.Locale;

/** Parses and prints Indian-style prices: 40000, 40k, 60L, 2Cr, 1.5Cr. Stored as whole rupees. */
public final class Price {
    private Price() { }

```

Things to notice: 70 sq m was stored as 753 sq ft and 400 sq yd as 3600 sq ft; the `bellandur` search returns the bellandur listing first and the sarjapur listing (nearby) last; after `MarkSold`, property 1 disappears from searches but still shows as SOLD in Jill's shortlist; bad input produces an error line and the program continues.

Concurrency & edge cases

- **Storage:** `ConcurrentHashMap`s; each user's shortlist is a concurrent set; `Property.markSold` is `synchronized` so two "mark sold" calls cannot both succeed.
- **A search racing a sale** may still show a property that is being sold at that instant — acceptable for listings (eventual consistency: different readers may briefly see different values, but they all catch up soon); a purchase flow would re-check status under a lock.
- **Edge cases handled:** duplicate registration, unregistered user, unknown property, own-property shortlist, duplicate shortlist, shortlisting a sold property, non-owner mark sold, double sale, bad price/size/unit/type, non-positive values, missing fields.

Extensions & follow-up questions

- **Descending sort / multiple sort keys?** `SortBy` holds a comparator; add a direction flag and `.reversed()`, or accept a list of keys and chain `thenComparing`.
- **Fuzzy location ("Bellandur Road")?** Normalise locations to ids through a `LocationResolver` interface (gazetteer / geocoding — a directory of place names / turning an address into map coordinates).
- **"Within 5 km"?** Store latitude/longitude and filter by haversine distance (the standard formula for the distance between two points on a sphere); at scale use a geo-index (a lookup structure for finding things by location: geohash, R-tree) or a search engine with geo queries.
- **Fast search over millions?** Secondary indexes (by location, type, rooms) or Elasticsearch/OpenSearch; price and size as numeric range fields.
- **Notifications on price drop for shortlisted items?** Observer on `Property` price changes → notify users who shortlisted it.

Real-world example

Property portals like 99acres, MagicBricks and NoBroker let you filter by locality, budget, BHK count, buy/rent and area, and often suggest nearby localities when results are few; Indian listings commonly quote prices in lakhs and crores — exactly why the statement asks you to parse `60L` and `2Cr`.

In the interview

Start with the model and units (show `Price.parse` handling `90L`, and `AreaUnit`). Then implement register → list → search with *one* filter → add filters as predicates → sort. Shortlist, mark sold and the views are small after that. Call out the Builder and predicate list as your extensibility story, and the "normalise at the boundary" principle.

Self-check

- **Q:** How does a buyer searching in sq m match a seller who listed in sq yd? → **A:** Both are converted to sq ft at parse time; search compares sq ft.
- **Q:** Why store shortlists as ids rather than objects? → **A:** Status is read live from the property, so SOLD shows without extra updates.
- **Q:** What does a single number mean in the price field? → **A:** "At most X" (for size it means "at least X").
- **Q:** How do you add a "furnished" filter? → **A:** A field on `Property`, an optional field in `SearchCriteria`, and one predicate line in `search`.

TL;DR

Normalise price and size at the edges, turn every optional criterion into a predicate and AND them together, sort by (location rank, chosen key, id), and keep shortlists as ids so status stays live.

21.6 Design a Loan Ledger — "Ledger Co" (Navi)

Problem & clarifying questions

This problem (kumaransg/LLD, `ledger_company_navi`) is the Geektrust "Ledger Co" backend (server-side logic, no screens) challenge; the repository files it under Navi, which has used it as a hiring exercise. Banks lend money to borrowers; borrowers repay in **EMIs** (Equated Monthly Instalments — the same amount every month) and may also pay a **lump sum** (a one-off extra payment) at any point. The program reads commands and answers balance questions:

Command	Meaning
`LOAN BANK BORROWER P N R`	Borrower takes principal `P` (the amount borrowed) for `N` years at `R`% simple interest (interest charged only on the original principal, never on interest) per year.
`PAYMENT BANK BORROWER LUMP_SUM EMI_NO`	A lump sum paid right after EMI number `EMI_NO`.
`BALANCE BANK BORROWER EMI_NO`	Print `BANK BORROWER AMOUNT_PAID EMIS_LEFT` as of (after) EMI number `EMI_NO`.

Rules from the statement: interest `I = P × N × R / 100` (R is a percentage); total repayable `A = P + I`; monthly EMI = `A / (N × 12)` **rounded up** to a whole number (86.67 → 87, and even 100.10 → 101); amount paid as of EMI *k* = `k × EMI` + every lump sum whose EMI number is *k* or less (a lump sum "after EMI 10" *is* included in `BALANCE ... 10`); EMIs left = remaining amount ÷ EMI, **rounded up** (23.1 → 24); and if the last EMI is more than what is still owed, it shrinks to exactly that amount. A lump sum therefore reduces the *number* of EMIs, never the EMI amount. Only `BALANCE` produces output, in the form `BANK_NAME BORROWER_NAME AMOUNT_PAID NO_OF_EMIS_LEFT`.

Question	Answer used
Can amount paid exceed `A`?	No — capped at `A` (then EMIs left = 0). This is also the "last EMI shrinks" rule: the final payment is only what is left.
Is interest a whole number?	The statement defines rounding only for the EMI and the EMI count. We *assume* interest is also rounded up to a whole unit (say so to the interviewer); every official sample has whole-number interest, so both samples come out the same either way.
One loan per bank-borrower pair?	Yes — the pair identifies the loan; a second `LOAN` for the same pair is an error.
`EMI_NO` beyond the tenure (the loan's total length)?	Error. `EMI_NO = 0` is valid (before any EMI).

Requirements

Functional: LOAN, PAYMENT, BALANCE exactly as above; reproduce the official sample outputs. **Non-functional:** input from a list/file; one bad line must not stop the rest; interest rule replaceable; exact arithmetic (`BigDecimal`).

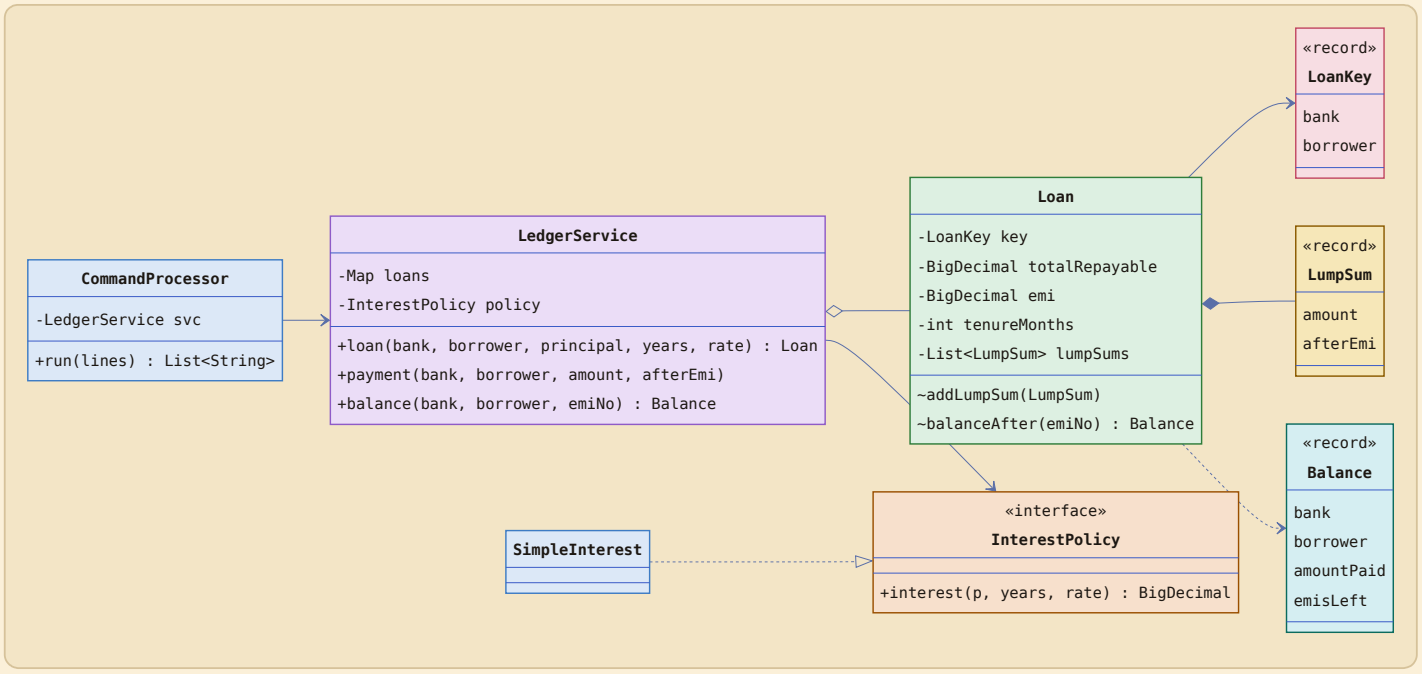
Use cases

Actor	Use cases
Bank	records a loan
Borrower	pays lump sums
Anyone (support agent, borrower app)	asks for the balance after EMI *k*

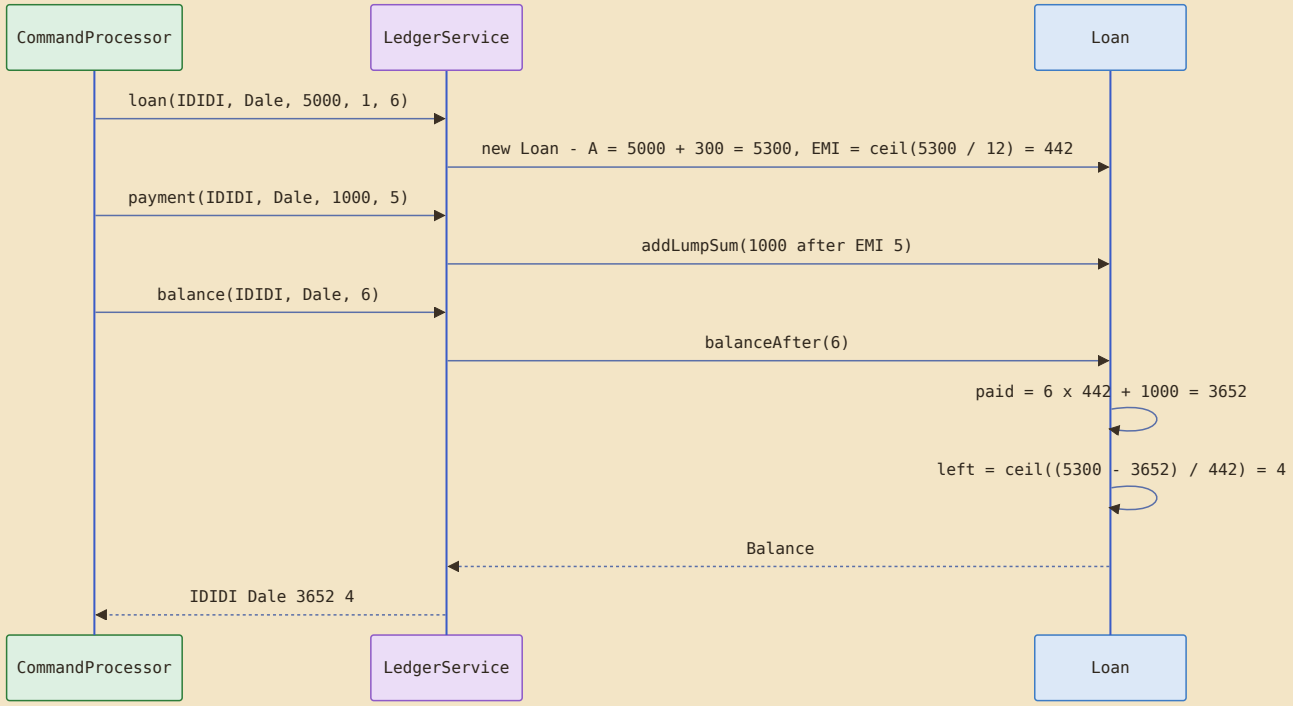
Core entities

Class	Kind	Responsibility
`LoanKey`	record	(bank, borrower) — the loan's identity; a perfect `Map` key because records implement `equals/hashCode` (the two methods a map uses to decide whether two keys are the same).
`Loan`	class	Computes `A` and EMI once; stores lump sums; derives a `Balance` for any EMI number.
`LumpSum`	record	amount + "after EMI number".
`Balance`	record	Output line: bank, borrower, amount paid, EMIs left.
`InterestPolicy` / `SimpleInterest`	interface / class	Strategy for total interest.
`LedgerService`	class	Store of loans; the three operations.
`CommandProcessor`	class	Parses lines, validates argument counts and numbers, collects output.
`LedgerException`	exception	Readable failure.

Class diagram



Key flows



Worked example (Sample 2, Shelly): P = 15000, N = 2, R = 9 → I = 2700, A = 17700, EMI = ⌈17700 / 24⌉ = ⌈737.5⌉ = 738. After 12 EMIs plus a 7000 lump sum: paid = 12 × 738 + 7000 = 15856; remaining = 1844; EMIs left = ⌈1844 / 738⌉ = ⌈2.499⌉ = 3. Output `UON Shelly 15856 3`.

Design decisions & patterns used

Decision	Why	Alternative rejected
Derive balance from facts (A, EMI, lump sums) on every query	Queries can ask about *any* EMI number, even one before a later payment. Storing a running balance would need replays.	Mutable `remaining` field updated per command — breaks when a BALANCE asks about an earlier EMI.
`InterestPolicy` Strategy	Simple interest today; reducing-balance or compound tomorrow without touching `Loan`.	Formula hard-coded in `Loan`.
`LoanKey` record as map key	Value semantics (two keys with the same fields count as equal) for free (`equals/hashCode`).	Concatenated string `"IDIDI#Dale"` — fragile.
`BigDecimal` + explicit `RoundingMode.CEILING`	The statement's rounding is "always up"; ceiling on integers is exact.	`Math.ceil` on doubles — fine for small numbers but floating error (tiny inaccuracies of binary floating-point numbers) can bite (e.g. a value like 4.000000001 ceils to 5).
Driver returns `List<String>`	Easy to compare with the expected output in a test.	Printing inside the service.

Java implementation

```java
// File: lld/ch21/ledger/LoanKey.java
package lld.ch21.ledger;

/** A borrower can hold one loan per bank; (bank, borrower) identifies it. */
public record LoanKey(String bank, String borrower) { }
```

```java
// File: lld/ch21/ledger/LumpSum.java
package lld.ch21.ledger;

import java.math.BigDecimal;

/** Extra payment made right after EMI number `afterEmi`. */
public record LumpSum(BigDecimal amount, int afterEmi) { }
```

```java
// File: lld/ch21/ledger/Balance.java
package lld.ch21.ledger;

import java.math.BigDecimal;

public record Balance(String bank, String borrower, BigDecimal amountPaid, int emisLeft) {
    @Override public String toString() { return bank + " " + borrower + " " + amountPaid.toPlainString() + " " +
emisLeft; }
}
```

```java
// File: lld/ch21/ledger/InterestPolicy.java
package lld.ch21.ledger;

import java.math.BigDecimal;

/** Strategy for total interest. The problem uses simple interest; a bank could plug in another rule. */
public interface InterestPolicy {
    BigDecimal interest(BigDecimal principal, BigDecimal years, BigDecimal ratePercent);
}
```

```java
// File: lld/ch21/ledger/SimpleInterest.java
package lld.ch21.ledger;

import java.math.BigDecimal;
import java.math.RoundingMode;

/** I = P * N * R / 100, rounded UP to a whole unit (the statement rounds amounts up). */
public class SimpleInterest implements InterestPolicy {
    @Override public BigDecimal interest(BigDecimal p, BigDecimal n, BigDecimal r) {
        return p.multiply(n).multiply(r).divide(BigDecimal.valueOf(100), 0, RoundingMode.CEILING);
    }
}
```

```java
// File: lld/ch21/ledger/Loan.java
package lld.ch21.ledger;

import java.math.BigDecimal;
import java.math.RoundingMode;
import java.util.ArrayList;
import java.util.List;

/**
 * Loan with fixed EMI. Amount repaid A = P + I. EMI = ceil(A / (N*12)).
 * Lump sums shorten the loan (fewer EMIs) but never change the EMI amount.
 */
public class Loan {
    private final LoanKey key;
    private final BigDecimal totalRepayable;
    private final BigDecimal emi;
    private final int tenureMonths;
    private final List<LumpSum> lumpSums = new ArrayList<>();

    }
}
```

Output:

```
== Sample 1
IDIDI Dale 1000 55
IDIDI Dale 8000 20
MBI Harry 1044 12
MBI Harry 0 24
== Sample 2
IDIDI Dale 1326 9
IDIDI Dale 3652 4
UON Shelly 15856 3
MBI Harry 9044 10
== Edge cases
SBI Asha 1120 0
ERROR Loan already exists for SBI Asha  [LOAN SBI Asha 5 1 1]
ERROR No loan for HDFC Nobody  [BALANCE HDFC Nobody 1]
ERROR EMI number out of range: 13  [BALANCE SBI Asha 13]
ERROR Not a number: ten  [PAYMENT SBI Asha ten 1]
ERROR Unknown command REFUND  [REFUND SBI Asha 1]
```

The first two blocks are exactly the expected outputs of the two official Geektrust samples. In the edge-case block, Asha's 2000 lump sum after EMI 1 overpays a 1120 loan, so the amount paid is capped at 1120 and 0 EMIs remain.

Concurrency & edge cases

- **Concurrency:** loans live in a `ConcurrentHashMap` (`putIfAbsent` makes "one loan per pair" atomic); `Loan`'s lump-sum list is guarded by `synchronized` methods, so a `PAYMENT` and a `BALANCE` on the same loan do not interfere.
- **Edge cases handled:** duplicate loan, unknown loan, EMI number < 0 or > tenure, non-positive principal/years, negative rate, non-positive lump sum, overpayment (capped), wrong argument count, non-numeric values, unknown command, blank lines.

Extensions & follow-up questions

- **Reducing-balance (amortised) EMI like real banks?** (Reducing-balance: each month's interest is charged only on what is still owed; amortised: spread into equal payments that cover interest and principal.) New `InterestPolicy`/`EmiCalculator`: `EMI = P·r·(1+r)^n / ((1+r)^n − 1)` with monthly rate `r`; balance after k months uses the amortisation schedule. The `Loan` API stays the same.
- **Lump sum that should reduce the EMI instead of the tenure?** Make that a `PrepaymentPolicy` (REDUCE_TENURE / REDUCE_EMI) chosen per loan.
- **Late payments and penalties?** Record actual payment events with dates instead of assuming EMIs are paid on time; derive "EMIs paid" from them.
- **Read from a file?** `Files.readAllLines(Path.of(args[0]))` fed into the same `run` method — the driver's job, no core change.

Real-world example

Indian lenders such as Navi, banks and NBFCs (non-banking financial companies: lenders that are not licensed banks) show borrowers an EMI schedule and let them "part-prepay" a loan; most offer a choice between reducing the tenure (fewer EMIs, the Ledger Co rule) or reducing the EMI amount. Real loans use reducing-balance interest rather than the flat simple interest in this puzzle — a good point to raise when asked about extensions.

In the interview

Show the three formulas first and compute one sample by hand — it proves you understood the rounding. Then code `Loan.balanceAfter` (the heart), the service, and the command loop. Run both samples. Emphasise "state = facts, balances = derived", and the interest Strategy.

Self-check

- **Q:** Why ceil the EMI? → **A:** A floor would leave a shortfall at the end; rounding up guarantees N × 12 EMIs cover `A` (the final instalment may be smaller).
- **Q:** A `PAYMENT` after EMI 10 — does `BALANCE ... 5` include it? → **A:** No; only lump sums with `afterEmi ≤ 5` count.
- **Q:** Why is the balance computed rather than stored? → **A:** Queries may ask about any EMI number in any order; derivation is always consistent.

- **Q:** Where do you add compound interest (interest that is also charged on earlier interest)? → **A:** A new `InterestPolicy` implementation injected into `LedgerService`.

> **TL;DR**

EMI = ⌈(P + PNR/100) / 12N⌉. Store loan facts and lump sums; derive paid and EMIs-left on demand with ceiling rounding. Interest rule is a Strategy; the driver is a tiny command loop.

21.7 Design an Inventory Management System

Problem & clarifying questions

A very common machine-coding and OOD question (asked in e-commerce — online shopping — and quick-commerce — groceries delivered in minutes — interviews): track **products** (SKUs — stock keeping units, one id per sellable item) stored in several **warehouses**; record every **stock movement** (goods received, shipped, transferred between warehouses, adjusted after a physical count); fulfil orders by choosing warehouses; and raise **reorder alerts** when stock runs low.

Question	Answer used
Is stock tracked per warehouse?	Yes: (SKU, warehouse) → quantity.
Can an order be split across warehouses?	Yes; the choice of warehouses is a pluggable strategy (nearest city first, or most stock first).
Partial shipments if stock is short?	No — all-or-nothing.
When is a reorder alert raised?	When *total* stock of a SKU drops to or below its reorder point. Once per dip (no alert spam); re-armed when stock recovers.
How much to reorder?	Up to the product's max level (`max − current`).
Negative stock?	Never.

> **Requirements**

Functional

1. Add products (with reorder point and max level) and warehouses.
2. Receive stock (inbound) into a warehouse.
3. Ship an order quantity, allocating across warehouses by a strategy.
4. Transfer stock between warehouses.
5. Adjust stock after a physical count (cycle count).
6. Query stock per warehouse and total; list the movement history of a SKU.
7. Reorder alerts to subscribers.

Non-functional

- **No overselling** (selling more units than are in stock) under concurrent orders.
- Operations on different products run in parallel.
- Full audit trail (a complete record of every change; here every change is a movement).

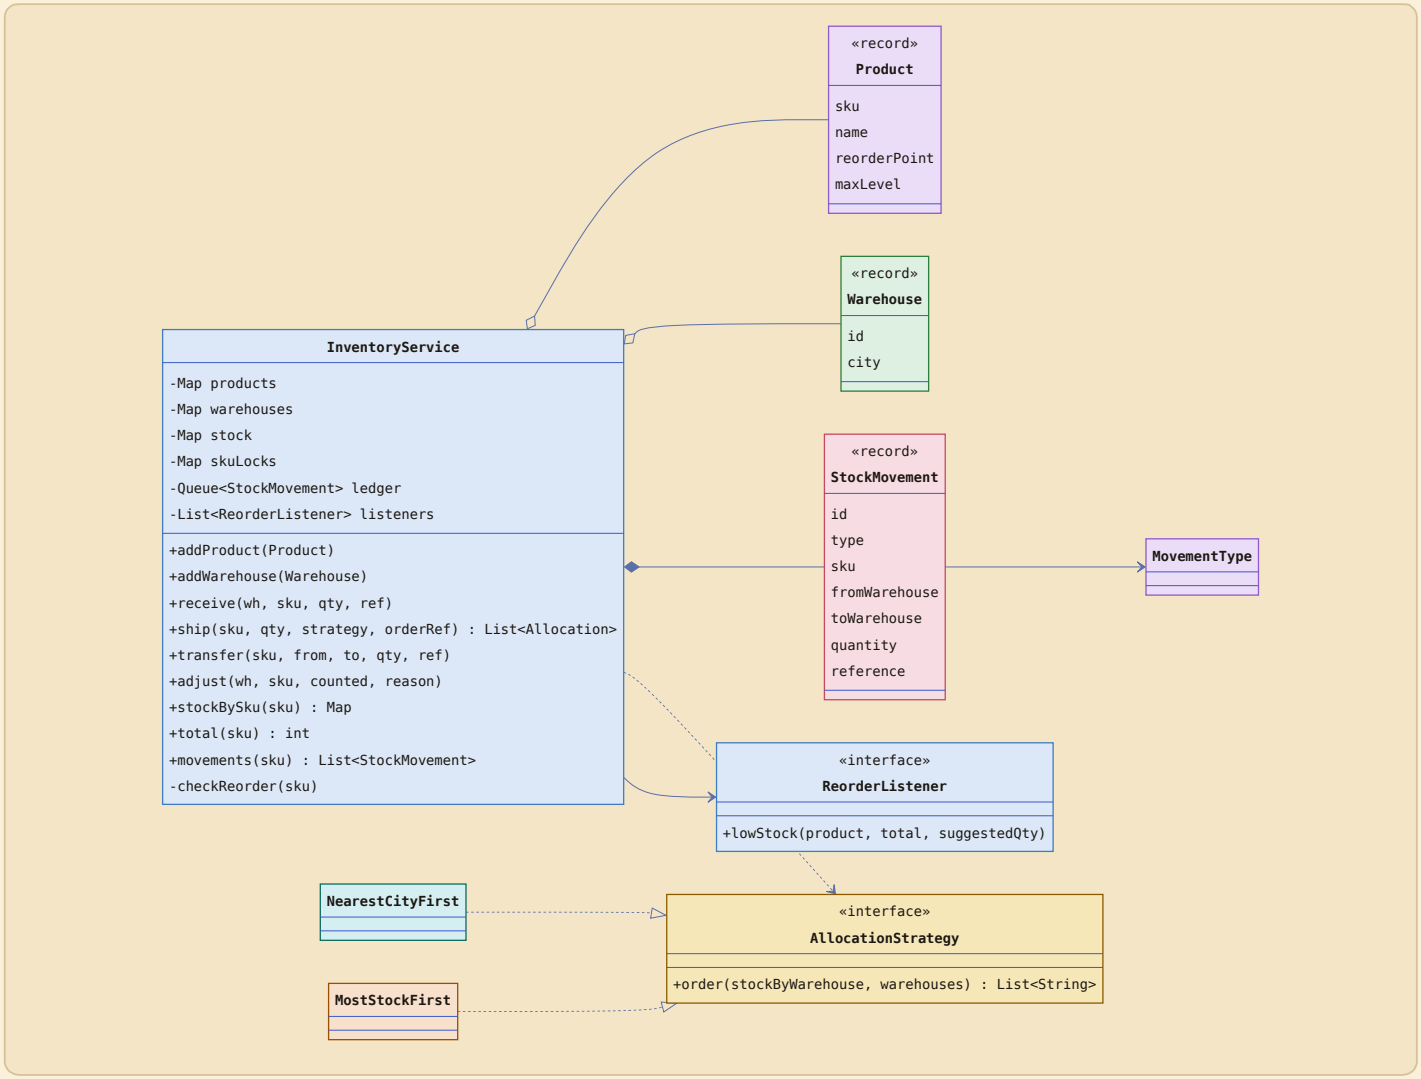
Use cases

Actor	Use cases
Warehouse staff	receive stock, transfer, cycle-count adjust
Order service (system)	ship / allocate order
Purchasing team (subscriber)	receives reorder alerts
Manager	views stock and movement history

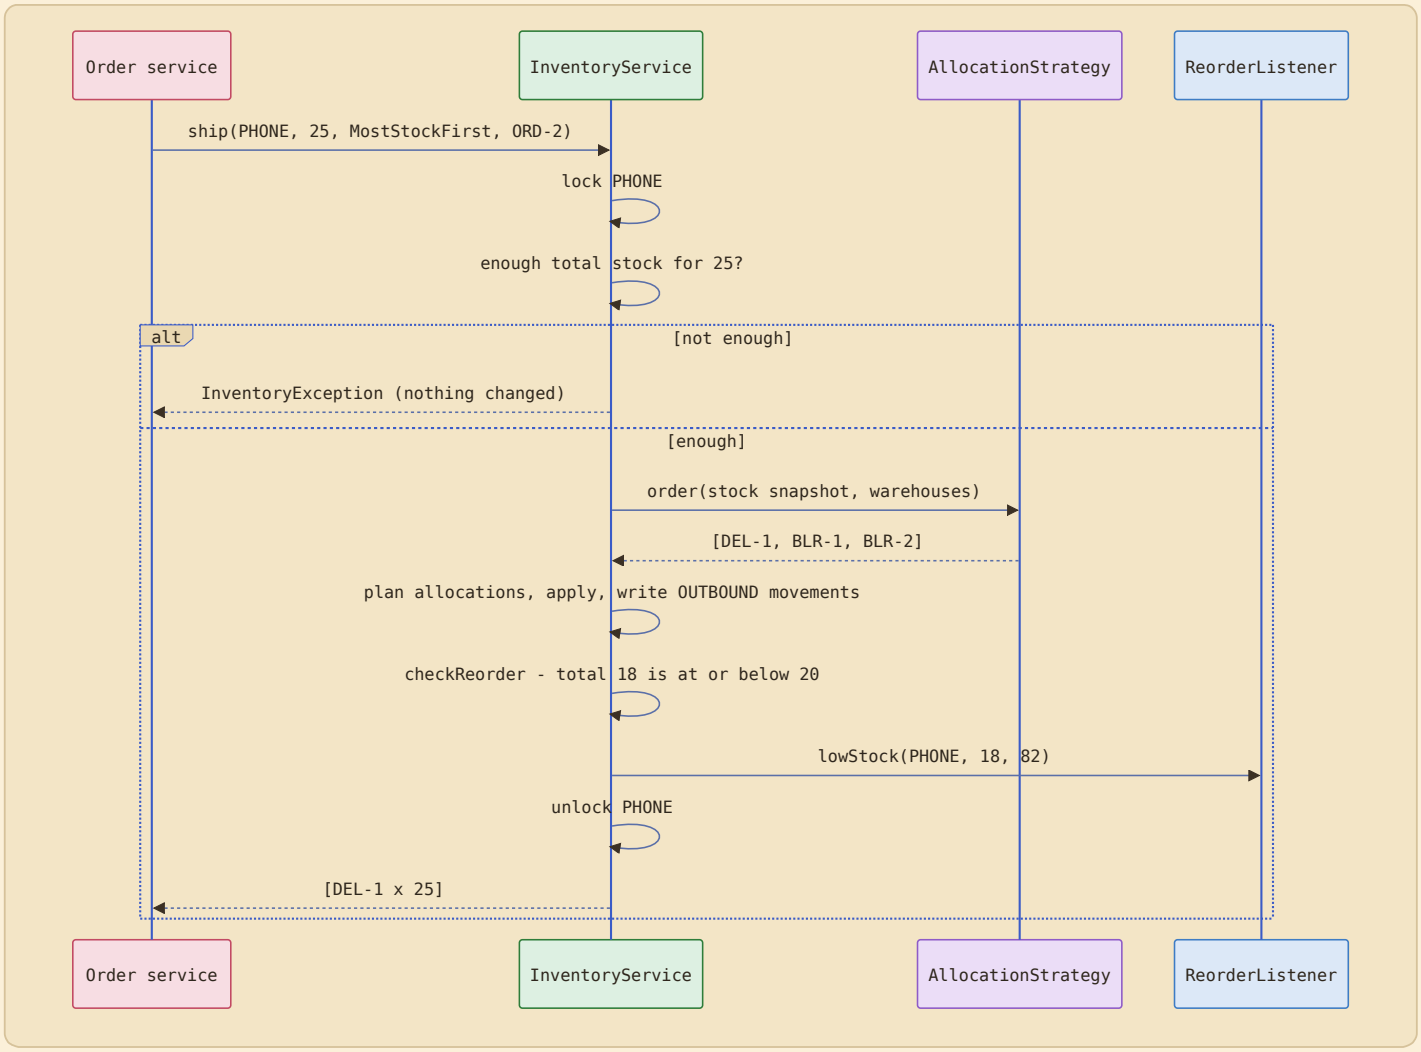
Core entities

Class	Kind	Responsibility
`Product`	record	SKU, name, reorder point, max level (validated).
`Warehouse`	record	id, city.
`StockMovement`	record	Append-only ledger line (type, sku, from, to, qty, reference).
`MovementType`	enum	INBOUND, OUTBOUND, TRANSFER, ADJUSTMENT.
`Allocation`	record	"take q from warehouse w" — part of a shipment plan.
`AllocationStrategy` + `NearestCityFirst`, `MostStockFirst`	interface + strategies	Order in which warehouses are drained.
`ReorderListener`	interface	Observer for low-stock alerts.
`InventoryService`	class	Stock levels, per-SKU locking, movements, alerts.
`InventoryException`	exception	Readable failure.

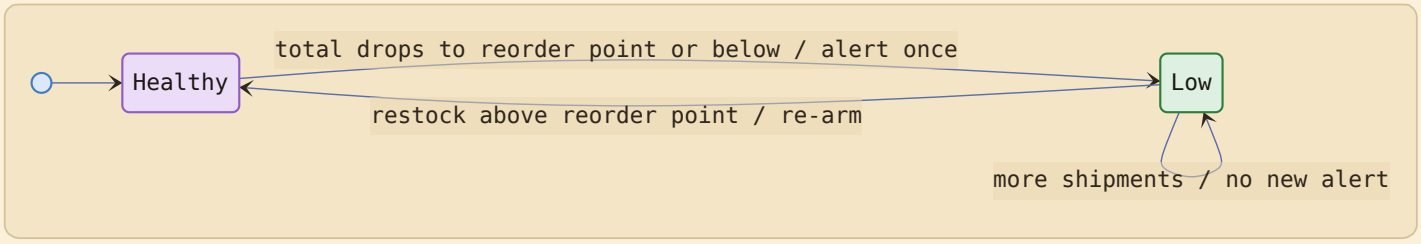
Class diagram



Key flows



Order service
InventoryService
AllocationStrategy
ReorderListener
ship(PHONE, 25, MostStockFirst, ORD-2)
lock PHONE
enough total stock for 25?
alt
[not enough]
InventoryException (nothing changed)
[enough]
order(stock snapshot, warehouses)
[DEL-1, BLR-1, BLR-2]
plan allocations, apply, write OUTBOUND movements
checkReorder - total 18 is at or below 20
lowStock(PHONE, 18, 82)
unlock PHONE
[DEL-1 x 25]
Order service
InventoryService
AllocationStrategy
ReorderListener



Healthy
total drops to reorder point or below / alert once
restock above reorder point / re-arm
Low
more shipments / no new alert

Design decisions & patterns used

Decision	Pattern	Why	Alternative rejected
One lock per SKU	Lock striping by key (a separate lock for each group of keys)	An order for one SKU touches several warehouses; a per-SKU lock covers all of them with no lock-ordering puzzle, while different SKUs never contend.	One lock per (SKU, warehouse) — needs lock ordering for multi-warehouse orders; one global lock — no parallelism.
Plan, then apply in `ship`	—	Check total first and build the full plan before changing anything → all-or-nothing.	Deduct warehouse by warehouse and roll back on shortage.
`AllocationStrategy`	Strategy	Business wants different policies (speed vs fewer split parcels); each is a small class.	`if (mode == ...)` in `ship`.
Append-only `StockMovement` **ledger**	Event log / audit	Every change is explainable; levels can be rebuilt by replaying; adjustments record the delta (the change, e.g. −3), not just the new number.	Updating quantities with no history.
`ReorderListener` **with once-per-dip**	Observer + edge-triggering (fire once when a value crosses a line)	Purchasing is notified once when stock crosses the threshold, not on every sale.	Level-triggered alerts (fire every time while the value is below the line) on every movement — spam.
Strategy gets a snapshot copy	Defensive copy (hand out a copy so the receiver cannot change your original)	A strategy cannot accidentally modify live stock.	Passing the live map.

Java implementation

```java
// File: lld/ch21/inventory/Product.java
package lld.ch21.inventory;

/** reorderPoint: raise an alert when total stock falls to this level or below. */
public record Product(String sku, String name, int reorderPoint, int maxLevel) {
    public Product {
        if (reorderPoint < 0 || maxLevel <= reorderPoint) throw new InventoryException("Need 0 <= reorderPoint < maxLevel");
    }
}
```

```java
// File: lld/ch21/inventory/Warehouse.java
package lld.ch21.inventory;

public record Warehouse(String id, String city) { }
```

```java
// File: lld/ch21/inventory/MovementType.java
package lld.ch21.inventory;

public enum MovementType { INBOUND, OUTBOUND, TRANSFER, ADJUSTMENT }
```

```java
// File: lld/ch21/inventory/StockMovement.java
package lld.ch21.inventory;

/** Append-only ledger line. Stock levels can always be rebuilt by replaying these. */
public record StockMovement(int id, MovementType type, String sku, String fromWarehouse, String toWarehouse,
                            int quantity, String reference) {
    @Override public String toString() {
        return "#%d %-10s %s qty=%+d %s->%s (%s)".formatted(id, type, sku, quantity,
                fromWarehouse == null ? "-" : fromWarehouse, toWarehouse == null ? "-" : toWarehouse, reference);
    }
}
```

```java
// File: lld/ch21/inventory/Allocation.java
package lld.ch21.inventory;

== movement ledger for PHONE
  #1 INBOUND    PHONE qty=+30 -->BLR-1 (PO-1)
  #2 INBOUND    PHONE qty=+40 -->DEL-1 (PO-2)
  #3 INBOUND    PHONE qty=+5 -->BLR-2 (PO-3)
  #4 OUTBOUND   PHONE qty=-30 BLR-1->- (ORD-1)
  #5 OUTBOUND   PHONE qty=-2 BLR-2->- (ORD-1)
  #6 TRANSFER   PHONE qty=+15 DEL-1->BLR-1 (TR-1)
  #7 OUTBOUND   PHONE qty=-25 DEL-1->- (ORD-2)
  #8 OUTBOUND   PHONE qty=-1 BLR-1->- (ORD-3)
  #9 ADJUSTMENT PHONE qty=-2 -->BLR-1 (damaged)
  #10 INBOUND    PHONE qty=+90 -->BLR-1 (PO-4)
  #11 OUTBOUND   PHONE qty=-90 BLR-1->- (ORD-4)
== concurrency: 200 one-unit orders race for 50 cases
  [ALERT] CASE low: 10 left, reorder 190 to reach 200
  shipped=50 rejected=150 left=0
```

Reading the output: the Bengaluru order drained BLR-1 then BLR-2 before touching Delhi; the reorder alert fired once when total PHONE stock fell to 18 (≤ 20) and not again at 17; after a restock pushed the total above 20 the alert re-armed and fired again when stock fell back; the ledger explains every unit; and with 200 concurrent one-unit orders for 50 cases, exactly 50 shipped — no overselling.

Concurrency & edge cases

- **Overselling:** check-total → plan → apply runs under the SKU's `ReentrantLock`; concurrent orders for the same SKU are serialised.
- **Parallelism:** different SKUs use different locks.
- **Ledger:** a `ConcurrentLinkedQueue` (a thread-safe queue that needs no lock) — lock-free appends from many SKU threads at once, insertion order kept, and iteration never throws `ConcurrentModificationException` (the error Java raises when a collection changes while it is being looped over). (A `CopyOnWriteArrayList` would copy the whole ledger on every movement — right for rarely-changing lists, wrong for an append-heavy log.)

- **Listeners:** `CopyOnWriteArrayList` — read on every alert, changed almost never, which is exactly its use case. Listener calls happen while holding the SKU lock — fine for quick callbacks; for slow ones (email), hand off to an executor (a pool of threads that runs submitted tasks) so the lock is not held during I/O (input/output, such as network or disk calls).
- **Edge cases handled:** unknown SKU/warehouse, non-positive quantities, negative counted quantity, transfer to the same warehouse, transfer or order larger than stock, invalid product thresholds, duplicate SKU/warehouse, "no change" adjustments (not logged).

Extensions & follow-up questions

- **Reservations (cart holds)?** Track `onHand` and `reserved` per (SKU, warehouse); available = onHand − reserved; reservations expire after a timeout; shipping converts a reservation into an OUTBOUND.
- **Batches / expiry dates (groceries, medicines)?** Stock per batch with expiry; allocate FEFO (first-expiry-first-out) — just another `AllocationStrategy`.
- **Distances instead of cities?** `NearestFirst` sorting by a `DistanceService` result.
- **Automatic purchase orders?** A `ReorderListener` that creates a PO (purchase order: a formal request to a supplier) for `max − current` and marks it pending so a second alert does not create a duplicate.
- **Multiple services / database?** Stock rows with optimistic versioning (`UPDATE ... SET qty = qty - ? WHERE qty >= ? AND version = ?`), and the movement ledger as an event stream (e.g. Kafka, a system that stores and delivers an ordered log of events) consumed by analytics.

Real-world example

Amazon's fulfilment network and Flipkart's warehouses decide which fulfilment centre ships each order based on factors like proximity and stock, and may split an order across centres — the job of `AllocationStrategy`. Shopify lets merchants hold inventory at multiple locations and set a fulfilment priority order among them. Quick-commerce apps (Blinkit, Zepto, Swiggy Instamart) run many small "dark stores" (warehouses closed to the public that only serve online orders), where accurate per-store stock and fast reorder alerts are essential.

In the interview

Start with the data shape: `stock[sku][warehouse] = qty` plus an append-only movement list. Code receive and ship (with the plan-then-apply and the per-SKU lock) first; they carry most of the marks. Then transfer and adjust (both tiny), then the reorder observer with once-per-dip, then allocation strategies. Run the 200-thread demo to prove "no overselling".

Self-check

- **Q:** Why does `ship` check the total before building the plan? → **A:** To reject short orders before any warehouse is touched (all-or-nothing).
- **Q:** Why is a per-SKU lock enough for a multi-warehouse order? → **A:** An order involves exactly one SKU, and all of that SKU's warehouses are covered by its one lock.
- **Q:** How do you add FEFO? → **A:** Add batch-level stock and a new `AllocationStrategy`; `ship` does not change.
- **Q:** Why record adjustments as movements? → **A:** So shrinkage/damage is auditable and levels can be rebuilt from the ledger.

TL;DR

Stock per (SKU, warehouse), every change is a ledger movement, a lock per SKU prevents overselling, allocation is a Strategy, and low-stock alerts are an edge-triggered Observer.

21.8 Design a Unix File Search (`find`)

Problem & clarifying questions

The Unix (the operating-system family that includes Linux and macOS) `find` command walks a directory tree (folders inside folders) and prints every entry that passes a set of tests, for example `find /var/log -type f -size +10M -mtime +7` ("regular files under /var/log bigger than 10 MiB, last changed more than 7 days ago"; 1 MiB = 1,048,576 bytes). The machine-coding version asks you to build a small `find`: a file-system model, a set of **filters**, a way to **combine** them with AND / OR / NOT, and a clean API for the search options. It is a favourite

because the obvious solution (one method with ten optional parameters and a pile of `if`s) is exactly what the interviewer wants you to avoid.

Three words used below: a **predicate** (or *test*) is a yes/no question about one entry ("is its name `*.log`?"); a **glob** is a filename pattern with wildcards (`*` = any characters, `?` = one character, `[0-9]` = one character from a set); **depth** is how many levels below the start directory an entry sits (the start itself is depth 0).

Question	Answer used
Real disk or in-memory?	In-memory tree, so runs are identical; a `java.nio` (Java's file and I/O library) adapter (a class that wraps one API to fit another interface) is an extension.
Which tests?	Name glob (case-sensitive and insensitive), type (file / directory), size, modification age, owner, empty.
How are tests combined?	AND, OR, NOT and parentheses, with `find`'s precedence (which operator is applied first when there are no parentheses): NOT binds tightest, then AND, then OR. Two tests side by side mean AND.
Size semantics?	Like GNU `find` (the standard version on Linux, from the GNU project): the size is **rounded up** to the unit before comparing, so `-size -1M` matches only empty files. Size tests apply to files only.
Other options?	`mindepth`, `maxdepth`, a result limit, and **pruning** (skip whole directories such as `node_modules`, a JavaScript project's often huge folder of downloaded libraries).
API or command line?	Both: a fluent (written as one chain of method calls, `a().b().c()`) **Builder** API for code, and a parser for `find`-style command lines.
Output order?	Pre-order depth-first (go as deep as possible down one branch before the next; a directory is listed before its contents), children in name order.
Huge trees?	Stream results as they are found; no recursion (a method calling itself; deep trees must not overflow the stack — the limited memory that holds pending method calls); a parallel variant as an extension.

Requirements

Functional

1. Model files and directories (name, owner, modification time, size).
2. Search from a start path with any combination of tests joined by AND / OR / NOT.
3. Options: min/max depth, result limit, pruned directory names.
4. Parse `find` command lines into the same search criteria.
5. Clear errors for bad paths, unknown tests, malformed sizes and unbalanced parentheses.

Non-functional

- **Open/Closed**: a new test = one new class, no change to the search loop or the parser's structure.
- Memory: stream results; handle very deep trees.
- Thread safety: searching while files are being added must not throw.

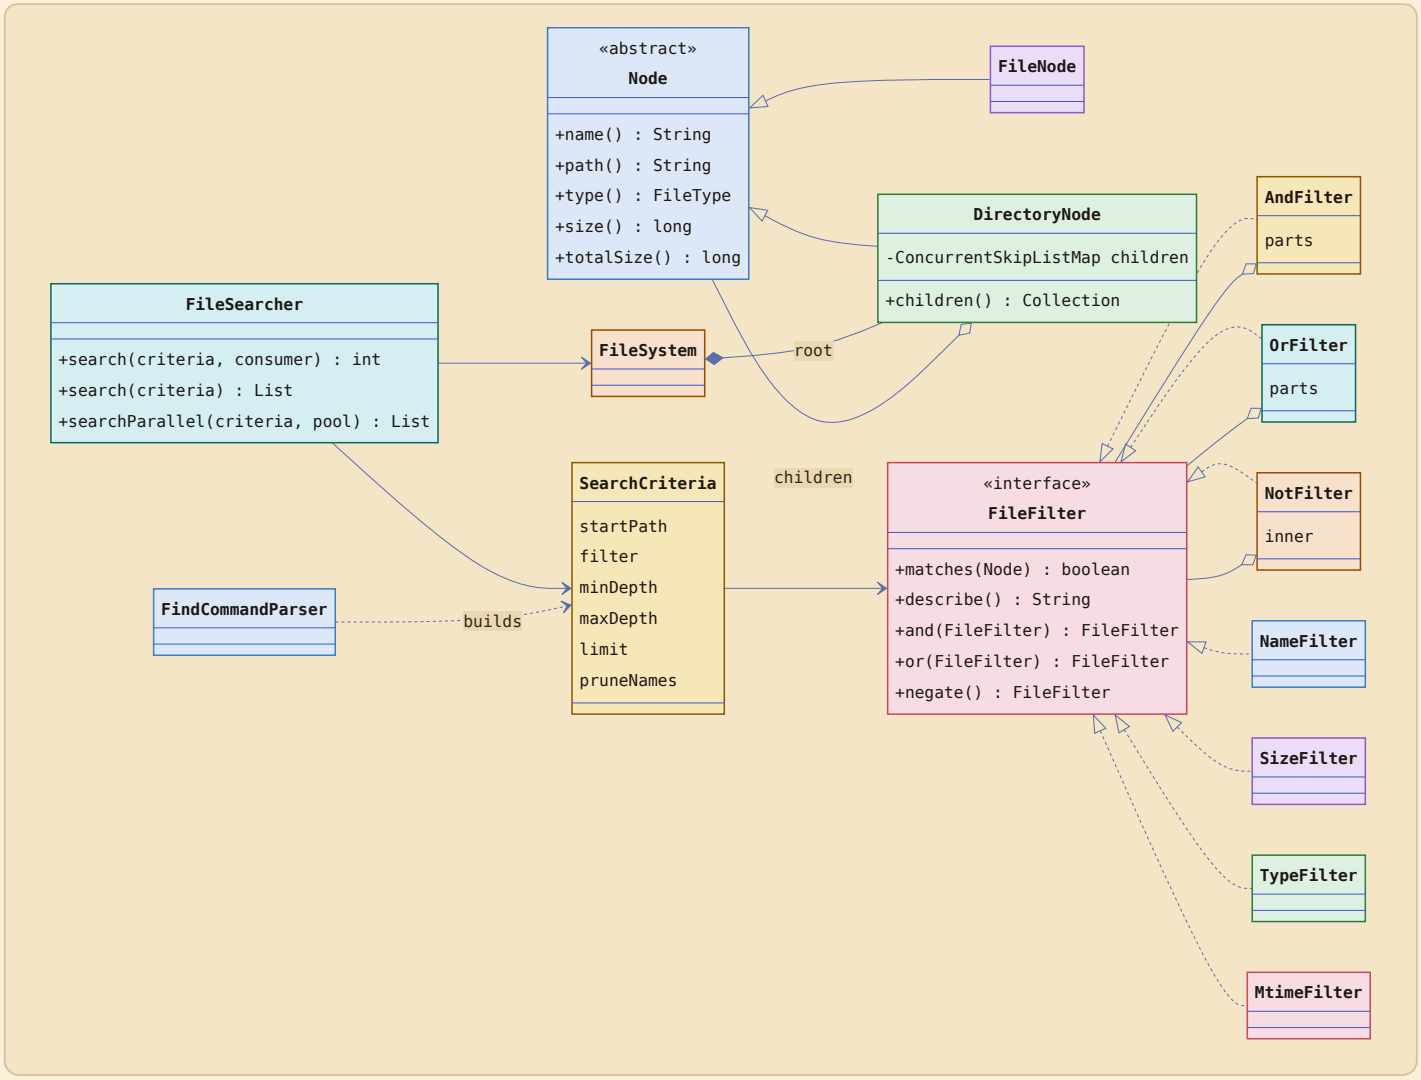
Use cases

Actor	Use cases
Developer (API user)	build criteria with the Builder, run a search, stream results
Shell user (someone typing commands into a terminal)	type a `find` command line, see matching paths or a clear error
Ops script (an operations team's automation script)	find big old logs (`-size +10M -mtime +7`) to archive, find empty directories to clean

Core entities

Class	Kind	Responsibility
`Node`	abstract sealed class (cannot be created directly, and only the listed subclasses may extend it)	**Composite** component: name, parent, owner, modified time, `path()`, `size()`, `totalSize()`.
`FileNode` / `DirectoryNode`	classes	Leaf and container; a directory keeps its children sorted in a `ConcurrentSkipListMap` (a sorted map that many threads can use at once).
`FileSystem`	class	Root, `mkdirs`, `createFile`, `resolve(path)`.
`FileFilter`	interface	**Specification**: `matches(node)`, `describe()`, and default `and` / `or` / `negate`.
`AndFilter`, `OrFilter`, `NotFilter`	records	**Composite** filters: a tree of filters that is itself a filter.
`Filters`	factory	Leaf tests: name/iname glob, type, size, mtime, owner, empty, match-all.
`SearchCriteria` + `Builder`	class	Immutable search description (start, filter, depths, limit, prune set), built fluently and validated once.
`FileSearcher`	class	Iterative DFS (depth-first search) with an explicit stack (a last-in, first-out list); streams results to a `Consumer`; optional fork/join version (Java's framework that splits a task into subtasks run in parallel, then joins the results).
`FindCommandParser`	class	Recursive-descent parser (one method per grammar rule, the methods calling each other) for `find` expressions → `SearchCriteria`.
`SearchException`	exception	Readable failure.

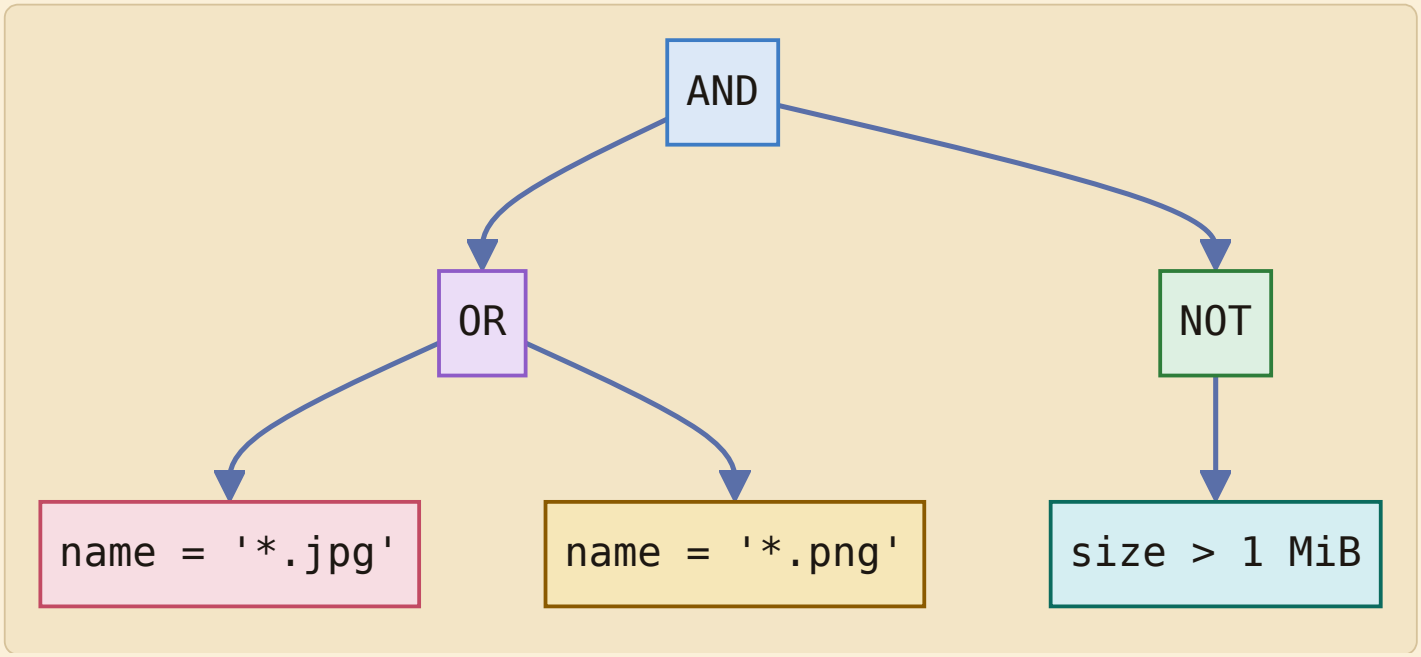
Class diagram



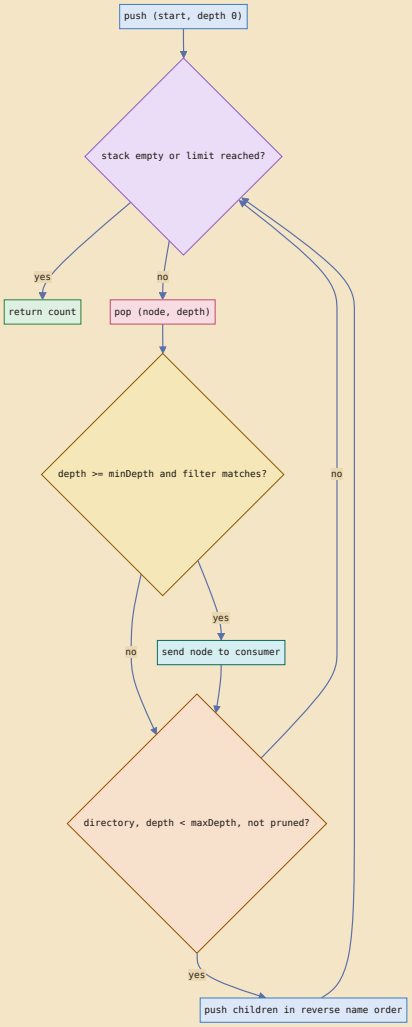
Two Composites sit side by side: the **file tree** (a directory is a node that contains nodes) and the **filter tree** (an AND is a filter that contains filters). The searcher walks the first and asks the second one question per entry.

Key flows

Parsing `find /home ( -name '*.jpg' -o -name '*.png' ) ! -size +1M` produces this filter tree:



The search loop (explicit stack, pre-order):



Operator precedence (from lowest to highest): `-o` (OR) < `-a` or nothing (AND) < `!` (NOT) < `( … )`. So `-name a -o -name b -type f` means `a OR (b AND file)` — a classic surprise, and the reason `find` users write parentheses.

Design decisions & patterns used

Decision	Pattern	Why	Alternative rejected
Each test is a small class with `matches(node)`	**Specification**	A new test is one record; the search loop never changes (Open/Closed)	`search(name, ext, minSize, maxSize, type, …)` with a growing list of `if`s
`AndFilter` / `OrFilter` / `NotFilter` hold other filters	**Composite**	Arbitrary nesting (`(a OR b) AND NOT c`) with one interface; the parser's output *is* this tree; `describe()` prints it	Lambdas (short anonymous functions) only (`a.and(b)`) — work, but cannot be printed or inspected (compare §21.1's `TaskFilter`)
`Node` / `FileNode` / `DirectoryNode`	**Composite**	The searcher and `totalSize()` treat files and directories uniformly	`instanceof` ("is this object of type X?") checks everywhere, or separate file and directory lists
`SearchCriteria.Builder`	**Builder**	Many optional settings; named calls; validation (`mindepth ≤ maxdepth`) once in `build()`; immutable result	Telescoping constructors or a mutable settings bag
Recursive-descent `FindCommandParser`	Interpreter-style parser	One method per precedence level makes precedence explicit and testable	Splitting on `-o` with string hacks
Iterative DFS with an explicit `ArrayDeque`	—	No `StackOverflowError` (the crash when the call stack runs out) on very deep trees; easy to add a limit	Recursion
Results go to a `Consumer<Node>`	Streaming / callback	Prints as it finds, like `find`; memory does not grow with the result count	Always building a full `List`
AND / OR short-circuit (stop as soon as the answer is known)	—	Put cheap tests first (`-name` before a size lookup on a real disk)	Evaluating every test
`ConcurrentSkipListMap` for children	Concurrent collection	Sorted (deterministic output) and safe to iterate while files are added	`TreeMap` (throws `ConcurrentModificationException`)

Java implementation

The file-system model:

```java
// File: lld/ch21/filesearch/FileType.java
package lld.ch21.filesearch;

public enum FileType { FILE, DIRECTORY }
```

```java
// File: lld/ch21/filesearch/SearchException.java
package lld.ch21.filesearch;

/** Bad path, bad option or bad expression: a readable message, never a stack trace for the user. */
public class SearchException extends RuntimeException {
    public SearchException(String message) { super(message); }
}
```

```java
// File: lld/ch21/filesearch/Node.java
package lld.ch21.filesearch;

import java.time.Instant;

/**
 * Composite pattern: a file-system entry is either a leaf (FileNode) or a container
 * (DirectoryNode) that holds more entries. Callers treat both through this one type.
 */
public abstract sealed class Node permits FileNode, DirectoryNode {
    private final String name;
    private final DirectoryNode parent;
    private final String owner;
    private final Instant modified;

    protected Node(String name, DirectoryNode parent, String owner, Instant modified) {
        this.name = name; this.parent = parent; this.owner = owner; this.modified = modified;
    }

    public String name() { return name; }
    public DirectoryNode parent() { return parent; }
    public String owner() { return owner; }
    public Instant modified() { return modified; }

    public abstract FileType type();

    /** Size in bytes of this entry alone (0 for a directory, as far as our filters care). */
    public abstract long size();

    /** du-style size: a file's own size; a directory's is the sum over everything inside it (Composite recursion).
*/
    public abstract long totalSize();

    public String path() {
        if (parent == null) return "/";
        String p = parent.path();
        return (p.equals("/") ? "" : p) + "/" + name;
    }

    @Override public String toString() { return path(); }
}
```

```java
// File: lld/ch21/filesearch/FileNode.java
package lld.ch21.filesearch;

import java.time.Instant;

public final class FileNode extends Node {
    private final long size;

    FileNode(String name, DirectoryNode parent, String owner, Instant modified, long size) {
        super(name, parent, owner, modified);
        if (size < 0) throw new SearchException("Negative size for " + name);
        this.size = size;
    }

    @Override public FileType type() { return FileType.FILE; }
    @Override public long size() { return size; }
    @Override public long totalSize() { return size; }
}
```

```java
// File: lld/ch21/filesearch/DirectoryNode.java
package lld.ch21.filesearch;

import java.time.Instant;
import java.util.Collection;
import java.util.concurrent.ConcurrentSkipListMap;

public final class DirectoryNode extends Node {
    /** Sorted by name (deterministic output) and safe to read while another thread adds files. */
    private final ConcurrentSkipListMap<String, Node> children = new ConcurrentSkipListMap<>();

    DirectoryNode(String name, DirectoryNode parent, String owner, Instant modified) {
        super(name, parent, owner, modified);
    }

    @Override public FileType type() { return FileType.DIRECTORY; }
    @Override public long size() { return 0; }
    @Override public long totalSize() { return children.values().stream().mapToLong(Node::totalSize).sum(); }

    public Collection<Node> children() { return children.values(); }
    public Node child(String name) { return children.get(name); }
    public boolean isEmpty() { return children.isEmpty(); }

    void add(Node n) {
        if (children.putIfAbsent(n.name(), n) != null)
            throw new SearchException(n.path() + " already exists");
    }
}
```

```java
// File: lld/ch21/filesearch/FileSystem.java

        return fs;
    }
}
```

How the code works, part by part

- **Globs.** `NameFilter.toRegex` turns `*` into `.*`, `?` into `.`, keeps `[...]` sets (turning `[!...]` into `[^...]`) and quotes every other character, then compiles the regex once, when the filter is built. Like `find -name`, it matches only the last path component, and `*` also matches names that start with a dot.
- **Size.** `SizeFilter` parses `[+-]N[cbkMG]` (no suffix = 512-byte blocks, as in `find`), rounds the file size **up** to whole units, then compares: `+` means more than N units, `-` fewer, no sign exactly N.
- **Age.** `MtimeFilter` computes the age in whole days (the fraction is dropped) against an injected `now`, so the demo is repeatable.
- **Builder.** Each `where(...)` call is ANDed with earlier ones; `build()` checks depths and the limit and freezes everything into an immutable `SearchCriteria`.
- **Search.** `FileSearcher.search` pushes the start node, then pops, tests, emits and pushes children in reverse name order so they come off the stack in name order. It stops descending at `maxDepth` and at pruned directory names, and stops entirely at the limit.
- **Parser.** `parseOr` → `parseAnd` → `parseUnary`: one method per precedence level. `parseAnd` treats two tests side by side as AND; `-maxdepth`/`-mindepth` are options that can appear anywhere, so every level skips them first.
- **Parallel.** `searchParallel` forks one task per sub-directory (files are tested inline), waits for all, then joins results in name order — the same list, in the same order, as the sequential search.

Output:

```
== Builder API ==
$ from / where (name='*.log' AND type=f)
   /home/asha/projects/app/build.log
   /var/log/app.log

== bad input gives a clear message ==
   find / -size 10X                  -> Invalid -size '10X' (use e.g. +10M, -1k, 100c)
   find / ( -name a                  -> Missing ')'
   find /nope -name x                -> No such file or directory: /nope
   find / -frobnicate                -> Unknown predicate '-frobnicate'
   find / -type x                    -> -type takes f or d, not 'x'
   find / -maxdepth 1 -mindepth 3    -> mindepth 3 > maxdepth 1
   find / -name                      -> -name needs an argument
```

```
== Composite sizes (du -s) ==
   /home/asha                              13,281,280 bytes
   /home/asha/projects/app/node_modules     1,560,576 bytes
   /var/log                                66,060,288 bytes

== Parallel search on a big generated tree ==
   from /data where (name='*.csv' AND size+500k AND mtime-10)
   sequential=1600 parallel=1600 same order=true first=/data/d000/sub0/f060.csv last=/data/d199/sub4/f099.csv
```

Reading the output: `-size +1M` kept the two large photos and dropped the 900 KB one; the prune option skipped `node_modules`, so only the two Java files match `*.java OR *.js`; `-size -1M` found only the empty `todo.md` — the rounding gotcha, even though `notes.txt` is only 2 KB; `-mindepth 2 -maxdepth 2 -type d` lists directories exactly two levels below `/home/asha`; the bracket glob `app.log.[0-9]` matches the rotated log but not `app.log`. Every bad input produced a one-line message. The composite `totalSize()` gives `du`-style totals (`du` is the Unix disk-usage command), and on a generated tree of 20,000 files the sequential and parallel searches returned the same 1,600 paths in the same order.

Concurrency & edge cases

- **Adding files during a search:** children live in a `ConcurrentSkipListMap`, whose iterators are *weakly consistent* — iterators (the objects that step through a collection) never throw, and may or may not show an entry added after the iteration started (like `find` on a live disk).
- **Parallel search:** tasks only read the tree and each builds its own list; there is no shared mutable state, so no locks are needed.
- **Deep trees:** the sequential walk uses a heap-allocated stack (an ordinary object in main memory, not the limited call stack). (The fork/join version recurses one task per directory; fine for normal depths.)
- **Symbolic links / cycles** (real file systems): track visited `(device, inode)` pairs (an inode is the file system's internal id for a file; a symbolic link is a file that points to another path) or do not follow links by default — GNU `find` does not follow symbolic links unless asked (`-L`).
- **Edge cases handled:** start path missing or a file; `mindepth > maxdepth`; unknown predicate; missing argument; bad `-size`/`-mtime`/`-type` values; unbalanced parentheses; an unclosed `[` in a glob is treated as a literal; limit reached mid-walk.

Extensions & follow-up questions

- **Search a real disk?** An adapter that wraps `java.nio.file.Path` + `BasicFileAttributes` as `Node`s, or use `Files.walkFileTree` with a `FileVisitor` that returns `SKIP_SUBTREE` for pruned directories.
- **Actions (`-delete`, `-exec`)?** A `Consumer<Node>` per action (Command pattern); `-delete` must walk depth-first *post-order*, meaning children are visited before their directory.
- **Content search (`grep -r`, the Unix tool that searches inside files)?** A `ContainsTextFilter` — put it last in the AND so cheap name/size tests reject most files first.
- **Faster repeated searches?** Build an index (name → paths, like `locate`/`updatedb`, Unix tools that pre-build a filename database) and accept that it can be stale.
- **More tests (`-newer file`, `-perm`, `-regex`)?** One record each in `Filters` plus one `case` in the parser.
- **Sort by size or date?** Collect, then sort with a `Comparator` — a Strategy, as in PropertyHunt (§21.5).

Real-world example

GNU `find` (from GNU findutils) evaluates its expression left to right with exactly this precedence (`!`, then implicit or explicit `-a`, then `-o`) and short-circuits; its manual documents the "`-size -1M` only matches empty files" rounding and the default of not following symbolic links. Java's own `Files.find(start, maxDepth, BiPredicate)` and `Files.walk` take a depth limit and a predicate — the same split between *walking* and *testing* used here. IDE "Find in files" dialogs and desktop search boxes build the same kind of filter tree from checkboxes instead of a command line.

In the interview

Spend the first 10 minutes on the model (`Node`, `FileNode`, `DirectoryNode`) and the `FileFilter` interface with two leaves (name, size) — that alone lets you demo a search. Then add `AndFilter`/`OrFilter`/`NotFilter`, the Builder with depth options, and the iterative walk. Add the parser last, and only if time allows: interviewers mostly

score the filter design and extensibility. Say the Open/Closed point out loud: "a new filter is one class; the searcher never changes".

Self-check

- **Q:** What does `find -name a -o -name b -type f` mean? → **A:** `a OR (b AND file)`, because AND binds tighter than OR.
- **Q:** Why does `-size -1M` match only empty files? → **A:** Sizes are rounded up to whole MiB, so any non-empty file is at least 1 unit, which is not less than 1.
- **Q:** Why are the AND/OR/NOT filters records rather than lambdas? → **A:** They can be printed (`describe()`), inspected and built by the parser as a visible tree.
- **Q:** How does pruning differ from filtering out a directory? → **A:** Pruning stops the walk from entering it (nothing inside is visited); a filter only hides the directory entry itself.
- **Q:** Why an explicit stack instead of recursion? → **A:** Very deep trees would overflow the call stack; an explicit stack also makes the limit easy.

TL;DR

Two Composites — the file tree and the filter tree. Filters are Specifications (`matches`) combined with AND / OR / NOT; the Builder describes the search once and validates it; an iterative DFS streams matches; a recursive-descent parser turns `find` command lines into the same criteria, with `!` > AND > OR precedence and GNU's rounded-up `-size`.

Chapter summary

Problem	Core entities	Key pattern(s)	Concurrency point	Trap to avoid
Task Management	Task, TaskStatus, TaskService	Specification filters, enum state machine, Observer	per-task `synchronized`	TODO → DONE jumps; filters as many parameters
Digital Wallet	Wallet, Transaction, Offer	Strategy offers, idempotency, funded cashback	lock both wallets in id order	`double` money; check-then-act on keys; cashback created from nothing
Event Calendar	TimeSlot, Event, EventStore	Strategy for representatives, plan-then-save	atomic check-and-book	closed intervals; trusting the sample blindly
Coding Blox	Contest, Level, User	Command map, Strategy (solver, scoring)	atomic rating update	unseeded randomness; running a contest twice
PropertyHunt	Property, SearchCriteria	Builder + predicate list, Strategy sort	synchronized mark-sold	comparing "90L" strings; stale shortlist copies
Ledger Co	Loan, LumpSum, Balance	Strategy interest, derived state	synchronized lump sums	storing a running balance; floor instead of ceil
Inventory	StockMovement, AllocationStrategy	Strategy allocation, Observer alerts	per-SKU lock	partial shipments; alert spam
Unix find	Node (Composite), FileFilter, SearchCriteria	Specification + Composite filters, Builder, recursive-descent parser	weakly consistent children map; read-only parallel walk	parameter-list search methods; `-o` vs AND precedence

The pattern behind all eight: entities guard their own rules, services orchestrate, strategies hold the "X or Y" rules, repositories hide storage, the driver parses and prints, and every error is a clear message — not a crash.

Chapter 22 — Revision: Cheat Sheets & Glossary

What you will learn in this chapter

- How to revise the whole handbook in 15 minutes, or in one evening the night before.
- The LLD (low-level design: the classes and code inside one program) answer framework on one page (Chapter 1).
- OOP, relationships and UML arrows on one page (Chapters 2–3).
- SOLID, the other design principles, and the clean-code rules as tables (Chapters 4–6).
- All 24 code smells with the refactorings that cure them (Chapter 7).
- All 23 GoF patterns (the classic catalogue by the "Gang of Four" authors) plus the extras, and a "which pattern?" table sorted by symptom (Chapters 8–11).
- The concurrency toolbox, a deadlock checklist and a "which `java.util.concurrent` class?" table (`java.util.concurrent` is Java's standard package of thread-safety tools) (Chapters 12–13).
- A map of every case study: entities, patterns, concurrency concern, and where to find it (Chapters 14–21).
- A machine-coding checklist, an edge-case checklist, and a glossary of about 200 terms.

Nothing in this chapter is new. Every row is a summary of a section in Chapters 1–21, and the right-hand column tells you where to go for the full explanation. This chapter has no code.

How to read the references. "§12.17" means section 12.17. Chapters 5 and 6 number their sections from 1 inside the chapter, so "Ch 5 §13" means section 13 of Chapter 5 (Fail Fast). Chapters 16, 17 and 19 have unnumbered case studies, so they are referenced by name, for example "Ch 16 · Car Rental".

New to a term? Every technical word in the tables below, from `API` and `JVM` to `TTL` and `SKU`, has a one-line definition in the glossary (22.11). A **TL;DR** ("too long; didn't read") heading marks a short summary.

22.1 How to revise

In 15 minutes (the morning of the interview)

Minutes	Read	Why
0–3	22.2 (the framework)	You will use it in the first minute of the interview
3–6	22.4 (SOLID one-pager) and the relationship table in 22.3	The two things asked about most often by name
6–10	"Which pattern?" table in 22.7	Patterns should come from a signal, not from memory
10–13	Concurrency cheat sheet and deadlock checklist in 22.8	Every booking/inventory problem has a race
13–15	The row(s) of 22.9 for the problems you expect	One sentence per problem: entities, pattern, the atomic step

The night before (about 2 hours)

1. **Read 22.2–22.8 slowly** (45 min). For each table row, say out loud *one example from the handbook*. If you cannot, open the referenced section.
2. **Pick three case studies** from 22.9 you have not practised recently (45 min). For each: write requirements, list classes, draw the class diagram, and name the one hard method, without looking. Then compare with the chapter's TL;DR.
3. **Scan the glossary** (22.11) and mark any term you cannot explain in one sentence (20 min). Read those sections only.
4. **Stop.** Sleep matters more than one more pattern.

Common mistakes when revising

- Re-reading chapters instead of **recalling** first and then checking. Recall is what the interview tests.
- Memorising all 23 patterns equally. Six come up in almost every round (22.7): Strategy, Factory, Observer, State, Singleton, Builder.
- Skipping the "when *not* to use it" column. Interviewers ask "would you always do that?" (§4.13).

22.2 The LLD interview answer framework (one page)

Source: Chapter 1 (§1.2, §1.4–§1.10, §1.12, §1.14).

TL;DR

Clarify → requirements → use cases → entities → relationships → class diagram → key flows → patterns/SOLID → code → edge cases/concurrency → extensions. Say each step out loud as you enter it.

The eleven steps

#	Step	Ask yourself	Output
1	Clarify	Who uses it? Single site or many?	Shared understanding
2	Requirements	Functional? Non-functional (thread-safe, extensible, in-memory)? **Out of scope?**	8–12 numbered lines + out-of-scope list
3	Use cases	What can each actor do?	Actor → use-case list
4	Entities	Which nouns hold state or behaviour? Which are just values?	Classes, one sentence each
5	Relationships	Uses / knows / has / owns / is-a? How many?	Typed lines with multiplicity
6	Class diagram	Fields, key methods, interfaces, enums	UML class diagram
7	Key flows	Steps of the 2–3 main use cases; lifecycle of the core object	Sequence / activity / state diagram
8	Patterns & SOLID	A rule that varies? A lifecycle? Many listeners? Two reasons to change?	1–2 named patterns + one rejected
9	Code	Interfaces, enums, models, services, driver	Running code for the main flows
10	Edge cases & concurrency	Bad input? Full? Two users, one seat?	Validation, exceptions, locks
11	Extensions	"What if X is added?"	Short answers, maybe one class

Time budgets

45-minute OOD (object-oriented design) round		**90-minute machine-coding round (write runnable code)**	
Clarify requirements	5–8 min	Read, requirements, assumptions	5–10 min
Actors and use cases	3–5 min	Model: entities, enums, service interfaces	10–15 min
Find the classes	8–10 min	Core flow end to end	30–40 min
Connect the classes	8–10 min	Remaining features, validation, edge cases	15–20 min
Write the code	12–15 min	Polish, one extension point, demo	5–10 min
		Buffer	5 min (never zero)

Rule of thumb: roughly **a quarter of the hour goes before you name a class**, and in machine coding you **get something running by the halfway mark** (§1.2).

Finding classes (§1.6)

- **Nouns → candidate classes; verbs → methods.** A verb with no class to live on means a class is missing.
- Cut candidates with five tests: is it a **value**? the **same thing** under another name? does it have **changing state**? does anything **call** it? does it differ in **behaviour or only data**?
- **Different data → field or enum. Different behaviour → class.**
- One sentence per class, **no "and"**. Put each method where its data is (Information Expert).
- Beginners most often forget the **record-keeping class** (ticket, loan, booking) and the **rule class** (rate, strategy).

What the interviewer judges (§1.2)

1. Did you **bound** the problem? 2. Does each class have **one job** you can say in a sentence? 3. Are the **relationships** right? 4. Does the **code match the diagram**? 5. Can you explain a **trade-off** (the choice and the rejected option)?

Machine coding adds: does it **run**, is it **modular**, **readable**, does it **handle bad input**, and (senior roles) is shared state **thread-safe**.

Code habits interviewers notice (§1.10)

Habit	Instead of
Pass time in (`long nowMinute`, `Instant now`, injected `Clock`)	Reading the clock inside logic
Money as `BigDecimal` from strings, or whole cents in a `long`	`double` (0.1 + 0.2 ≠ 0.3)
`IllegalArgumentException` / `IllegalStateException` / a custom exception	Silent failure or error codes
`Optional` when "not found" is normal	Returning `null`
`private final` fields	Public mutable fields
Domain names (`ParkingTicket`)	`Manager`, `Helper`, `Data2`

Skeleton: **Models → Repositories → Strategies → Services → Driver** (§1.10). The driver is the `main` class that feeds sample commands to the services and prints the results.

In the interview

30-second answer (from §1.14): "I clarify and write 8 to 12 requirements with an out-of-scope list, list actors and use cases, pick classes from the nouns and give each one responsibility, connect them and draw a class diagram, sketch the key flow, run a quick SOLID check and pick one or two patterns where the signal is clear, then code the two or three core flows, handle edge cases and concurrency, and finish with extensions and trade-offs."

Common mistakes (§1.14)

Mistake	Fix
Coding in minute two	8–13 minutes on requirements and actors first
No out-of-scope list	Write it down and agree it
One subclass per value (`CompactSpot`, `LargeSpot`)	Different data → field/enum
God class (`ParkingLotManager`)	One sentence per class; split on "and"
Inheritance for reuse ("Car extends Engine")	Composition
Pattern stuffing	One or two patterns, each with its signal
All twelve classes at equal depth	Two or three flows fully
Ignoring two users on one resource	Lock or atomic operation on the shared state
Non-running code in machine coding	Thin end-to-end path running by halfway

22.3 OOP & relationships cheat sheet

Source: Chapter 2 (OOP) and Chapter 3 (relationships and UML).

The four pillars (§2.3–§2.6)

Pillar	One line	Java tools	Smell when missing
Encapsulation (§2.3)	Data is private; only the owning class's methods change it, and they enforce the rules (the *invariants*: facts that must always hold)	`private` fields, no setters, validation in constructors	Public fields; setters that break invariants
Abstraction (§2.4)	Expose only what callers need; hide how	Interfaces, abstract classes, small public API	Callers reach into internals
Inheritance (§2.5)	Child reuses and specialises parent — **only when "child is a parent" is truly correct**	`extends`, `super`, `@Override`	Subclass refuses or throws on parent methods
Polymorphism (§2.6)	One call, different behaviour per object; removes type switches	Overriding + dynamic dispatch (the method is picked from the object's real class at run time)	`switch` / `instanceof` chains on type

Encapsulation vs abstraction: hiding *data* behind rule-enforcing methods vs hiding *complexity* behind a minimal set of operations (Ch 2 self-check).

Other OOP facts worth one line each

Topic	Remember	Where
Overloading vs overriding	Compile time, by declared parameter types vs run time, by the actual object. Fields and `static` methods are not polymorphic (statics are hidden, not overridden)	§2.7
`this`, `static`, `final`	Current object; one per class; cannot be reassigned/overridden/extended	§2.2
Interfaces	Contracts; can have `default`, `static`, `private` methods; a functional interface has one abstract method (lambdas: short inline functions such as `x -> x * 2`)	§2.8
Enums	Fixed sets with fields and behaviour ("which spot types fit a truck" lives on `VehicleType`)	§2.10
Composition over inheritance	Avoids fragile base classes; allows run-time swapping	§2.11, Ch 5 §6
`equals` / `hashCode`	Equal objects must have equal hash codes; override both or hash collections break	§2.12
Immutability & records	Final class, private final fields, no setters, defensive copies. Records are only **shallowly** immutable — copy collections in the compact constructor	§2.13
Access modifiers	Default to `private`; package-private = same package only	§2.14
Generics	Type-safe reusable infrastructure; **PECS**: producer `extends`, consumer `super`	§2.15
Coupling & cohesion	Low coupling (between classes), high cohesion (inside a class)	§2.16
OOA → OOD → OOP	What the problem is → how, with objects → code. Connections that carry data become objects	§2.17

Abstract class vs interface (§2.9)

	Abstract class	Interface
Instantiable?	No	No
Instance fields (state)	Yes	No (only `public static final` constants)
Constructors	Yes	No
Method bodies	Any	`default`, `static`, `private` only
How many per class	**One** (`extends`)	**Many** (`implements`)
Relationship expressed	"is a" (shared identity and state)	"can do" (capability / role)
Typical use	Shared state + partial implementation for a close family (Template Method)	Contracts, roles, strategies, test seams

Rule of thumb: start with an interface; add an abstract class underneath when implementations share real state or a fixed algorithm (JDK, the Java Development Kit's standard library: `List` + `AbstractList` + `ArrayList`).

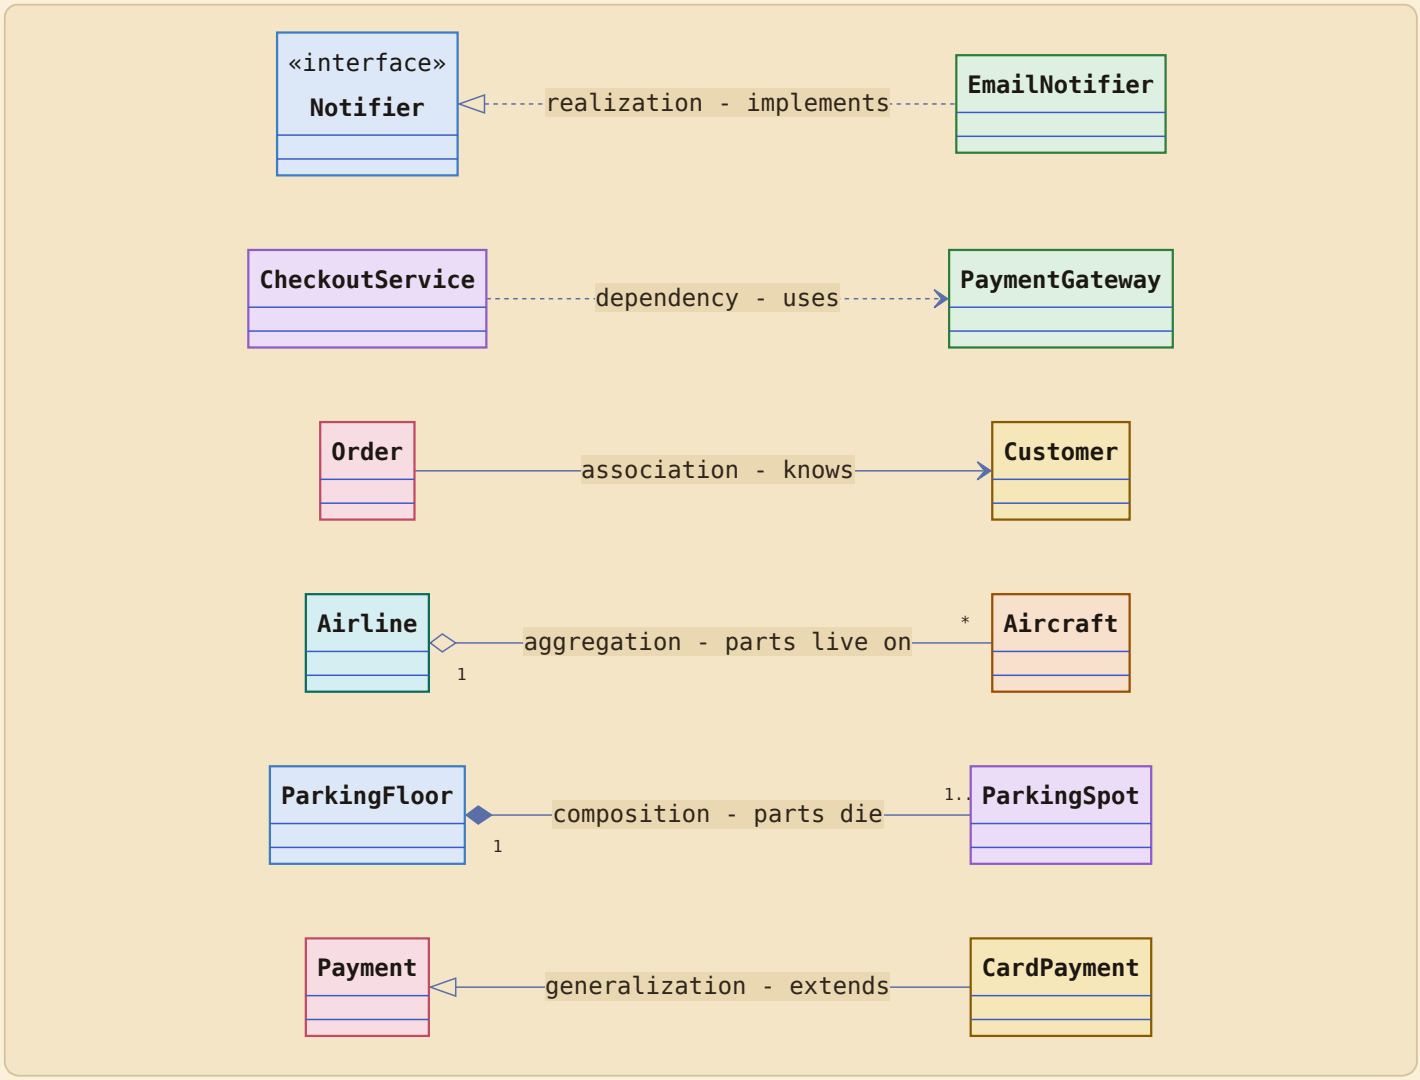
The six relationships (§3.2–§3.8)

Weakest to strongest coupling: **dependency, association, aggregation, composition, realization, generalization** (§3.16).

Relationship	Phrase	UML line	Java shape	Lifetime	Example
Dependency (§3.5)	A *uses* B	dashed, open arrow → B	B as parameter / local / return / static call	none	`CheckoutService` uses `PaymentGateway`
Association (§3.2)	A *knows* B	solid line (arrow for one-way)	field of type B, created elsewhere	independent	`Order` → `Customer`
Aggregation (§3.3)	A *has* B, parts live on	solid, hollow ◇ at A (the whole)	field/collection, parts passed in	B outlives A	`Airline` ◇— `Aircraft`
Composition (§3.4)	A *owns* B	solid, filled ◆ at A (the whole)	A creates B, hides it, B not shared	B dies with A	`ParkingFloor` ◆— `ParkingSpot`
Realization (§3.7)	A *implements* B	dashed, hollow △ at B	`implements`	—	`EmailNotifier` ⇢ `Notifier`
Generalization (§3.6)	A *is a* B	solid, hollow △ at B	`extends`	—	`CardPayment` → `Payment`

Choosing, in order (§3.8): interface A promises to fulfil → realization. Substitutable with no refused methods → generalization. Not kept in a field → dependency. Part that dies with the whole → composition. Part that outlives it → aggregation. Otherwise → association.

UML arrow legend (Mermaid)



Mermaid	Meaning
`A ..> B`	A depends on B
`A --> B`	A associated with B, navigable A to B
`A -- B`	association (both ways / unspecified)
`A o-- B`	aggregation, A is the whole
`A *-- B`	composition, A is the whole
`B <|.. A`	A realizes interface B
`B <|-- A`	A extends B
`A "1" *-- "1..*" B`	with multiplicities

Multiplicity → code (§3.17): `1` required field; `0..1` `Optional`/nullable; `1..*` non-empty collection checked in the constructor; exact numbers checked in constructors. Visibility: `+` public, `-` private, `#` protected, `~` package.

UML diagrams in the interview (§3.9–§3.15)

Diagram	Use it for	Budget in 45 min
Use case (§3.10)	Scope: actors + what each does. «include» = always; «extend» = sometimes	Usually spoken, 3–5 min
Class (§3.11)	**The answer.** 10–15 boxes, every line typed, with multiplicity	Always drawn, 10–15 min
Sequence (§3.12)	Call order between objects (3–4 objects, 6–8 messages)	One behaviour diagram only
Activity (§3.13)	A flow that branches; fork/join for parallel steps	"
State machine (§3.14)	One object's lifecycle; transition label `event [guard] / action`	"

UML has 14 diagram types: 7 structural, 7 behavioural (§3.9).

Common mistakes

- Diamond at the wrong end (it goes at the **whole**); triangle at the wrong end (it goes at the **parent/interface**) (§3.8).
- Lines without type or multiplicity (§3.8).
- Inheritance used to share data; subclasses that only pass a constant to `super` → one class with an enum field (§3.16).

22.4 SOLID one-pager

Source: Chapter 4 (§4.2, §4.7–§4.10, §4.12–§4.15), smells from Chapter 7 (§7.4).

TL;DR

SOLID = five names for the ways code becomes painful to change. **Use them to diagnose, not as a checklist**, apply a fix when a real change asks for it, and always say what the fix costs.

Principle	One-line rule	Smell that signals a violation	Fix	Patterns that help
S — Single Responsibility (§4.2)	A class should have one reason to change (one actor asks for its changes)	The responsibility sentence needs an "and"; *Divergent Change*, *Large Class*	Split by actor (Extract Class); each new class needs a name that stands alone	Command, Proxy, Decorator (each concern in its own class)
O — Open/Closed (§4.7)	Add new behaviour by adding code, not by editing working code	A `switch`/`if` chain over a type; *Repeated Switches*, *Shotgun Surgery*	Put the part that *has* varied behind an interface; add variants as classes (Replace Conditional with Polymorphism)	Strategy, Template Method, Decorator, Factory Method, Observer, Command, Visitor
L — Liskov Substitution (§4.8)	A subtype must be usable anywhere its parent is expected	Subclass throws, does nothing, or refuses a parent method; *Refused Bequest*	Better parent, a narrower interface, or composition (Replace Subclass with Delegate)	Composite, Null Object
I — Interface Segregation (§4.9)	No client should depend on methods it does not use	Empty method bodies or `UnsupportedOperationException` in implementers; fat interfaces	Split into **role interfaces**, one per kind of caller	Adapter
D — Dependency Inversion (§4.10)	Depend on abstractions, not concrete details; the policy owns the abstraction	A high-level class does `new` of (or names) a low-level one; cannot test without the real DB (database)/provider	Inject an interface owned by the high-level class; `main` wires the details	Strategy, Factory Method / Abstract Factory, Adapter, Observer

LSP in detail (§4.8, TL;DR): a subclass must accept at least as much, promise at least as much, keep invariants and history, and throw nothing new. Square/Rectangle is worse than `Penguin.fly()` throwing because it fails **silently** (wrong area, no error).

Five-minute pass over your diagram (§4.13, §1.8)

Run S → O → L → I → D over the diagram you just drew. **Two findings is a good pass; five means rework; zero means you did not look.** S and O earn the most credit: O is what interviewers probe with a late requirement ("what if trucks are charged differently?" → "add a class").

Related ideas (§4.3–§4.6, §4.14)

Idea	Question it asks
SRP	How many actors can ask this class to change?
Cohesion	Do the parts of this class belong together?
Coupling	How much does A depend on B?
Separation of Concerns	Is each area of work in its own module?
SRP vs ISP	SRP splits **classes** (guards the worker); ISP splits **interfaces** (guards the caller)
DIP vs DI vs IoC	DIP = principle (depend on abstractions); DI = technique (pass dependencies in); IoC = the broader idea that a framework calls your code; IoC containers (libraries such as Spring that create and wire objects for you) perform DI

Common mistakes: over-engineering (§4.15)

Warning sign	Principle misapplied	Do instead
`XHelper`, `XUtils`, `XManager2` after a split	SRP	Split by actor; names must stand alone
Six small classes that always change in the same commit	SRP over-split	Merge them back
Interface + factory + registry for one implementation	OCP (*Speculative Generality*)	Write the `if`; refactor at the second or third case (rule of three)
A subclass that "works" by silently doing nothing	LSP	Better parent or composition
One interface per method	ISP over-split	Group by caller into role interfaces
An interface in front of stable `String`-like classes	DIP	Invert only volatile dependencies
A DI container for a 200-line program	DIP	Wire by hand in `main`

YAGNI is the counterweight: SOLID says *what* a good seam looks like; YAGNI says *when* to cut it.

In the interview

Say **observation → cost → fix → price of the fix**, and describe before you label: "`Reporting` implements nine methods but calls two — an interface segregation problem" (§4.13).

22.5 Other design principles and Clean Code rules

Other principles (Chapter 5)

Principle	One-line idea	Smell it fixes	Key Java tool	Where
DRY	Each piece of knowledge has one authoritative home	Duplicated rules drifting apart	Value objects, constants, methods	Ch 5 §1
KISS	Choose the simplest design that works	Over-engineering	Plain code, `switch` expressions	Ch 5 §2
YAGNI	Don't build features before they are needed	Speculative Generality	Delete unused code	Ch 5 §3
Law of Demeter	Only talk to your immediate friends	Train wrecks `a.getB().getC().do()`	Intent-revealing delegate methods	Ch 5 §4
Tell, Don't Ask	Tell objects what to do; don't pull their data out and decide for them	Anemic model, Feature Envy	Command methods on the owner	Ch 5 §5
Composition over inheritance	Prefer "has-a" to "is-a" for reuse	Fragile base class	Forwarding / decorators	Ch 5 §6
Program to an interface	Depend on supertypes, choose the concrete class once at the edge	Hard-wired concrete dependencies	Interfaces + DI	Ch 5 §7
Encapsulate what varies	Isolate the part that changes behind an interface	Growing type switches	Strategy, lambdas	Ch 5 §8
Loose coupling	Interacting objects know little about each other	God orchestrators	Observer, events, DI	Ch 5 §9
Hollywood Principle / IoC	"Don't call us, we'll call you" — the framework owns the flow	Duplicated skeletons	Template Method, callbacks, DI	Ch 5 §10
Separation of Concerns	Each part handles one concern	Spaghetti code	Layers, MVC	Ch 5 §11, §4.5
Least Astonishment	Do what the name promises and nothing more	Hidden side effects	Honest names, `Optional`	Ch 5 §12
Fail fast	Detect problems early and loudly	Distant `NullPointerException`s	Guard clauses, `requireNonNull`	Ch 5 §13
Immutability	Objects never change after creation	Aliasing, races	Records, `List.copyOf`	Ch 5 §14
Design by Contract	Preconditions (caller), postconditions (method), invariants (always)	Magic error values	Checks at method entry/exit	Ch 5 §15
GRASP	Nine guidelines for "which class should do this?"	God classes	Expert, Creator, Controller…	Ch 5 §16
Domain-Driven Design	Model the business: bounded contexts, entities vs value objects, small aggregates, domain events, repositories per root	Anemic model, big ball of mud, primitive obsession	Records as value objects, aggregate roots, events + outbox (events saved in the same transaction as the data, published afterwards)	Ch 5 §17

GRASP in one line each (Ch 5 §16.1–§16.9):

Guideline	Rule
Information Expert	The class with the data does the work
Creator	The container (or the one with the initial data) creates
Controller	A thin non-UI object receives each system event and delegates
Low Coupling	Choose the design with fewer, more stable dependencies
High Cohesion	Each class does one related set of things
Polymorphism	Let each type implement the varying behaviour; don't switch on types
Pure Fabrication	Invent a helper class (e.g. a repository) when no domain class is a clean home
Indirection	Put a middleman between things that shouldn't know each other
Protected Variations	Wrap what's unstable behind a stable interface

Tensions to mention (Ch 5 summary): DRY vs loose coupling (sharing code couples its users); YAGNI vs encapsulate-what-varies (abstract only real or clearly predicted variation); Law of Demeter vs cohesion (too many delegates → Middle Man); Information Expert vs SoC (domain objects compute, fabrications persist).

Clean Code rules checklist (Chapter 6)

Area	Rule of thumb	Where
Names	Reveal intent; pronounceable; searchable; one word per concept; code reads like the requirement	Ch 6 §1
Functions	Small; do one thing; one level of abstraction; top-down (stepdown); ≤ 2–3 arguments; **no flag arguments**; no hidden side effects; commands *or* queries (CQS); exceptions, not error codes	Ch 6 §2
Comments	Say it in code; comment only the *why*, warnings, legal text, public contracts; delete commented-out code	Ch 6 §3
Formatting	Newspaper order (headline first); related things close; one automated team style	Ch 6 §4
Objects vs data structures	Objects hide data and expose behaviour; data structures expose data; no hybrids; no train wrecks	Ch 6 §5
Error handling	Unchecked exceptions with context; wrap vendor exceptions; empty collections / `Optional` / special case instead of `null`; never pass `null`; always clean up	Ch 6 §6
Boundaries	Keep third-party code behind your own interfaces; learn it with tests	Ch 6 §7
Unit tests	Three laws of TDD (Test-Driven Development: write a failing test first); one concept per test; Given–When–Then; **F.I.R.S.T.** (Fast, Independent, Repeatable, Self-validating, Timely)	Ch 6 §8
Classes	Small by responsibility; cohesive; open for extension; depend on abstractions	Ch 6 §9
Systems	Build objects in one place (composition root) and inject them; cross-cutting concerns in proxies/aspects	Ch 6 §10
Simple design	Beck: passes the tests → reveals intention → no duplication → fewest elements (*Clean Code* swaps the middle two)	Ch 6 §11
Concurrency	Separate concurrency code; share as little as possible; use the library; keep locks small; plan shutdown	Ch 6 §12
Smells	The C/E/F/G/J/N/T heuristics catalogue as a review vocabulary	Ch 6 §14
Code review	Correctness → design → readability → tests → security → performance → operability; automate style; small PRs (pull requests: proposed changes sent for review)	Ch 6 §15
Error strategy	Classify, translate at boundaries, retry only transient + idempotent (safe to repeat) with backoff (waiting longer between attempts), one global handler that logs once	Ch 6 §16
Testing strategy	Many unit, some integration, few E2E (end-to-end, whole-system); right test double (a stand-in such as a mock or fake); verify state over interactions; don't mock what you don't own	Ch 6 §17

Boy Scout Rule: leave the code a little cleaner than you found it (Ch 6 intro).

22.6 Code smells → refactorings (all 24)

Source: Chapter 7 (§7.2 smells, §7.3 catalogue, §7.4 lookup table). ***Bold*** *= the usual first move.*

#	Smell	Signal (one line)	Group	Refactorings that cure it
1	Mysterious Name (§7.2.1)	Name doesn't say what it does/holds (`data`, `proc()`, `Manager`)	2nd-ed extra	**Change Function Declaration**, Rename Variable, Rename Field
2	Duplicated Code (§7.2.2)	Same structure in more than one place	Dispensables	**Extract Function**, Slide Statements, Pull Up Method
3	Long Function (§7.2.3)	You want a comment to explain a block	Bloaters	**Extract Function**, Replace Temp with Query, Introduce Parameter Object, Preserve Whole Object, Replace Function with Command, Decompose Conditional, Replace Conditional with Polymorphism, Split Loop
4	Long Parameter List (§7.2.4)	Many parameters, same types, boolean flags	Bloaters	Replace Parameter with Query, **Preserve Whole Object**, **Introduce Parameter Object**, Remove Flag Argument, Combine Functions into Class
5	Global Data (§7.2.5)	Readable and writable from anywhere (incl. mutable singletons)	2nd-ed extra	**Encapsulate Variable** (then shrink its scope)
6	Mutable Data (§7.2.6)	Shared data changed after creation	2nd-ed extra	**Encapsulate Variable**, Split Variable, Slide Statements, Extract Function, Separate Query from Modifier, Remove Setting Method, Replace Derived Variable with Query, Combine Functions into Class/Transform, Change Reference to Value
7	Divergent Change (§7.2.7)	One class changed for many different reasons (SRP)	Change Preventers	**Split Phase**, Move Function, Extract Function, **Extract Class**
8	Shotgun Surgery (§7.2.8)	One change forces many small edits in many classes	Change Preventers	**Move Function**, **Move Field**, Combine Functions into Class/Transform, Split Phase, Inline Function, Inline Class
9	Feature Envy (§7.2.9)	Method uses another class's data more than its own	Couplers	**Move Function**, Extract Function
10	Data Clumps (§7.2.10)	Same group of values always travel together (`startDate, endDate`)	Bloaters	**Extract Class**, **Introduce Parameter Object**, Preserve Whole Object
11	Primitive Obsession (§7.2.11)	Money as `double`, status as `String`	Bloaters	**Replace Primitive with Object**, Replace Type Code with Subclasses, Replace Conditional with Polymorphism, Extract Class, Introduce Parameter Object
12	Repeated Switches (§7.2.12)	The *same* switch on a type code in several places	OO Abusers	**Replace Conditional with Polymorphism**
13	Loops (§7.2.13)	Classic loop that filters/maps/aggregates	2nd-ed extra	**Replace Loop with Pipeline**
14	Lazy Element (§7.2.14)	A class/function that doesn't pull its weight	Dispensables	**Inline Function**, **Inline Class**, Collapse Hierarchy
15	Speculative Generality (§7.2.15)	Hooks "we might need someday"; abstract class with one subclass	Dispensables	Collapse Hierarchy, Inline Function, Inline Class, Change Function Declaration, Remove Dead Code

#	Smell	Signal (one line)	Group	Refactorings that cure it
16	Temporary Field (§7.2.16)	Field set only in some situations, `null` otherwise	OO Abusers	**Extract Class**, Move Function, Introduce Special Case
17	Message Chains (§7.2.17)	`order.getCustomer().getAddress().getCity()`	Couplers	**Hide Delegate**, Extract Function, Move Function
18	Middle Man (§7.2.18)	Most methods just forward to another class	Couplers	**Remove Middle Man**, Inline Function, Replace Superclass/Subclass with Delegate
19	Insider Trading (§7.2.19)	Two modules poke at each other's internals	Couplers	**Move Function**, **Move Field**, Hide Delegate, Replace Subclass/Superclass with Delegate
20	Large Class (§7.2.20)	Too many fields/methods — a God Class	Bloaters	**Extract Class**, Extract Superclass, Replace Type Code with Subclasses
21	Alternative Classes with Different Interfaces (§7.2.21)	Same job, different method names (`sendMail` vs `dispatch`)	OO Abusers	**Change Function Declaration**, Move Function, Extract Superclass
22	Data Class (§7.2.22)	Only fields and getters/setters; others manipulate it	Dispensables	**Encapsulate Record**, Remove Setting Method, Move Function, Extract Function, Split Phase
23	Refused Bequest (§7.2.23)	Subclass doesn't want inherited methods, or throws on them (LSP)	OO Abusers	Push Down Method/Field, **Replace Subclass with Delegate**, **Replace Superclass with Delegate**
24	Comments (§7.2.24)	Comment used as deodorant for unclear code	Dispensables	**Extract Function**, Change Function Declaration, Introduce Assertion

Smell family → principle violated (§7.4)

Smell family	Principle
Divergent Change, Large Class	SRP
Repeated Switches, Shotgun Surgery	OCP
Refused Bequest	LSP
Long Parameter List with flags, fat interfaces	ISP / clean function design
Global Data, Mutable Data	Encapsulation
Hard-wired `new` of concrete dependencies	DIP
Duplicated Code	DRY
Speculative Generality	YAGNI
Message Chains, Insider Trading	Law of Demeter
Feature Envy, Data Class	Tell, Don't Ask

Refactoring toward patterns (§7.6)

Smell	Refactor toward
Switch/if-chain choosing an algorithm	Strategy
Methods that check and change a status field	State
`if (x == null)` at many call sites	Null Object / Special Case
Sibling subclasses with the same skeleton	Template Method
Many confusing constructors	Factory Method / creation methods
Complex object built by many ordered calls	Builder
Undo/queueing needed; huge function with shared locals	Command
Logging/caching mixed into a core class	Decorator
Objects polling for changes; hard-coded notification	Observer
Two classes, same job, different interfaces	Adapter
Subclass explosion from feature combinations	Strategy / Decorator / Bridge
A pattern that no longer earns its keep	Remove it (Inline Class, Collapse Hierarchy)

Refactoring = changing structure without changing behaviour, in small steps, with tests as the safety net. Wear one of **two hats** at a time: adding function or refactoring (§7.1.1).

22.7 Design patterns: all 23 GoF + extras

Source: Chapters 8–11. Catalogue in §8.3; comparisons in §8.15, §9.8, §10.7, §11.6, §11.8.

Count: 5 creational + 7 structural + 11 behavioral = **23**. **Class-scoped** (inheritance) patterns: Factory Method, class Adapter, Template Method, Interpreter; almost everything else is object-scoped (composition) (§8.3).

Creational (Chapter 8)

Pattern	Intent (one line)	Use when	Java / JDK example	Commonly confused with	Where
Singleton	Exactly one instance with a global access point	There really must be exactly one (config, pool, registry)	`Runtime.getRuntime()`; Spring (a popular Java framework) singleton-scoped beans	A global variable; a DI singleton scope (preferred for testing)	§8.8
Factory Method	Subclasses decide which concrete class to create via an overridable method	Shared procedure, varying product; others will add types	`Collection.iterator()`	Simple Factory (one method with a switch)	§8.10
Abstract Factory	Create *families* of related objects without naming concrete classes	Products must match; swap a whole set at once	`DocumentBuilderFactory`; JDBC (Java's database API) `Connection`	Factory Method (one product by inheritance vs a family by composition)	§8.11
Builder	Build a complex object step by step; one validating `build()`	Many optional fields, cross-field validation, immutable result	`StringBuilder`, `HttpClient.newBuilder()`	A plain constructor (fine for a handful of required fields); telescoping constructors	§8.12
Prototype	Create new objects by copying a configured instance	Setup is expensive, or only the interface is known	Copy constructors, `ArrayList.clone()`	Memento (a snapshot to restore, not a copy to use)	§8.13

Singleton notes (§8.8, §8.17): eager, holder-class or `enum` (most robust: blocks duplicates made through reflection, i.e. code calling private constructors by name, or through serialization, i.e. saving to bytes and reading back); double-checked locking needs a `volatile` field. It is global state that hurts testing — prefer injecting one shared instance. Many case studies reject it (Ch 14 self-check).

Structural (Chapter 9)

Pattern	Intent (one line)	Use when	Java / JDK example	Commonly confused with	Where
Adapter	Convert one interface into another that clients expect	"The vendor API doesn't match ours" (after the fact)	`Arrays.asList`, `InputStreamReader`	Bridge (same shape, but Bridge is designed up front); Facade	§9.1
Bridge	Split abstraction from implementation so both vary independently	Class names with two nouns; two dimensions multiplying classes	JDBC `Connection` + drivers	Adapter; Strategy (same shape)	§9.2
Composite	Treat single objects and trees uniformly	Part-whole trees (files, menus, UI)	`java.awt.Container` is a `Component` holding `Component`s	Decorator (also wraps a component, but adds behaviour to one)	§9.3
Decorator	Add responsibilities dynamically by wrapping; same interface, stackable	"Sometimes logging, sometimes caching, sometimes both"	`BufferedInputStream`, `Collections.synchronizedList`	Proxy (same shape; Proxy *controls access*); Chain of Responsibility (in CoR someone can stop the flow)	§9.4
Facade	One simple entry point to a complex subsystem	Every caller repeats the same multi-step sequence	SLF4J (a logging facade library) `LoggerFactory`, service layers	Adapter (converts one object's interface); Mediator	§9.5
Flyweight	Share intrinsic (immutable) state across huge numbers of objects	Millions of near-identical objects	`Integer.valueOf`, `String.intern()`	Object Pool (reuses objects one borrower at a time; flyweights are shared at once)	§9.6
Proxy	A stand-in that controls access (lazy, remote, protective, caching)	It's expensive, remote or restricted	`java.lang.reflect.Proxy`, Spring `@Transactional`, Hibernate (maps objects to database tables) lazy load	Decorator	§9.7

Memory hooks (§9.8): Adapter *make it fit* · Decorator *add to it* · Proxy *guard it* · Facade *simplify it* · Bridge *split it* · Composite *nest it* · Flyweight *share it*.

Behavioral (Chapters 10–11)

Pattern	Intent (one line)	Use when	Java / JDK example	Commonly confused with	Where
Chain of Responsibility	Pass a request along handlers until one handles (or stops) it	Several checks, any may reject; handler not known in advance	Servlet `Filter` chain; `java.util.logging` handlers	Decorator (every layer always runs)	§10.1
Command	Turn a request into an object: queue, log, retry, undo	Undo/redo, job queues, scheduling	`Runnable` / `Callable`; Swing `UndoManager`	Strategy (Strategy = *how*; Command = *what*)	§10.2
Iterator	Traverse a collection without exposing how it is stored	Walk a collection/tree/paged API	`Iterator`, `Spliterator`, JDBC `ResultSet`	Visitor (what to do at each node)	§10.3
Mediator	Centralise communication between peers in one coordinator	Many objects interact in tangled ways; order of reactions matters	Chat servers, UI controllers; `Executor` / `Timer` are a loose fit (§10.4)	Observer (broadcast, no coordination); Facade	§10.4
Memento	Capture and restore state without breaking encapsulation	Undo, checkpoints, rollback	A `record` snapshot; DB `ROLLBACK`, Git commits (real-world)	Command undo (store actions, not states); Prototype	§10.5
Interpreter	One class per grammar rule; evaluate sentences of a small language	User-written rules/expressions	`java.util.regex.Pattern`, SpEL (Spring's expression language)	Composite (same tree); Visitor (many operations over the AST, the abstract syntax tree a parser builds)	§10.6
Observer	Notify many dependents automatically when one object changes	An open-ended set of independent listeners	`PropertyChangeListener`, `java.util.concurrent.Flow`, Spring `@EventListener`	Mediator; pub-sub (Observer through a broker, §20.6)	§11.1
State	Behaviour changes with internal state, as if the class changed	Many states/transitions; methods repeat a `switch` on status	TCP connection (GoF's example), order lifecycles. `Thread.State` is only an enum of states, not the pattern	Strategy (same diagram; states know each other and advance themselves)	§11.2
Strategy	Make a family of algorithms interchangeable behind one interface	Several ways to do one job, chosen at run time	`Comparator`; `RejectedExecutionHandler` policies	State; Template Method; Decorator (Strategy *replaces* a rule, Decorator *wraps* one)	§11.3

Pattern	Intent (one line)	Use when	Java / JDK example	Commonly confused with	Where
Template Method	Fixed algorithm skeleton in a base class; subclasses fill in steps	Long fixed flow, a few varying steps	`AbstractList`, `InputStream.read(byte[],…)`, `HttpServlet.service()`	Strategy (Template = inheritance, one step varies; Strategy = composition, whole algorithm varies)	§11.4
Visitor	Add operations to a stable set of classes without changing them (double dispatch)	Many new operations over a fixed type set (ASTs)	`javax.lang.model.element.ElementVisitor`; `FileVisitor` is named after it but is really a tree-walk callback	Iterator; in Java 21, **sealed types + pattern-matching `switch`** usually replace it	§11.5

Beyond GoF: extras you will meet

Pattern	Intent (one line)	Use when	Java / real example	Commonly confused with	Where
Simple Factory (idiom)	One `create(type)` method maps a type value to a class	Small, stable set of types chosen by config	`Calendar.getInstance()`, `EnumSet.noneOf`	Factory Method	§8.9
Object Pool	Borrow and return a bounded set of expensive objects	DB connections, limited resources	HikariCP (a database connection pool), `ThreadPoolExecutor`	Flyweight	§8.14
Null Object	A do-nothing implementation instead of `null`	`null` checks everywhere for an optional collaborator	`Collections.emptyList()`, `OutputStream.nullOutputStream()`	`Optional` (for lookups)	§11.7.1
Dependency Injection	Receive collaborators (as interfaces) through the constructor	Classes create their own collaborators; hard to test	Spring constructor injection; a hand-wired `main`	Service Locator (anti-pattern: the class asks for its dependencies)	§11.7.2
Repository	Collection-like interface over storage	Business logic mixed with storage code	Spring Data `CrudRepository`	DAO (table-oriented)	§11.7.3
Specification	A named, combinable business rule (`isSatisfiedBy`, and/or/not)	Same rule in queries and validation; finder-method explosion	`Predicate`; Spring Data JPA `Specification`	—	§11.7.4
MVC	Separate model, view and controller (Observer + Strategy + Composite)	UI, input handling and rules tangled	Spring MVC; Swing `JTable` + `TableModel`	MVP, MVVM (relatives)	§11.7.5
Event Sourcing (lite)	Store the events; derive current state by replaying them	Full history, audit, time travel	Append-only logs	Plain audit log	§11.7.6

"Which pattern?" by problem symptom

Combined from §8.5, §8.15, §9.8, §11.8 and §7.6.

If you see / need…	Use	Not to be confused with
One operation, several interchangeable rules chosen at run time (pricing, matching, routing)	**Strategy**	State, Template Method
The class to create depends on a type value; caller shouldn't know the concrete class	**Factory** (Simple Factory / Factory Method)	Abstract Factory
Products must always match as a family	**Abstract Factory**	Factory Method
Constructor has ~6+ arguments, many optional	**Builder**	—
Another one of *this*, cheaply or without knowing its class	**Prototype**	Memento
Exactly one instance must exist	**Singleton** (or DI singleton scope)	A convenient global handle
Expensive objects created and destroyed repeatedly	**Object Pool**	Flyweight
Existing class has the wrong interface	**Adapter**	Facade, Bridge
Two dimensions multiplying classes (`WindowsButton`, `MacButton`, …)	**Bridge**	Adapter
Tree of part-whole objects treated the same	**Composite**	Decorator
Add behaviour in combinations without editing the class	**Decorator**	Proxy
Every caller repeats the same five steps into a subsystem	**Facade**	Mediator
Millions of near-identical objects	**Flyweight**	Object Pool
Lazy load, access control, remote, caching (same interface)	**Proxy**	Decorator
A request must pass several checks; any may reject it	**Chain of Responsibility**	Decorator (all layers run)
Undo/redo, queue, schedule, retry or log *requested actions*	**Command**	Strategy
Evaluate user-written rules in a small language	**Interpreter** (+ Specification)	Visitor
Walk a collection/tree/paged API without exposing structure	**Iterator**	Visitor
Many objects depend on each other and the **order** of reactions matters	**Mediator**	Observer
Roll back to an earlier state without exposing internals	**Memento**	Command undo
One change must reach an open-ended set of listeners	**Observer** (or a broker)	Mediator
Three or more methods repeat one `switch` over a status; legal actions depend on it	**State** (or enum + guarded method for 3–4 states)	Strategy
Several classes share a long fixed flow, differ in a few steps	**Template Method**	Strategy
Many new operations over a stable set of types	**Visitor**, or sealed types + pattern matching	Iterator
`null` checks everywhere	**Null Object** / `Optional`	—
Classes create their own collaborators	**Dependency Injection**	Service Locator
Business logic mixed with storage	**Repository**	DAO
Same rule duplicated in queries and validation	**Specification**	—

Three questions for the famous look-alikes (§11.8):

1. Do the alternatives reference each other? Yes → **State**. No → **Strategy** (or Bridge if chosen once at wiring).
2. Can one participant stop the flow? Yes → **Chain of Responsibility**. Everyone always runs → **Decorator**. Everyone is told, nobody stops anyone → **Observer**.

3. Does a central object decide what happens next? Yes → **Mediator**. Each listener decides for itself → **Observer**.

The six that come up in almost every round (§1.9, §8.5)

Pattern	Signal	Do not use when
Strategy	One operation, several swappable rules	Only one rule exists and nothing hints at a second
Factory	Creation depends on a type value	Only one concrete class exists
Observer	Several listeners the source should not know	A single listener the source already references
State	Behaviour depends on status; many transitions	3–4 states handled by one guarded method
Singleton	Genuinely exactly one	You just want a global handle
Builder	Many optional fields; long constructor	A handful of required fields

Common mistakes (§8.6)

Anti-pattern	Fix
God Object (one class does everything)	Split by responsibility; push behaviour to the data owners
Golden Hammer (favourite pattern everywhere)	Start from the problem's signal
Pattern overuse ("patternitis") — factories for one class, single-implementation interfaces	YAGNI: add the pattern when the second variant arrives
Singletonitis (singletons as globals)	Dependency injection
Cargo-cult patterns (structure without intent)	Name the property the pattern gives you, or drop it

In the interview

Use **one or two** patterns in a 45-minute design, placed where their signal appears, and **name one you rejected** and why (§8.5, §8.16).

22.8 Concurrency cheat sheet

Source: Chapter 12 (concepts) and Chapter 13 (classic problems).

TL;DR (§12.28)

Races come from **shared mutable state**. Make the critical section atomic, or remove sharing/mutability. Visibility needs **happens-before** edges. Prevent deadlock with **lock ordering** or **tryLock + back-off**. In LLD: name the contended resource, keep **check + claim atomic**, lock fine-grained and in order, and say what changes with many servers.

Primitive | use for | gotcha

Primitive	Use for	Gotcha	Where
`synchronized`	Making a multi-step update atomic (mutex + visibility)	Don't lock on a changing reference, a boxed value or a string literal; no slow I/O while holding it; readers must use the same lock	§12.7
`ReentrantLock`	Same as `synchronized` plus try/timed/fair locking and `Condition`s	Call `lock()` **just before** `try`, `unlock()` in `finally`; fairness is noticeably slower	§12.8
`tryLock(timeout)`	Give up if the lock is busy; deadlock prevention with back-off	Never `unlock()` when `tryLock` returned `false`; don't retry in a tight loop (livelock)	§12.9
`ReentrantReadWriteLock`	Many readers, few writers	Cannot upgrade read → write (self-deadlock); don't modify under the read lock; writer starvation in non-fair mode	§12.10
`StampedLock`	Read-mostly data with optimistic reads	**Not reentrant**; `validate` the stamp before using values read optimistically	§12.10
`volatile`	Visibility of a flag or a published immutable snapshot	Gives visibility, **not** atomicity: `count++` is still a race	§12.6
`AtomicInteger` / `AtomicLong` / CAS	Lock-free counters and single-variable claims	Separate `get()` then `set()` is still a race — use `compareAndSet` / `updateAndGet`; no side effects in the lambda (may run several times); ABA → `AtomicStampedReference`	§12.15
`LongAdder`	Very hot counters (metrics)	Use instead of `AtomicLong` when contention is high	§12.15
`Semaphore(N)`	Limit concurrent access to N; signalling between threads	Release in `finally`; don't release when `acquire` never succeeded	§12.12
`wait/notifyAll`, `Condition`	Waiting for a condition on shared state	Always `while`, never `if` (spurious wakeups); hold the monitor; `notify()` can wake the wrong thread; state change without notify = lost wakeup	§12.13
`CountDownLatch`	Wait for N events once	One-shot; `countDown()` in `finally`, `await(timeout)`	§12.14
`CyclicBarrier` / `Phaser`	N threads meet at each phase (reusable)	Fewer threads than parties → everyone waits forever	§12.14
`ConcurrentHashMap`	Shared map	`containsKey` then `put` is a race — use `putIfAbsent` / `computeIfAbsent` / `merge`; no slow work or recursive updates inside `compute`; no `null` keys/values	§12.16
`CopyOnWriteArrayList`	Read-mostly lists (listener lists)	Every write copies the array	§12.16
`BlockingQueue` (bounded)	Handing work between threads (producer–consumer)	Unbounded queue → no back-pressure → memory blow-up; one poison pill per consumer	§12.22
`ExecutorService` / `ThreadPoolExecutor`	Running tasks on a bounded pool	Call `shutdown()`; `newFixedThreadPool` has an **unbounded** queue; exceptions in `submit`ted tasks are lost unless you call `get()`; tasks waiting on tasks in the same pool → thread-starvation deadlock	§12.4, §12.21
Virtual threads	Many blocking I/O tasks	Pinning (Java 21–23: blocking inside `synchronized`); heavy `ThreadLocal`s waste memory	§12.4, §12.24

Primitive	Use for	Gotcha	Where
`ForkJoinPool` / parallel streams	Splitting CPU work	Use a threshold: tiny tasks cost more to schedule than to run; subtasks must touch disjoint data	§12.26, §13.10
`CompletableFuture`	Combining async results (`thenApply`, `thenCombine`, `allOf`)	Handle errors with `exceptionally` rather than calling `get()` at every step	§12.4
`ThreadLocal`	Per-thread state (thread confinement)	Clear it (`remove()`) in pooled threads, or values leak into the next task	§12.24
Immutability / confinement	Avoiding synchronization entirely	`final List` is not immutable if the list is mutable and exposed	§12.24

Which `java.util.concurrent` class for which job (§12.26)

I need to…	Use
Increment a shared counter	`AtomicInteger` / `AtomicLong`; `LongAdder` if very hot
Stop a loop from another thread	`volatile boolean` flag or `interrupt()`
Make a multi-step update atomic	`synchronized` or `ReentrantLock`
Give up if the lock is busy	`tryLock(timeout)`
Many readers, few writers	`ReentrantReadWriteLock`, `StampedLock`, or an immutable snapshot in a `volatile` field
Limit concurrent access to N	`Semaphore(N)`
Wait for a condition on shared state	`Lock` + `Condition` (or `wait/notifyAll`) in a `while` loop
Wait for N events once	`CountDownLatch`
N threads meet each phase	`CyclicBarrier` / `Phaser`
Hand work between threads	Bounded `BlockingQueue`
Shared map	`ConcurrentHashMap` with `putIfAbsent` / `compute` / `merge`
Read-mostly list	`CopyOnWriteArrayList`
Run tasks	`ExecutorService` (bounded); virtual threads for blocking I/O
Split CPU work	`ForkJoinPool` / parallel streams
Combine async results	`CompletableFuture`
Avoid synchronization entirely	Immutability, thread confinement

Deadlock checklist (§12.17–§12.19)

A deadlock needs **all four Coffman conditions**; break any one and it cannot happen.

#	Condition	How to break it
1	Mutual exclusion	Lock-free/immutable data, shareable resources (read locks)
2	Hold and wait	Acquire everything at once, or `tryLock` and release everything on failure
3	No preemption	Timeouts (`tryLock(timeout)`), leases that expire
4	Circular wait	**Global lock ordering** (always lock the lower id first)

- [ ] Do I ever hold two locks? If yes, is there **one global order** (account id, seat id), with a tie-breaker for equal keys?

- [ ] Do I call a **listener, callback or another object's synchronized method while holding my lock**? Move it outside the lock.
- [ ] Do tasks in a bounded pool **wait for other tasks in the same pool**? (thread-starvation deadlock)
- [ ] Are retries randomised (**jitter**) so two threads don't back off in lockstep? (livelock, §12.18)
- [ ] Could one thread wait forever while others progress? Consider fairness (§12.19).
- [ ] Detection: a thread dump (`jstack` / `jcmd`) prints "Found one Java-level deadlock"; `ThreadMXBean.findDeadlockedThreads()`.

Deadlock vs livelock vs starvation: nobody progresses and all wait / everybody runs but nobody progresses / some progress while one never does (§12.27).

The LLD concurrency recipe (§12.25)

1. **Name the shared mutable state** (free spots, seat → owner, stock).
2. **State the invariant** ("a seat has at most one booking", "stock ≥ 0").
3. **Find the critical operation** — usually a check-then-act (*find free → assign*).
4. **Pick the smallest tool that makes it atomic:** one item → `queue.poll()`, `putIfAbsent`, `compareAndSet`; several items all-or-nothing → per-item locks **in sorted order**; across servers → DB constraints/transactions, optimistic versioning, or a distributed lock.
5. **Choose granularity:** per floor / show / SKU, not one global lock.
6. **Handle time:** holds with expiry, timeouts, idempotent retries.

Classic problems (§13.12)

Problem	Key primitive	Invariant to state
FooBar (§13.1)	2 semaphores	Exactly one permit exists across both
Zero Even Odd (§13.2)	3 semaphores	Zero dispatches; one permit circulates
FizzBuzz (§13.3)	monitor + `notifyAll`	Predicates partition 1..n
H2O (§13.4)	2 semaphores + barrier	≤ 2 H and ≤ 1 O per round
Dining Philosophers (§13.5)	ordered locks / n−1 semaphore	No circular wait
TTL (time to live) cache (§13.6)	`ConcurrentHashMap` + `compute` + conditional remove	Never return or keep expired data
Striped map (§13.7)	lock array	Each bucket belongs to exactly one stripe
Blocking queue (§13.8)	lock + 2 conditions	0 ≤ count ≤ capacity; wait in loops
Bloom filter (§13.9)	atomic OR	Bits only go 0 → 1; no false negatives
Merge sort (§13.10)	Fork/Join	Subtasks touch disjoint ranges
Token-bucket rate limiter (§13.11)	lock or CAS on immutable state	Refill + take is one atomic step

Common mistakes (§12.25 and throughout Chapter 12)

- A global `synchronized` on `ParkingLot.park()` — correct, but serialises every gate.
- Checking availability with one call and booking with another (check-then-act).
- Locking seats in the order the user clicked them (deadlock between two multi-seat bookings).
- Forgetting that in-memory locks don't work across multiple app servers.
- Swallowing `InterruptedException` — rethrow, or restore the flag with `Thread.currentThread().interrupt()` (§12.3).
- Calling `run()` instead of `start()` (§12.3).

22.9 Case-study map

Source: Chapters 14–21. "Concurrency concern" is the race each chapter guards against, and "atomic step" is how.

Everyday objects (Chapter 14)

Problem	Key entities	Patterns used	Concurrency concern	Where
Parking lot	`ParkingLot`, `ParkingFloor`, `ParkingSpot`, `Vehicle`, `Ticket`, `DisplayBoard`, `SpotType`/`VehicleType` enums	Strategy (pricing, spot-finding), Factory (electric spots), Observer (boards); Singleton rejected	Two gates take one spot → atomic `pollFirst` + CAS; per-ticket lock for payment; `putIfAbsent` for plates	§14.1
Vending machine	`VendingMachine`, `Slot`, `Inventory`, `CashBox`, `Denomination`, `VendingState` + 5 states	**State** (the whole design)	`synchronized` machine; change-making by bounded coin-change DP (dynamic programming: build the answer from smaller amounts), not greedy (always take the biggest coin)	§14.2
Coffee machine	`CoffeeMachine`, `Recipe`, `RecipeBook`, `IngredientStore`, `OrderResult` (sealed)	Observer (low stock), recipes as data	Two orders take the last milk → one `ReentrantLock` around check + deduct; notify outside the lock	§14.3
ATM	`Atm`, `AtmState` + 4 states, `Transaction` (sealed), `NoteHandler`, `CashDispenser`, `BankService`, `Account`	State (session), Command (transactions), Chain of Responsibility (note cassettes)	Overdraw from two ATMs → per-account lock; transfers lock in id order	§14.4
Elevator	`Elevator`, `StopList` (two sorted sets), `Door`, `Dispatcher`, `DispatchStrategy`, `Building`	Strategy (dispatch) + modes; LOOK scheduling	Per-car lock, synchronized dispatcher; tick-driven `step()`	§14.5
Traffic signal	`Intersection`, `TrafficLight`, `Phase`, `SignalState` + 5 states, `TimingPolicy`, `SafetyMonitor`	State (timed), Strategy (timing), Observer (lights)	Synchronized tick; safe with a timer thread plus emergency threads	§14.6
Shipping locker	`LockerStation`, `Compartment`, `Booking`, `CompartmentSelector`, `PickupResult` (sealed), `LockerListener`, `LockerNetwork`	Strategy (door choice), Observer (SMS text messages), enum state machines, sealed results	Two carriers, one door → station lock around choose-and-mark; lazy expiry of holds and pickup windows; hashed single-use codes, keypad lockout	§14.7

Booking & inventory (Chapters 15–16)

Problem	Key entities	Patterns used	Concurrency concern	Where
Library	`Book` (title) vs `BookItem` (copy), `Member`, `BookLending`, `LendingService`, `Catalog`	Strategy (fines), notifier interface; FIFO (first in, first out) reservation queue per title	Last copy lent twice → lock member then copy (fixed order)	§15.1
Movie tickets (BookMyShow)	`Show`, `ShowSeat`, `Booking`, `SeatLockProvider`, `BookingService`, `CancellationPolicy`	Strategy (refund rule), gateway behind an interface	Book `ShowSeat`s; all-or-nothing hold with TTL → pay → atomic commit; refund if hold lost	§15.2
Concert tickets	`SeatedInventory`, `GaPool`, `SeatState` (sealed), `Hold`, `VirtualWaitingRoom`, `PurchaseLimiter`	Sealed seat states, waitlist	Extreme contention → CAS per seat, CAS counter for GA (general admission, unseated), FIFO waiting room, per-user limits, TTL holds with a reaper	§15.3
Hotel	`Hotel`, `Room`, `RoomBooking`, `Invoice`, `RoomCharge`, `Payment` subclasses, `FrontDesk`	Template Method (`RoomCharge`)	Room × night reserved atomically in `synchronized Room.tryReserve`	§15.4
Car rental	`Vehicle`, `DateRange`, `Reservation`, `Bill`/`BillItem`, `ReservationAddOn`, `PricingStrategy`	Template Method (add-ons), Strategy + Decorator (pricing), state machine	Availability is about **dates** → `Vehicle.tryBook(range)` synchronized	Ch 16 · Car Rental
Restaurant	`Menu`/`MenuSection`/`MenuItem`, `Table`, `Reservation`, `Order`, `Meal`/`MealItem`, `Kitchen`, `Check`	Observer (order ready), Strategy (chef assignment, payment), state machine	Two receptionists, one table → `Table.tryHold(time)` synchronized; listeners after the lock	Ch 16 · Restaurant
Airline	`Flight` vs `FlightInstance`, `Seat` vs `FlightSeat`, `FlightReservation`, `Itinerary`, `FareStrategy`	Strategy + Decorator (fares), Facade	Selling one seat twice → `FlightInstance.holdSeats` all-or-nothing under the instance lock	Ch 16 · Airline
Course registration	`Course` vs `Section`, `Student`, `RegistrationRule`s, `Registrar`	Chain of rules / Specification	Overselling a section → section lock inside a student lock (fixed order)	Ch 16 · Course Registration

Games (Chapter 17)

Problem	Key entities	Patterns used	Concurrency concern	Where
Blackjack + deck	`Card`, `Deck<T>`, `Shoe`, `Hand`, `BlackjackScoring`, `PlayerStrategy`, `DealerPolicy`	Strategy (player, dealer); injected randomness	One table = one thread; shared balances need an atomic wallet service	Ch 17 · Blackjack
Chess	`Piece` (sealed) + subclasses, `SlidingPiece`, `Board`, `Move`, `Rules`, `Game`	Polymorphic pieces, Factory Method, Command + Memento (undo)	`synchronized` game so a move and a resignation don't interleave	Ch 17 · Chess
Tic-tac-toe	`Board` (row/col/diagonal counters), `Game`, `Player`, `MoveStrategy`	Strategy (players)	Many games in a `ConcurrentHashMap`; per-game lock	Ch 17 · Tic-Tac-Toe
Snake & ladder	`Board`, `Jump`, `Dice`, `Rules`, `OverflowRule`, `WinStrategy`, `Game`	Strategy (dice, overflow, win)	Each game its own `Random` and its own thread of turns	Ch 17 · Snake and Ladder
2048	`LineMerger`, `Board`, `TileSpawner`, `Game`, `Direction`	Strategy (spawner); one pure merge function	Single-threaded; `synchronized move` if UI and input threads both call it	Ch 17 · 2048

Platforms (Chapters 18–19)

Problem	Key entities	Patterns used	Concurrency concern	Where
Stack Overflow	`Post` (sealed) → `Question` / `Answer` / `Comment`, `Member`, `Tag`, `Bounty`, `QuestionIndex`	Strategy (reputation), Observer (badges), Facade; inverted index	Two votes at once → `synchronized` post; `AtomicInteger` reputation	§18.1
Cricinfo	`Match` → `Innings` → `Over` → `Ball`, `Team`, `Playing11`, `StatQuery`	Template Method (stat queries), Observer (live pages)	Two scorers → `synchronized` match; observers in `CopyOnWriteArrayList`	§18.2
LinkedIn	`Member`, `Profile`, `SocialContent`, `ConnectionInvitation`, `ConnectionService`, `SearchIndex`, `FeedService`	State (invitation), Strategy (feed ranking, notifications), Facade	Symmetric connections → all graph changes synchronized on the service	§18.3
Facebook	`Member`, `Audience` (sealed), `PrivacyList`, `FriendService`, `VisibilityService`, `NewsFeedService`	Strategy (feed ranker), Observer (notifications)	Accept can't leave a one-way friendship → synchronized service, concurrent adjacency sets	§18.4
Amazon	`Product`, `ShoppingCart`, `Order`, `OrderLog`, `Payment`, `Shipment`, `Customer` → `Guest` / `Member`	Strategy (payment), Observer (notifications), order state machine, Facade	Last unit, two buyers → `synchronized Product.reserve`; all-or-nothing multi-line reservation	Ch 19 · Amazon
Stock brokerage + exchange	`Order` → Market/Limit/StopLoss/StopLimit, `OrderPart`, `StockLot`, `OrderBook`, `MatchingEngine`	Observer (fills), Template Method (statements), trade-price policy	Over-spending → reserved funds; one lock per symbol; price-then-time matching	Ch 19 · Stock Brokerage
Auction	`AuctionListing`, `Bid`, `BidResult`, `AuctionService`, `AuctionListener`	Observer, Specification (search), status state machine	Concurrent bids → all bid rules in one per-listing critical section; notify after unlocking	Ch 19 · Auction
Music streaming (Spotify)	`Song` / `Album` / `Artist`, `MusicLibrary`, `Playlist`, `MusicPlayer`, `PlaybackOrder`, `Recommender`	Strategy (play order, recommendations), Observer (plays), plan rules in an enum	Two devices press "next" → `synchronized` player methods	Ch 19 · Music Streaming
Food delivery (Swiggy) + FoodKart	`Restaurant`, `Cart`, `Order`, `DeliveryAgent`, `DeliveryAssignmentStrategy`, `RestaurantSelectionStrategy`	Strategy (assignment, selection, payment), Observer, order state machine	Kitchen capacity reserved atomically; riders claimed with CAS	Ch 19 · Food Delivery
Grocery store (POS, point of sale)	`Register`, `Sale`, `LineItem`, `PricingEngine`, `ItemPromotion` / `BasketPromotion`, `TaxPolicy`, `Tender` (sealed), `Receipt`, `Inventory`	Strategy (offers, tax, payment gateway), Facade (register), Observer (stock), sale state machine	Registers share stock → atomic `merge`, may go negative, edge-triggered alerts; returns claimed with `compute`	Ch 19 · Grocery Store

Pattern-driven components (Chapter 20)

Problem	Key entities	Patterns used	Concurrency concern	Where
Splitwise	`Expense`, `SplitStrategy` (Equal/Exact/Percent), `Share`, `Ledger`, `DebtSimplifier`	Strategy (splits)	One signed number per pair, one mutator; `BigDecimal`, no lost cents	§20.1
Notification service	`NotificationChannel` (abstract), channels, `SendRule`, `ChannelFactory`, `DeliveryListener`	Template Method (channels), Strategy (send rules), Observer, Simple Factory, Adapter	Rate-limit check-then-act gap; idempotency	§20.2
In-memory cache / LRU	`Cache<K,V>`, `Node`, `DoublyLinkedList`, `EvictionPolicy`, `Cache.Builder`, `ShardedCache`	Strategy (eviction), Observer (removals), Builder	One lock (a `get` is a write in LRU); listeners outside the lock; shard to scale	§20.3
Ride sharing (Uber)	`Rider`, `Driver`, `Trip`, `MatchingStrategy`, `PricingStrategy`, `SurgePricing`	Strategy ×3, Decorator (surge), trip state machine	Double-booking a driver → atomic claim (`AtomicBoolean`)	§20.4
Logging framework	`Logger`, `LogManager`, `LogRecord`, `Appender`, `AsyncAppender`, `Formatter`	Chain of Responsibility (hierarchy), Singleton (`LogManager`), Strategy (formatters), Template Method (appender), Decorator (async)	Thread-safe sinks; never block on a full queue; never crash the app	§20.5
Pub-sub	`Broker`, `Topic`, `Subscription`, `Subscriber`, `Message`	Observer through a broker	One dispatcher per subscription; ack after processing (at-least-once) → idempotent subscribers	§20.6
Rate limiter	`Limiter` (TokenBucket, FixedWindow, SlidingWindowLog/Counter), `CompositeLimiter`, `LimiterFactory`	Strategy, Simple Factory, Composite, Facade	Atomic refill-check-take; one limiter per key via `computeIfAbsent`; Redis (a shared in-memory store) + Lua (a script Redis runs atomically) across servers	§20.7

Machine-coding problems (Chapter 21)

Problem	Key entities	Patterns used	Concurrency concern	Where
Task management	`Task`, `TaskStatus`, `TaskService`, `TaskRepository`, `TaskFilter`	Specification (filters), Strategy (sorts), Observer, enum state machine	Per-task `synchronized`	§21.1
Digital wallet	`Wallet`, `Transaction`, `Money`, `Offer`, `WalletService`	Strategy (offers), idempotency key	Lock both wallets in a global (id) order; debit before credit; total conserved	§21.2
Event calendar (Flipkart)	`TimeSlot` (half-open), `Event`, `EventStore`, `RepresentativeSelector`, `CalendarService`	Strategy (representative), plan-then-save	Atomic check-and-book	§21.3
Coding Blox (Flipkart)	`Contest`, `Level`, `User`, `Question`, `SolveSimulator`, `CommandProcessor`	Command map, Strategy (solver, scoring)	Atomic rating update; don't run a contest twice	§21.4
PropertyHunt (ClearTrip)	`Property`, `SearchCriteria` (+ Builder), `PropertyService`	Builder + predicate list, Strategy (sort)	Synchronized mark-sold	§21.5
Ledger Co (Navi)	`Loan`, `LumpSum`, `Balance`, `InterestPolicy`, `LedgerService`	Strategy (interest), derived state, command loop	Synchronized lump sums	§21.6
Inventory management	`Product`, `Warehouse`, `StockMovement`, `AllocationStrategy`, `ReorderListener`	Strategy (allocation), Observer (edge-triggered alerts)	Overselling → lock per SKU (stock-keeping unit: one product variant)	§21.7
Unix file search (`find`)	`Node` → `FileNode` / `DirectoryNode`, `FileFilter`, `AndFilter` / `OrFilter` / `NotFilter`, `SearchCriteria` (+ Builder), `FileSearcher`, `FindCommandParser`	Specification + Composite (filters and file tree), Builder, recursive-descent parser	Weakly consistent children map; read-only fork/join walk	§21.8

> **TL;DR — what every case study teaches**
>
> - **Name the real unit of inventory** (copy, show seat, room-night, vehicle-day) (Ch 15 summary).
> - **Every "if free then take" is one atomic step** — a monitor, a CAS, or a conditional `UPDATE` (Ch 15 summary).
> - **Put rules on the object that owns the data**; the service only orders the steps (Ch 16, Ch 20 summaries).
> - **Strategy** for the rule most likely to change; **Observer** for "tell someone when it happens"; **State** (or an enum state machine) for lifecycles.
> - **Inject** time and randomness; money in `BigDecimal` or integer cents; call listeners **outside** locks.

22.10 Machine-coding and edge-case checklists

Source: §21.0 (and §1.10).

Machine-coding checklist

Before coding (0–20 min)

- [ ] Read the statement twice; mark **mandatory vs bonus**; ask clarifying questions.
- [ ] Put the statement's sample input into the driver as a `List<String>` of commands.
- [ ] Ask: "Where does it need to be thread-safe?" (wallets and inventory: always yes).
- [ ] Nouns → entities, verbs → service methods. Pick the 1–2 patterns the statement begs for ("can be sorted by X or Y" → Strategy).

- [ ] Create the six packages: **model, repository, service, strategy, exception, driver**.

While coding (20–75 min)

- [ ] Implement mandatory requirements **in the statement's order**; run the driver after each one (at least every 15 minutes).
- [ ] Entities guard their own invariants (e.g. `Task.changeStatus` rejects `TODO → DONE`).
- [ ] Services return data and throw domain exceptions; **no `System.out` in services**.
- [ ] Repository = interface + `ConcurrentHashMap` implementation; IDs from an `AtomicInteger`.
- [ ] Driver = `Map<String, Consumer<String[]>>` command processor; catch domain exceptions per command, **print and continue**.

Before you stop (75–90 min)

- [ ] Edge cases and validation done (see below); custom exceptions with readable messages.
- [ ] Thread-safety where money or stock is shared; say where the lock is and why.
- [ ] Bonus only after every mandatory feature runs.
- [ ] Clean names, delete dead code, run everything once more, prepare a 2-minute walkthrough.

Rubric the interviewer uses (§21.0)

#	Criterion	How to score well
1	Working, demo-able code	Thin end-to-end path in the first hour; never finish with code that doesn't compile
2	Functional completeness	Mandatory first, in order
3	Clean models	Enums for fixed sets, records for values, classes for things that change
4	Separation of concerns	Driver → Service → Repository
5	Extensibility	New rule = new class (Strategy, Specification)
6	Edge cases & failure handling	Custom exceptions; the driver keeps going
7	Readability	Names from the statement's nouns and verbs
8	Concurrency (when asked)	Say where the lock is; demo with a thread pool if time allows
9	Tests (bonus)	A tiny `assert`-style self-check in `main` is enough

Edge-case checklist (§1.10, §21.0, case studies)

Category	Questions to ask your code
Input	`null`, empty, negative, zero, duplicate IDs, unknown IDs, invalid numbers
Ownership	Wrong user acting on someone else's object; a player moving out of turn
Capacity	Full lot, zero seats left, empty playlist, max loans reached, party larger than any table
State	Paying twice, exiting without entering, cancelling a delivered order, moving after game over, running a contest twice
Time	Exit before entry, holds/bookings expiring, part hours (round up?), an event exactly at the end instant (half-open intervals), late returns
Money	`BigDecimal` scale and rounding; no lost cents in splits; compare with `compareTo`, not `equals` (Ch 4 money note)
Concurrency	Two threads booking the same seat/spot/rider; multi-item bookings locking in sorted order; retries that must be idempotent
Failure	Payment declined after a hold; hold lost before payment → compensating refund; listener throws
Randomness	Seeded `Random` or a scripted strategy so the demo is repeatable

Common mistakes (§21.0)

Mistake	Instead
20 minutes on a perfect class diagram	Enums/records first; the diagram lives in names
One `Manager` with 15 maps	One service per area + repositories
`System.out.println` inside a service	Services return data; the driver prints
`double` for money	`BigDecimal` with a fixed scale, or whole units in a `long`
Crashing on the first bad command	Catch domain exceptions in the driver loop
Bonus before mandatory	Mandatory in order; bonus last
`Random` without a seed	Seed it, or put randomness behind a Strategy
`LocalDate.now()` in logic	Inject a `java.time.Clock`

22.11 Glossary

Alphabetical. "Where" gives the chapter (and section) where the term is explained in full. Besides the design vocabulary, the list covers the everyday Java, tooling and domain words the case studies use (`JVM`, `Redis`, `SKU`, `UPI` …), so a newcomer can look up anything a chapter takes for granted. System-design terms such as latency, throughput, caching, message brokers and eventual consistency are explained in more depth in System Design Fundamentals.

Term	Plain meaning	Where
ABA problem	A value changes A → B → A, so a compare-and-swap cannot notice the change; fix with a version stamp (`AtomicStampedReference`)	Ch 12 §12.15
Abstract class	A class that cannot be instantiated; may hold state, constructors, finished and abstract methods	Ch 2 §2.9
Abstract Factory	Creational pattern that creates families of matching objects without naming their classes	Ch 8 §8.11
Abstraction	Exposing only what callers need and hiding how it is done (interface or abstract class)	Ch 2 §2.4
Access modifiers	`public`, `protected`, package-private, `private`: who can see a member	Ch 2 §2.14
Activity diagram	UML flowchart of a process, with decisions, swimlanes and fork/join	Ch 3 §3.13
Actor	Someone or something that uses the system (customer, admin, the system itself)	Ch 1 §1.5
Adapter	Structural pattern that converts one interface into the one the client expects	Ch 9 §9.1
Aggregate (DDD)	A cluster of objects changed as one unit; only its root is reachable from outside, and the root guards the invariants	Ch 5 §17
Aggregation	"Has-a" where the part can outlive the whole; hollow diamond at the whole	Ch 3 §3.3
Anemic domain model	Classes with data but no behaviour; the logic lives in services that pull the data out	Ch 5 §5
Anti-corruption layer	Translation layer at a bounded context's border that keeps a foreign or legacy model out of yours	Ch 5 §17
Anti-pattern	A common "solution" that reliably causes more problems than it solves	Ch 8 §8.6
AOP (aspect-oriented programming)	Adding cross-cutting behaviour (logging, transactions) around many methods without editing them, usually via generated proxies	Ch 5 §11, Ch 9 §9.7
API	Application Programming Interface: the set of public methods (or endpoints) other code is allowed to call	Ch 2 §2.6, §2.14
Appender / formatter	Logging roles: an appender writes a log record somewhere (console, file); a formatter turns it into text	Ch 20 §20.5
Append-only log	Messages are only ever added at the end; readers track their own offset	Ch 20 §20.6
Assertion	A check in code or a test that a condition is true, failing loudly if it is not	Ch 6 §8
Association	A class keeps a reference to another it does not own; solid line	Ch 3 §3.2
Association class	A class that holds data about a link itself (e.g. `Enrollment{grade}`)	Ch 3 §3.11
AST (abstract syntax tree)	The tree a parser builds from an expression or program, one node per piece of grammar	Ch 10 §10.6
Asynchronous vs synchronous	The caller carries on and gets the result later vs the caller waits until the work finishes	Ch 3 §3.12, Ch 20 §20.5
At-least-once delivery	A message may be delivered more than once, never lost; consumers must be idempotent	Ch 20 §20.6
Atomic variable	`AtomicInteger` / `AtomicLong` / `AtomicReference`: lock-free single-variable updates using CAS	Ch 12 §12.15
Atomicity / atomic operation	An operation that happens completely or not at all, with no other thread able to see it half-done	Ch 12 §12.5

Term	Plain meaning	Where
Audit log	An append-only record of who did what and when, kept for checking later	Ch 10 §10.2, Ch 21
Authentication vs authorization	Proving who you are (login, PIN) vs checking what you are allowed to do	Ch 6 §10, Ch 14 §14.4
Back-pressure	Slowing producers when consumers can't keep up, e.g. with a bounded queue	Ch 12 §12.22
BFS / DFS	Breadth-first search (visit neighbours level by level) vs depth-first search (go deep down one path, then back up)	Ch 18 §18.3, Ch 21 §21.8
`BigDecimal`	Exact decimal type used for money; build from strings, compare with `compareTo`	Ch 1 §1.10, Ch 4 (money note)
Big-O notation	Shorthand for how running time or memory grows with input size: `O(1)` constant, `O(log n)`, `O(n)` linear	Ch 20 §20.3
Blocking call	A call that makes the thread wait (for I/O, a lock or a queue) before it can continue	Ch 12 §12.4
Bloom filter	Probabilistic set: may say "maybe present" wrongly, never says "absent" wrongly	Ch 13 §13.9
Boilerplate	Repetitive code that must be written but carries no real logic (getters, `equals`, `hashCode`)	Ch 2 §2.13
Bounded context	Boundary inside which one domain model and one vocabulary apply consistently (often one team or service)	Ch 5 §17
Bounded queue	A queue with a fixed capacity; producers wait or are refused when it is full	Ch 12 §12.22
Boy Scout Rule	Leave the code a little cleaner than you found it	Ch 6 (intro)
Bridge	Structural pattern splitting an abstraction from its implementation so both vary independently	Ch 9 §9.2
Broker	A middleman service that receives messages from publishers and delivers them to subscribers	Ch 20 §20.6
Build tool	A program (Maven, Gradle) that downloads dependencies, compiles, tests and packages the code	Ch 3 §3.5
Builder	Creational pattern that builds a complex object step by step, validated in `build()`	Ch 8 §8.12
Busy waiting (spinning)	A thread repeatedly checking a condition in a loop instead of sleeping; wastes CPU	Ch 12 §12.6
Bytecode	The compact instruction format `javac` produces and the JVM runs	Ch 12
Callback	A function you hand to other code so it can call you back when something happens	Ch 5 §10
Caretaker / Originator	Memento roles: the originator makes and restores snapshots; the caretaker stores them without looking inside	Ch 10 §10.5
Carrier thread	The real OS thread that a virtual thread runs on while it is not blocked	Ch 12 §12.4
CAS (compare-and-swap)	Atomic "set to new value only if it still equals the expected value"	Ch 12 §12.15
Chain of Responsibility	Behavioral pattern passing a request along handlers until one handles or stops it	Ch 10 §10.1
Characterisation test	A test that records what existing code does now, before you refactor it	Ch 7 §7.8
Checked vs unchecked exception	Checked exceptions must be declared or caught (compiler-enforced); unchecked ones (`RuntimeException` subclasses) need not be	Ch 2 §2.5, Ch 6 §6

Term	Plain meaning	Where
Check-then-act	Read a condition, then act on it, as two steps: a race unless made atomic	Ch 12 §12.5, §12.25
Circuit breaker	Stops calling a failing dependency for a while after repeated errors, then tries again carefully	Ch 5 §13
Circular wait	T1 waits for T2's lock while T2 waits for T1's; one of the four deadlock conditions	Ch 12 §12.17
Class	A blueprint for objects: fields plus methods	Ch 2 §2.2
Class diagram	UML diagram of classes, fields, methods and relationships — "the answer" in an LLD round	Ch 3 §3.11
Class explosion	Subclasses multiplying across two dimensions (`WindowsButton`, `MacButton`, …)	Ch 9 §9.2
Classpath	The list of folders and JAR files where the JVM looks for classes	Ch 1 §1.3
Clean code	Code whose intent is obvious to the next reader and which is easy to change safely	Ch 6 (intro)
Coarse- vs fine-grained locking	One big lock for everything (simple, slow under load) vs many small locks per item (faster, harder to get right)	Ch 12 §12.11
Code review	A peer reads a change before merge: correctness first, then design, readability, tests, security, performance	Ch 6 §15
Code smell	A surface symptom that usually signals a deeper design problem; not a bug by itself	Ch 7 §7.2
Coffman conditions	Mutual exclusion, hold and wait, no preemption, circular wait: all four needed for deadlock	Ch 12 §12.17
Cohesion	How closely the things inside one class belong together; high is good	Ch 2 §2.16, Ch 4 §4.3
Coin-change DP	Finding the fewest coins (or whether change is possible) by building answers for smaller amounts first	Ch 14 §14.2
Collections framework	Java's built-in data structures (`List`, `Set`, `Map`, `Queue`) and their implementations	Ch 2
Command	Behavioral pattern turning a request into an object so it can be queued, logged or undone	Ch 10 §10.2
Command–Query Separation (CQS)	A method either changes state or returns a value, not both	Ch 6 §2
Commit / rollback	Make a transaction's changes permanent vs throw all of them away	Ch 10 §10.5, Ch 15 §15.2
`Comparator` / `Comparable`	An object that orders two values from outside vs a class's own natural order (`compareTo`)	Ch 1 §1.9, Ch 11 §11.3
Compensation	Undoing a completed step with a new action (e.g. a refund) because money can't be rolled back	Ch 15 §15.2
Compile time vs run time	When `javac` checks and translates the code vs when the program is actually executing	Ch 2 §2.7
`CompletableFuture`	A future you can chain (`thenApply`, `thenCombine`) to combine asynchronous results	Ch 12 §12.4
Composite	Structural pattern that lets clients treat single objects and trees the same way	Ch 9 §9.3
Composition	"Owns" relationship: the part is created and hidden by the whole and dies with it; filled diamond	Ch 3 §3.4

Term	Plain meaning	Where
Composition over inheritance	Reuse behaviour by holding and delegating rather than subclassing	Ch 2 §2.11, Ch 5 §6
Composition root	The one place (usually `main`) where objects are created and wired together	Ch 6 §10
Compound interest	Interest charged on the principal plus interest already added	Ch 21 §21.6
Concurrency	Several tasks in progress at once, possibly sharing data	Ch 12 §12.1
Concurrency vs parallelism	Many tasks in progress (structure) vs many executing at the same instant (hardware)	Ch 12 §12.1
`ConcurrentHashMap`	Thread-safe map with atomic compound operations (`putIfAbsent`, `compute`, `merge`)	Ch 12 §12.16
Condition variable	Lets a thread wait until shared state meets a condition (`wait/notify`, `Condition`)	Ch 12 §12.13
Constructor	Special method that runs when an object is created and sets up its fields	Ch 2 §2.2
Constructor chaining	One constructor calling another with `this(...)`	Ch 2 §2.2
Contention	Many threads competing for the same lock or variable at once, making them wait	Ch 12 §12.7, §12.11
Context switch	The OS pausing one thread and resuming another on a CPU core; costs time	Ch 12 §12.1
Controller (GRASP)	A thin non-UI object that receives each system event and delegates	Ch 5 §16.3
`CopyOnWriteArrayList`	Thread-safe list that copies on every write; good for read-mostly listener lists	Ch 12 §12.16
`CountDownLatch`	One-shot gate that opens after N `countDown()` calls	Ch 12 §12.14
Coupling	How much one class depends on another's details; low is good	Ch 2 §2.16, Ch 4 §4.4
CPU	The processor; each core runs one thread at a time	Ch 12 §12.1
CQRS	Command Query Responsibility Segregation: separate models for writing data and for reading it	Ch 5 §17
Creator (GRASP)	The class that contains, records or has the data for A should create A	Ch 5 §16.2
Critical section	Code that touches shared state and must run in one thread at a time	Ch 12 §12.5
Cron	A schedule format (minute, hour, day…) for running a job at fixed times	Ch 10 §10.6
Cross-cutting concern	Behaviour needed in many places (logging, security, transactions) that doesn't belong to one class	Ch 4 §4.5, Ch 6 §10
CRUD	Create, Read, Update, Delete: the four basic storage operations	Ch 5 §17
CSV	Comma-separated values: a plain-text table, one row per line	Ch 5 §3
`CyclicBarrier`	Reusable meeting point where N threads wait for each other	Ch 12 §12.14
Daemon thread	A background thread that does not keep the JVM alive once all normal threads end	Ch 12 §12.4
DAO (Data Access Object)	A class that wraps the SQL for one table; closer to the database than a Repository	Ch 11 §11.7.3
Data Class (smell)	A class with only fields and getters/setters, manipulated by others	Ch 7 §7.2.22
Data Clumps (smell)	The same group of values always travelling together	Ch 7 §7.2.10
Database transaction	A group of database changes that succeed or fail together	Ch 12 §12.25, Ch 15

Term	Plain meaning	Where
Dead code	Code that is never run or whose result is never used; delete it	Ch 6 §13, Ch 7
Dead-letter queue	Where messages go after retries are exhausted, for later inspection	Ch 20 §20.6
Deadlock	Two or more threads each wait forever for a resource another holds	Ch 12 §12.17
Debit / credit	Taking money out of an account vs putting money in	Ch 14 §14.4, Ch 21 §21.2
Decorator	Structural pattern adding behaviour by wrapping an object behind the same interface	Ch 9 §9.4
Deep vs shallow copy	Copying nested objects too vs sharing them with the original	Ch 8 §8.13
Defensive copy	Copying a mutable object passed in or handed out so outsiders can't change your internals	Ch 2 §2.13
Delegation	An object handing a job to another object it holds, instead of doing it itself	Ch 2 §2.11, Ch 5 §6
Dependency	"Uses" relationship: B appears only as a parameter, local, return type or static call; dashed arrow	Ch 3 §3.5
Dependency injection (DI)	Supplying a class's collaborators from outside (usually via the constructor)	Ch 4 §4.10, Ch 11 §11.7.2
Dependency Inversion Principle	High- and low-level code both depend on abstractions owned by the high-level policy	Ch 4 §4.10
`Deque` / `ArrayDeque`	Double-ended queue: add and remove at both ends; the usual Java stack and queue	Ch 7 §7.7
Derive, don't store	Compute counts and totals from the underlying records so they can't drift	Ch 18 §18.5
Design by Contract	Preconditions (caller's duty), postconditions (method's promise), invariants (always true)	Ch 5 §15
Design pattern	A named, reusable solution to a recurring design problem	Ch 8 §8.1
Director	Optional Builder role that runs a fixed sequence of building steps	Ch 8 §8.12
Distributed lock	A lock shared by several servers, kept in an external store (database, Redis)	Ch 12 §12.25
Divergent Change (smell)	One class changed for many different reasons	Ch 7 §7.2.7
Domain event	Past-tense record of a business fact (`OrderPlaced`) that other parts of the system react to	Ch 5 §17
Domain exception	A custom exception named after a business rule (`InsufficientBalanceException`)	Ch 21 §21.0
Domain-Driven Design (DDD)	Modelling software on the business: bounded contexts, entities, value objects, aggregates, domain events, repositories	Ch 5 §17
Double dispatch	Choosing a method by both the element's and the visitor's type (Visitor's `accept`)	Ch 11 §11.5
Double-checked locking	Lazy singleton that checks, locks, checks again; the field must be `volatile`	Ch 8 §8.8
Driver (machine coding)	The `main` class that feeds commands to the services and prints results	Ch 1 §1.10, Ch 21 §21.0
DRY	Don't Repeat Yourself: each piece of knowledge has one authoritative home	Ch 5 §1
DTO (Data Transfer Object)	A plain data holder used only to carry values across a boundary (API, layer)	Ch 2 §2.3

Term	Plain meaning	Where
Dynamic dispatch	The JVM picks an overridden method from the object's actual class at run time	Ch 2 §2.6–§2.7
Dynamic programming (DP)	Solving a problem by combining saved answers to smaller sub-problems	Ch 14 §14.2
Edge-triggered alert	Fires once when a value crosses a threshold, not on every update while it stays past it	Ch 19 · Grocery Store, Ch 21 §21.7
EMI	Equated monthly instalment: the fixed amount repaid each month on a loan	Ch 21 §21.6
Encapsulate what varies	Isolate the part that changes behind an interface	Ch 5 §8
Encapsulation	Data kept private; only the owning class's methods change it and enforce its rules	Ch 2 §2.3
Entity (DDD)	Object defined by an identity that survives changes; two entities are equal when their ids are equal	Ch 5 §17
Enum (with behaviour)	A fixed set of named constants that can carry fields and methods	Ch 2 §2.10
`EnumMap` / `EnumSet`	Very fast map and set implementations whose keys are the constants of one enum	Ch 2 §2.10
`equals`/`hashCode` contract	Equal objects must have equal hash codes	Ch 2 §2.12
Event Sourcing	Store the stream of changes (events); rebuild state by replaying them	Ch 11 §11.7.6
Event-driven	Parts of the system react to published events instead of calling each other directly	Ch 5 §9
Eventual consistency	Copies of data may disagree for a short time but converge once updates stop	Ch 5 §17
Eviction	Removing entries from a cache to make room (LRU, LFU, FIFO)	Ch 20 §20.3
Exception	An object thrown to signal an error, which unwinds the call stack until something catches it	Ch 6 §6
`ExecutorService`	Runs submitted tasks on a pool of threads; separates what to run from how	Ch 12 §12.4
Exponential backoff	Waiting longer after each failed retry (1 s, 2 s, 4 s…), usually with jitter	Ch 6 §16
Expression problem	Visitor makes adding operations cheap but adding types expensive (and the reverse for plain polymorphism)	Ch 11 §11.5
Facade	Structural pattern giving one simple entry point to a complex subsystem	Ch 9 §9.5
Factory Method	Creational pattern where subclasses decide which product to create	Ch 8 §8.10
Fail fast	Detect problems early and loudly (guard clauses, `requireNonNull`)	Ch 5 §13
Fairness	Serving waiting threads roughly in order so none starves; costs throughput	Ch 12 §12.19
Fan-out	One event or post copied to many receivers (followers' feeds, subscribers)	Ch 18 §18.4, Ch 20 §20.6
Feature Envy (smell)	A method more interested in another class's data than its own	Ch 7 §7.2.9
Field	A variable that belongs to an object (instance field) or to the class (`static` field)	Ch 2 §2.2
FIFO / LIFO	First in, first out (a queue) vs last in, first out (a stack)	Ch 12 §12.8, Ch 15
F.I.R.S.T.	Clean tests are Fast, Independent, Repeatable, Self-validating, Timely	Ch 6 §8
Flag argument	A boolean parameter that makes a function do two things; split it instead	Ch 6 §2

Term	Plain meaning	Where
Flyweight	Structural pattern sharing intrinsic state among many fine-grained objects	Ch 9 §9.6
Fork/Join	Split a task recursively into subtasks run in parallel, then combine results	Ch 12 §12.26, Ch 13 §13.10
Fragile base class	A change in a parent class silently breaks subclasses	Ch 5 §6
Framework	A library that owns the program's flow and calls your code at set points (Spring, JUnit)	Ch 5 §10
Functional interface	An interface with one abstract method, usable with lambdas	Ch 2 §2.8
Functional requirement	A behaviour the system must have ("a customer takes a ticket")	Ch 1 §1.5
GA (general admission)	Unnumbered standing or seating tickets sold as a count, not as named seats	Ch 15 §15.3
Garbage collection (GC)	The JVM automatically freeing memory of objects nothing refers to any more	Ch 12
Generalization	"Is-a" (inheritance) relationship; solid line, hollow triangle at the parent	Ch 3 §3.6
Generics	Type parameters (`List<T>`) for type-safe reusable code	Ch 2 §2.15
Geohash	Encodes a latitude/longitude as a short string; nearby places share a prefix, so it works as a search key	Ch 20 §20.4
Getter / setter	Methods that read (`getX`) or change (`setX`) a field	Ch 2 §2.3
Git	The version-control tool that records every change to the code as commits	Ch 4 §4.2
Glob	Filename wildcard pattern: `*` any characters, `?` one character, `[0-9]` one character from a set	§21.8
Global Data (smell)	Data readable and writable from anywhere, including mutable singletons	Ch 7 §7.2.5
God class / God Object	One class that knows and does almost everything	Ch 8 §8.6, Ch 7 §7.2.20
GoF	"Gang of Four": the four authors of the 1994 book that catalogued the 23 classic design patterns	Ch 8 §8.2
Golden Hammer	Applying a favourite tool or pattern to every problem	Ch 8 §8.6
Graph	Nodes joined by edges (people and connections, stops and routes)	Ch 18 §18.3
GRASP	Larman's nine guidelines for assigning responsibilities to classes	Ch 5 §16
Greedy algorithm	Always take the best-looking choice right now; fast, but not always correct (e.g. coin change)	Ch 14 §14.2
GST	Goods and Services Tax, India's sales tax	Ch 19 · Grocery Store
Guard clause	An early check-and-return/throw at the top of a method instead of nested `if`s	Ch 7 §7.3.5, Ch 5 §13
Half-open interval	A time range `[start, end)` that includes the start but not the end, so back-to-back bookings don't clash	Ch 15 §15.4, Ch 21 §21.3
Happens-before	Java Memory Model rule guaranteeing one action's effects are visible to another	Ch 12 §12.6
Hash function / hash code	Turns a value into a number used to pick a bucket; equal values must give equal hashes	Ch 2 §2.12
Hash table / `HashMap`	Key-value store that finds an entry in about constant time by hashing the key	Ch 2 §2.12

Term	Plain meaning	Where
Heap vs stack (memory)	Where objects live (shared by all threads) vs each thread's own area for local variables and calls	Ch 12 §12.2
Heuristic	A rule of thumb that is usually right and cheap to apply, not a guarantee	Ch 6 §14
Hexagonal architecture	Ports and adapters: the domain core defines interfaces; databases, UIs and vendors plug in from outside	Ch 20 §20.4
High Cohesion (GRASP)	Assign responsibilities so each class does related work	Ch 5 §16.5
HLD vs LLD	Many services and machines vs classes inside one application	Ch 1 §1.2
Hold with TTL	A temporary claim (e.g. seats during payment) that expires automatically	Ch 15 §15.2
Holder-class idiom	Lazy singleton created inside a nested static class; the JVM's class loading makes it thread-safe	Ch 8 §8.8
Hollywood Principle	"Don't call us, we'll call you": the framework calls your hooks	Ch 5 §10
HTTP	The request/response protocol browsers and web services use	Ch 3 §3.12
IDE	Integrated development environment (IntelliJ, Eclipse): editor plus compiler, debugger and refactoring tools	Ch 7
Idempotency	Running an operation twice has the same effect as once; an idempotency key enforces it	Ch 21 §21.2, Ch 20 §20.6
Identity vs equality	Same object in memory (`==`) vs same value (`equals`)	Ch 2 §2.12
Immutability	Objects that never change after creation; safe to share between threads	Ch 2 §2.13, Ch 5 §14
Indirection (GRASP)	Put an intermediate object between two things that shouldn't know each other	Ch 5 §16.8
Information Expert (GRASP)	The class that has the data does the work	Ch 5 §16.1
Inheritance	A child class reuses and specialises a parent (`extends`); only for true is-a	Ch 2 §2.5
In-memory	Data kept only in the program's RAM, lost when it stops; the default in LLD rounds	Ch 1 §1.4
Insider Trading (smell)	Two modules exchanging too much private information	Ch 7 §7.2.19
Instance	One object created from a class	Ch 2 §2.2
Integration test	Tests several real parts together (e.g. service plus database), slower than a unit test	Ch 6 §17
Interface	A contract of methods; a class can implement many	Ch 2 §2.8
Interface Segregation Principle	No client should depend on methods it does not use	Ch 4 §4.9
Interning	Keeping one shared copy of each equal value (`String.intern()`)	Ch 9 §9.6
Interpreter	Behavioral pattern with one class per grammar rule, evaluating sentences of a small language	Ch 10 §10.6
Interrupt	A polite request to a thread to stop what it is doing; blocking calls react by throwing `InterruptedException`	Ch 12 §12.3
Intrinsic vs extrinsic state	Flyweight's shared, immutable part vs the per-use part passed in by the caller	Ch 9 §9.6
Invariant	A fact about an object that must always be true ("balance is never negative")	Ch 5 (key terms), §15
Inversion of Control (IoC)	The framework controls the flow and calls your code; DI is one way to achieve it	Ch 5 §10, Ch 4 §4.14

Term	Plain meaning	Where
Inverted index	A map from each word/tag to the list of items containing it, for search	Ch 18 §18.1
Invoker / Receiver	Command roles: the invoker triggers commands; the receiver does the real work	Ch 10 §10.2
I/O	Input/output: reading or writing files, network or database; slow compared with CPU work	Ch 12 §12.4
Iterator	Behavioral pattern for traversing a collection without exposing its storage	Ch 10 §10.3
JAR	Java archive: a zip file of compiled classes and resources	Ch 4 §4.7
Java Memory Model (JMM)	Rules for when one thread's writes become visible to another	Ch 12 §12.6
`java.time`	Java's date-time API: `Instant` (a moment), `Duration`, `LocalDate`, and `Clock` (injectable "now")	Ch 1 §1.10
JDBC	Java's standard API for talking to relational databases	Ch 8 §8.11
JDK	Java Development Kit: compiler, tools and the standard library	Ch 2
JIT compiler	Part of the JVM that turns hot bytecode into fast machine code while the program runs	Ch 12
Jitter	Random extra delay added to retries so many clients don't retry at the same instant	Ch 6 §16, Ch 12 §12.18
JPA / Hibernate	Java's standard for mapping objects to database tables, and its most popular implementation	Ch 9 §9.7
JSON	A text format for structured data: objects in `{}`, lists in `[]`	Ch 3 §3.2
JUnit	The standard Java unit-testing framework	Ch 6 §8
JVM	Java Virtual Machine: runs compiled Java bytecode and manages memory and threads	Ch 2, Ch 12
Kafka	A distributed append-only log used as a durable message broker	Ch 20 §20.6
KISS	Keep It Simple: choose the simplest design that works	Ch 5 §2
KYC	Know Your Customer: identity checks a financial app must do before allowing higher limits	Ch 21 §21.2
Lambda	A short anonymous function, e.g. `x -> x * 2`, usable wherever a functional interface is expected	Ch 2 §2.8
Large Class (smell)	A class trying to do too much; a God Class	Ch 7 §7.2.20
Latency	How long one operation takes from start to finish	Ch 1 §1.4
Law of Demeter	Only talk to your immediate friends; avoid `a.getB().getC()` chains	Ch 5 §4
Lazy Element (smell)	A class or function that doesn't pull its weight	Ch 7 §7.2.14
Lazy expiry	Deleting an expired entry only when someone next touches it, instead of by a timer	Ch 13 §13.6, Ch 14 §14.7
Lazy initialization	Creating an object only when it is first needed	Ch 8 §8.8
Lease	A lock or hold that expires automatically after a set time unless renewed	Ch 12 §12.9
Least Astonishment	Code should do what its name promises and nothing more	Ch 5 §12
Ledger	An append-only list of money movements from which balances are derived	Ch 20 §20.1, Ch 21
Legacy code	Existing code, often without tests, that is risky to change	Ch 7 §7.8
LFU / MRU	Cache eviction that removes the least frequently used vs the most recently used entry	Ch 20 §20.3

Term	Plain meaning	Where
Linked list	A chain of nodes where each points to the next (doubly linked: also the previous)	Ch 20 §20.3
`LinkedHashMap`	A `HashMap` that also remembers insertion or access order; the shortcut for an LRU cache	Ch 20 §20.3
Linter / static analysis	Tools that read code without running it and flag likely bugs or style issues	Ch 6 §15
Liskov Substitution Principle	A subtype must be usable anywhere its parent is expected, with no surprises	Ch 4 §4.8
Listener	An object registered to be told when an event happens (the observer in Observer)	Ch 11 §11.1
Livelock	Threads keep reacting to each other and running, but none makes progress	Ch 12 §12.18
Lock ordering	Always acquire locks in one global order to prevent circular wait	Ch 12 §12.17
Lock striping	Guarding a map with an array of locks, each covering some buckets	Ch 13 §13.7
Lombok	A library that generates boilerplate (getters, builders) from annotations at compile time	Ch 8 §8.12
Long Function (smell)	A function too long to understand at a glance	Ch 7 §7.2.3
Long Parameter List (smell)	Many parameters, often of the same type or boolean flags	Ch 7 §7.2.4
`LongAdder`	Counter that scales better than `AtomicLong` under heavy contention	Ch 12 §12.15
LOOK scheduling	Elevator keeps moving in one direction while stops remain ahead, then reverses	Ch 14 §14.5
Loops (smell)	A classic loop where a stream pipeline would state the intent more clearly	Ch 7 §7.2.13
Loose coupling	Interacting objects know as little about each other as possible	Ch 5 §9
Lost wakeup	A signal sent before the waiter started waiting, so the waiter sleeps forever	Ch 12 §12.13
Low Coupling (GRASP)	Assign responsibilities to keep dependencies few and stable	Ch 5 §16.4
LRU cache	Evicts the least recently used entry; hash map + doubly linked list gives O(1)	Ch 20 §20.3
Lua	A small scripting language; Redis runs a Lua script as one atomic step	Ch 20 §20.7
Machine-coding round	LLD round where working, runnable in-memory code is the answer (90–120 min)	Ch 1 §1.2, Ch 21 §21.0
Market vs limit order	Buy or sell now at the best available price vs only at a given price or better	Ch 19 · Stock Brokerage
Matching engine	Per-symbol order book matching buy and sell orders by best price, then oldest first	Ch 19 · Stock Brokerage
MDC	Mapped Diagnostic Context: per-thread key-values (request id, user) automatically added to log lines	Ch 20 §20.5
Mediator	Behavioral pattern centralising communication between peers in one coordinator	Ch 10 §10.4
Memento	Behavioral pattern capturing and restoring state without exposing internals	Ch 10 §10.5
Memory leak	Memory that is never freed because something still holds references to objects no longer needed	Ch 11 §11.1, Ch 12 §12.24
Message Chains (smell)	`a.getB().getC().getD()` navigation	Ch 7 §7.2.17

Term	Plain meaning	Where
Message queue	A buffer service where producers leave messages for consumers to process later	Ch 20 §20.6
Method	A function that belongs to a class	Ch 2 §2.2
Method reference	Shorthand for a lambda that just calls a method, e.g. `String::length`	Ch 2 §2.8
Microservice vs monolith	Many small independently deployed services vs one deployable application	Ch 5 §17
Middle Man (smell)	A class whose methods mostly forward to another class	Ch 7 §7.2.18
Mixin	A small interface with `default` methods that adds a capability to many classes	Ch 4 §4.3
Mock / stub / fake	Test doubles: a mock checks calls were made, a stub returns canned answers, a fake is a simple working version	Ch 6 §17
Mockito	The most common Java library for creating mocks in tests	Ch 6 §8
Module / package	A group of related classes; in Java a package is a folder-level namespace	Ch 2 §2.14
Monitor	The lock built into every Java object, used by `synchronized` and `wait/notify`	Ch 12 §12.7
Multiplicity	How many objects take part at each end of a relationship (`1`, `0..1`, `*`, `1..*`)	Ch 3 §3.2
Mutable Data (smell)	Shared data changed after creation, causing surprises elsewhere	Ch 7 §7.2.6
Mutation testing	Deliberately breaking the code in small ways to check the tests notice	Ch 6 §17
Mutex	A lock that lets only one thread into a critical section	Ch 12 §12.7
MVC	Model–View–Controller; a compound of Observer, Strategy and Composite	Ch 11 §11.7.5
Mysterious Name (smell)	A name that doesn't say what the thing does or holds	Ch 7 §7.2.1
Non-functional requirement	A quality: thread safety, extensibility, in-memory storage, latency	Ch 1 §1.5
Null Object	A do-nothing implementation used instead of `null`	Ch 11 §11.7.1
`NullPointerException` (NPE)	Thrown when you call a method or read a field through a `null` reference	Ch 5 §13
Object	One instance of a class with real values	Ch 2 §2.2
Object Pool	Borrow and return a bounded set of expensive objects	Ch 8 §8.14
Observer	Behavioral pattern notifying many dependents when one object changes	Ch 11 §11.1
Offset	A position number in a log or list; each reader remembers its own	Ch 20 §20.6
OOA / OOD / OOP	Analysis (what) → design (how, with objects) → programming (code)	Ch 2 §2.17
Open/Closed Principle	Open for extension, closed for modification: add code, don't edit working code	Ch 4 §4.7
Optimistic locking	Read with a version; the write succeeds only if the version is unchanged	Ch 12 §12.10, §12.25
`Optional`	A container that may be empty; return it when "not found" is normal	Ch 1 §1.10
Order book	Per-stock lists of waiting buy and sell orders, sorted by price then time	Ch 19 · Stock Brokerage
OTP	One-time password: a short code valid for a single use, usually sent by SMS	Ch 5 §13, Ch 20 §20.2
Outbox (transactional)	Save events in a table in the same transaction as the data, and publish them afterwards, so neither is lost	Ch 5 §17

Term	Plain meaning	Where
`OutOfMemoryError`	Thrown when the JVM cannot find memory for a new object	Ch 12 §12.2
Out-of-scope list	Written list of what you will not build; shrinks the problem	Ch 1 §1.5
Overloading	Same method name, different parameters; chosen at compile time	Ch 2 §2.7
Overriding	Subclass replaces a parent's method; chosen at run time	Ch 2 §2.7
Payment gateway	An external service that actually charges cards or UPI; hidden behind your own interface	Ch 15 §15.2, Ch 19
PECS	Producer `extends`, consumer `super` — the rule for generic wildcards	Ch 2 §2.15
Pessimistic locking	Lock a row before changing it (e.g. `SELECT … FOR UPDATE`) so nobody else can touch it meanwhile	Ch 12 §12.5, Ch 15 §15.2
Phaser	A reusable, flexible barrier for threads meeting in phases	Ch 12 §12.14, §12.26
PII	Personally identifiable information (names, phone numbers) that must not leak into logs	Ch 6 §15
Pinning	A virtual thread stuck on its carrier thread while it blocks	Ch 12 §12.4
Pipeline	Data flowing through a sequence of steps, each feeding the next (streams, filters, middleware)	Ch 7 §7.2.13
PLU code	Four-digit price look-up code for loose produce, keyed at the till together with the scale weight	Ch 19 · Grocery Store
Plugin	A piece of code added to a system through a known interface without editing the system	Ch 4 §4.7
PNR	Passenger name record: the booking reference for an airline reservation	Ch 16 · Airline
Poison pill	A special message telling a consumer to stop; one per consumer	Ch 12 §12.22
Polymorphism	One call behaves differently depending on the object; removes type switches	Ch 2 §2.6, Ch 5 §16.6
POS	Point of sale: the till where a sale is rung up and paid	Ch 19 · Grocery Store
Precondition / postcondition	What must be true before a call (caller's duty) / what the method promises after it	Ch 4 §4.8, Ch 5 §15
Primitive Obsession (smell)	Using `double`, `String`, `int` for domain concepts like money or status	Ch 7 §7.2.11
`PriorityQueue`	A queue that always hands out the smallest (or highest-priority) element first; a binary heap inside	Ch 16 · Course Registration
Process	A running program with its own memory; it contains one or more threads	Ch 12 §12.2
Producer–consumer	Threads hand work through a (bounded) queue	Ch 12 §12.22
Program to an interface	Depend on supertypes; pick the concrete class once, at the edge	Ch 5 §7
Protected Variations (GRASP)	Wrap points of instability behind a stable interface	Ch 5 §16.9
Prototype	Creational pattern creating new objects by copying a configured one	Ch 8 §8.13
Proxy	Structural pattern: a stand-in controlling access to another object	Ch 9 §9.7
Pub-sub	Observer through a broker: publishers and subscribers don't know each other	Ch 20 §20.6
Pure Fabrication (GRASP)	An invented helper class (e.g. a repository) when no domain class fits	Ch 5 §16.7
Pure function	A function whose result depends only on its inputs and which changes nothing else	Ch 11 §11.7.6, Ch 17 · 2048

Term	Plain meaning	Where
Qualified association	An association looked up by a key (`Library [isbn] → Book`, i.e. a `Map`)	Ch 3 §3.11
Race condition	The result depends on the timing of threads touching shared mutable state	Ch 12 §12.5
Rate limiter	Caps how many requests a key may make per time window (token bucket, windows)	Ch 13 §13.11, Ch 20 §20.7
Read-write lock	Many readers at once, or one writer	Ch 12 §12.10
Realization	A class implements an interface; dashed line, hollow triangle at the interface	Ch 3 §3.7
Record	Compact Java class for immutable data; only shallowly immutable	Ch 2 §2.13
Recursion	A function that solves a problem by calling itself on a smaller part	Ch 9 §9.3
Recursive-descent parser	A parser with one method per grammar rule, each calling the others	Ch 10 §10.6, Ch 21 §21.8
Redis	A fast shared in-memory key-value store, often used for caches, counters and distributed locks	Ch 20 §20.7
Reentrancy	A thread may re-acquire a lock it already holds	Ch 12 §12.8
`ReentrantLock`	Explicit lock with try/timed/fair locking and conditions	Ch 12 §12.8
Refactoring	Changing internal structure without changing observable behaviour	Ch 7 §7.1
Reflection	Code inspecting or calling classes, fields and methods at run time by name	Ch 8 §8.8
Refused Bequest (smell)	A subclass that doesn't want, or throws on, inherited methods	Ch 7 §7.2.23
Regex	Regular expression: a pattern language for matching text	Ch 10 §10.6
Repeated Switches (smell)	The same `switch` on a type code in several places	Ch 7 §7.2.12
Repository	Collection-like interface that hides storage from business logic	Ch 11 §11.7.3
Requirement	One thing the system must do, written so you can check it	Ch 1 §1.5
REST	A style of HTTP API built around resources (URLs) and verbs (GET, POST…)	Ch 5 §1
Retry	Trying a failed operation again; safe only if the operation is idempotent	Ch 6 §16
Role interface	A small interface serving one kind of caller (the ISP fix)	Ch 4 §4.9
Rule of three	Refactor to an abstraction at the second or third case, not the first	Ch 4 §4.15
`RuntimeException`	Base class of unchecked exceptions	Ch 2 §2.5
Saga	A long business process split into local steps, each with a compensating action if a later step fails	Ch 3 §3.12, Ch 15
Scalability	How well a system keeps working as users, data or load grow	Ch 1 §1.14
`ScheduledExecutorService`	Runs tasks after a delay or repeatedly at a fixed rate	Ch 13 §13.6
Schema	The defined structure of stored data (tables, columns, types)	Ch 2 §2.17
SDK	Software development kit: a vendor's ready-made library for calling its service	Ch 9 §9.1
Sealed type	A type whose permitted subtypes are fixed, enabling exhaustive `switch`	Ch 11 §11.5
Seam	A place where you can swap behaviour (e.g. an interface) without editing the code around it; used for testing	Ch 2 §2.9, Ch 7 §7.7

Term	Plain meaning	Where
Seed	The starting number for a pseudo-random generator; the same seed gives the same sequence	Ch 17
Semaphore	A counter of permits that limits concurrent access or signals between threads	Ch 12 §12.12
Separation of Concerns	Each part of the program handles one concern	Ch 4 §4.5, Ch 5 §11
Sequence diagram	UML diagram of messages between objects over time	Ch 3 §3.12
Serialization	Turning an object into bytes or text (and back) for storing or sending	Ch 8 §8.8
Service Locator	Anti-pattern where a class asks a registry for its dependencies, hiding them	Ch 11 §11.7.2
Sharding	Splitting data across independent parts (each with its own lock) to scale	Ch 20 §20.3
Shotgun Surgery (smell)	One change forces many small edits across many classes	Ch 7 §7.2.8
Side effect	Anything a function does besides returning a value (changing a field, writing a file)	Ch 5 §12, Ch 6 §2
Signaling	One thread tells another that something has happened (semaphore, latch)	Ch 12 §12.20
Simple Factory	One method mapping a type value to a class; an idiom, not GoF	Ch 8 §8.9
Single Responsibility Principle	A class should have one reason (one actor) to change	Ch 4 §4.2
Singleton	Creational pattern ensuring exactly one instance with global access	Ch 8 §8.8
SKU	Stock-keeping unit: one sellable product variant tracked in inventory	Ch 21 §21.7
SLF4J	A logging facade: code logs through its API and any logging library can sit underneath	Ch 9 §9.5
Sliding window	Rate-limit algorithm counting requests in a moving time window (log or counter)	Ch 20 §20.7
SMS / SMTP	Text messages to phones / the protocol for sending email	Ch 20 §20.2
Snapshot	A copy of state at one moment, used to restore it or to read it safely	Ch 10 §10.5
SOLID	SRP, OCP, LSP, ISP, DIP: five guidelines that keep one change from spreading	Ch 4 §4.1
Specification	Named, combinable business-rule object with `isSatisfiedBy`	Ch 11 §11.7.4
Speculative Generality (smell)	Hooks and abstractions added "in case" but never used	Ch 7 §7.2.15
Split tender	Paying one bill with several payment methods (e.g. part UPI, part cash)	Ch 19 · Grocery Store
Spring	The most widely used Java application framework; creates and wires objects (DI), web, data access	Ch 4 §4.14, Ch 11 §11.7.2
Spurious wakeup	A waiting thread wakes with no signal; why `wait()` sits in a `while` loop	Ch 12 §12.13
SQL	The language for querying and updating relational databases	Ch 11 §11.7.3
Stack trace	The list of method calls active when an exception was thrown; shows where it came from	Ch 6 §6
`StampedLock`	Read-write lock with optimistic reads; not reentrant	Ch 12 §12.10
Starvation	One thread never gets the resource while others keep progressing	Ch 12 §12.19

Term	Plain meaning	Where
State (pattern)	Behavioral pattern where an object's behaviour changes with its internal state	Ch 11 §11.2
State machine diagram	UML diagram of one object's states and transitions (`event [guard] / action`)	Ch 3 §3.14
Stateless vs stateful	Keeps no data between calls (safe to share) vs remembers data between calls	Ch 1 §1.6
`static`	Belongs to the class, one per class, not to each object	Ch 2 §2.2
Stop-loss / stop-limit	Orders that wake up when the price hits a trigger, then sell at market / at a limit price	Ch 19 · Stock Brokerage
Strategy	Behavioral pattern making algorithms interchangeable behind one interface	Ch 11 §11.3
Stream (Java)	A pipeline over a collection (`filter`, `map`, `collect`) that states what, not how	Ch 2 §2.8, Ch 7 §7.2.13
Subclass / superclass	The child class that `extends` / the parent it extends	Ch 2 §2.5
`synchronized`	Java keyword that runs a block or method under an object's monitor: one thread at a time, with visibility	Ch 12 §12.7
TCP	The internet protocol that delivers a reliable, ordered byte stream between two machines	Ch 11 §11.2
Technical debt	Shortcuts in code that make future changes slower until someone cleans them up	Ch 7 §7.1
Telescoping constructors	A ladder of constructors each adding one more parameter; Builder replaces it	Ch 8 §8.12
Tell, Don't Ask	Tell objects what to do instead of pulling their data out to decide	Ch 5 §5
Template Method	Behavioral pattern: fixed algorithm skeleton in a base class, steps in subclasses	Ch 11 §11.4
Temporary Field (smell)	A field set only in some situations and empty otherwise	Ch 7 §7.2.16
Test double	Anything standing in for a real dependency in a test: dummy, stub, spy, mock, fake	Ch 6 §17
Test-Driven Development (TDD)	Failing test → make it pass → refactor, in very short cycles	Ch 6 §8
Thread	An independent path of execution inside a process, sharing its memory	Ch 12 §12.2
Thread confinement	Keeping data inside one thread so it never needs locking	Ch 12 §12.24
Thread dump	A snapshot of every thread's state and call stack (`jstack`, `jcmd`) used to diagnose hangs	Ch 12 §12.3
Thread pool	A fixed set of reusable threads fed from a task queue	Ch 12 §12.21
Thread states	NEW, RUNNABLE, BLOCKED, WAITING, TIMED_WAITING, TERMINATED	Ch 12 §12.3
Thread-safe	Gives correct results even when many threads call it at the same time	Ch 12 §12.5
Thread-starvation deadlock	Tasks in a bounded pool wait for tasks queued behind them in the same pool	Ch 12 §12.17, §12.21
Throughput	How much work gets done per unit of time (requests per second)	Ch 12 §12.11
Timeout	A limit on how long to wait before giving up	Ch 12 §12.9
TL;DR	"Too long; didn't read": a short summary at the end of each section or chapter	Every chapter
Token bucket	Rate-limit algorithm: tokens refill at a fixed rate; each request takes one; allows bursts	Ch 13 §13.11

Term	Plain meaning	Where
`toString`	Method returning a readable text form of an object, used in logs and printing	Ch 2 §2.12
`TreeMap` / `TreeSet`	Sorted map and set (red-black tree inside); support "next higher" and range queries	Ch 14 §14.5
`tryLock`	Acquire a lock only if free (or within a timeout); otherwise give up	Ch 12 §12.9
TTL (time to live)	How long an entry or hold stays valid before it expires	Ch 13 §13.6, Ch 15 §15.2
Two hats	While coding you are either adding function or refactoring, never both at once	Ch 7 §7.1.1
Type erasure	Java removes generic type arguments after compiling, so `List<String>` and `List<Integer>` are the same class at run time	Ch 2 §2.15
Ubiquitous language	One vocabulary shared by domain experts and the code (`place()`, not `setStatus(2)`)	Ch 5 §17
UI	User interface: the screens or controls a person interacts with	Ch 11 §11.7.5
UML	Unified Modeling Language: 14 diagram types, 7 structural and 7 behavioural	Ch 3 §3.9
Unit test	A fast test of one small piece of code in isolation	Ch 6 §8
UPI	Unified Payments Interface: India's instant bank-to-bank mobile payment system	Ch 19, Ch 21 §21.2
Use case	One thing an actor can do with the system	Ch 1 §1.5, Ch 3 §3.10
Use-case diagram	UML diagram of actors, use cases and the system boundary («include», «extend»)	Ch 3 §3.10
UTC	Coordinated Universal Time: the time-zone-free reference clock for storing timestamps	Ch 16 · Airline
Value object	A small immutable object defined by its values (money, date range), usually a record	Ch 2 §2.13, Ch 5 §1, Ch 5 §17
Virtual threads	Lightweight JVM-managed threads for large numbers of blocking tasks (Java 21)	Ch 12 §12.4
Virtual waiting room	FIFO queue that admits buyers gradually during a ticket rush	Ch 15 §15.3
Visibility (memory)	Whether a write by one thread can be seen by another; not guaranteed without `volatile`, locks or other happens-before edges	Ch 12 §12.6
Visitor	Behavioral pattern adding operations to a stable set of classes via double dispatch	Ch 11 §11.5
`volatile`	Makes writes to a field visible to other threads; does not make `x++` atomic	Ch 12 §12.6
Webhook	A URL a service calls to notify you that something happened (e.g. "payment succeeded")	Ch 15 §15.2
Wildcard (generics)	`?` in a generic type: `? extends T` (read from it), `? super T` (write to it)	Ch 2 §2.15
Work stealing	Idle threads in a fork/join pool take queued tasks from busy threads	Ch 12 §12.26
Wrapper	An object that holds another and adds or changes behaviour around it (decorators, adapters, boxed primitives)	Ch 9 §9.4
Write-through / write-back	Cache writes go to storage immediately vs later in batches	Ch 20 §20.3
YAGNI	You Aren't Gonna Need It: don't build features before they are needed	Ch 5 §3

Self-check

- **Q:** Name the eleven framework steps in order. **A:** Clarify, requirements, use cases, entities, relationships, class diagram, key flows, patterns & SOLID, code, edge cases & concurrency, extensions.
- **Q:** Where does the diamond go, and what does filled mean? **A:** At the whole; filled = composition (the part dies with the whole).
- **Q:** A `switch (vehicleType)` computes fees. Which principle, smell and pattern? **A:** OCP; Repeated Switches (if it repeats); Strategy.
- **Q:** Decorator vs Proxy vs Chain of Responsibility? **A:** Decorator adds behaviour and every layer runs; Proxy controls access; in CoR one handler can stop the flow.
- **Q:** State vs Strategy? **A:** States know each other and advance themselves; strategies are chosen from outside.
- **Q:** Four Coffman conditions, and the usual fix? **A:** Mutual exclusion, hold and wait, no preemption, circular wait; global lock ordering.
- **Q:** Why is `volatile` not enough for `count++`? **A:** Visibility, not atomicity; use `AtomicInteger` or a lock.
- **Q:** The six machine-coding packages? **A:** model, repository, service, strategy, exception, driver.
- **Q:** What makes every booking problem safe? **A:** Naming the real unit of inventory and making "if free then take" one atomic step (plus holds that expire).

TL;DR

- **Framework:** clarify → requirements → use cases → entities → relationships → diagram → flows → patterns/SOLID → code → edge cases/concurrency → extensions.
- **Classes:** different data → field; different behaviour → class; one sentence per class; composition over inheritance.
- **SOLID** diagnoses change pain; always state the cost of the fix, and know when not to apply it.
- **Patterns** come from signals: Strategy (rules vary), Factory (type value → class), Observer (many listeners), State (lifecycle), Singleton (exactly one), Builder (many optional fields). Use one or two, name a rejected one.
- **Concurrency:** find the shared state, state the invariant, make check-then-act atomic with the smallest tool, lock in a fixed order, notify outside locks.
- **Machine coding:** run early and often, mandatory first, services return data, the driver prints and keeps going.
