Low-Level Design Handbook

OOP · UML · SOLID · Clean Code · Refactoring · Design Patterns · Concurrency · 45+ case studies in Java

22 parts · one place to study LLD: DesignGurus courses + classic books + GitHub problem sets, combined

what it is | problem | how it works | trade-offs | real world | interview | self-check | TL;DR

Personal study notes. Course diagrams belong to DesignGurus. Not for redistribution.

Contents

1. **Chapter 1 — The LLD Interview & How to Approach It**
   - 1.1 What this round is, and what this handbook covers
   - 1.2 How the interview runs
   - 1.3 A complete answer in five minutes: "Design a music playlist"
   - 1.4 The step-by-step answer framework
   - 1.5 From one line to a list of requirements
   - 1.6 Finding the classes
   - 1.7 Connecting the classes (preview)
   - 1.8 Keeping the design honest with SOLID
   - 1.9 The design patterns that come up in this round
   - 1.10 Code, edge cases and concurrency: how to write interview code
   - 1.11 Worked mini-example, end to end: a small parking lot
   - 1.12 Communication tips
   - 1.13 How to use this handbook, and a study plan
   - 1.14 Common mistakes
   - In the interview
   - Self-check
   - TL;DR
2. **Chapter 2 — OOP Fundamentals**
   - 2.1 What object-oriented programming is
   - 2.2 Classes, objects, constructors, `this`, `static` and `final`
   - 2.3 Encapsulation
   - 2.4 Abstraction
   - 2.5 Inheritance
   - 2.6 Polymorphism (and the full bank example)
   - 2.7 Compile-time vs runtime polymorphism: overloading vs overriding
   - 2.8 Interfaces (default, static, private methods, functional interfaces)
   - 2.9 Abstract classes vs interfaces
   - 2.10 Enums with fields and behaviour
   - 2.11 Composition over inheritance
   - 2.12 Object identity vs equality: the `equals` / `hashCode` contract
   - 2.13 Immutability and records
   - 2.14 Access modifiers and packages
   - 2.15 Generics basics for LLD
   - 2.16 Coupling and cohesion (the yardsticks)
   - 2.17 Object-oriented analysis and design (OOA / OOD / OOP)
   - Chapter summary: in the interview
   - Self-check (whole chapter)
   - TL;DR
3. **Chapter 3 — Class Relationships & UML**
4. **Part A — Class Relationships**
   - 3.1 The big picture: what a "relationship" really claims
   - 3.2 Association (uni-directional, bi-directional, multiplicity)
   - 3.3 Aggregation
   - 3.4 Composition
   - 3.5 Dependency
   - 3.6 Generalization (inheritance)
   - 3.7 Realization (interface implementation)
   - 3.8 Decision guide: choosing the relationship between two classes
5. **Part B — UML**
   - 3.9 What UML is (structural vs behavioural diagrams)
   - 3.10 Use-case diagrams
   - 3.11 Class diagrams
   - 3.12 Sequence diagrams
   - 3.13 Activity diagrams
   - 3.14 State machine diagrams
6. **Part C — UML in the interview**
   - 3.15 How much UML to draw in an interview
   - 3.16 Chapter self-check
   - 3.17 TL;DR
7. **Chapter 4 — SOLID Principles**
   - 4.1 What SOLID is and why you should learn it
   - 4.2 Single Responsibility Principle (SRP)
   - 4.3 Cohesion
   - 4.4 Coupling
   - 4.5 Separation of Concerns (SoC)
   - 4.6 SRP vs cohesion vs coupling vs SoC — one table
   - 4.7 Open/Closed Principle (OCP)
   - 4.8 Liskov Substitution Principle (LSP)
   - 4.9 Interface Segregation Principle (ISP)
   - 4.10 Dependency Inversion Principle (DIP)
   - 4.11 Refactoring one class through all five principles
   - 4.12 SOLID and design patterns
   - 4.13 SOLID in the design interview
   - 4.14 Common questions about SOLID (with short answers)
   - 4.15 Over-engineering: the warnings in one place
   - Chapter self-check
   - TL;DR
8. **Chapter 5 — More Design Principles**
   - 1. DRY — Don't Repeat Yourself
   - 2. KISS — Keep It Simple, Stupid
   - 3. YAGNI — You Aren't Gonna Need It
   - 4. Law of Demeter (Principle of Least Knowledge)
   - 5. Tell, Don't Ask
   - 6. Composition over Inheritance
   - 7. Program to an Interface, Not an Implementation
   - 8. Encapsulate What Varies
   - 9. Strive for Loosely Coupled Designs
   - 10. The Hollywood Principle (Inversion of Control)
   - 11. Separation of Concerns (SoC)
   - 12. Principle of Least Astonishment (POLA)

- 13. Fail Fast
- 14. Immutability
- 15. Design by Contract (DbC)
- 16. GRASP — General Responsibility Assignment Software Patterns
- 16.1 Information Expert
- 16.2 Creator
- 16.3 Controller
- 16.4 Low Coupling
- 16.5 High Cohesion
- 16.6 Polymorphism
- 16.7 Pure Fabrication
- 16.8 Indirection
- 16.9 Protected Variations
- 17. Domain-Driven Design (DDD) Essentials
- Chapter summary — how the principles fit together

9. **Chapter 6 — Clean Code**
   - What is clean code, and why bother?
   - 1. Meaningful Names
   - 2. Functions
   - 3. Comments
   - 4. Formatting
   - 5. Objects and Data Structures
   - 6. Error Handling
   - 7. Boundaries
   - 8. Unit Tests
   - 9. Classes
   - 10. Systems
   - 11. Emergence — Kent Beck's Four Rules of Simple Design
   - 12. Concurrency
   - 13. Successive Refinement and the Case Studies (Chapters 14–16: how clean code is actually written)
   - 14. Smells and Heuristics (the checklist)
   - 15. Code Review Checklist (best practices)
   - 16. Error-Handling Strategy (best practices for real services)
   - 17. Testing Strategies (unit vs integration, test doubles, mocks)
   - Chapter summary
10. **Chapter 7 — Refactoring**
    - 7.1 Refactoring fundamentals
    - 7.2 Code smells
    - 7.3 The refactoring catalogue
    - 7.4 Smell → refactorings lookup table
    - 7.5 Worked example — from messy to clean in six compiling steps
    - 7.6 Refactoring toward patterns
    - 7.7 Putting it together
    - 7.8 Full source code and output
11. **Chapter 8 — Design Patterns: Introduction & Creational Patterns**
12. **Part A — Design patterns: the big picture**
    - 8.1 What is a design pattern?
    - 8.2 A short history: from buildings to the "Gang of Four"
    - 8.3 The three categories and all 23 GoF patterns
    - 8.4 The OO principles behind every pattern
    - 8.5 How to pick a pattern
    - 8.6 Anti-patterns: when patterns go wrong
13. **Part B — Creational patterns**
    - 8.7 Creational patterns at a glance
    - 8.8 Singleton
    - 8.9 Simple Factory (an idiom, not a GoF pattern)
    - 8.10 Factory Method
    - 8.11 Abstract Factory
    - 8.12 Builder
    - 8.13 Prototype
    - 8.14 Bonus — Object Pool
    - 8.15 Creational patterns compared
    - 8.16 Chapter self-check
    - 8.17 Chapter TL;DR
14. **Chapter 9 — Structural Design Patterns**
    - 9.0 What structural patterns are
    - 9.1 Adapter Pattern
    - 9.2 Bridge Pattern
    - 9.3 Composite Pattern
    - 9.4 Decorator Pattern
    - 9.5 Facade Pattern
    - 9.6 Flyweight Pattern
    - 9.7 Proxy Pattern
    - 9.8 Putting it all together — comparison
15. **Chapter 10 — Behavioral Design Patterns (Part 1)**
    - 10.0 Behavioral patterns: the big picture
    - 10.1 Chain of Responsibility
    - 10.2 Command
    - 10.3 Iterator
    - 10.4 Mediator
    - 10.5 Memento
    - 10.6 Interpreter
    - 10.7 Chapter recap: the six patterns side by side
16. **Chapter 11 — Behavioral Design Patterns (Part 2) & Beyond GoF**
    - 11.1 Observer
    - 11.2 State
    - 11.3 Strategy
    - 11.4 Template Method
    - 11.5 Visitor
    - 11.6 GoF behavioral patterns: quick-reference summary
    - 11.7 Beyond GoF: patterns every LLD interview expects
    - 11.8 Choose the right behavioral pattern
17. **Chapter 12 — Concurrency & Multithreading for LLD (Java)**
18. **Part A — Foundations**
    - 12.1 Concurrency vs parallelism
    - 12.2 Processes vs threads

- 12.3 Thread lifecycle & states
- 12.4 Creating threads: `Thread`, `Runnable`, `Callable`, `ExecutorService`, virtual threads

19. **Part B — What goes wrong**
    - 12.5 Race conditions & critical sections
    - 12.6 Java Memory Model basics: visibility, happens-before, `volatile`
20. **Part C — Locks**
    - 12.7 Mutex (mutual exclusion) and `synchronized`
    - 12.8 `ReentrantLock` and reentrancy
    - 12.9 Try-lock & timed locking
    - 12.10 Read-write locks: `ReadWriteLock` and `StampedLock`
    - 12.11 Coarse-grained vs fine-grained locking
21. **Part D — Coordination**
    - 12.12 Semaphores
    - 12.13 Condition variables: `wait/notify` and `Condition`
    - 12.14 `CountDownLatch` and `CyclicBarrier`
22. **Part E — Lock-free**
    - 12.15 Compare-and-swap (CAS) & atomics
    - 12.16 Concurrent collections
23. **Part F — Liveness failures**
    - 12.17 Deadlock
    - 12.18 Livelock
    - 12.19 Starvation (and fairness)
24. **Part G — Concurrency patterns**
    - 12.20 Signaling pattern
    - 12.21 Thread pool pattern
    - 12.22 Producer-consumer pattern
    - 12.23 Reader-writer pattern
    - 12.24 Immutability & thread confinement
25. **Part H — Concurrency in LLD interviews**
    - 12.25 How concurrency shows up in LLD interviews (parking, seat booking, inventory)
    - 12.26 Choosing the right tool (cheat sheet)
    - 12.27 Chapter self-check
    - 12.28 Chapter TL;DR
26. **Chapter 13 — Classic Concurrency Problems**
    - 13.1 Print FooBar Alternately (LeetCode 1115)
    - 13.2 Print Zero Even Odd (LeetCode 1116)
    - 13.3 Fizz Buzz Multithreaded (LeetCode 1195)
    - 13.4 Building H2O (LeetCode 1117)
    - 13.5 Dining Philosophers (LeetCode 1226)
    - 13.6 Thread-safe cache with TTL
    - 13.7 Design a (simplified) Concurrent HashMap — lock striping
    - 13.8 Thread-safe bounded Blocking Queue (two ways)
    - 13.9 Concurrent Bloom Filter
    - 13.10 Multi-threaded Merge Sort (Fork/Join)
    - 13.11 Rate limiter — token bucket (thread-safe)
    - 13.12 Chapter summary
    - 13.13 Chapter self-check
    - 13.14 Chapter TL;DR
27. **Chapter 14 — Case Studies: Everyday Objects**
    - 14.1 Design a Parking Lot
    - 14.2 Design a Vending Machine
    - 14.3 Design a Coffee Vending Machine
    - 14.4 Design an ATM
    - 14.5 Design an Elevator System
    - 14.6 Design a Traffic Signal Control System
    - 14.7 Design a Shipping Locker System
    - Chapter summary
28. **Chapter 15 — Case Studies: Booking & Inventory (Part 1)**
    - Why booking problems are interview favourites
    - 15.1 Design a Library Management System
    - 15.2 Design a Movie Ticket Booking System (BookMyShow)
    - 15.3 Design a Concert Ticket Booking System
    - 15.4 Design a Hotel Management System
    - Chapter summary
29. **Chapter 16 — Case Studies: Booking & Inventory (Part 2)**
    - Design a Car Rental System
    - Design a Restaurant Management System
    - Design an Airline Management System
    - Design a Course Registration System
    - Chapter summary
30. **Chapter 17 — Case Studies: Games & Rules**
    - Design Blackjack and a Deck of Cards
    - Design Chess
    - Design Tic-Tac-Toe
    - Design Snake and Ladder
    - Design 2048
    - Chapter summary
31. **Chapter 18 — Case Studies: Platforms & Feeds (Part 1)**
    - 18.0 What platform problems test
    - 18.1 Design Stack Overflow
    - 18.2 Design Cricinfo
    - 18.3 Design LinkedIn
    - 18.4 Design Facebook
    - 18.5 Chapter summary
32. **Chapter 19 — Case Studies: Commerce & Marketplaces (Part 2 of Platforms)**

- Design Amazon — Online Shopping System
- Design an Online Stock Brokerage System
- Design an Online Auction System
- Design a Music Streaming Service (Spotify)
- Design an Online Food Delivery Service (Swiggy) + FoodKart
- Design a Grocery Store (POS & Checkout)
- Chapter summary

33. **Chapter 20 — Case Studies: Pattern-Driven Components**
    - 20.1 Design Splitwise
    - 20.2 Design a Notification Service
    - 20.3 Design an In-Memory Cache (and an LRU Cache from scratch)
    - 20.4 Design a Ride Sharing Service (Uber)
    - 20.5 Design a Logging Framework
    - 20.6 Design a Pub-Sub System
    - 20.7 Design a Rate Limiter
    - 20.8 Chapter summary
    - 20.9 Chapter self-check
    - 20.10 Chapter TL;DR
34. **Chapter 21 — Case Studies: Machine-Coding Round Problems**
    - 21.0 How the machine-coding round works
    - 21.1 Design a Task Management System
    - 21.2 Design a Digital Wallet Service
    - 21.3 Design an Event Calendar (Flipkart)
    - 21.4 Design a LeetCode-like Coding Platform — "Coding Blox" (Flipkart)
    - 21.5 Design a Property Listing Site — "PropertyHunt" (ClearTrip)
    - 21.6 Design a Loan Ledger — "Ledger Co" (Navi)
    - 21.7 Design an Inventory Management System
    - 21.8 Design a Unix File Search (`find`)
    - Chapter summary
35. **Chapter 22 — Revision: Cheat Sheets & Glossary**
    - 22.1 How to revise
    - 22.2 The LLD interview answer framework (one page)
    - 22.3 OOP & relationships cheat sheet
    - 22.4 SOLID one-pager
    - 22.5 Other design principles and Clean Code rules
    - 22.6 Code smells → refactorings (all 24)
    - 22.7 Design patterns: all 23 GoF + extras
    - 22.8 Concurrency cheat sheet
    - 22.9 Case-study map
    - 22.10 Machine-coding and edge-case checklists
    - 22.11 Glossary
    - Self-check
    - TL;DR

Chapter 1 — The LLD Interview & How to Approach It

What you will learn in this chapter

- What the low-level design (LLD) round is, what it is called at different companies, and how it differs from the system design round.
- The difference between the **object-oriented design (OOD) round** and the **machine-coding round**.
- A complete answer, start to finish, before any theory (a music playlist in Java).
- A repeatable, step-by-step framework that turns one sentence into working code, with a time budget.
- How to turn one line into requirements, how to find classes, how to check a design with SOLID (five rules of thumb that keep classes easy to change), and which six patterns come up most.
- What interviewers actually score, how to talk while you design, and the mistakes that cost the most.
- A study plan and a map of this handbook (Chapters 1–22).
- A second worked mini-example (a small parking lot) run through every step of the framework.

1.1 What this round is, and what this handbook covers

What it is

The **low-level design** round gives you **a single application** to design while an interviewer watches, usually within 45–60 minutes (a machine-coding round stretches this to 90 minutes or 2 hours). The servers underneath are not your concern. What you design is **the set of classes inside the program**: a parking lot, a vending machine, a chess game, Splitwise (an app that splits shared expenses between friends), an elevator.

A few words we will use all the time:

Term	Meaning
Class	A named type in code. It holds some data (fields) and the methods (functions that belong to the class) that work on that data.
Object	One concrete instance of a class, with real values in its fields.
Responsibility	The one job a class does, which you should be able to state in a single sentence.
Relationship	How two classes are connected: one uses, holds, owns, or extends the other.
UML	Unified Modeling Language: the standard set of symbols for drawing classes and their relationships.
Design pattern	A named, reusable answer to a design problem that keeps coming up (for example Strategy or Observer).

Everyday analogy: system design is the **city plan** (roads, power stations, water pipes). Low-level design is the **floor plan of one house**: which rooms exist, what each room is for, and which doors connect them.

Plenty of engineers write classes daily and still struggle here, because day-to-day work seldom makes you **explain aloud** why each class exists and **justify** the way they connect. This round is exactly that.

What you should be able to do after this handbook

- Turn one sentence ("Design a parking lot") into a bounded list of requirements, with an explicit out-of-scope list.
- Pick out the classes a problem calls for, with **exactly one job** apiece.
- Decide how any pair of classes is related, and draw that link without mistakes.
- Code the handful of Java methods behind the core flows until they actually execute.
- Say which design pattern you used **and which one you rejected**, and why.

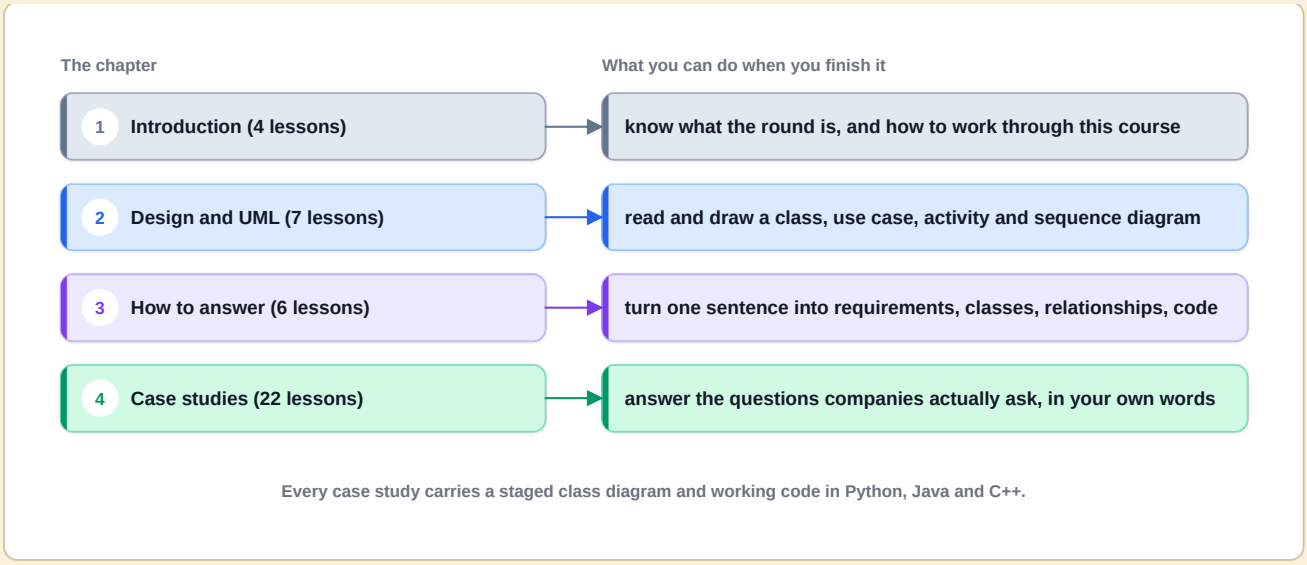

Figure — The four parts of the course material this handbook absorbs: introduction, design and UML notation, the answering method, and the case studies (course diagram)

The figure above shows the four building blocks of preparation: first understand the round (this chapter), then the notation (UML), then the **method** for answering, then many worked case studies. This handbook follows the same arc but goes wider: it adds full chapters on OOP, SOLID, the classic design principles, clean code, refactoring (improving the structure of code without changing what it does), all 23 GoF patterns (the classic catalogue from the 1994 "Gang of Four" book), and concurrency (several pieces of work running at the same time and sharing data), so that you do not need a second resource.

What every case study in this handbook contains

Once you have read one case study you always know what comes next, because each one follows the same template:

- The question, and the requirements chosen to design against (with an out-of-scope list).
- The actors and their use cases (often as a use case diagram, a picture of who uses the system and for what).
- The class diagram, built up in stages so you follow the reasoning instead of staring at a finished picture.
- Diagrams for the most important flows (activity diagrams show the steps of a process; sequence diagrams show the messages objects send each other, in time order).
- Working Java code with a driver `Main` (a small class whose `main` method runs the example) and its real output.
- The design patterns the answer uses, named, **only where it really uses one**.
- An "Extensions & follow-up questions" section: the simplifications made, and what to say when the interviewer notices them.

Who this is for

- You have an interview coming up and this round is part of it.
- You write object-oriented code at work but have never had to defend a class diagram out loud.
- You prepared for system design and discovered this is a different round with different rules.

It also pays off outside interviews: the same step-by-step method is how you split a new feature into classes at work when nobody has designed it yet.

What you need already

- **Some object-oriented language**, well enough that a class with a constructor (the special method that sets up a new object) plus a few methods reads easily to you. Every example here is in **Java 21** (a recent long-term-support release of Java).
- You do **not** need UML (Chapter 3 teaches it from zero).
- You do **not** need system design knowledge. That round asks how a product survives millions of users (servers, databases, caches, queues; see System Design Fundamentals if those words are new). This round stays **inside one process** (one running program: classes, fields, methods, relationships). Practising one round gives you little for the other.
- You do not need data structures and algorithms beyond the basics (lists, maps, sets, queues, heaps). That is a separate round. (Quick refresher: a **list** keeps items in order, a **map** looks a value up by its key, a **set**

holds no duplicates, a **queue** hands items out first-in, first-out, and a **heap** always gives you the smallest or largest item quickly.)

What this handbook will not do

It will not teach you a programming language from scratch (it assumes you can already read one). It will not give you scripts to memorise. A memorised answer is useless the moment the question is one you have not seen. **The reusable part is the method.**

TL;DR

The LLD round = design the classes inside one application, out loud, then code the main flows. Prerequisite: one OO language. The method beats memorised answers.

1.2 How the interview runs

What it is

The interviewer says one sentence, for example "Design a parking lot", and then stops talking. Nothing in that sentence tells you how many classes they want, whether to code, or how long you have. **That silence is the hard part.** This section removes it.

The round has several names, all meaning roughly the same thing:

Name	Where you hear it	What is different
Object-oriented design (OOD) interview	US big tech, many product companies	Whiteboard/doc: requirements, classes, diagram, code for main flows.
Low-level design (LLD)	Indian product companies, general usage	Same as OOD; the umbrella term.
Machine-coding round	Commonly reported at Indian product companies such as Flipkart, Swiggy and PhonePe	Same idea, but **working, runnable code is mandatory** at the end, usually in a 90-minute to 2-hour window.

LLD vs HLD (system design). Same product, different zoom level:

	Low-level design (this handbook)	High-level / system design
Scope	Inside one application or service	Many services and machines
Vocabulary	Classes, interfaces, fields, methods, relationships, patterns	Servers, load balancers, databases, caches, queues, sharding
Output	Class diagram + code	Architecture diagram + capacity numbers
Typical question	"Design the classes for a parking lot"	"Design a parking-lot booking service for 10 million users"

(For the right-hand column: a **load balancer** spreads incoming requests across several servers, and **sharding** splits one big database into pieces stored on different machines. You will not need either in this round.)

OOD round vs machine-coding round

	OOD / LLD discussion round	Machine-coding round
Duration	45–60 minutes	Usually about 90 minutes of coding (often 2 hours including evaluation)
Where	Whiteboard, shared doc, or IDE (code editor with build and run tools)	Your own IDE, on your laptop or a remote machine
What you produce	Requirements, use cases, class diagram, code for 2–3 main flows	A **complete, running program** implementing the minimum required features
Storage	Not discussed much	**In-memory** (maps and lists); no real database unless asked
Interaction	Continuous conversation with the interviewer	Problem statement up front, mostly silent coding, then a **demo and code walkthrough**
What is judged	Bounding the problem, responsibilities, relationships, trade-offs, patterns	Working code, **data models**, **service interfaces** a client could call, **extensibility** (can a new feature be added without rewriting), readability, edge cases, sometimes tests and thread safety
Common failure	Talking without converging, or coding too early	Not finishing, or finishing with one giant class that cannot be extended

The machine-coding round, as commonly described by candidates, works like this: you get a problem statement with a **minimum set of features**; within the time window you must choose the data structures, design **service interfaces** that a client (for example a command-line driver, a small program you run from a terminal) would use, and present **working code** together with the reasoning behind your design and the patterns you used. It is especially common for SDE-1 and SDE-2 hiring (Software Development Engineer job levels: entry level and mid level).

A few words from the table above: **data models** are the classes that hold the problem's data (a `Ticket`, a `Spot`); a **service interface** is the set of public methods a caller uses (`park`, `exit`); **edge cases** are unusual inputs at the boundaries (empty, full, negative, duplicate); **thread safety** means the code stays correct when several **threads** (independent lines of execution inside one program) use it at the same moment.

How it works: the five core steps

Every question in this handbook is answered with the same five core steps (Section 1.4 expands them into a finer checklist):

1. **Clarify the requirements** — turn one sentence into a short written list of things the system must do.
2. **Find the actors and use cases** — who uses the system (actors) and what each of them does (use cases).
3. **Find the classes** — turn requirements into classes; give each one responsibility.
4. **Connect the classes** — decide how each pair relates; record it in a class diagram.
5. **Write the code** — the classes plus the 2–3 methods that implement the main flows.

Getting the order right matters more than going fast. Each step feeds the next. Skip step 1 and step 3 has nothing to work from: you end up inventing classes no requirement asked for.

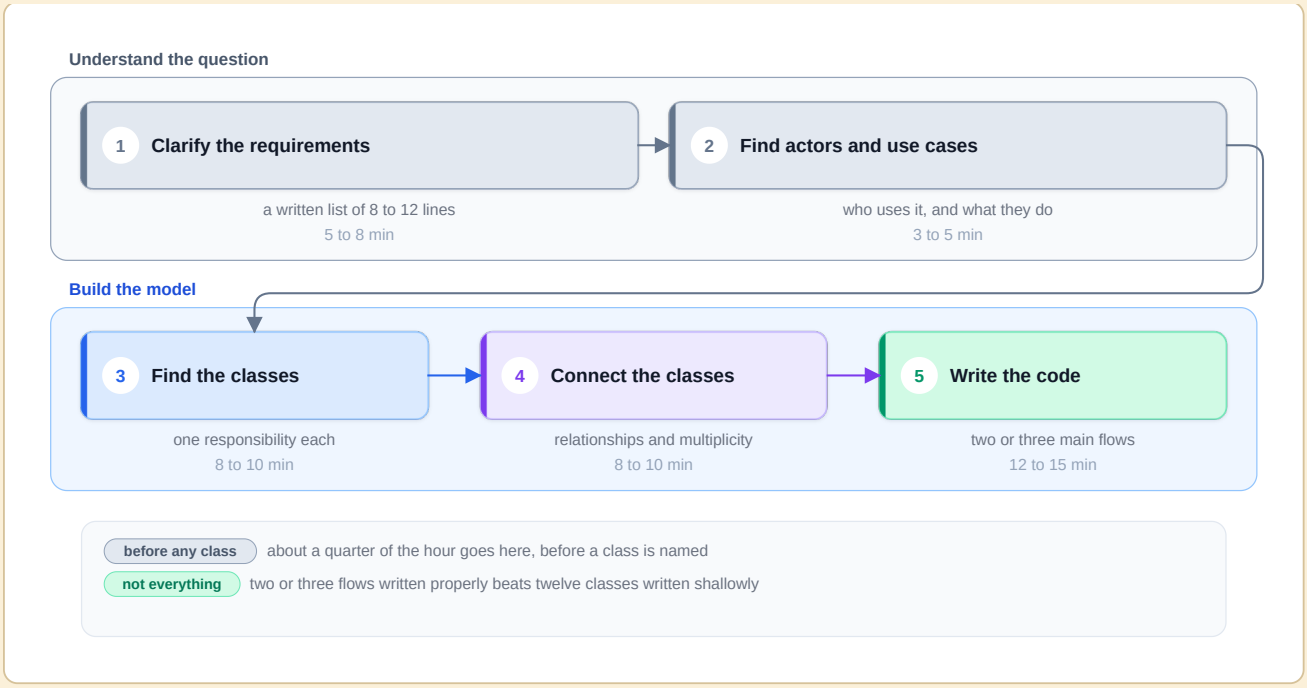

Figure — The five steps split into "understand the question" and "build the model", with a time budget for each (course diagram)

In the figure above, notice two things. First, up to **a quarter of the hour is spent before a single class is named** (requirements plus actors). Second, the code step is the largest single block, yet it covers only two or three flows.

Nobody completes the whole product in the time, and you are not expected to. The design is judged on the part you chose to build properly, not on how much of the product you touched.

Time-boxing

45-minute OOD round:

Step	Time	What exists at the end
Clarify requirements	5–8 min	A written list of 8–12 requirements + out-of-scope list
Actors and use cases	3–5 min	2–4 actors, 6–10 use cases
Find the classes	8–10 min	Class list, one responsibility each
Connect the classes	8–10 min	Class diagram with relationships and multiplicity (how many of each)
Write the code	12–15 min	2–3 methods that implement the main flows

90-minute machine-coding round (a budget that works well in practice):

Phase	Time	Output
Read the statement, list requirements and assumptions	5–10 min	Comment block at the top of `Main.java`
Model: entities, enums, service interfaces	10–15 min	Empty classes/interfaces that compile
Implement the core flow end to end	30–40 min	One happy path running from a driver `main`
Remaining features + validation + edge cases	15–20 min	All "must have" features working
Polish: names, exceptions, one extension point, demo script	5–10 min	Clean output you can demo
Buffer	5 min	Never zero

In this table, code that **compiles** is code the Java compiler accepts, so it can run; **enums** are types with a fixed list of named values (more in Section 1.6); the **happy path** is the main flow with valid input and nothing going wrong.

Rule of thumb: **get something running by the halfway mark**. A running partial solution beats a beautiful non-compiling one.

What the interviewer is actually judging

The interviewer is not counting classes. They watch for:

1. **Did you bound the problem?** A design for a clear, bounded set of requirements beats a broad design for an unbounded one.
2. **Does each class have one job you can state in one sentence?** If one sentence cannot describe a class, it is normally two classes glued together.
3. **Are the relationships right?** Holding, owning, and extending are different choices; a wrong one is visible immediately.
4. **Does the code match the diagram?** If the code has a method that the diagram has nowhere to put, either the code or the diagram is wrong.
5. **Can you explain a trade-off?** Each design decision has a road taken and a road not taken; naming both scores higher than naming only one.

Machine-coding rounds add: **does it run**, is it **modular** (can a new vehicle type / payment method / rule be added by adding a class), is it **readable** (names, small methods), does it **handle bad input** gracefully, and (for senior roles) is shared state **thread-safe**.

Notice what is **not** on the list: perfect UML notation, or using every diagram type. **What is graded is the model; the notation is just the way you present it.**

A worked example of size

Take the parking lot. About 12 requirements produce about 12 classes with about 15 relationships between them. Three classes implement the main flows: one hands out a ticket, one holds a vehicle, one prices the stay. You write those three properly. You name the other nine and describe each in a sentence. That is a complete answer in 45 minutes.

The most expensive mistake is writing all twelve classes at the same level of detail. It feels thorough, but the clock runs out before any single flow works end to end.

> **TL;DR**
>
> OOD, LLD and machine coding are one family of rounds; machine coding requires running code in ~90 minutes. Follow five steps in order, spend a quarter of the time before naming a class, and build two or three flows properly rather than twelve classes shallowly.

1.3 A complete answer in five minutes: "Design a music playlist"

Let's see a complete answer first and save the theory for later. It is small on purpose: a screenful of classes, a single diagram, a page of Java. Later case studies are roughly ten times the size, yet they follow **the identical outline**. Don't worry if some diagram notation is unfamiliar; Chapter 3 covers it.

Step 1: requirements

The interviewer says only: "Design a music playlist." Three clarifying questions produce three requirements:

- Songs sit in a playlist, and **their sequence is significant**.
- Someone can ask for **the following song**, and the player keeps track of its current position.
- A user can turn **shuffle** on, and the play order changes.

Out of scope, agreed out loud: user accounts, downloads, storage, and the audio itself. An explicit "not building" list earns as much credit as the "building" list.

Step 2: actors and use cases

Anyone or anything outside the application that interacts with it is an **actor**. This example has just one, the **listener**, who does three things: adds a song, plays the next one, switches shuffle on. For so small a question this takes ten seconds; for a parking lot it costs three minutes and repays ten, since **the actors reveal which classes have to exist**.

Step 3: classes, one sentence each

Class	Responsibility (one sentence, no "and" where possible)
`Song`	Holds a title, an artist and a length; knows about itself and nothing else.
`Playlist`	Holds songs in order; stores them, does not play them.
`PlayOrder` (interface)	Picks the position to play after the current one. It is an interface since several ordering rules exist.
`InOrder`	Walks through positions in insertion order.
`Shuffled`	Plays positions in a shuffled order decided once, up front.
`Player`	Holds a playlist and an order, and remembers the current position.

An **interface** names a set of methods without saying how they work. The key insight: **a rule that can vary becomes its own type.** Without shuffle, `Player` could just count upwards and `PlayOrder` would not exist. With shuffle, "what plays next" has two versions, so it becomes `PlayOrder`, and the player no longer needs to know which version it holds.

A useful test: if a responsibility sentence needs the word **"and"** to join two unrelated jobs, the class is probably two classes.

Step 4: connect them

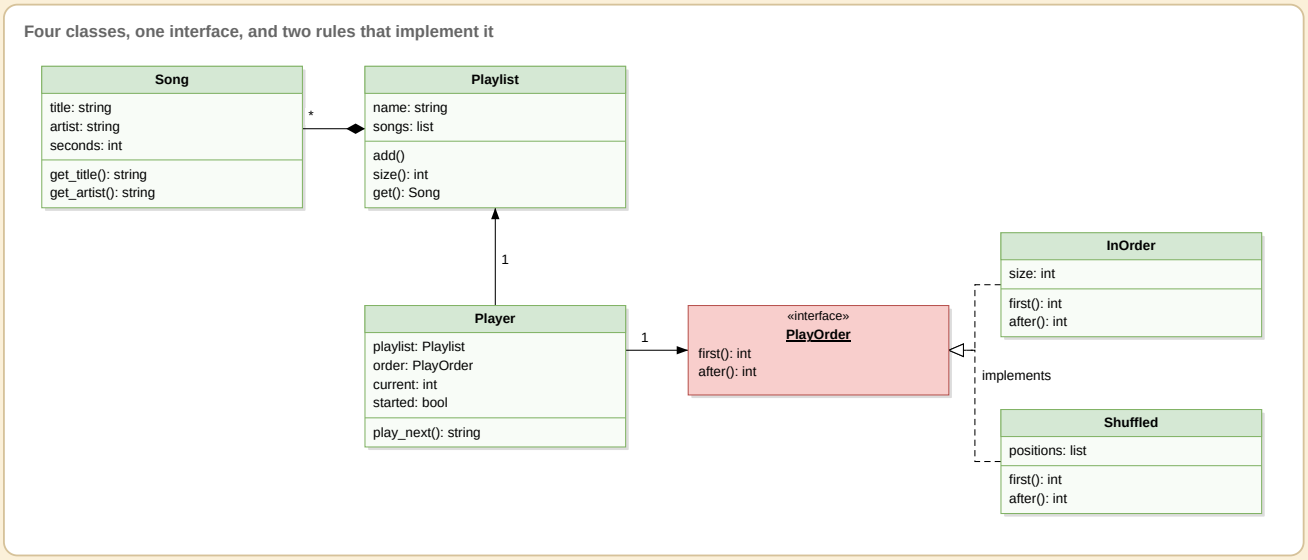

Figure — The playlist design: Playlist owns many Songs, Player uses a PlayOrder, and InOrder and Shuffled implement PlayOrder (course diagram)

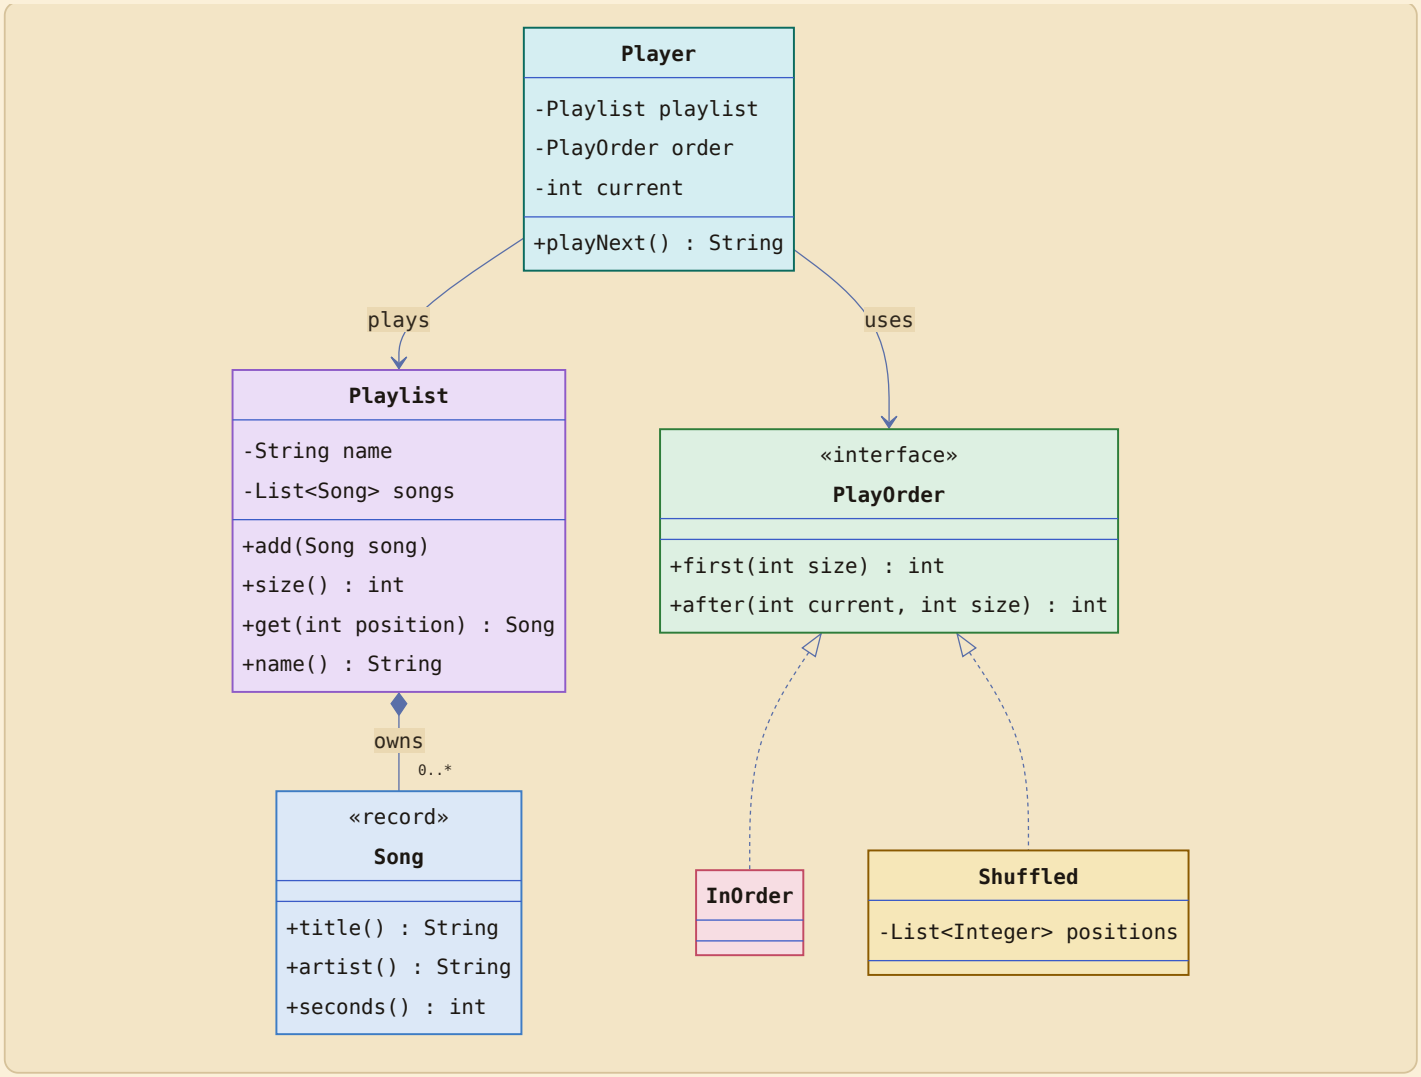
Three facts from the figure above are exactly what an interviewer checks:

- The **filled diamond** between `Playlist` and `Song` means the playlist **owns** its songs (composition); the `*` means it owns **many**.
- A **plain arrow** running from `Player` to `PlayOrder` says the player **relies on** an ordering without owning one. Its head touches the **interface** only, not `InOrder` or `Shuffled`.
- The **dashed arrows with hollow triangles** mean `InOrder` and `Shuffled` **implement** `PlayOrder`. A third rule later is one extra box; nothing already drawn changes.

Here is the same design for the Java code below:



Step 5: the code

> **Key term — reading the Java below:** A `package` line groups related classes, much like a folder. `implements PlayOrder` promises that the class provides every method of that interface, and `@Override` marks a method that fulfils such a promise (the compiler checks it). `final` on a class means no other class may extend it; on a field it means the field is set once and never reassigned. `private` hides a field or method from code outside the class.

```java
// File: code/lld/ch01/playlist/InOrder.java
package lld.ch01.playlist;

/** Plays positions in the order the songs were added. */
public final class InOrder implements PlayOrder {
    @Override public int first(int size) { return size == 0 ? NONE : 0; }
    @Override public int after(int current, int size) { return current + 1 < size ? current + 1 : NONE; }
}
```

```java
// File: code/lld/ch01/playlist/PlayOrder.java
package lld.ch01.playlist;

/** The rule that decides which position plays next. A rule that varies becomes its own type. */
public interface PlayOrder {
    int NONE = -1;                          // "there is no next position"

    int first(int size);                    // first position to play, or NONE if empty
    int after(int current, int size);       // position after 'current', or NONE at the end
}
```

```java
// File: code/lld/ch01/playlist/Player.java
package lld.ch01.playlist;

/** Holds a playlist and an order, and remembers where it is. It never asks WHICH order it holds. */
public final class Player {
    private final Playlist playlist;
    private final PlayOrder order;          // depends on the interface, not on InOrder/Shuffled
    private int current = PlayOrder.NONE;
    private boolean started = false;

    public Player(Playlist playlist, PlayOrder order) {
        this.playlist = playlist;
        this.order = order;
    }

    public String playNext() {
        if (!started) {
            current = order.first(playlist.size());
            started = true;
        } else if (current != PlayOrder.NONE) {          // once at the end, stay at the end
            current = order.after(current, playlist.size());
        }
        if (current == PlayOrder.NONE) return "end of playlist";
        Song s = playlist.get(current);
        return "playing " + s.title() + " by " + s.artist();
    }
}
```

```java
// File: code/lld/ch01/playlist/Playlist.java
package lld.ch01.playlist;

import java.util.ArrayList;
import java.util.List;

/** Holds songs in order. It stores them; it does not play them. */
public final class Playlist {
    private final String name;
    private final List<Song> songs = new ArrayList<>();   // composition: the playlist owns its list

    public Playlist(String name) { this.name = name; }

    public void add(Song song) { songs.add(song); }
    public int size()          { return songs.size(); }
    public Song get(int position) { return songs.get(position); }
    public String name()       { return name; }
}
```

```java
// File: code/lld/ch01/playlist/Shuffled.java
package lld.ch01.playlist;

import java.util.List;

/**
 * Plays positions in an order decided once, up front. The order is injected
 * (not generated inside) so the program prints the same output every run: deterministic = testable.
 */
public final class Shuffled implements PlayOrder {
    private final List<Integer> positions;

    public Shuffled(List<Integer> positions) { this.positions = List.copyOf(positions); }

    @Override public int first(int size) { return positions.isEmpty() ? NONE : positions.get(0); }

    @Override public int after(int current, int size) {
        int i = positions.indexOf(current);
        return (i >= 0 && i + 1 < positions.size()) ? positions.get(i + 1) : NONE;
    }
}
```

```java
// File: code/lld/ch01/playlist/Song.java
package lld.ch01.playlist;

/** A song knows about itself and nothing else. A record = immutable data carrier. */
public record Song(String title, String artist, int seconds) {
    public Song {
        if (title == null || title.isBlank()) throw new IllegalArgumentException("title required");
        if (seconds <= 0) throw new IllegalArgumentException("length must be positive");
    }
}
```

```java
// File: code/lld/ch01/playlist/Main.java
package lld.ch01.playlist;

import java.util.List;

public class Main {
    public static void main(String[] args) {
        Playlist mix = new Playlist("Morning mix");
        mix.add(new Song("Sunrise", "Ada Lane", 201));
        mix.add(new Song("Blue Line", "The Meridians", 187));
        mix.add(new Song("Paper Boats", "Nori Kim", 243));

        run("in order", new Player(mix, new InOrder()), mix.size());
        run("shuffled", new Player(mix, new Shuffled(List.of(2, 0, 1))), mix.size());
    }

    private static void run(String label, Player player, int songs) {
        System.out.println(label + ":");
        for (int i = 0; i <= songs; i++) {          // one extra call shows the end
            System.out.println("  " + player.playNext());
        }
    }
}
```

Run it: `cd chapters/01-lld-interview-approach/code && javac --release 21 -d /tmp/lld_01 $(find . -name '*.java') && java -cp /tmp/lld_01 lld.ch01.playlist.Main`

(`javac` is the Java compiler, which turns `.java` source files into runnable `.class` files; `java` then runs them, and `-cp` (classpath) tells it where those files are.)

Output:

```
in order:
  playing Sunrise by Ada Lane
  playing Blue Line by The Meridians
  playing Paper Boats by Nori Kim
  end of playlist
shuffled:
  playing Paper Boats by Nori Kim
  playing Sunrise by Ada Lane
  playing Blue Line by The Meridians
  end of playlist
```

Explaining each part:

- `Song` is a Java **record**: an immutable (cannot change after creation) data carrier whose fields, constructor, accessors (getter methods such as `title()`), `equals`, `hashCode` and `toString` (the standard methods for comparing objects, using them as map keys, and printing them) are generated. The compact constructor (a constructor with no parameter list, used just to check the values) validates input.
- `Playlist` keeps its list `private` (encapsulation: hiding a class's data so it can only be reached through the class's own methods). Callers can add and read, but cannot replace the list.
- `PlayOrder` is the variation point (the place where different behaviours can be plugged in). `NONE = -1` is an interface constant meaning "nothing more to play".
- `Shuffled` is **given** its order instead of generating one with `Random`. This makes the output identical on every run, which makes the design **testable**. (In production you would inject a `Random` with a seed, or a shuffled list produced elsewhere. To **inject** something is to hand it in from outside, usually through the constructor; a **seed** is a fixed starting number that makes `Random` produce the same sequence every time.)
- `Player` depends on the interface `PlayOrder`, not on a concrete class (a real class you can create objects from, as opposed to an interface). One `Player` gives both behaviours, and **nothing in it tests which mode is active**. (Its only `if`s track *where* it is: the first call asks `first`, later calls ask `after`, and once it has reached the end it stays there instead of asking the order again.)

What to notice

- **One requirement turned into a type.** Shuffle occupied a single line of the requirements, yet it produced an interface plus two implementations. That is the usual flow: **classes come out of requirements**, and it never runs backwards.
- **Each class has exactly one job.** A `Song` has no idea any playlist contains it. A `Playlist` is unaware that playback happens. A `Player` never learns how the next position gets picked.
- **The design is open to changes you did not build.** "Repeat one song" and "play in reverse" are just new classes implementing `PlayOrder`; nothing already written is reopened. (This is the Strategy pattern and the Open/Closed Principle, Chapters 4 and 11.)
- **Things were left out on purpose:** pause, volume, queue, time. In an interview you **announce** these gaps yourself instead of waiting to be caught. Every case study in this handbook ends with an "Extensions & follow-up questions" section for the same reason.

TL;DR

A complete answer = a short bounded requirement list, a few one-sentence classes, one diagram, and code for the main flow. A rule that varies becomes an interface, and the class that uses it never asks which version it holds.

1.4 The step-by-step answer framework

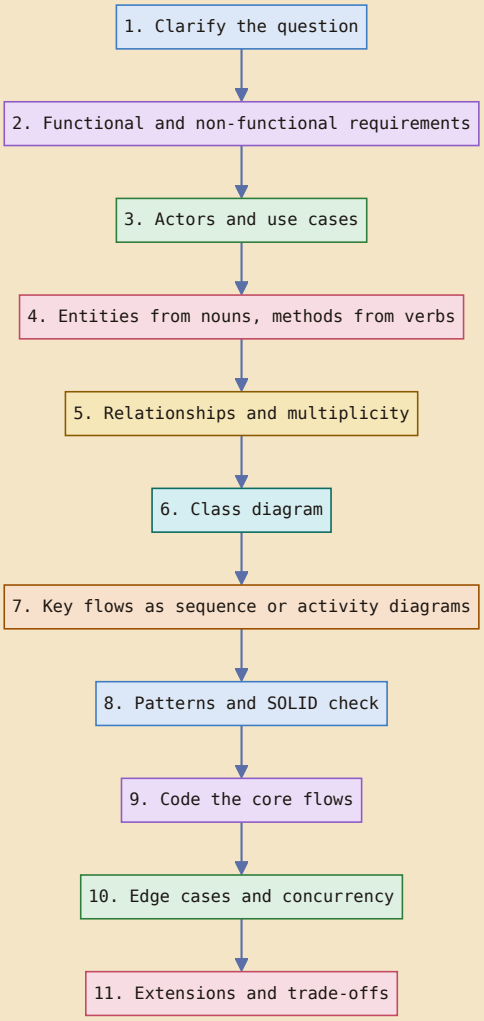
What it is

A checklist you run on **every** LLD question, so the question stops being "where do I start?" and becomes a series of small questions with known answers. It expands the five core steps into eleven finer ones.

The problem it solves

Without a framework, candidates either freeze, or jump straight into code and discover missing requirements at minute 35. The framework makes your progress **visible** to the interviewer, which is itself part of the score.

How it works



#	Step	Questions to ask yourself	Output	Core step
1	**Clarify**	Who uses it? What exactly is "a parking lot" here? Single location or many?	Shared understanding	Requirements
2	**Requirements**	What must it do (functional)? How well (non-functional: thread-safe, extensible, in-memory, latency, i.e. response time)? What is out of scope?	8–12 numbered lines + out-of-scope list	Requirements
3	**Use cases**	For each actor, what can they do?	Actor → use case list (or use case diagram)	Actors & use cases
4	**Entities**	Which nouns hold state or behaviour? Which are just values (fields/enums)?	Class list with one-sentence responsibilities	Classes
5	**Relationships**	Uses, has, owns, or is-a? How many (1, 0..1, *)?	Relationship list	Connect
6	**Class diagram**	Fields, key methods, interfaces, enums	UML class diagram	Connect
7	**Key flows**	What happens step by step for the 2–3 main use cases? What states does the core object go through?	Sequence / activity / state diagram (states and the moves between them)	Connect
8	**Patterns & SOLID**	Is there a rule that varies (Strategy)? A lifecycle (fixed states an object moves through: State)? Many listeners (Observer)? Any class with two reasons to change?	Named patterns + rejected alternatives	Check
9	**Code**	Interfaces, enums, models, services, a driver `main`	Running code for main flows	Code
10	**Edge cases & concurrency**	Invalid input? Full capacity? Two users grabbing the same seat?	Validation, exceptions, locks	Code
11	**Extensions**	What would change if requirement X is added?	Short answers, maybe one extra class	Wrap-up

(Row 10 in plain words: an **exception** is Java's way of signalling an error that stops the normal flow, and a **lock** lets only one thread at a time run a protected piece of code.)

Trade-offs

Do this	Instead of this	Why
Spend 8–13 minutes on steps 1–3	Coding at minute 2	Unbounded scope wastes far more time later
Code 2–3 flows fully	Stub 12 classes (empty placeholders)	Interviewers judge depth on the chosen part
Name one or two patterns where the signal appears	Apply six patterns	Over-engineering (building more flexibility than the problem needs) is scored as poor judgement
Pass time into methods (`nowMinute`) and hold money as `BigDecimal` (Java's exact decimal type; or whole cents in a `long`)	Call `System.currentTimeMillis()` inside the logic, and use `double` (binary floating-point number) for money	Deterministic (same input, same output) and testable; `double` cannot represent values like 0.10 exactly, so sums drift

When not to use it (rigidly)

If the interviewer steers ("skip requirements, I care about the class model"), follow them. The framework is a default order, not a contract. In a machine-coding round, steps 5–7 are often done in your head or as a short comment; the code **is** the diagram.

TL;DR

Clarify → requirements → use cases → entities → relationships → class diagram → key flows → patterns/SOLID → code → edge cases/concurrency → extensions. Say each step out loud as you enter it.

1.5 From one line to a list of requirements

What it is

Each **requirement** states a single capability, phrased so you can test whether the design delivers it. "Customers can pay at the exit" qualifies. "The parking lot should be good" does not.

- **Functional requirement** — a behaviour: "a customer takes a ticket at an entry panel".
- **Non-functional requirement** — a quality: "two entry panels must never assign the same spot" (thread safety), "adding a new vehicle type must not change existing classes" (extensibility), "data kept in memory" (storage).

Analogy: an architect never starts drawing before asking how many people will live in the house and whether they need a garage.

The problem it solves

This is not an interview trick: real products start the same way, with a short request someone has to turn into a specification. "Design a parking lot" is four words. The expected design has about twelve classes. Everything in between is yours to decide. Without a written list:

- **The design has no edges.** You keep adding classes (season tickets, number-plate recognition) and write no code.
- **You cannot defend a choice.** Asked "why is there no `Reservation` class?", the only honest answer is "I did not think of it". With a list, the answer is "reservations were out of scope; we agreed that at minute four".
- **You cannot tell when you are finished.** A bounded list turns an open request into a task with an end.

How it works: the four questions

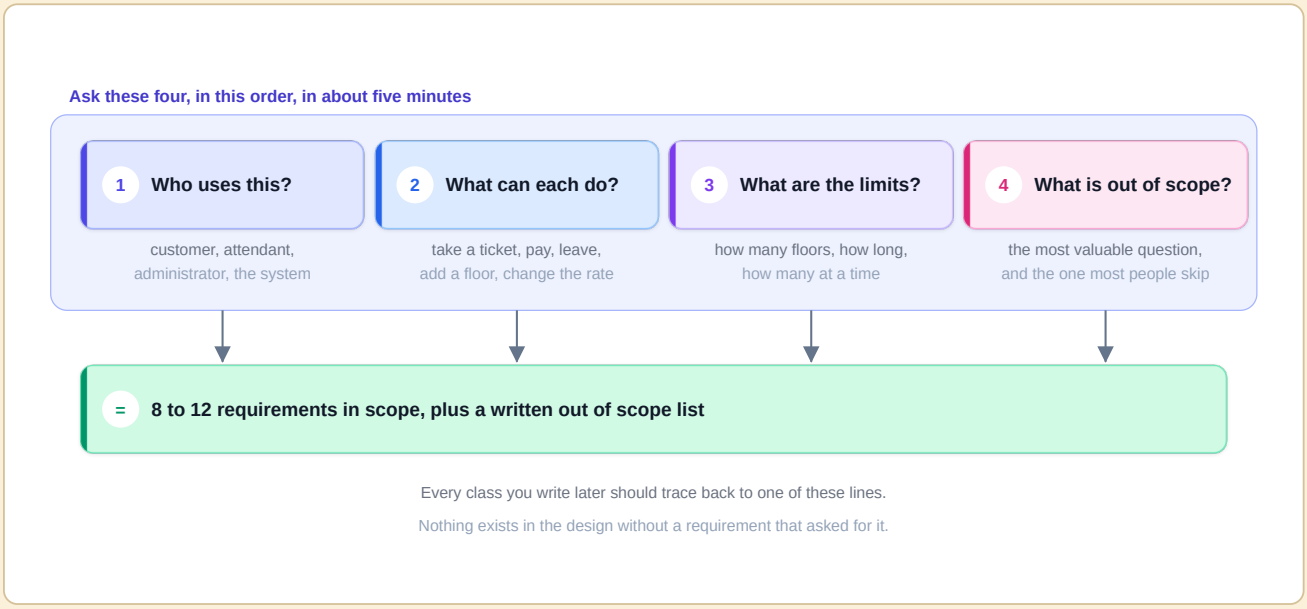


Figure — Four questions asked in order produce 8–12 in-scope requirements plus a written out-of-scope list (course diagram)

As the figure above shows, ask these in order; they take about five minutes and cover most products:

1. **Who uses this?** These are the **actors**. Parking lot: customer, attendant, administrator, and the system itself. Each brings requirements the others do not.
2. **What can each of them do?** One actor at a time, list actions. Each action is a **use case**. A customer takes a ticket, parks, pays, leaves. An admin adds floors and changes prices. Most of the list comes from here.
3. **What are the limits?** The numbers and rules: floor count, kinds of spot, maximum booking length, how many books one member can borrow. **Limits turn into constants and validation checks.** They are also the simplest requirements to gather.
4. **What is out of scope?** Hardly anyone asks this, yet it pays off most. It is the only one of the four questions that makes the problem **smaller**.

Scope questions worth asking in almost any problem:

- "Do payments belong to my design, or can I treat an external payment service as given?"
- "Is there one site, or do several sites share an account?"
- "Are users and permissions part of the model, or may I take a logged-in user for granted?"

Each answer adds or removes two or three classes, so ask early. If the interviewer says "your choice", treat it as permission, not a dodge: **choose, say it out loud, write it down**. An assumption you state clearly counts just like an answer you were given.

What good looks like: the parking lot in ten lines

In scope

1. The lot has multiple floors; each floor has many parking spots.
2. Spot types: compact, large, handicapped, motorbike, electric.
3. Vehicle types: car, van, truck, motorbike, electric car.
4. A customer takes a ticket at an entrance panel on arrival.
5. A customer pays at an exit panel, at a floor portal, or to an attendant.
6. Payment is by cash or card.
7. Charges are per hour, with the hourly rate depending on how long the stay lasts.
8. Each floor shows how many spots of each type are free.
9. The system refuses entry when no suitable spot is free.
10. Admins may add floors, spots and panels, and may update the rate.

Out of scope: season passes, licence-plate recognition, booking before arrival, refunds, reports across several sites.

Every line above becomes a class, a field, or a method. **If no line asked for it, it does not go in the design.**

Make each requirement checkable

- **Put a number on it.** Rather than "a member can borrow a few books", write "a member may have **no more than five** books out at once". That number turns into a constant, and the constant turns into a check inside one method.
- **Name the actor.** Not "books can be reserved" but "**a member** can reserve a copy that is currently on loan" (you reserve a copy that is out so you get it next). Now you know which class the method belongs to.

A line written like this is close to a test case: you can point at one method and say "requirement 5 lives here".

Use cases

A **use case** is one goal an actor achieves with the system ("customer pays for parking"). A **use case diagram** (Chapter 3) draws actors as stick figures and use cases as ovals. In a 45-minute round a bulleted list is enough:

Actor	Use cases
Customer	take ticket, park, pay (cash/card), exit
Attendant	collect cash payment, help customer
Admin	add floor, add spot, add panel, change rate
System	assign spot, update display boards, refuse entry when full

Common mistakes

- **Saying yes to every idea.** Reservations come up and you accept. Multiple sites, accepted too. Twenty minutes on, you have 22 requirements and nothing designed. Declining is allowed: "Let me park reservations for now and get ticketing and payment working end to end first; I'll come back to it if time allows." Interviewers see that as a **strong** move, because it proves you can protect a fixed time budget from an open-ended ask.
- Forgetting non-functional requirements (concurrency, extensibility).
- Writing vague lines with no number and no actor.

In the interview

> **30-second answer** (to "how do you start an LLD question?"): "I ask four questions: who uses it, what each actor does, what the limits are, and what is out of scope. I write 8 to 12 numbered requirements and an out-of-scope list, confirm them with you, and then every class I create must trace back to one of those lines."

Follow-ups:

- *"Why not just start designing?"* — Without a boundary the design grows forever and I cannot defend omissions. Five minutes here saves fifteen later.
- *"What if I say 'your choice'?"* — I pick the simpler option, say it out loud, and write it as an assumption, so the decision is visible and reversible.

Self-check

- **Q:** Which of the four questions makes the problem smaller? **A:** "What is out of scope?"
- **Q:** Rewrite "users can book some seats" as a checkable requirement. **A:** "A customer can hold at most 10 seats for one show; held seats are released after 10 minutes if unpaid."
- **Q:** Where do limits end up in code? **A:** As constants plus a validation check in the method that owns the data.

TL;DR

Four questions (who, what, limits, out of scope) → 8–12 checkable lines with numbers and actors, plus an out-of-scope list. Saying "no" to extra scope is a strength.

1.6 Finding the classes

What it is

A reliable ten-minute method to go from requirements to a class list: **collect candidates, cut the ones that are not classes, give each survivor one job.**

How it works

1. **Underline the nouns** in the requirements. For the parking lot they fall into rough groups. Structure: parking lot, floor, spot, compact spot, large spot, entrance panel, exit panel, display board, portal. Vehicles: vehicle, car, van, truck, motorbike. People: customer, attendant, administrator. Money and time: ticket, payment, cash, card, rate, hour. That is deliberately too many: treat them as **candidates**. Since every one was taken from the requirements, none of them is made up.
2. **Underline the verbs.** Park, take a ticket, pay, leave, refuse entry, show free spots, add a floor, change the rate. **Each verb turns into a method** and has to land on some class. A verb with no home means a class is missing.
3. **Cut candidates with five tests:**

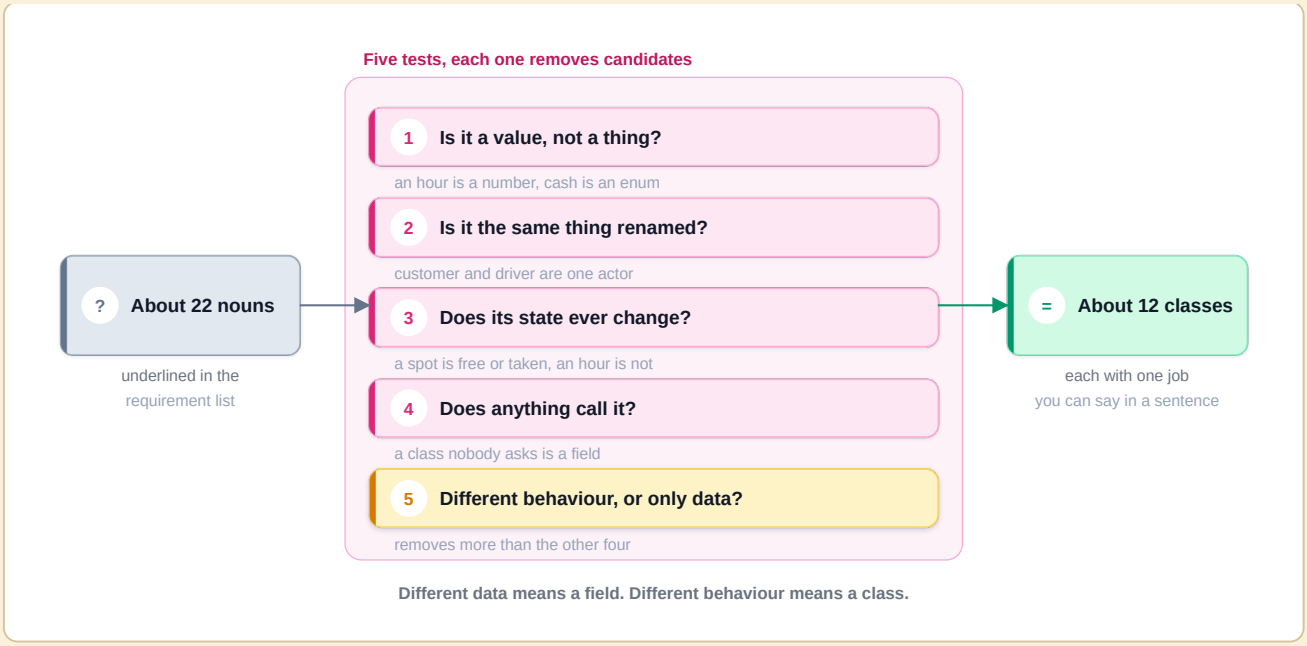

Figure — About 22 nouns pass through five tests and about 12 classes survive, each with one job (course diagram)

#	Test	Example	Result
1	Is it a **value** rather than a thing?	An hour is just a number, a licence plate just a string, and cash or card are options of a payment type	Field or **enum** constant (an enum is a fixed set of named values)
2	Is it just **another name** for a candidate already listed?	Customer and driver describe one actor; portal and panel could be a single class installed in several places	Merge, pick one name
3	Does it have **state that changes**?	A spot is free or occupied; an hour never changes	Changing state → class
4	Does anything **call** it?	Nobody ever asks an `Hour` object a question	Never called → it is a value
5	Does it differ in **behaviour** or only in **data**?	Compact vs large spot differ only in which vehicle fits; cash vs card payment behave differently	**Different data → a field. Different behaviour → a class.**

Applied to the parking-lot nouns, tests one to four cut the list to about fifteen; test five brings it to roughly twelve, removing more than the other four combined. Compact, large and handicapped spots all hold a vehicle, report free or occupied, and carry a number; they differ only in which vehicle kind is allowed. A difference like that is **data**, so a single `ParkingSpot` class gets a `type` field. Paying cash means checking enough money was given; paying by card means calling a provider and waiting for its reply. That difference is **behaviour**, so it earns two classes. Watch for this smell (a surface sign that something is probably wrong) in a diagram: five subclasses (classes that extend another class, their parent) whose only content is handing a different constant up to the parent. They are a single field pretending to be classes.

4. **Give each class one responsibility**, in one sentence with no "and":

Class	Responsibility
`ParkingLot`	Issues tickets and can tell when no space is left
`ParkingFloor`	Owns a level's spots and locates an empty one
`ParkingSpot`	Tracks if it is occupied and by which vehicle
`Vehicle`	Carries its plate number and the spot types it can use
`ParkingTicket`	Notes the vehicle, the spot it took, and the entry time
`ParkingRate`	Converts a duration in hours into a price
`Payment`	Collects the money and says if that worked
`ParkingDisplayBoard`	Shows how many spots of each type are free

`ParkingLot`'s sentence admits two jobs (issuing tickets **and** knowing fullness/assigning spots). In a longer design you would split it into a spot-assignment part and a ticketing part. In 45 minutes, **naming the tension out loud is enough**.

5. **Put each method where the data is.** "Find a free spot" touches the spot collection, which the floor owns → `ParkingFloor`. "Price the stay" touches the rate card → `ParkingRate`. "Take a ticket" touches the ticket store → `ParkingLot`. If a method needs data from three classes, it is probably in the wrong place; move it to the class that owns most of what it touches. (This is the GRASP "Information Expert" idea and the cure for the *Feature Envy* smell, Chapters 5 and 7. GRASP is a set of guidelines for deciding which class gets which job; *Feature Envy* is a method that uses another class's data more than its own.)

Common mistakes

- One subclass per value (`CompactSpot`, `LargeSpot` ... with no behaviour).
- Missing the **record-keeping** class (ticket, loan, booking) and the **rule** class (rate, strategy). These two are the classes beginners most often forget.
- "Manager" god classes that do everything (a *god class* is one huge class that owns most of the program's logic).

Self-check

- **Q:** Car, van and truck: subclasses or enum? **A:** If they differ only in size/which spots fit, an enum `VehicleType` (or a field). If they have genuinely different behaviour, subclasses.
- **Q:** A verb has no class to live on. What does that tell you? **A:** A class is missing.
- **Q:** A class has fields but no verbs. What is it? **A:** Probably a value (record/field), not a full class.

TL;DR

Nouns → candidate classes, verbs → methods. Cut values, duplicates, stateless and never-called nouns. **Different data = field; different behaviour = class.** One sentence per class, method goes where its data is. Twelve classes with one clear job each beat twenty that overlap.

1.7 Connecting the classes (preview)

Once you have the classes, decide for each pair: does one **use** the other briefly (dependency), **hold** a reference (association), **contain** parts that can live alone (aggregation), **own** parts that die with it (composition), or **is** it a kind of the other (inheritance, where a class extends another and reuses its code / realization, where a class implements an interface)? Then add **multiplicity** (1, 0..1, 1..*, *). Chapter 3 teaches every relationship and UML symbol in detail. For now, remember the most common beginner error: using **inheritance** where **composition** is right. The test is the sentence "A **is a** B". A car is not an engine, so `Car` has an `Engine`.

1.8 Keeping the design honest with SOLID

What it is

SOLID is five rules (one per letter) that catch the common ways a class diagram goes wrong. Chapter 4 teaches them in depth. In the interview, use them as **five quick checks** run over the diagram you just drew, in about five minutes.

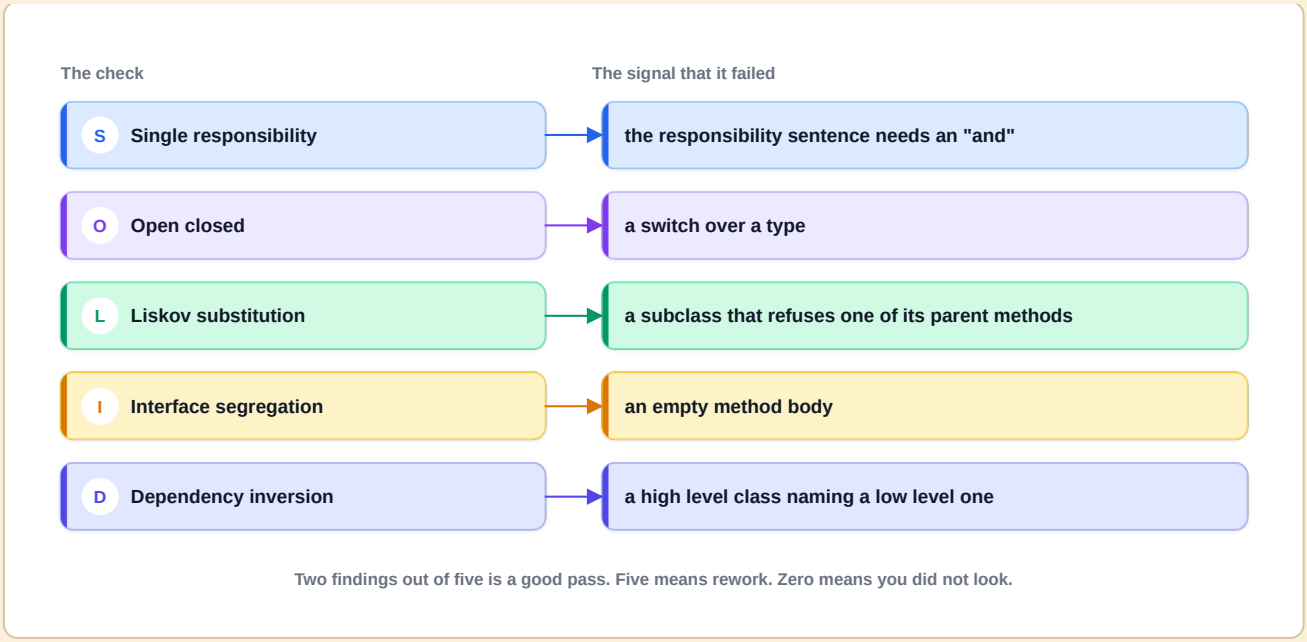

Figure — The five SOLID checks and the signal that each one has failed (course diagram)

How it works: run the five checks in this order

Check	Rule in one line	Signal that it failed (from the figure above)	Quick check
S — Single responsibility	A class should have one reason to change	The responsibility sentence needs an "and"	Name the change that would force an edit; two unrelated changes → split
O — Open/closed	Add behaviour without editing existing code	A `switch` / `if` chain over a type	Pick one likely new feature; if it edits three classes, the design is closed to the wrong thing
L — Liskov substitution	A subclass must work anywhere its parent works	A subclass that throws, does nothing, or refuses a parent method	Read each inheritance arrow: can the child be handed to code expecting the parent?
I — Interface segregation	No class should implement methods it does not use	Empty method bodies	Split the interface until every implementer uses everything
D — Dependency inversion	Depend on an interface, not a concrete class	A high-level class constructs or names a low-level one	Could you test the class without the real database/provider?

(In the **D** row, **high-level** code holds the business rules, while **low-level** code does one technical job such as talking to a database or a payment provider.)

Examples from the parking lot:

- **S:** a `ParkingLot` that both assigns spots and prints receipts changes when pricing changes **and** when the layout changes → two classes.
- **O:** pricing written as a switch over rate types means a weekend rate edits the class that prices everything. With pricing behind a small interface, the weekend rate is a new class.
- **L:** re-read every inheritance arrow at the end, because arrows are often added late when time is short. A `ReadOnlySpot extends ParkingSpot` whose `occupy` throws would fail the check: code that expects any spot to accept a vehicle breaks when handed that child.
- **I:** a library `Search` interface with four methods is fine if the catalog truly implements all four; it is not fine if half the implementers throw on two of them.
- **D:** a `ParkingLot` that does `new CreditCardTransaction()` cannot be tested without a payment provider and cannot take cash without an edit. Make it depend on `Payment`, and let something else decide which kind arrives.

The two that earn the most credit

- **Single responsibility** improves your class list: twelve well-named classes beat six classes doing three things each.

- **Open/closed** is what interviewers probe, usually as a late new requirement: "What if trucks are charged differently?" Answering "add a class" beats "add a branch to this switch".

When not to use it

- **Do not add an interface for everything.** An interface with one implementer, added "because SOLID", is indirection (an extra layer between the caller and the real code) with no benefit. Add it when a second implementation exists or is clearly coming (or when you need a test double, a fake stand-in object used in tests).
- **Do not split beyond what a reader can follow.** Thirty two-method classes are as bad as one god class. The one-sentence test is the boundary.

Each rule targets a **specific problem**. Apply it where your design shows that problem; applying it where the problem is absent only adds cost.

A five-minute pass over the parking lot

Check	Finding
S	`ParkingLot` issues tickets and finds spots: two reasons to change. Split if time allows; otherwise say it.
O	Pricing sits behind `ParkingRate`, so a new rate is a new class. Passes.
L (re-reading the inheritance arrows)	Five spot subclasses add no behaviour. Strictly this is not a Liskov violation (each would substitute fine); it is the "different data → field" test from 1.6 caught a second time while reading the arrows. Collapse them into a `type` field.
I	No wide interfaces. Passes.
D	The lot depends on `Payment`, not on the card class. Passes.

Two real findings, each explainable in a sentence: that is a good pass. **Five findings** usually means the design needs rework; **zero** usually means you did not really look.

TL;DR

Run S-O-L-I-D as five two-minute checks on your own diagram before the interviewer does. S and O earn the most credit. Do not add single-implementer interfaces or over-split.

1.9 The design patterns that come up in this round

What it is

A **design pattern** is a named solution to a design problem that keeps recurring. There are dozens (the Gang of Four book catalogues 23; Chapters 8–11 cover all of them). **Six** appear in this round often enough to know by name. The name turns a paragraph into two words and tells the interviewer you have seen the problem before. **A misapplied pattern hurts you more than an unknown one**, so learn each pattern together with the **signal** that says it applies.

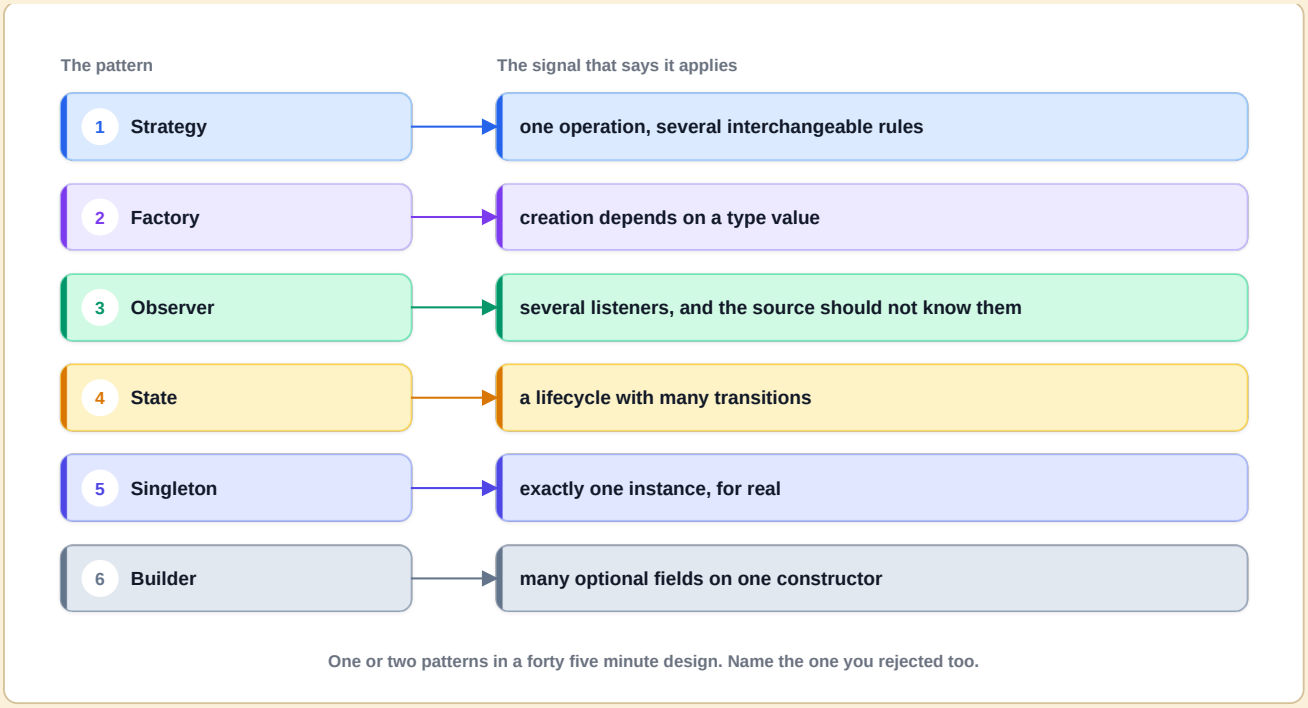

Figure — The six patterns most used in this round and the signal for each (course diagram)

Pattern	Signal (from the figure above)	Typical place	Parking lot / library example
Strategy	One operation, several interchangeable rules chosen at run time (while the program runs)	Pricing, matching, sorting, ranking, routing	`ParkingRate` interface with `HourlyRate`, `WeekendRate`, `MonthlyPass`. Answers "what if the rules change?", the most common late question
Factory	Creation depends on a type value; caller should not know the concrete class	Vehicles, spots, payments, notifications	A factory turns a type/enum into a `Vehicle`, so the entrance panel does not know every vehicle class. Keep it small: a factory **method** is usually enough
Observer	One thing changes, several others must know, and the source should not know them	Display boards, notifications, live updates, event logs	When a spot fills, all boards/panels registered on it update; adding a board changes nothing in the spot. With only **one** listener, a direct call is enough (e.g. notifying the member who reserved a returned book)
State	Behaviour depends on the current state, with a fixed set of transitions	Tickets, orders, bookings, loans, vending machines	Ticket: active → paid → closed. Book copy: available, reserved, loaned, lost. Each state class knows what is allowed, so illegal transitions become impossible. For 3–4 states, an **enum + one guarded method** is simpler: say so
Singleton	Exactly one instance must exist	The top-level object (`ParkingLot`, `Library`)	Private constructor + one accessor. Say out loud: it must be **thread-safe** (lock or eager creation, i.e. built when the class loads), and it is **global state** (data any code anywhere can reach and change), which hurts testing; many teams inject one shared instance instead
Builder	Many optional fields; the constructor is getting long	A book copy, a booking, a search query	`BookItem` with barcode, price, format, dates, rack: eight constructor args are easy to swap by mistake (two strings side by side compile fine). A builder sets fields **by name**. It is a readability fix, not a structural one

What to say about each one

- **Strategy:** without it, the pricing method grows a `switch` and every new rate edits it. With it, the lot holds one rate object and calls it; a new rate is a new class.
- **Factory:** it goes hand in hand with open/closed, since registering a new type happens in **a single spot**: the factory. Giving every product type its own factory class is heavier than a 45-minute design calls for.
- **Observer:** the simple version has the floor recompute and push to its single board. With Observer the **spot is the subject** and boards, entrance panels and floor portals register as observers; the spot never learns who is listening.

- **State:** without it, every method starts by checking the current status and the legal transitions are scattered across the class. With it, each state class knows what is allowed from there, so illegal moves cannot be expressed. Choose it only when the transition table is large, and say why.
- **Singleton:** expect the same two follow-ups (thread safety and testability) nearly every time; being able to state that trade-off counts for more than knowing the pattern.
- **Builder:** mention it when your own constructor reaches about six arguments, then move on.

Choosing patterns without overusing them

Pattern	Reach for it if	Skip it if
Strategy	A single operation has several swappable rules	Only one rule exists and a second is not in sight
Factory	Which object to build hinges on a type value	Just one concrete class exists
Observer	Several listeners; source should not know them	One listener the source already holds
State	The lifecycle has lots of transitions	A single guarded method covers three states
Singleton	There truly must be one instance	The real goal is just easy global access
Builder	Many optional fields	Three required fields

One or two patterns is the right number in a 45-minute design. Six patterns in one answer usually means the design is driven by patterns rather than by the requirements.

Nothing lands better than a **comparison**: "The rate gets Strategy because a second rate is likely. The ticket does not get State, since one guard is enough for three statuses." It proves you understand what the pattern gives and what it costs.

Real-world examples

- **Strategy:** `java.util.Comparator` passed to `List.sort`; Spring Security's pluggable `PasswordEncoder` implementations.
- **Factory** (static factory methods that hide the concrete class returned): `java.util.concurrent.Executors.newFixedThreadPool(...)`, `List.of(...)`, `Calendar.getInstance()`.
- **Observer:** Swing/AWT listeners (`ActionListener`), `java.beans.PropertyChangeListener`, Spring `ApplicationEvent` listeners.
- **State:** order lifecycle in e-commerce (placed → paid → shipped → delivered); TCP connection states.
- **Singleton:** `java.lang.Runtime.getRuntime()`; Spring beans are singleton-scoped **per container** by default (not the GoF class-enforced singleton).
- **Builder:** `StringBuilder`, `java.net.http.HttpRequest.newBuilder()`, `Stream.builder()`.

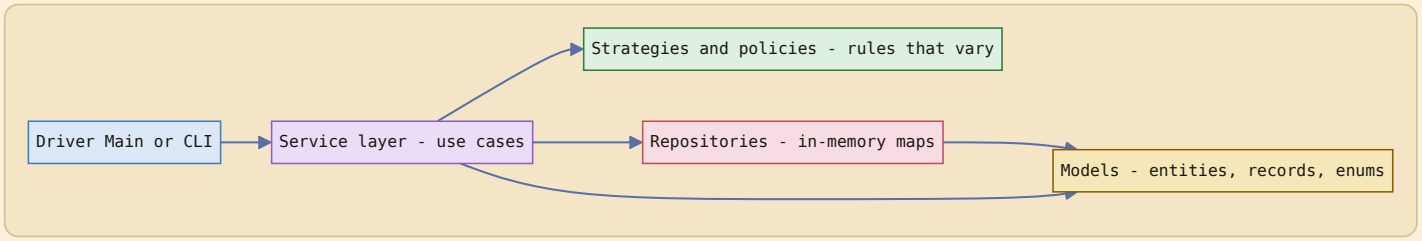
(Names in this list: **Spring** is a popular Java framework whose *container* creates and wires your application objects, called *beans*; **Swing/AWT** are Java's older desktop user-interface toolkits; **TCP** is the network protocol that keeps a reliable connection between two machines, see System Design Fundamentals; a **thread pool** is a fixed set of reusable worker threads.)

TL;DR

Know six by name: Strategy, Factory, Observer, State, Singleton, Builder. Use one or two where their signal appears, and name the one you rejected.

1.10 Code, edge cases and concurrency: how to write interview code

How it works: a machine-coding skeleton that scales



1. **Models** — entities (`ParkingSpot`; objects with an identity whose state changes over time), value objects (`record Vehicle`; plain data compared by its values), enums (`VehicleType`). Encapsulate state; validate in constructors.
2. **Repositories** — classes whose only job is storing and finding objects: an in-memory `Map<Id, Entity>` behind a small interface, so a database could replace it later.
3. **Strategies / policies** — every rule that might vary (pricing, spot selection, splitting a bill).
4. **Services** — the use cases (`park`, `exit`, `bookSeats`). This is the **service interface** a client calls.
5. **Driver** — a `Main` that runs a scripted scenario (or reads commands) and prints clear output for the demo.

Habits that interviewers notice:

- **Pass time in** (`long nowMinute`, `Instant now`, where `Instant` is Java's type for a point in time) rather than reading the clock inside the method: same input → same output → testable.
- **Hold money as** `BigDecimal` (built from strings such as `new BigDecimal("3.50")`) or as whole cents in a `long`; never `double`. This handbook uses `BigDecimal` in domain code.
- **Fail loudly on bad input**: `IllegalArgumentException` for bad arguments, `IllegalStateException` for wrong state, custom exceptions (`SpotNotAvailableException`) where they clarify.
- **Return** `Optional` (a box that either holds a value or is empty, used instead of returning `null`) when "not found" is a normal outcome.
- **Keep fields** `private final` unless they must change.
- **Name things after the domain** (`ParkingTicket`, not `Data2`).

Edge cases and concurrency checklist

Category	Questions
Input	null (no object at all), empty, negative, duplicate IDs, unknown IDs
Capacity	Full lot, empty playlist, zero seats left, max loans reached
State	Paying twice, exiting without entering, cancelling a delivered order
Time	Exit before entry, bookings expiring, part hours (round up?)
Concurrency	Two threads booking the same seat or taking the same spot: use `synchronized`, a `ReentrantLock`, or atomic structures such as `ConcurrentHashMap.computeIfAbsent`; lock the **smallest** shared thing that keeps the invariant

> **Key term — threads, locks and atomicity:** A **thread** is one independent line of execution; a server handling two panels at once runs two threads over the same objects. `synchronized` and `ReentrantLock` are Java's ways to let only one thread at a time into a block of code. An **atomic** operation happens all at once from other threads' point of view, with no half-finished moment they can see; `ConcurrentHashMap` is a thread-safe map that offers such operations. An **invariant** is a rule about the data that must always hold, such as "one spot holds at most one vehicle".

Chapters 12 and 13 cover concurrency in depth.

TL;DR

Models → repositories → strategies → services → driver. Inject time, use `BigDecimal` (or cents) for money, validate, return `Optional`, guard shared state.

1.11 Worked mini-example, end to end: a small parking lot

This runs every step of the framework on a deliberately small version of the classic question, so you can see the whole shape once. (A full parking lot with multiple panels, payments and display boards appears in the case-study chapters.)

Problem & clarifying questions

"Design a parking lot." Questions asked, with the answers we assume:

Question	Answer
Single lot or many?	Single lot, one or more floors
Which vehicles?	Motorbike, car, truck
Which spot types?	Motorbike, compact, large; a smaller vehicle may use a bigger spot
Payment?	Out of scope: we compute the fee; a payment service collects it
Pricing?	Hourly, tiered, part hours round up; trucks pay double; must be swappable (weekend flat rate)
Concurrency?	Several entry/exit panels may act at the same time

Requirements

Functional

1. The lot has floors; each floor has spots of type MOTORBIKE, COMPACT or LARGE.
2. A motorbike fits MOTORBIKE or COMPACT; a car fits COMPACT or LARGE; a truck fits LARGE only. The smallest fitting spot is tried first.
3. On entry, the system assigns a free fitting spot and issues a ticket (id, vehicle, spot, entry time).
4. If no fitting spot is free, entry is refused.
5. On exit, the ticket is closed, the spot freed and the fee returned.
6. Fee: $4.00 first hour, $3.50 for hours 2–3, $2.50 per hour after; part hours round up; minimum one hour; trucks pay double.
7. The pricing rule can be swapped at run time (e.g. a flat $10 weekend rate).
8. A floor can report how many spots of a type are free.

Non-functional: in-memory; thread-safe entry/exit; new pricing rules or vehicle types must not require editing existing services; deterministic (time passed in).

Out of scope: payment collection, reservations, display boards, number-plate recognition, multiple lots.

Use cases

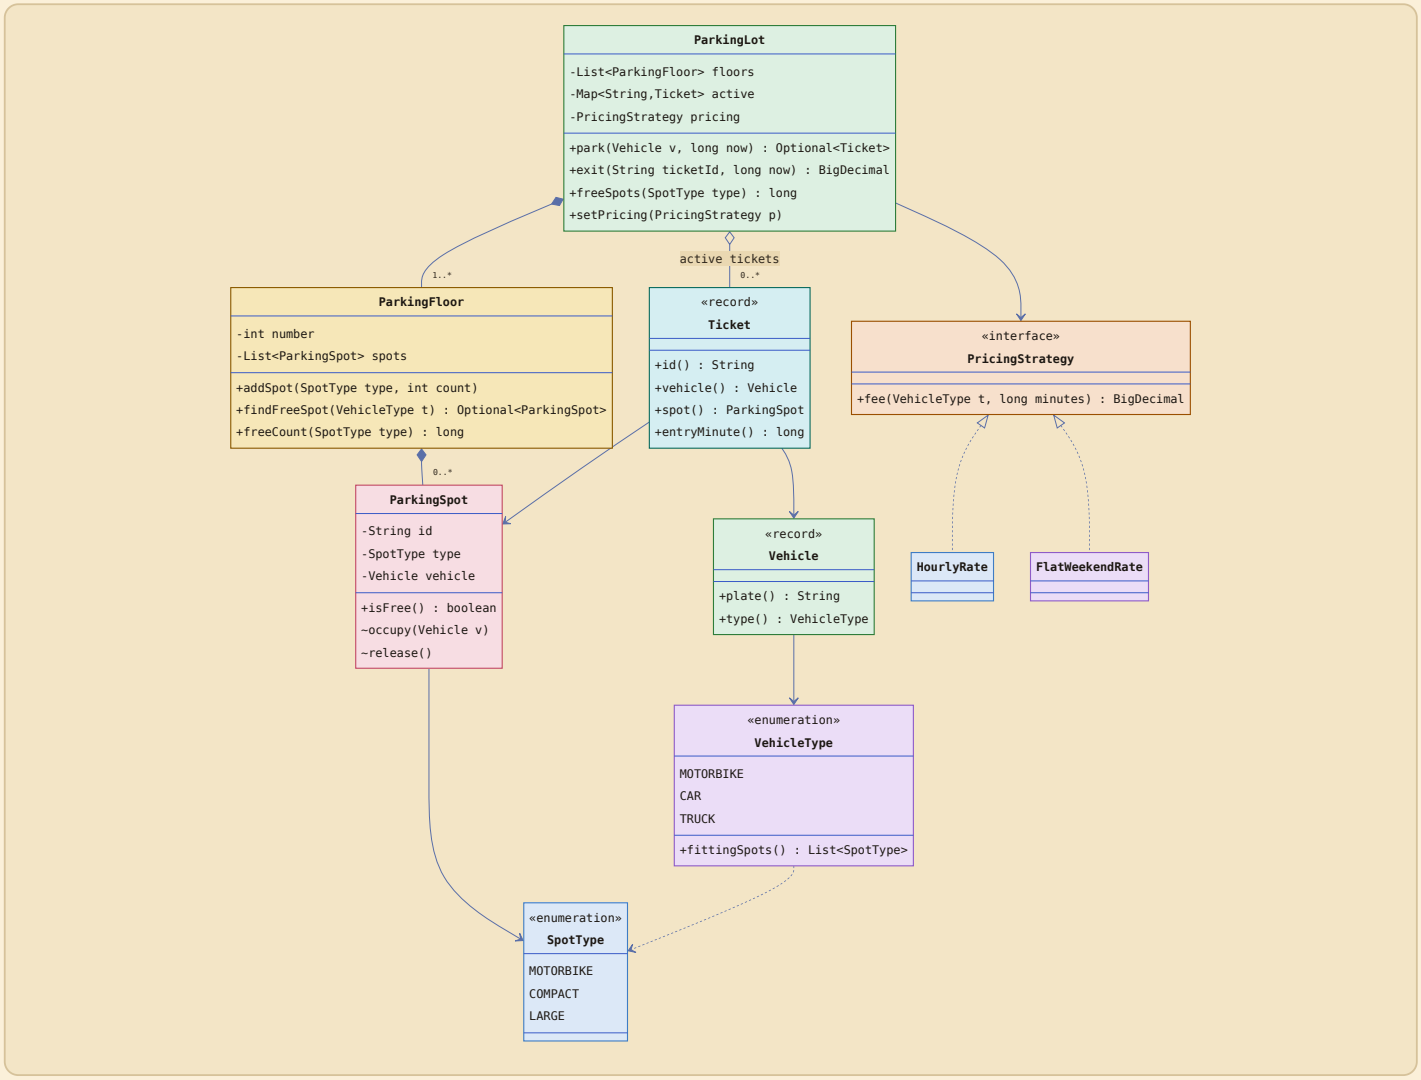
Actor	Use cases
Driver (customer)	enter and get ticket, exit and see fee
Admin	add floor/spots, change pricing rule
System	find free spot, refuse entry when full, compute fee

Core entities

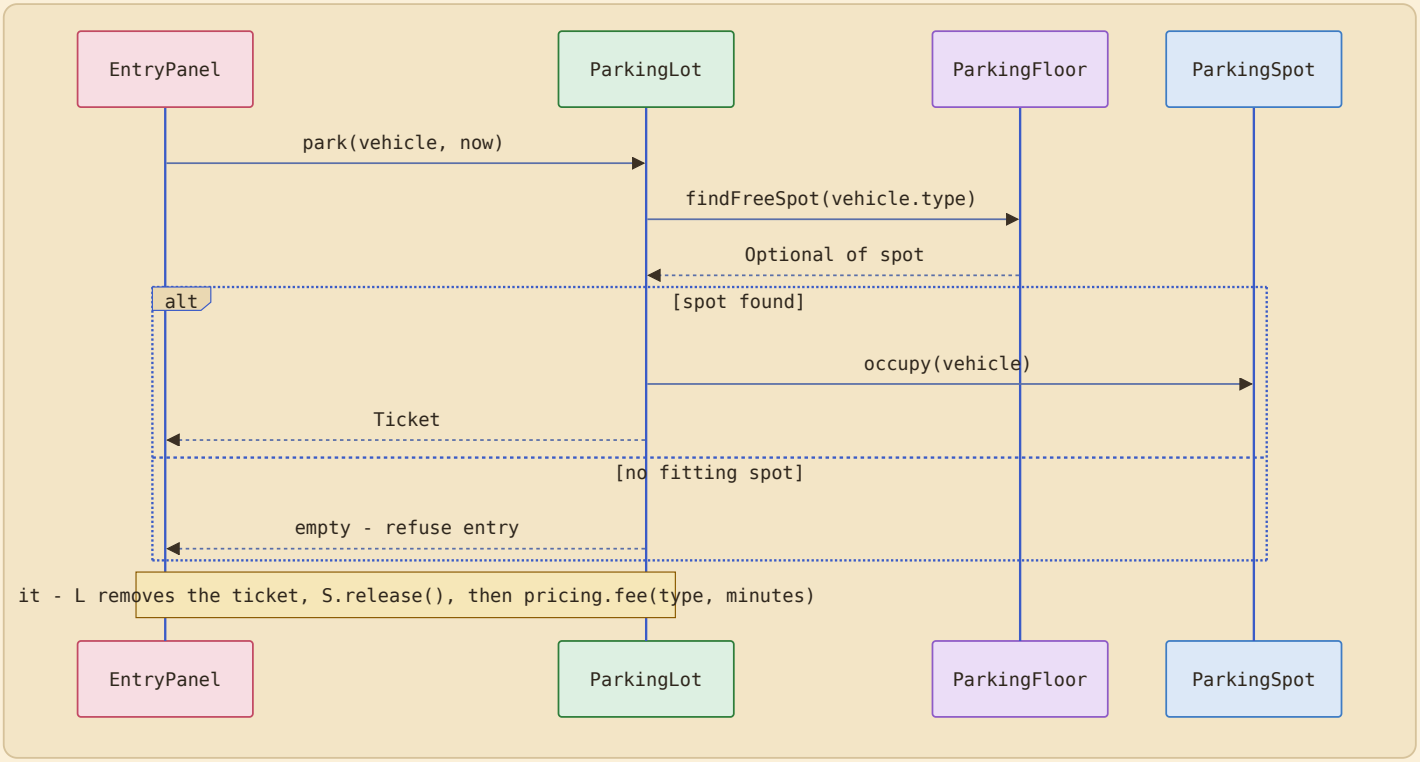
Class	Kind	Responsibility
`SpotType`	enum	The spot sizes
`VehicleType`	enum	Vehicle kinds, each knowing which spot types fit (smallest first)
`Vehicle`	record	Plate + type (pure data)
`ParkingSpot`	class	Tracks if it is occupied and by which vehicle
`ParkingFloor`	class	Holds spots on one floor and finds a free fitting one
`Ticket`	record	Records which vehicle went into which spot, and when (the "connection object")
`PricingStrategy`	interface	Turns a stay into a fee (`BigDecimal`)
`HourlyRate`, `FlatWeekendRate`	classes	Two pricing rules
`ParkingLot`	class	Issues and closes tickets; the service the panels call

Notice the **"different data → field"** rule: spot sizes are an enum, not three subclasses, because they do not behave differently.

Class diagram



Key flows



Design decisions & patterns used

Decision	Why	Alternative rejected
Strategy for pricing (`PricingStrategy`)	A second rule (weekend) is explicitly required; new rules = new classes (open/closed)	A `switch` over a rate enum inside `ParkingLot`
Spot and vehicle types as **enums**	They differ in data only	One subclass per spot type
`Ticket` as a **record**	A ticket is a fact that never changes after issue. (A record is only *shallowly* immutable: its fields cannot be reassigned, but the `ParkingSpot` it points to still changes state.)	Mutable ticket with setters (methods that change fields)
Money as `BigDecimal`	Exact decimal arithmetic; `3.50 + 3.50` is exactly `7.00`	`double` (binary fractions, rounding drift)
`synchronized` on `park` / `exit` / `freeSpots`	Two panels must never get the same spot; lot-wide lock is simple and correct for this size	Per-floor locks (better throughput, i.e. more requests handled per second; more complex; mention as an extension)
No Singleton for `ParkingLot`	Injecting one instance keeps it testable	Global `getInstance()`
No State pattern for tickets	Only active/closed; a map of active tickets is enough	State classes per ticket status

Java implementation

```java
// File: code/lld/ch01/parkinglot/FlatWeekendRate.java
package lld.ch01.parkinglot;

import java.math.BigDecimal;

/** A NEW rule added later: flat $10.00 per visit. Added as a class; no existing code was edited (open-closed). */
public final class FlatWeekendRate implements PricingStrategy {
    private static final BigDecimal FLAT = new BigDecimal("10.00");

    @Override public BigDecimal fee(VehicleType type, long minutesParked) { return FLAT; }
}
```

```java
// File: code/lld/ch01/parkinglot/HourlyRate.java
package lld.ch01.parkinglot;

import java.math.BigDecimal;

/** $4.00 for the first hour, $3.50 for hours 2 and 3, $2.50 per hour after that. Part hours round up. Trucks pay double. */
public final class HourlyRate implements PricingStrategy {
    private static final BigDecimal FIRST_HOUR = new BigDecimal("4.00");
    private static final BigDecimal HOURS_2_TO_3 = new BigDecimal("3.50");
    private static final BigDecimal LATER_HOURS = new BigDecimal("2.50");

    @Override
    public BigDecimal fee(VehicleType type, long minutesParked) {
        long hours = Math.max(1, (minutesParked + 59) / 60);    // ceiling, minimum one hour
        BigDecimal total = BigDecimal.ZERO;
        for (long h = 1; h <= hours; h++) {
            total = total.add(h == 1 ? FIRST_HOUR : (h <= 3 ? HOURS_2_TO_3 : LATER_HOURS));
        }
        return type == VehicleType.TRUCK ? total.multiply(BigDecimal.TWO) : total;
    }
}
```

```java
// File: code/lld/ch01/parkinglot/ParkingFloor.java
package lld.ch01.parkinglot;

import java.util.ArrayList;
import java.util.List;
import java.util.Optional;

/** Holds the spots on one floor and finds a free one. Not thread-safe on its own: ParkingLot calls it under its lock. */
public final class ParkingFloor {
    private final int number;
    private final List<ParkingSpot> spots = new ArrayList<>();

    public ParkingFloor(int number) { this.number = number; }

    public void addSpot(SpotType type, int count) {
        for (int i = 1; i <= count; i++) {
            spots.add(new ParkingSpot("F" + number + "-" + type.name().charAt(0) + i, type));
        }
    }

    /** First free spot, trying the vehicle's preferred (smallest) spot type first. */
    public Optional<ParkingSpot> findFreeSpot(VehicleType vehicleType) {
        for (SpotType wanted : vehicleType.fittingSpots()) {
            for (ParkingSpot s : spots) {
                if (s.type() == wanted && s.isFree()) return Optional.of(s);
            }
        }
        return Optional.empty();
    }

    public long freeCount(SpotType type) {
        return spots.stream().filter(s -> s.type() == type && s.isFree()).count();
    }
}
```

```java
// File: code/lld/ch01/parkinglot/ParkingLot.java
package lld.ch01.parkinglot;

import java.math.BigDecimal;
import java.util.HashMap;
import java.util.List;
import java.util.Map;
import java.util.Optional;

/**
 * Issues tickets and closes them. Time is PASSED IN (not read from the clock) so runs are
 * repeatable. Every method that reads or changes spots, tickets or pricing is synchronized on
 * the lot, so two entrance panels cannot hand out the same spot.
 */
public final class ParkingLot {
    private final List<ParkingFloor> floors;
    private final Map<String, Ticket> active = new HashMap<>();
    private PricingStrategy pricing;
    private int nextTicket = 1;

    public ParkingLot(List<ParkingFloor> floors, PricingStrategy pricing) {
        this.floors = List.copyOf(floors);
        this.pricing = pricing;
    }

    public synchronized Optional<Ticket> park(Vehicle v, long nowMinute) {
        for (ParkingFloor floor : floors) {
            Optional<ParkingSpot> spot = floor.findFreeSpot(v.type());
            if (spot.isPresent()) {
                spot.get().occupy(v);
                Ticket t = new Ticket("T" + nextTicket++, v, spot.get(), nowMinute);
                active.put(t.id(), t);
                return Optional.of(t);
            }
        }
        return Optional.empty();              // lot full for this vehicle type -> refuse entry
    }

    /** Closes the ticket, frees the spot and returns the fee. */
    public synchronized BigDecimal exit(String ticketId, long nowMinute) {
        Ticket t = active.get(ticketId);
        if (t == null) throw new IllegalArgumentException("unknown or already closed ticket " + ticketId);
        if (nowMinute < t.entryMinute()) throw new IllegalArgumentException("exit before entry");
        active.remove(ticketId);               // validate first, then change state
        t.spot().release();
        return pricing.fee(t.vehicle().type(), nowMinute - t.entryMinute());
    }

    /** Free spots of one type across all floors, read under the same lock as park/exit. */
    public synchronized long freeSpots(SpotType type) {
        return floors.stream().mapToLong(f -> f.freeCount(type)).sum();
    }

    public synchronized void setPricing(PricingStrategy pricing) { this.pricing = pricing; }
}
```

```java
// File: code/lld/ch01/parkinglot/ParkingSpot.java
package lld.ch01.parkinglot;

/** Knows whether it is free and which vehicle is in it. */
public final class ParkingSpot {
    private final String id;
    private final SpotType type;
    private Vehicle vehicle;                // null = free

    public ParkingSpot(String id, SpotType type) { this.id = id; this.type = type; }

    public boolean isFree()      { return vehicle == null; }
    public SpotType type()       { return type; }
    public String id()           { return id; }

    void occupy(Vehicle v) {                // package-private: only the lot may change a spot
        if (!isFree()) throw new IllegalStateException(id + " is taken");
        vehicle = v;
    }
    void release() { vehicle = null; }
}
```

```java
// File: code/lld/ch01/parkinglot/PricingStrategy.java
package lld.ch01.parkinglot;

import java.math.BigDecimal;

/** Strategy: turns a stay into an amount of money. Money is BigDecimal, never double (no binary rounding errors).
*/
public interface PricingStrategy {
    BigDecimal fee(VehicleType type, long minutesParked);
}
```

```java
// File: code/lld/ch01/parkinglot/SpotType.java
package lld.ch01.parkinglot;

/** Spot kinds differ only in data (which vehicles fit), so they are enum values, not subclasses. */
public enum SpotType { MOTORBIKE, COMPACT, LARGE }
```

```java
// File: code/lld/ch01/parkinglot/Ticket.java
package lld.ch01.parkinglot;

/** Records which vehicle went into which spot, and when. The "connection object" between Vehicle and Spot. */
public record Ticket(String id, Vehicle vehicle, ParkingSpot spot, long entryMinute) { }
```

```java
// File: code/lld/ch01/parkinglot/Vehicle.java
package lld.ch01.parkinglot;

/** A vehicle is pure data: its plate and its type. */
public record Vehicle(String plate, VehicleType type) { }
```

```java
// File: code/lld/ch01/parkinglot/VehicleType.java
package lld.ch01.parkinglot;

import java.util.List;

/** Each vehicle type knows which spot types fit it, smallest first. */
public enum VehicleType {
    MOTORBIKE(List.of(SpotType.MOTORBIKE, SpotType.COMPACT)),
    CAR(List.of(SpotType.COMPACT, SpotType.LARGE)),
    TRUCK(List.of(SpotType.LARGE));

    private final List<SpotType> fits;

    VehicleType(List<SpotType> fits) { this.fits = fits; }

    public List<SpotType> fittingSpots() { return fits; }
}
```

```java
// File: code/lld/ch01/parkinglot/Main.java
package lld.ch01.parkinglot;

import java.math.BigDecimal;
import java.util.List;

public class Main {
    public static void main(String[] args) {
        ParkingFloor ground = new ParkingFloor(0);
        ground.addSpot(SpotType.MOTORBIKE, 1);
        ground.addSpot(SpotType.COMPACT, 1);
        ground.addSpot(SpotType.LARGE, 1);
        ParkingLot lot = new ParkingLot(List.of(ground), new HourlyRate());

        Vehicle car   = new Vehicle("KA-01-1234", VehicleType.CAR);
        Vehicle truck = new Vehicle("KA-02-9999", VehicleType.TRUCK);
        Vehicle car2  = new Vehicle("KA-03-5555", VehicleType.CAR);

        Ticket t1 = lot.park(car, 0).orElseThrow();
        System.out.println(t1.id() + ": " + car.plate() + " -> spot " + t1.spot().id());
        Ticket t2 = lot.park(truck, 10).orElseThrow();
        System.out.println(t2.id() + ": " + truck.plate() + " -> spot " + t2.spot().id());
        System.out.println(car2.plate() + " -> " + lot.park(car2, 20).map(Ticket::id).orElse("refused, no suitable
spot"));

        System.out.println("free compact spots: " + lot.freeSpots(SpotType.COMPACT));
        System.out.println(t1.id() + " exits after 150 min, pays " + money(lot.exit(t1.id(), 150)));
        System.out.println(t2.id() + " exits after 50 min, pays " + money(lot.exit(t2.id(), 60)));

        lot.setPricing(new FlatWeekendRate());          // swap the strategy at run time
        Ticket t3 = lot.park(car2, 200).orElseThrow();
        System.out.println(t3.id() + ": " + car2.plate() + " -> spot " + t3.spot().id()
                + ", weekend exit pays " + money(lot.exit(t3.id(), 500)));

        try {
            lot.exit(t1.id(), 600);
        } catch (IllegalArgumentException e) {
            System.out.println("error: " + e.getMessage());
        }
    }

    private static String money(BigDecimal amount) { return "$" + amount.toPlainString(); }
}
```

Run: `java -cp /tmp/lld_01 lld.ch01.parkinglot.Main`

Output:

```
T1: KA-01-1234 -> spot F0-C1
T2: KA-02-9999 -> spot F0-L1
KA-03-5555 -> refused, no suitable spot
free compact spots: 0
T1 exits after 150 min, pays $11.00
T2 exits after 50 min, pays $8.00
T3: KA-03-5555 -> spot F0-C1, weekend exit pays $10.00
error: unknown or already closed ticket T1
```

Reading the output: the car took the compact spot, the truck the only large spot, so the third car was refused (requirement 4). 150 minutes = 3 hours = $4.00 + $3.50 + $3.50 = $11.00. The truck's 50 minutes round up to one hour, doubled = $8.00. After swapping the strategy at run time, the same service charges the flat $10. Closing a ticket twice is rejected.

Concurrency & edge cases

- `park` and `exit` are `synchronized` on the lot, so find-then-occupy is **atomic**: two panels cannot both see the same spot as free and both occupy it (a classic *check-then-act* race: a **race condition** is a bug whose result depends on which thread happens to run first).
- `freeSpots` is read under the **same** lock, so a display never sees a half-finished `park`. `ParkingFloor` itself is not thread-safe; it is only ever called through the lot.
- `exit` validates the ticket and the time **before** changing anything, so a rejected exit (for example exit before entry) leaves the ticket open.
- `ParkingSpot.occupy` also throws if the spot is taken: a second line of defence.
- Exit before entry, unknown ticket, and double exit all throw `IllegalArgumentException`.
- `occupy` / `release` are **package-private**, so code outside the package cannot change spot state directly.

Extensions & follow-up questions

Follow-up	Answer
"Add electric-vehicle spots with charging."	Add `ELECTRIC` to `SpotType`, add an `ELECTRIC_CAR` vehicle type whose fitting list starts with `ELECTRIC`. If charging has **behaviour** (meter, charging fee), then a `ChargingSpot` class or a charging component composed into the spot.
"Choose the nearest spot to the entrance instead of the first free one."	Extract a `SpotSelectionStrategy` interface (Strategy again), injected into `ParkingLot`.
"Update display boards when spots change."	Observer: spots/floors publish "spot freed/occupied" events; boards subscribe.
"Improve throughput with many panels."	Lock per floor (or per spot type) instead of the whole lot; or keep free spots in a `ConcurrentLinkedQueue` (a thread-safe queue) per type and `poll()` atomically.
"Add payment by cash or card."	`Payment` interface with `CashPayment`, `CardPayment`; `exit` returns the fee and a `PaymentService` collects it (dependency inversion).

In the interview

Spend about 5 minutes on the questions and requirement list above, 3 on actors, 8 on entities and the "enum vs subclass" decision, 8 on the diagram, and 15 on `park`, `exit` and `HourlyRate`. Close by naming Strategy (used), Singleton and State (rejected, with reasons), and the per-floor locking extension.

Self-check

- **Q:** Why is `SpotType` an enum and not a class hierarchy? **A:** Spot types differ only in data (which vehicles fit), not in behaviour.
- **Q:** What race does `synchronized` on `park` prevent? **A:** Two threads finding the same free spot and both occupying it (check-then-act).
- **Q:** How did adding a weekend rate respect open/closed? **A:** It was a new `PricingStrategy` class; no existing class was edited.

TL;DR

Small, complete, and honest: 8 requirements, 10 types, one Strategy, one lock, and a clear list of what was left out.

1.12 Communication tips

Do	Why
Think out loud, narrating the step you are in ("Now I'll list actors")	The interviewer scores your process, not only the result
Write things down (requirements, class list) where the interviewer can see them	Shared artefacts prevent misunderstandings
Confirm before moving on ("Does this scope look right?")	Cheap course corrections
State assumptions explicitly	An assumption said out loud counts like an answer from the interviewer
Offer trade-offs in pairs: "I chose X over Y because..."	Shows judgement
Welcome hints; treat the interviewer as a teammate	Collaboration is part of the evaluation
Say what you are leaving out and how you would add it	Turns a gap into a strength
Keep a clock in view; announce when you move to code	Prevents the "no code at minute 40" failure
Use domain names, not `Manager`, `Helper`, `Data`	Clear names are clear thinking
When stuck, go back to the requirements	Every class must trace back to a line

What **not** to do: go silent for minutes, argue with feedback, name `HashMap`s and threads in minute two (that is implementation, skipping analysis and design), or recite pattern definitions without a reason to use them.

1.13 How to use this handbook, and a study plan

Attempt first, then compare

There are two ways to work through case studies. The first is to **read** them. That is quick and pleasant but builds very little skill, because any finished design looks obvious after someone else has drawn it. The second is to **attempt each one yourself, then compare**. That is slower and less comfortable, and it is the approach that actually improves how you perform under pressure.

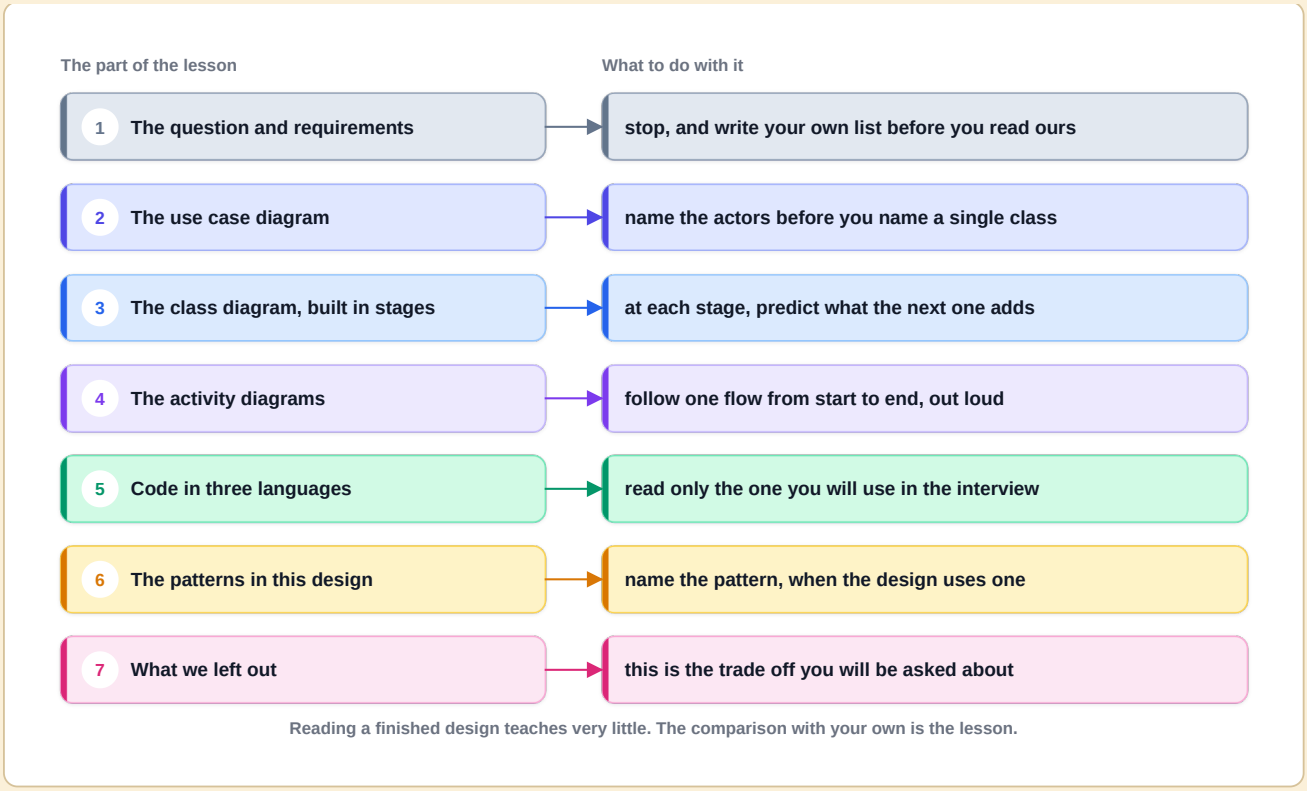


Figure — The parts of a case-study lesson and what to do at each one (course diagram)

As the figure above shows, every case study has the same parts, so you can decide in advance where to stop and think. Three stopping points matter most:

1. **Stop after the question.** Write your own requirement list (8–12 lines plus out of scope), then compare. If yours is shorter, the cause is usually not missing knowledge but **not asking enough questions**.
2. **Stop after the requirements.** Write your class list, one responsibility each, then read the class diagram. Most people are close but **two classes short**, and they are usually the same kind: **the thing that keeps a record** (ticket, loan, booking) and **the thing that decides a rule** (rate, strategy).
3. **Stop at each stage of the class diagram.** Predict what the next stage adds. A wrong guess is free, and each one shows you how an experienced designer thinks.

More habits:

- **Read the class diagram in stages.** Many case-study diagrams are built up step by step; you do not need to read the UML chapter first. Seeing a symbol inside a real design and then looking it up in Chapter 3 works well.
- **If a design decision looks wrong to you, write down why.** Arguing with a worked answer is good practice; several of these designs exist in their current form because someone disagreed with an earlier version.
- **Read one language's code** (here, Java). Reading multiple translations teaches nothing about design.
- **Do not skip the extensions / "what we left out" section.** It lists the simplifications and their trade-offs, and interviewers ask about exactly these. "I merged these two responsibilities to save time; here is how I would split them" is worth far more than hoping nobody asks.
- **Do not invent pattern names.** Where plain classes are enough, say so. Labelling a pattern the design does not use loses credibility.
- **After six or seven case studies, switch to timed runs**: a question you have already done, 45 minutes, blank page. You will not finish; nobody does. Measure two things: did you spend the first ten minutes on requirements and actors, and did you reach running code for at least one flow? These predict the real result better than the number of classes you drew.
- **Compile and run every example** (`bash tools/compile_all.sh` runs all chapters; `bash` is the Unix command shell and the `.sh` file is a script of commands).

Map of this handbook

Ch	Title	Use it for
1	The LLD interview & how to approach it	The method, time budget, study plan (this chapter)
2	OOP fundamentals	Classes, objects, the four pillars, interfaces, enums, equality, immutability, generics, OOA/OOD (object-oriented analysis / design)
3	Relationships & UML	Association, aggregation, composition, dependency; class, use case, activity, sequence, state diagrams
4	SOLID principles	The five principles in depth
5	Design principles	DRY (don't repeat yourself), KISS (keep it simple), YAGNI (you aren't gonna need it), composition over inheritance, Law of Demeter, GRASP and friends
6	Clean code	Naming, functions, comments, error handling, tests
7	Refactoring	Code smells and the named refactorings that fix them
8	Creational patterns	Singleton, Factory Method, Abstract Factory, Builder, Prototype
9	Structural patterns	Adapter, Bridge, Composite, Decorator, Facade, Flyweight, Proxy
10–11	Behavioural patterns	Strategy, Observer, State, Command, Template Method, Iterator, Chain of Responsibility, Mediator, Memento, Visitor, Interpreter; MVC (Model-View-Controller)
12	Concurrency concepts	Threads, locks, `java.util.concurrent`, thread-safety patterns
13	Concurrency problems	Producer–consumer, readers–writers, rate limiters and other classic problems
14	Case studies: everyday objects	Parking lot, vending machine, ATM, elevator, traffic signal, coffee machine
15–16	Case studies: booking and inventory	Library, movie tickets, concerts, hotels, car rental, restaurant, airline, course registration
17	Case studies: games	Chess, tic-tac-toe, snake and ladder, 2048, blackjack
18–19	Case studies: platforms	Social and Q&A sites, cricket scores, Amazon-style shopping, food delivery, auctions, stock brokerage and exchange, music streaming
20	Case studies: components	Caches (including LRU, which evicts the least recently used item), logger, rate limiter (caps how many requests are allowed per time window), pub-sub (publishers send messages to all subscribers of a topic), notifications, Splitwise, ride sharing and similar
21	Case studies: machine coding	90-minute style problems with runnable solutions: task manager, digital wallet, event calendar, coding contest platform, property listing, loan ledger, inventory
22	Cheat sheets & glossary	Last-day revision

Study plans

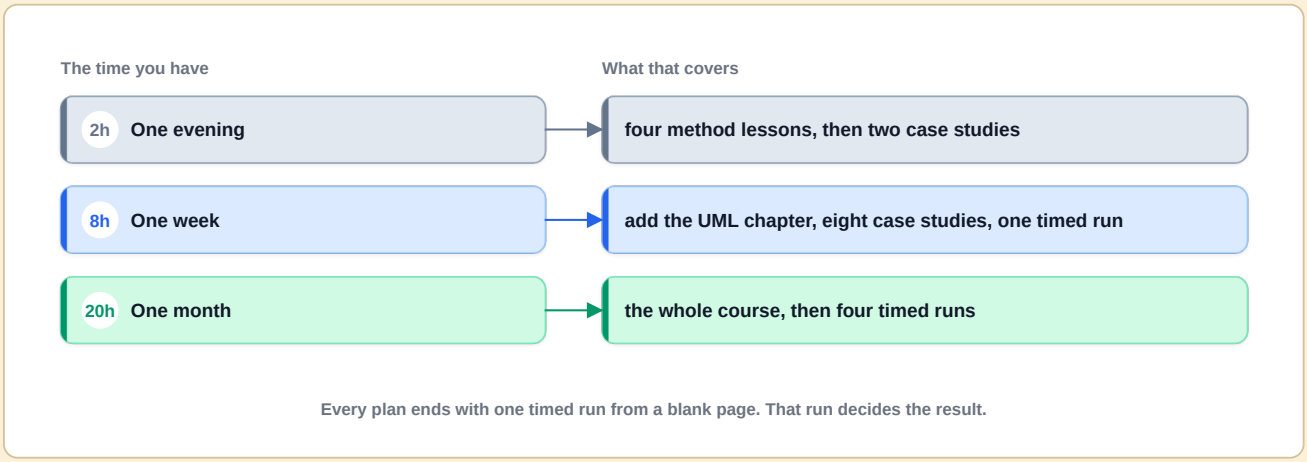

Figure — Three study plans for three amounts of time; every plan ends with one timed run from a blank page (course diagram)

Choose by the time you really have (your **calendar**), not the time you wish you had. The **method is worth more than any single case study**, and the first six case studies are worth more than the rest, because later ones repeat skills the earlier ones taught.

If the interview is tomorrow (about 2 hours)

Order	Read	Time
1	Section 1.2 (for the time budget)	10 min
2	Section 1.5 (requirements)	15 min
3	Section 1.6 (finding the classes)	15 min
4	Chapter 3: choosing the relationship between two classes	15 min
5	Chapter 3: class diagram notation	10 min
6	Parking lot case study, whole	30 min
7	Vending machine case study, whole	25 min

Two case studies show the structure twice. The parking lot is the most-asked question; the vending machine shows what to do when a design has a **lifecycle** (a fixed set of states an object moves through), the second most common kind of question. Do not start a third; write the five steps on a card and rehearse them.

If you have one week (about 8 hours, an hour a day)

Day	Do
1	Chapter 1 fully, plus Chapter 2 sections on the four pillars
2	Chapter 3: use case, class and activity diagrams (sequence diagrams later)
3	Parking lot, then library management (write your requirements first)
4	ATM, then vending machine
5	Movie ticket booking, then hotel management
6	Splitwise, then Amazon-style online shopping
7	**No new material.** Redo the parking lot from a blank page in 45 minutes

Day 7 matters most: days 1–6 fill your head with material, and day 7 checks that you can actually produce a design against the clock.

If you have one month (about 20 hours)

Week	Do
1	Chapters 1–4, then the first three case studies
2	Chapters 5, 8–11 (patterns) alongside case studies 4–10, two per session, always drawing your classes first
3	Chapters 12–13 (concurrency) and case studies 11–18; one timed run at the end of the week
4	Remaining case studies, Chapter 21 machine-coding problems, then three timed runs on questions you have read; Chapter 22 for revision

By week three the case studies feel repetitive. That means the method has been learned; keep going but read faster, checking your class list against the first diagram stages.

Beginner plan (six weeks, 5–6 hours a week) — if OOP itself is new to you:

Week	Do
1	Chapters 1–2; write and run every Chapter 2 example yourself
2	Chapters 3–5 (UML, SOLID, principles)
3	Chapters 6–7 (clean code, refactoring) and Chapter 8
4	Chapters 9–11 (remaining patterns); two small case studies
5	Chapters 12–13; four case studies including one with concurrency (ticket booking)
6	Chapter 21 machine-coding problems in 90-minute timed runs; Chapter 22

If you can only do six case studies, do these; they cover the skills the others repeat:

Case study	What it teaches
Parking lot	The canonical question, and how to bound one
Library management	Borrow, return and limits, a common family of questions
Vending machine	A lifecycle, one class per state
Movie ticket booking	Two people wanting the same seat: the concurrency question
Splitwise	Money, and a rule with several versions
Amazon online shopping	A question too big to finish, and choosing the part you build

Add a seventh, **an in-memory cache (LRU)**, if your target companies ask for a data structure rather than a product.

The night before: do not learn a new question (a half-understood design adds anxiety and will not be remembered). Instead: re-read the time budget (knowing you are *allowed* eight minutes on requirements stops you rushing), re-read the extensions section of one case study you have done, and write the five steps from memory: **requirements, actors and use cases, classes, relationships, code.**

1.14 Common mistakes

Mistake	Why it hurts	Fix
Coding in minute two	Missing requirements appear at minute 35	Spend 8–13 minutes on requirements and actors
No out-of-scope list	Scope creeps; omissions look like oversights	Write it down and agree it
Agreeing to every suggested feature	Nothing gets finished	"I'll leave X out and add it if time allows"
One subclass per value	Class explosion with no behaviour	Different data → field/enum
God class (`ParkingLotManager` does everything)	Fails single responsibility; untestable	One sentence per class, split on "and"
Missing the record class (ticket/loan/booking)	Data ends up on the wrong class (`dueDate` on `Book`)	Connection that carries data = an object
Inheritance for code reuse ("Car extends Engine")	Wrong "is-a"; fragile	Composition
Pattern stuffing	Looks like memorisation, not judgement	One or two patterns, with the signal
`switch` on type everywhere	Every new type edits many places	Polymorphism (one call, different behaviour per class) / Strategy
All twelve classes at equal depth	No flow works end to end	Two or three flows fully
Silent designing	Interviewer cannot credit your reasoning	Narrate each step
Ignoring concurrency when two users share a resource	Double booking	Lock or atomic operation on the shared state
Non-running code in machine coding	Often an automatic reject	Get a thin end-to-end path running by halfway
Using `double` for money, reading the clock inside logic	Rounding bugs, flaky demo	Cents/`BigDecimal`, inject time

---

In the interview

30-second answer (to "How do you approach a low-level design problem?"): "First I clarify and write 8 to 12 requirements with an explicit out-of-scope list. Then I list the actors and their use cases. From the nouns I pick the classes, cutting anything that is only a value, and give each class one responsibility. I connect them with the right relationships and draw a class diagram, sketch the key flow, and run a quick SOLID check and pick at most one or two patterns where the signal is clear. Then I code the two or three core flows, handle edge cases and concurrency, and finish by discussing extensions and trade-offs."

Follow-ups:

- *"How is this different from system design?"* — System design is about many machines and scale (databases, caches, queues). LLD stays inside one application: classes, interfaces, relationships and code.
- *"You won't finish; what matters?"* — Depth on the chosen part: a bounded scope, clean responsibilities, correct relationships, code that matches the diagram, and one trade-off I can defend.
- *"What changes in a machine-coding round?"* — The code must run. I keep storage in memory, define service interfaces and a driver, get the happy path working by halfway, then add features, validation and one extension point.
- *"How do you decide whether to use a pattern?"* — I look for the signal: several interchangeable rules → Strategy, lifecycle with many transitions → State, many listeners → Observer. If there is no signal, plain

classes are the better answer.

Self-check

- **Q:** Name the five core steps in order. **A:** Requirements, actors & use cases, classes, relationships, code.
- **Q:** How much of a 45-minute round goes before naming a class? **A:** Roughly a quarter (8–13 minutes).
- **Q:** What are the five things an interviewer judges? **A:** Bounded problem, one-sentence responsibilities, correct relationships, code matching the diagram, an explained trade-off.
- **Q:** What does a machine-coding round add? **A:** Working code within about 90 minutes, data models, service interfaces, extensibility, and a demo.
- **Q:** Which two classes do beginners most often miss? **A:** The record-keeping class (ticket/loan/booking) and the rule class (rate/strategy).
- **Q:** "Different data" vs "different behaviour"? **A:** Different data → field or enum. Different behaviour → separate class.
- **Q:** How many patterns in a 45-minute design? **A:** One or two, placed where the signal appears; name a rejected one too.
- **Q:** What should the last day of any study plan be? **A:** A timed run from a blank page.

TL;DR

- LLD/OOD = design the classes inside one application and code the main flows; machine coding = the same with running code in ~90 minutes.
- Clarify → requirements → use cases → entities → relationships → diagram → flows → patterns/SOLID → code → edge cases/concurrency → extensions.
- Spend a quarter of the time before naming a class; write an out-of-scope list.
- Different data → field; different behaviour → class; one sentence per class.
- Run SOLID as five quick checks; use one or two patterns where the signal appears.
- Code two or three flows properly; inject time, use `BigDecimal` (or cents) for money, guard shared state.
- Practise by attempting first, then comparing; finish every plan with a timed blank-page run.

Chapter 2 — OOP Fundamentals

What you will learn in this chapter

- What object-oriented programming (OOP) is and why the LLD round is really a test of it.
- Classes and objects, constructors, `this`, `static` vs instance members, and `final`.
- The four pillars — **encapsulation, abstraction, inheritance, polymorphism** — on one running bank example.
- Inheritance details (`super`, overriding rules) and polymorphism details (overloading vs overriding, dynamic dispatch).
- Interfaces (default, static, private methods, functional interfaces), abstract classes, and when to pick which.
- Enums with fields and behaviour.
- Composition over inheritance, identity vs equality (`equals`/`hashCode`), immutability and records.
- Access modifiers and packages, and the generics you actually need in LLD.
- Object-oriented analysis vs design vs programming (OOA / OOD / OOP), with a four-step process.

Every concept has a Java 21 example that compiles and runs; the real output is shown under each program.

How to run all examples: `cd chapters/02-oop-fundamentals/code && javac --release 21 -d /tmp/lld_02 $(find . -name '*.java') && java -cp /tmp/lld_02 lld.ch02.<package>.Main`

(`javac` is the Java compiler: it turns `.java` source files into `.class` files. `java` runs them on the **JVM**, the Java Virtual Machine, the program that executes compiled Java code; `-cp` says where the compiled classes live.)

Concept checklist (the commonly listed "must-know OOP concepts" and where each is covered):

Concept	Section	Concept	Section
Classes & objects	2.2	Interfaces (default/static/functional)	2.8
Constructors, constructor chaining	2.2	Abstract class vs interface	2.9
`this` keyword	2.2	Enums	2.10
`static` vs instance, `final`	2.2	Composition over inheritance	2.11
Encapsulation	2.3	Identity vs equality, `equals`/`hashCode`	2.12
Abstraction	2.4	Immutability & records	2.13
Inheritance, `super`, overriding rules	2.5	Access modifiers & packages	2.14
Polymorphism, overloading, dynamic dispatch	2.6–2.7	Generics basics	2.15
Coupling & cohesion	2.16	OOA / OOD / OOP	2.17

2.1 What object-oriented programming is

What it is

Object-oriented programming (OOP) is a style of programming that **bundles data with the code allowed to modify it**, packaging both into a single unit called an **object**.

Procedural programming separates the two: data sits in one place, and free-standing functions anywhere in the program can read and modify it. OOP instead **fences the data in**: the only code that can reach it is the object's own methods.

Analogy: a bank vault vs a pile of cash on a table. With the pile (procedural), anyone can take or add money and nobody enforces rules. With the vault (OOP), you must go through the teller (the methods), who checks every request.

The problem it solves

When any code can change any data, a rule such as "a balance can never go negative" has to be copied into every caller, and one forgotten copy is a bug. OOP puts each rule in **one place**, next to the data it protects, and lets a design grow by **adding new classes** instead of editing old ones.

Why this matters for the interview

Nobody in the LLD round will ask you to recite textbook definitions. What they want to see is you **breaking a problem into objects, assigning each one its responsibilities and data, and justifying that breakdown**. Every idea in this chapter is a tool for that.

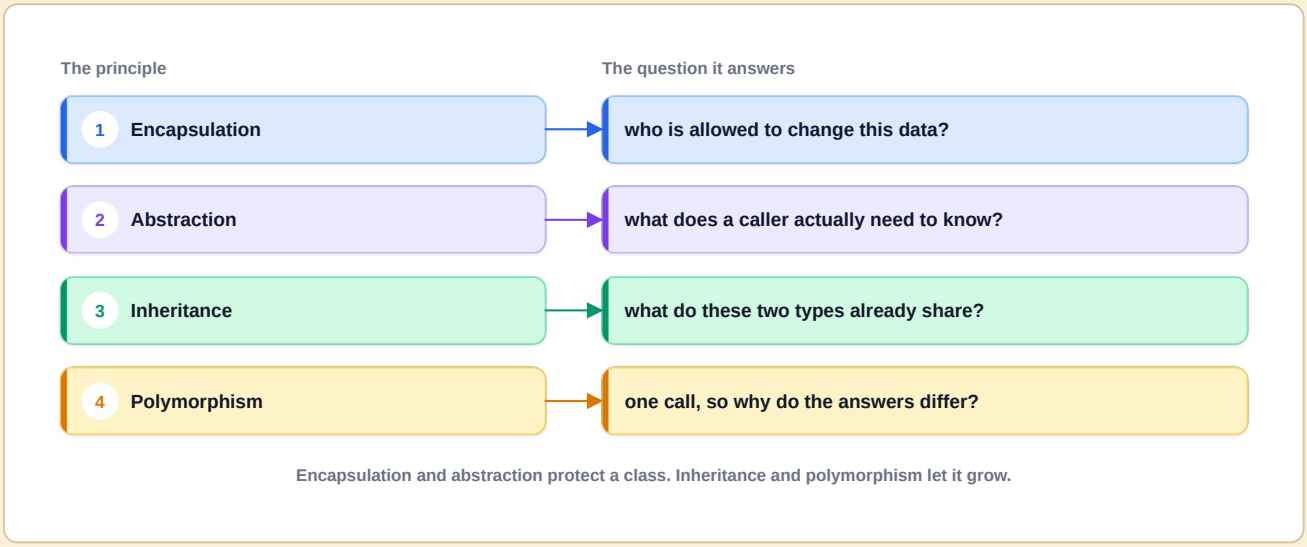

Figure — The four OOP principles and the question each one answers (course diagram)

As the figure above summarises, each pillar answers one design question:

Pillar	Question it answers
Encapsulation	Who is allowed to change this data?
Abstraction	What does a caller actually need to know?
Inheritance	What do these two types already share?
Polymorphism	One call, so why do the answers differ?

The first two pillars guard a single class; the last two let the design expand with new classes.

2.2 Classes, objects, constructors, `this`, `static` and `final`

What it is

- A **class** is the **blueprint**: it lists the fields a thing has and the operations it supports. You write it once.
- An **object** (instance) is **one concrete thing built from that blueprint**, holding actual values in its fields. You create as many as you need with `new`.
- A **field** is a variable that belongs to a class or object. A **method** is a function that belongs to a class or object.
- A **constructor** is special code that runs when an object is created. It has the class's name and **no return type**. Its job: put the new object into a **valid** state.
- `this` is a reference to **the current object** inside its own instance methods and constructors.
- `static` means "belongs to the **class**, shared by all objects". Without `static`, a member is an **instance** member: each object has its own copy.
- `final` means "cannot change": a `final` variable is assigned once, a `final` method cannot be overridden (replaced by a child class with its own version), a `final` class cannot be extended (used as the parent of another class; Section 2.5).

Examples: the `Account` class defines what any account looks like, while account `S-1` (owner Ada, balance 50,000 cents) is a single object of it. In an online shop, `Customer` is the class, and the particular shopper behind order 4192 from last Tuesday is an object.

How it works

1. `new Account("S-1", "Ada", 50_000)` allocates memory for the fields, sets them to defaults (0, `null` meaning "no object", `false`), then runs the constructor.
2. **Initialisation order:** static initialisers (`static` field assignments and `static { ... }` blocks of set-up code) run **once**, when the class is initialised (just before its first real use, such as the first `new` or the first static method call). For each `new`: the parent constructor runs first (`super(...)`, implicit if you do not write it), then instance field initialisers and instance initialiser blocks (plain `{ ... }` blocks inside the class body) in source order, then the rest of the constructor body.
3. If you write **no constructor**, the compiler adds a public no-argument **default constructor**. If you write any constructor, it does not.
4. **Overloaded constructors** (same name, different parameters) should **chain** to one canonical constructor (the single "main" constructor that all the others call) with `this(...)`, so validation lives in one place. In Java 21, `this(...)` or `super(...)` must be the **first statement**. (Java 25 relaxes this with "flexible constructor bodies", JEP 513 (a JDK Enhancement Proposal, the numbered documents that describe new Java features): statements that do not use the object under construction may come before the call. This book targets Java 21, so keep the call first.)
5. Uses of `this`: disambiguate a field from a parameter (`this.id = id`), pass the current object to another method, chain constructors (`this(...)`), and return the object for **fluent chaining** (`return this`).
6. `static` methods have **no** `this`: they cannot touch instance fields directly. Use them for utilities (small helper functions such as `Math.max`) and factories (methods that create and return objects).
7. Variables of class type hold **references** (like an address), not the object itself. `Account alias = a;` copies the reference: both names now point to the **same** object.

Java example

```java
// File: code/lld/ch02/classes/Account.java
package lld.ch02.classes;

/** A CLASS is the blueprint. Every Account OBJECT gets its own copy of the instance fields. */
public class Account {
    // static = belongs to the CLASS, shared by all objects
    private static int openedCount = 0;
    public static final long MIN_OPENING_CENTS = 0;

    // instance fields = belong to EACH object
    private final String id;
    private final String owner;
    private long balanceCents;

    /** Canonical constructor: does all validation in one place. */
    public Account(String id, String owner, long openingCents) {
        if (openingCents < MIN_OPENING_CENTS) throw new IllegalArgumentException("negative opening balance");
        this.id = id;                // 'this.id' is the field, 'id' is the parameter
        this.owner = owner;
        this.balanceCents = openingCents;
        openedCount++;               // shared counter
    }

    /** Overloaded constructor: chains to the canonical one with this(...). Must be the first statement. */
    public Account(String id, String owner) {
        this(id, owner, 0);
    }

    public Account deposit(long cents) {   // returns 'this' so calls can be chained
        if (cents <= 0) throw new IllegalArgumentException("deposit must be positive");
        this.balanceCents += cents;
        return this;
    }

    public long balanceCents() { return balanceCents; }
    public String id()         { return id; }
    public String owner()      { return owner; }

    public static int openedCount() { return openedCount; }  // static method: no 'this' available here

    @Override public String toString() { return id + "(" + owner + ", " + balanceCents + "c)"; }
}
```

```java
// File: code/lld/ch02/classes/Main.java
package lld.ch02.classes;

public class Main {
    public static void main(String[] args) {
        Account a = new Account("S-1", "Ada", 50_000);          // 3-arg constructor
        Account b = new Account("C-1", "Kai");                  // 2-arg constructor chains to 3-arg
        b.deposit(1_000).deposit(500);                          // chaining via 'return this'

        System.out.println("a = " + a);
        System.out.println("b = " + b);
        System.out.println("accounts opened (static, shared): " + Account.openedCount());

        Account alias = a;                                      // copies the REFERENCE, not the object
        alias.deposit(1);
        System.out.println("after alias.deposit(1), a = " + a + ", same object? " + (alias == a));

        try {
            new Account("X", "Bad", -5);
        } catch (IllegalArgumentException e) {
            System.out.println("constructor refused: " + e.getMessage());
        }
        System.out.println("accounts opened: " + Account.openedCount() + " (failed construction did not count)");
    }
}
```

Output:

```
a = S-1(Ada, 50000c)
b = C-1(Kai, 1500c)
accounts opened (static, shared): 2
after alias.deposit(1), a = S-1(Ada, 50001c), same object? true
constructor refused: negative opening balance
accounts opened: 2 (failed construction did not count)
```

Explaining each part: `openedCount` is `static`, so there is one counter for the class; `balanceCents` is an instance field, so each account has its own. The two-argument constructor calls `this(id, owner, 0)`, so validation is written once. `deposit` returns `this`, enabling `b.deposit(1_000).deposit(500)`. `alias == a` is `true` because both variables hold the same reference. The failing constructor threw **before** incrementing the counter, so no half-built object was counted: **validate first, then change state**.

Trade-offs

Choice	Benefit	Cost
Static members	Shared, no object needed	Global state (reachable from anywhere): hard to test and dangerous with threads (parts of a program running at the same time)
Many constructor overloads	Convenient	Confusing beyond 3–4; use a **Builder** (Chapter 8; a helper that collects settings step by step, then creates the object) or static factory methods
`final` fields	Safer, thread-friendlier	Must be set in every constructor

Common mistakes

- Putting per-object data in a `static` field (every object then shares it).
- Doing heavy work or calling overridable methods inside constructors (a subclass override may run before the subclass's fields are set).
- Forgetting `this.` so the parameter is assigned to itself (`id = id;`).
- Thinking `=` copies an object; it copies a reference.

Real-world examples

`Math.max`, `Integer.parseInt`, `List.of` are static methods; `StringBuilder.append` returns `this` for chaining; `String` is a `final` class.

In the interview

> **30-second answer:** "A class is the blueprint, an object is an instance with its own state. Constructors put an object into a valid state; I chain overloads with `this(...)` so validation lives once. Static members belong to the class and are shared, so I keep them for constants, utilities and factories and avoid mutable (changeable) static state."

- *"What happens if you define a constructor with arguments only?"* — The default no-arg constructor is no longer generated; `new X()` stops compiling.
- *"Can a static method use `this`?"* — No; there is no current object in a static context.
- *"Why avoid mutable static fields?"* — They are hidden global state shared by all threads and tests.

Self-check

- **Q:** How many copies of a `static` field exist for 1,000 objects? **A:** One.
- **Q:** What runs first: parent constructor or child field initialisers? **A:** Parent constructor.
- **Q:** What does `alias == a` compare? **A:** References (whether both point to the same object).

TL;DR

Class = blueprint, object = instance. Constructors create valid objects; chain them with `this(...)`. `static` = one per class; `final` = cannot change. Variables hold references.

2.3 Encapsulation

What it is

Encapsulation means an object hides its own data (**private**) and allows the outside world to modify it **only by calling methods the object itself defines and guards**. Analogy: a medicine bottle with a child-proof cap: the contents are reachable, but only through a mechanism that enforces the rules.

The problem it solves

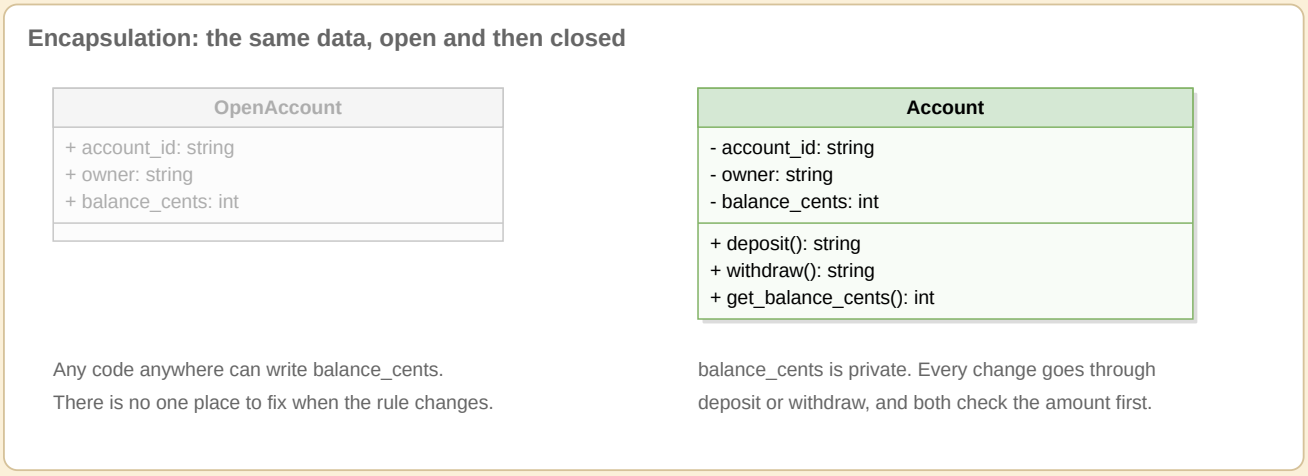

Figure — The same account data, first open (public fields anyone can write) and then closed (private fields changed only through deposit and withdraw) (course diagram)

The left side of the figure shows unprotected, public fields: **code in any file** may write a negative number into `balance`, and if the rule ever changes you have **nowhere central** to update it. (That open version exists only as a contrast; our code does not contain it.) The right side makes the balance private, and both `deposit` and `withdraw` validate the amount first. Overdrawing is therefore impossible: **every route to the balance goes through a method that can say no**. (The default `monthlyUpdate` on `Account` does nothing yet; it becomes useful in Section 2.6.)

How it works

1. Make fields `private` (and `final` where possible).
2. Expose **behaviour** (`deposit`, `withdraw`), not raw setters (`setBalance`; methods that simply overwrite a field).
3. Validate inside those methods: the rule lives **once**.
4. Return copies or unmodifiable views (read-only wrappers that throw if someone tries to change them) of internal collections (never the live list).
5. For every field, settle **which code may modify it**. When the honest answer is "nobody but this class", state it aloud in the interview: it turns a list of fields into a visible design decision.

Java example

The `Account` class of the bank example in Section 2.6 (package `lld.ch02.bank`) is the encapsulation example: `balanceCents` is `private`; `deposit` rejects non-positive amounts; `withdraw` rejects amounts larger than the balance; both are `final` so a subclass cannot weaken the rule.

Trade-offs

Benefit	Cost
Invariants (rules that must always hold) enforced in one place	A little more code than public fields
Internals can change without breaking callers	Over-encapsulating trivial data carriers is noise (use records)

When not to use it (strictly)

Plain data carriers with no rules (DTOs, Data Transfer Objects that only carry data between parts of a system; events, records of something that happened) do not need hand-written getters and validation; a **record** gives you private final fields and accessors for free.

Common mistakes

- **Getter/setter for every field** (a getter is a method that just returns a field; "anemic" objects): the data is technically private but anyone can still set anything. That is not encapsulation.
- Returning a mutable internal list (`return items;`), so callers modify your state behind your back.

Real-world examples

`java.lang.String` hides its internal byte array; `ArrayList` hides its backing array (the plain array that actually stores the elements) and `size`; `LocalDate` exposes only validated factory methods (`LocalDate.of(2026, 2, 30)` throws).

In the interview

> **30-second answer:** "Encapsulation hides state behind methods, and those methods are the single home of every rule about that state. For each field I ask who may change it; if only this class, it is private and changed through intention-revealing methods (named after the business action they perform) like `withdraw`, not a setter."

- *"Are getters and setters encapsulation?"* — Only partly. A setter with no rule is a public field in disguise. Prefer behaviour methods that enforce rules.

Self-check

- **Q:** Where should the "no negative balance" rule live? **A:** Inside `Account.withdraw`, once.

TL;DR

Private data + methods that enforce the rules = encapsulation. Expose behaviour, not setters.

2.4 Abstraction

What it is

Abstraction means giving a caller **just the operations it requires** while concealing **how** they are carried out. Put simply: encapsulation conceals **state**, abstraction conceals **design choices**, and the short list of operations stays valid even if everything behind it is rewritten. Analogy: a car's steering wheel and pedals. You drive without knowing about fuel injection, and the engine can be replaced by an electric motor without changing how you drive.

The problem it solves

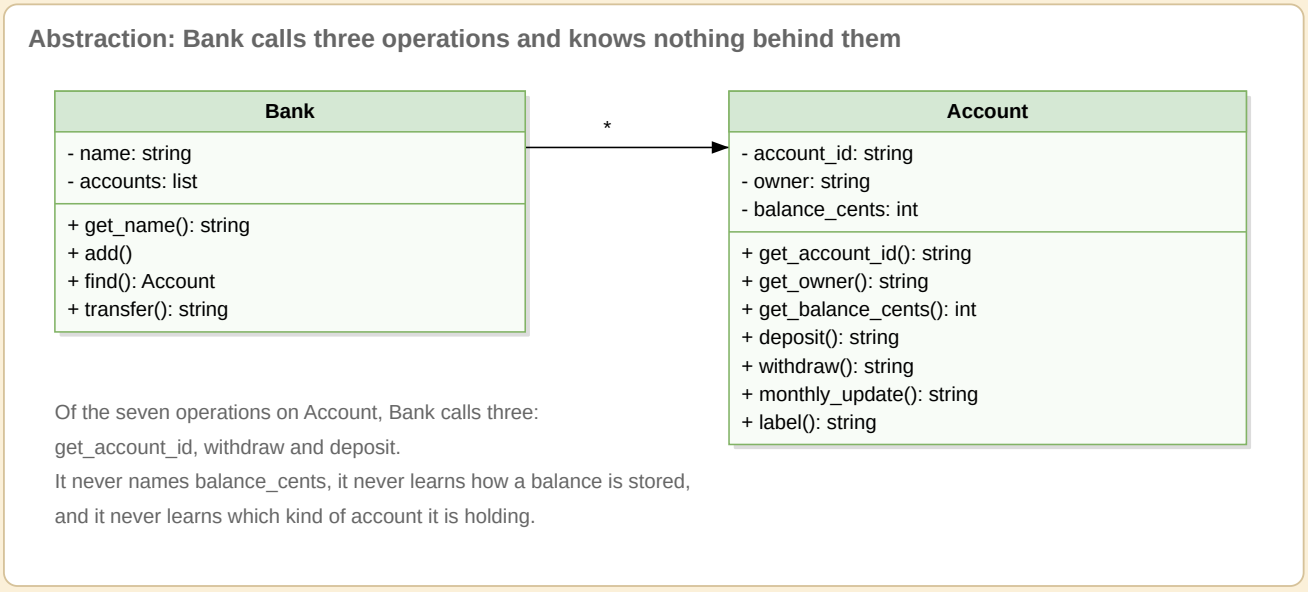

Figure — Of Account's seven public operations, Bank relies on three and sees nothing of what lies behind them (course diagram)

In the course diagram `Account` has seven public operations (it includes a `label()` helper; our Java `Account` has six: `id`, `owner`, `balanceCents`, `deposit`, `withdraw`, `monthlyUpdate`). Either way, `Bank.transfer` relies on only three of them: read the id, withdraw, deposit. `Bank` has no idea that balances are stored as whole cents, what checks an account performs, or that several account subclasses exist. That ignorance is the point: the balance could be moved from a `long` field into a database table and `transfer` would stay exactly as it is.

How it works

1. Decide the **smallest set of operations** a caller needs.
2. Name them after **what** they do (`transfer`), not how.
3. Put them on an interface (a named list of methods with no code, which classes promise to provide; Section 2.8) or the public surface of a class; keep everything else private.
4. Callers depend on that surface only.

Java example

`Bank.transfer` in Section 2.6 uses only `id()`, `withdraw()` and `deposit()`.

Trade-offs

Benefit	Cost
Callers are simpler and survive internal rewrites	A wrong abstraction is expensive to change later
Enables polymorphism (many implementations behind one surface)	Too many layers make code hard to follow

Common mistakes

- **Leaky abstraction:** the interface exposes implementation details (`getHashMapOfSeats()`).
- Abstracting too early, before two concrete cases exist.

Real-world examples

`java.util.List` (callers do not care whether it is an `ArrayList` or `LinkedList`); JDBC's `Connection`/`Statement` (JDBC, Java Database Connectivity, is Java's standard way to talk to SQL databases; same code for different databases); `java.io.InputStream`.

In the interview

> **30-second answer:** "Abstraction is exposing only what the caller needs. My test is the sentence 'the caller does not need to know that': whenever I can honestly say it, something moves behind the interface, the design shrinks, and I can change the implementation freely."

- *"Encapsulation vs abstraction?"* — Encapsulation hides and protects **data** with access control (keywords such as `private` that decide who may see a member, Section 2.14); abstraction hides **complexity and decisions** behind a small set of operations. They work together.

Self-check

- **Q:** Which three `Account` operations does `Bank.transfer` need? **A:** `id()`, `withdraw()`, `deposit()`.

TL;DR

Show the minimum surface; hide the how. "The caller does not need to know that."

2.5 Inheritance

What it is

Inheritance lets a new class (the **child**, subclass) start with everything an existing class (the **parent**, superclass) has, then **add** fields/methods or **replace** (override) some methods. In Java: `class SavingsAccount extends Account`. Analogy: a savings account **is a** bank account with one extra rule.

The problem it solves

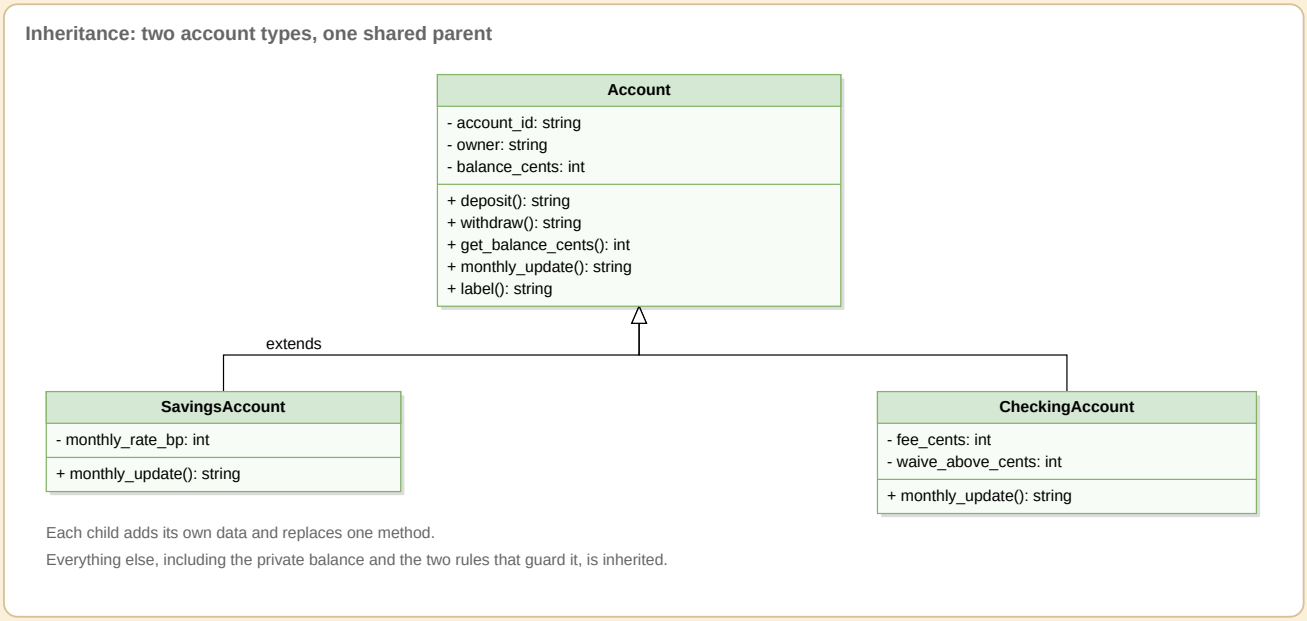

Figure — SavingsAccount and CheckingAccount extend Account; each adds its own data and replaces one method (course diagram)

Savings accounts earn interest; checking accounts take a monthly fee unless their balance clears a threshold. Apart from that, the two share everything: the balance, the deposit check and the withdrawal check, so all of that comes from the parent. In the figure, savings contributes one new field and checking two, and **each overrides a single method**; neither duplicates the balance or its rules. If the is-a sentence were false, the difference would belong in a **field**, not in a parent class.

How it works

1. Declare `class Child extends Parent`. Java allows **one** parent class (single inheritance of classes), but many interfaces.
2. The child inherits all **accessible** (non-private) members. Private fields still exist in the object but are reached only through the parent's methods. **Constructors are not inherited.**
3. The child constructor must call a parent constructor, `super(...)`, as its first statement (implicitly `super()` if omitted, which fails to compile if the parent has no no-arg constructor).
4. `super.method()` calls the parent's version from inside an override (reuse, then extend).
5. **Overriding rules:**

Rule	Detail
Same signature	Same method name and parameter types
Return type	Same, or a **subtype** (a type that extends or implements it) for reference types (*covariant return*); primitives (`int`, `long`, `boolean`...) must match exactly
Access	Same or **wider** (protected, i.e. visible to subclasses, → public is fine; public → protected is not)
Checked exceptions	May throw fewer or narrower checked exceptions, never new or broader ones; unchecked are free
Cannot override	`final` methods, `static` methods (they are **hidden**, not overridden), `private` methods (not inherited)
Annotation	Always write `@Override` (an annotation is an `@` tag that gives the compiler extra information): the compiler then catches typos and wrong signatures

(About the exceptions row: a **checked exception**, such as `IOException`, is one the compiler forces callers to catch or declare; an **unchecked exception**, such as `IllegalArgumentException`, extends `RuntimeException` and needs no declaration.)

6. Every class ultimately extends `java.lang.Object`, which is why every object has `toString`, `equals`, `hashCode` and `getClass`.
7. **The is-a test:** the sentence "a SavingsAccount **is an** Account" must be true in every situation. A car is not an engine, so `Car` should **hold** an `Engine` (Section 2.11).

Java example

See `SavingsAccount` and `CheckingAccount` in Section 2.6 (each calls `super(...)` and overrides `monthlyUpdate()`), and `Circle` in Section 2.7 (covariant return, `super.who()`, static-method hiding, field hiding).

Trade-offs

Benefit	Cost
Reuse of shared state and behaviour	**Tight coupling** (a change in one class forces changes in another): child depends on parent internals (fragile base class)
Enables polymorphism	Hierarchy is fixed at compile time (when the code is compiled, before it runs); single parent only
Natural for true "is-a" families	Deep hierarchies (more than 2–3 levels) are hard to reason about

When not to use it

- Only to **reuse code** when the is-a sentence is false (use composition).
- When the child would need to **disable** a parent method (throw `UnsupportedOperationException` or do nothing): that breaks the **Liskov Substitution Principle** (Chapter 4): the child can no longer stand in for the parent.
- For variations that differ **only in data** (use a field or enum).

Common mistakes

- `Square extends Rectangle` with independent `setWidth`/`setHeight`: code expecting a rectangle breaks.
- Forgetting `@Override` and silently **overloading** instead (e.g. `equals(Point p)` instead of `equals(Object o)`).
- Calling overridable methods from a parent constructor.

Real-world examples

Good: `FileInputStream extends InputStream`; Spring's (Spring is a popular Java application framework) `AbstractController`-style base classes. Known mistakes in the JDK (Java Development Kit: the compiler plus the standard library) itself: `java.util.Stack extends Vector` (a stack, which should only add and remove at the top, exposes random-access `insertElementAt`, which reaches any position), and `java.util.Properties extends Hashtable` (lets you put non-string entries).

In the interview

> **30-second answer:** "Inheritance lets a subclass reuse all of its parent's members, and it is only right when the sentence 'the child is a kind of the parent' holds in every situation. I use it for genuine type families, override with `@Override`, and if a child would have to disable a parent method I switch to composition, because that is a Liskov violation."

- *"Can you override a static method?"* — No. A static method with the same signature in the child **hides** the parent's; which one runs depends on the compile-time type (see Section 2.7 output).
- *"Can an override return a different type?"* — Only a subtype of the original (covariant return), e.g. `Circle copy()` overriding `Shape copy()`.

Self-check

- **Q:** Is `private` inherited? **A:** The field exists in the child object but the child cannot access it directly; private methods are not overridden.
- **Q:** Can an override reduce visibility from `public` to `protected`? **A:** No.

TL;DR

`extends` for true is-a families only. `super(...)` first, `@Override` always, never narrow access or disable parent behaviour.

2.6 Polymorphism (and the full bank example)

What it is

Polymorphism (Greek for "many forms") means **the same method call can do different things depending on the object it lands on**. The calling code works with a variable of the **parent type** and invokes a method by name; the concrete object behind that variable determines the behaviour. Analogy: a "start" button that starts a car, a washing machine or a laptop, each in its own way.

The problem it solves

Without it, code asks "what type are you?" everywhere: `if (a instanceof SavingsAccount) ... else if (a instanceof CheckingAccount) ...`. Every new type means finding and editing every such branch. With polymorphism, the branch disappears.

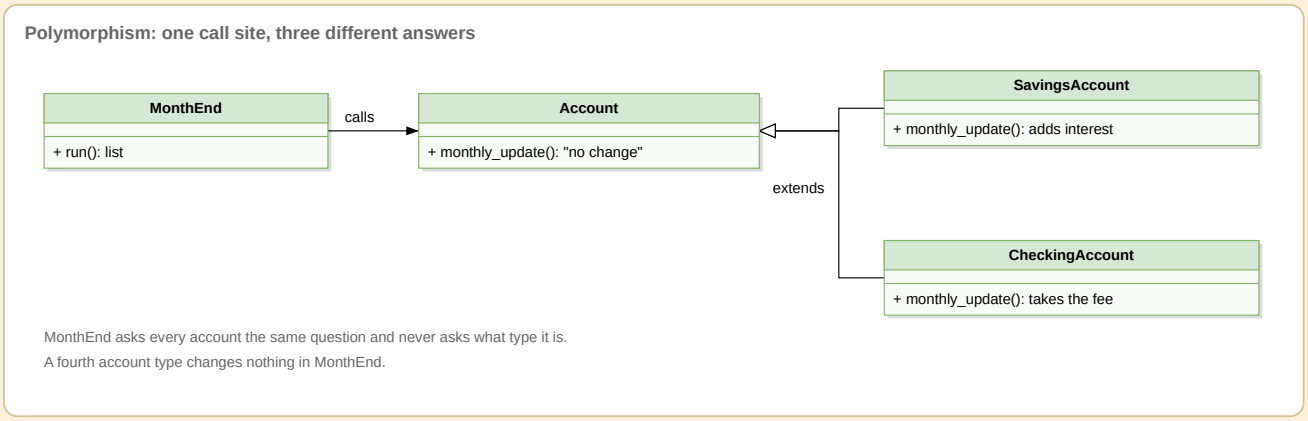

Figure — MonthEnd calls monthlyUpdate on every account and never asks which type it holds (course diagram)

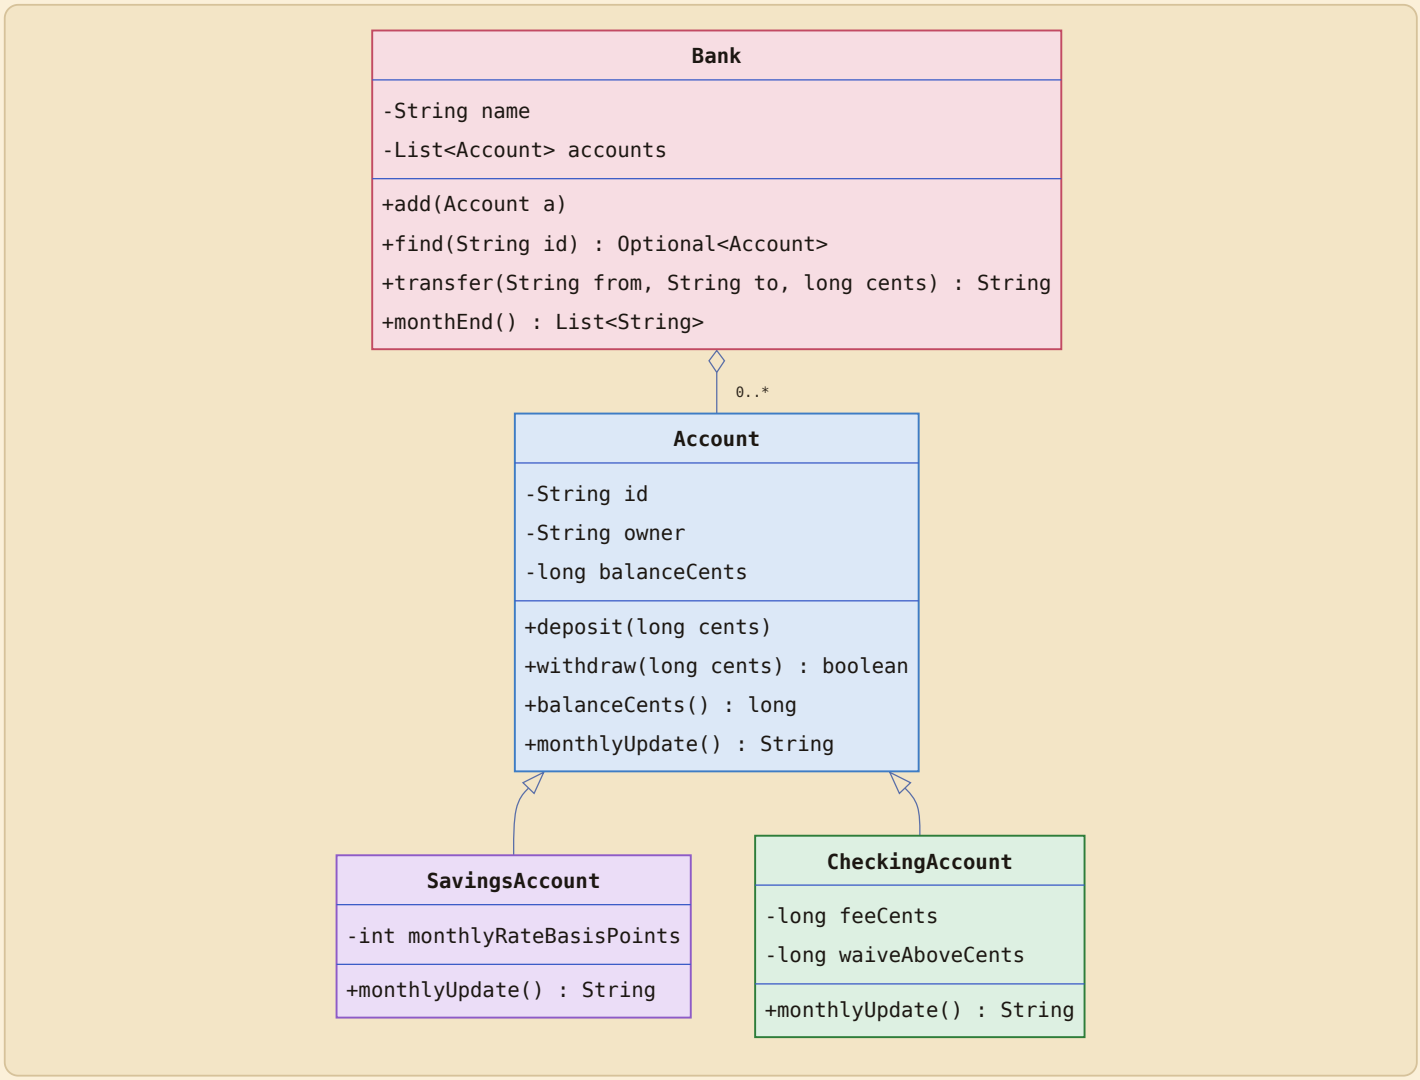
In the figure, the month-end loop sends the identical request to each account and **never checks which kind it is**; it contains no `if` about account types. Introduce a fourth account type next month and the loop needs no edit.

How it works

1. Declare the method on the parent type (or interface).
2. Each child overrides it.
3. Callers hold the **parent type** (`Account a`) and call the method.
4. At run time (while the program is running) the JVM looks at the **actual class of the object** and runs that class's version: **dynamic dispatch** (also called late binding).

Java example: the bank (encapsulation + abstraction + inheritance + polymorphism)



```java
// File: code/lld/ch02/bank/Account.java
package lld.ch02.bank;

/**
 * ENCAPSULATION: the balance is private; the only way to change it is through deposit/withdraw,
 * and both enforce the rules. The parent also defines the hook monthlyUpdate() for POLYMORPHISM.
 */
public class Account {
    private final String id;
    private final String owner;
    private long balanceCents;                    // hidden: nobody outside can set it to -5

    public Account(String id, String owner, long openingCents) {
        if (openingCents < 0) throw new IllegalArgumentException("negative opening balance");
        this.id = id;
        this.owner = owner;
        this.balanceCents = openingCents;
    }

    public final void deposit(long cents) {         // final: children may not weaken the rule
        if (cents <= 0) throw new IllegalArgumentException("deposit must be positive");
        balanceCents += cents;
    }

    public final boolean withdraw(long cents) {
        if (cents <= 0 || cents > balanceCents) return false;   // the one place the rule lives
        balanceCents -= cents;
        return true;
    }

    public final long balanceCents() { return balanceCents; }
    public final String id()         { return id; }
    public final String owner()      { return owner; }

    /** Default month-end behaviour. Subclasses OVERRIDE it. */
    public String monthlyUpdate() { return "no change"; }
}
```

```java
// File: code/lld/ch02/bank/Bank.java
package lld.ch02.bank;

import java.util.ArrayList;
import java.util.List;
import java.util.Optional;

/**
 * ABSTRACTION: Bank uses only id(), withdraw() and deposit(). It does not know how a balance is
 * stored, what rules an account applies, or which subclass it holds.
 */
public class Bank {
    private final String name;
    private final List<Account> accounts = new ArrayList<>();

    public Bank(String name) { this.name = name; }

    public void add(Account a) { accounts.add(a); }

    public Optional<Account> find(String id) {
        return accounts.stream().filter(a -> a.id().equals(id)).findFirst();
    }

    public String transfer(String fromId, String toId, long cents) {
        Account from = find(fromId).orElseThrow();
        Account to = find(toId).orElseThrow();
        if (!from.withdraw(cents)) return fromId + " rejected, not enough money";
        to.deposit(cents);
        return "moved " + Money.format(cents) + " from " + fromId + " to " + toId;
    }

    /** POLYMORPHISM: one call, a different result per object, and no 'if' on the account type. */
    public List<String> monthEnd() {
        List<String> lines = new ArrayList<>();
        for (Account a : accounts) {
            String what = a.monthlyUpdate();                // dynamic dispatch picks the override
            lines.add(a.id() + " (" + a.owner() + "): " + what + ", balance " + Money.format(a.balanceCents()));
        }
        return lines;
    }

    public List<Account> accounts() { return List.copyOf(accounts); }
    public String name() { return name; }
}
```

```java
// File: code/lld/ch02/bank/CheckingAccount.java
package lld.ch02.bank;

/** A checking account charges a monthly fee unless the balance is above a threshold. */
public class CheckingAccount extends Account {
    private final long feeCents;
    private final long waiveAboveCents;

    public CheckingAccount(String id, String owner, long openingCents, long feeCents, long waiveAboveCents) {
        super(id, owner, openingCents);
        this.feeCents = feeCents;
        this.waiveAboveCents = waiveAboveCents;
    }

    @Override
    public String monthlyUpdate() {
        if (balanceCents() >= waiveAboveCents) return "fee waived";
        return withdraw(feeCents) ? "fee " + Money.format(feeCents) : "fee could not be taken";
    }
}
```

```java
// File: code/lld/ch02/bank/Money.java
package lld.ch02.bank;

/** Utility: formats whole cents as dollars. Private constructor = cannot be instantiated. */
public final class Money {
    private Money() { }
    public static String format(long cents) { return String.format("$%d.%02d", cents / 100, cents % 100); }
}
```

```java
// File: code/lld/ch02/bank/SavingsAccount.java
package lld.ch02.bank;

/** INHERITANCE: a savings account IS an account; it adds a rate and replaces one method. */
public class SavingsAccount extends Account {
    private final int monthlyRateBasisPoints;      // 25 bp = 0.25 %

    public SavingsAccount(String id, String owner, long openingCents, int monthlyRateBasisPoints) {
        super(id, owner, openingCents);            // parent constructor runs first
        this.monthlyRateBasisPoints = monthlyRateBasisPoints;
    }

    @Override
    public String monthlyUpdate() {
        long interest = balanceCents() * monthlyRateBasisPoints / 10_000;
        if (interest > 0) deposit(interest);
        return "interest " + Money.format(interest);
    }
}
```

```java
// File: code/lld/ch02/bank/Main.java
package lld.ch02.bank;

public class Main {
    public static void main(String[] args) {
        Bank bank = new Bank("Gurus Bank");
        bank.add(new SavingsAccount("S-1", "Ada", 50_000, 25));
        bank.add(new CheckingAccount("C-1", "Kai", 8_000, 250, 50_000));
        bank.add(new Account("P-1", "Ravi", 3_000));

        System.out.println(bank.name() + ", opening balances:");
        for (Account a : bank.accounts()) {
            System.out.println("  " + a.id() + " (" + a.owner() + "): " + Money.format(a.balanceCents()));
        }
        System.out.println(bank.transfer("S-1", "C-1", 10_000));
        System.out.println(bank.transfer("S-1", "C-1", 90_000));
        System.out.println("month end:");
        bank.monthEnd().forEach(line -> System.out.println("  " + line));
    }
}
```

Output:

```
Gurus Bank, opening balances:
  S-1 (Ada): $500.00
  C-1 (Kai): $80.00
  P-1 (Ravi): $30.00
moved $100.00 from S-1 to C-1
S-1 rejected, not enough money
month end:
  S-1 (Ada): interest $1.00, balance $401.00
  C-1 (Kai): fee $2.50, balance $177.50
  P-1 (Ravi): no change, balance $30.00
```

Explaining each part:

- **Encapsulation:** `balanceCents` is private; `deposit`/`withdraw` are `final` and enforce the rules. The second transfer ($900 from an account holding $400) is refused inside `withdraw`.
- **Abstraction:** `Bank.transfer` only uses `id()`, `withdraw()`, `deposit()`.
- **Inheritance:** each child calls `super(...)` and adds one or two fields.
- **Polymorphism:** `monthEnd()` calls `a.monthlyUpdate()`: three accounts, one method name, three results (interest 0.25% of $400 = $1.00; checking balance $180 is below the $500 waiver so $2.50 is charged; the plain account uses the parent's "no change"). **No `if` asks which is which.**
- **Why `long` cents and not `BigDecimal` here:** money must never be a `double` (binary floating point cannot store 0.10 exactly, so sums drift). A `long` count of whole **cents** is exact too, and keeps this example about the four pillars rather than about arithmetic. Its limit is that it cannot hold a fraction of a cent: `balanceCents() * monthlyRateBasisPoints / 10_000` uses integer division, which **truncates** (rounds toward zero). With 40,000 cents at 25 bp the result is exactly 100 cents, but for 40,001 cents the 0.0025-cent remainder would be dropped. When a domain needs fractional amounts or an explicit rounding rule (interest, tax, currency conversion), use `BigDecimal` (Java's exact decimal-number type) with a stated `RoundingMode`, as the `Money` value object (a small object defined only by its values, Section 2.12) in Section 2.13 does. Interest is in **basis points** (1 bp = 0.01%).

How the four fit together

Encapsulation and abstraction guard a class: they settle **what is hidden** and what outsiders may see. Inheritance and polymorphism let the design expand: they make **a new requirement show up as an added class** rather than as surgery on an existing one. Designs that apply all four tend to look alike: hidden state, a small public API (application programming interface: the set of methods other code is allowed to call), a parent for the common parts, and subclasses that each override one method.

Trade-offs

Benefit	Cost
Removes type switches; open to new types	Behaviour is spread over several classes; you must look at the runtime type to know what runs
Enables Strategy, State, Command and most patterns (named, reusable designs; Chapters 8–11)	A virtual call (one resolved at run time) is marginally slower than a direct call (almost never matters)

Common mistakes

- Long `if/else` or `switch` over a type: almost always where polymorphism belongs. **Pointing this out to the interviewer earns more credit than actually refactoring (restructuring without changing behaviour) it.**
- Using `instanceof` chains to decide behaviour (fine for occasional data inspection, e.g. pattern matching in Java 21, which tests a type and binds a variable in one step, but not as the main dispatch mechanism in an OO model).

Real-world examples

`List.add` behaves differently for `ArrayList` and `LinkedList`; `Runnable.run()` executed by any `Executor` (a Java object that runs tasks, often on background threads); Spring injecting (handing in from outside) any implementation of an interface; `Comparator.compare` in `Collections.sort`.

In the interview

> **30-second answer:** "Polymorphism lets one call behave differently depending on the object receiving it. I code against the parent type or an interface, each subtype overrides the method, and the JVM picks the right one at run time. It removes type switches, so a new type is a new class, not an edit."

- *"Where would you use it in a parking lot?"* — Pricing (`PricingStrategy.feeCents`), payments (`Payment.pay`), spot selection.

Self-check

- **Q:** Which version of `monthlyUpdate` runs for `Account a = new SavingsAccount(...)`? **A:** `SavingsAccount`'s, chosen at run time.

TL;DR

Hold the parent type, call the method, let the object decide. Type switches are the signal that polymorphism is missing.

2.7 Compile-time vs runtime polymorphism: overloading vs overriding

What it is

	Overloading (compile-time / static polymorphism)	**Overriding (runtime / dynamic polymorphism)**
What	Same method name, **different parameter lists**, usually in the same class	Same signature re-implemented in a **subclass**
Decided by	The **compiler**, using the **declared (static) types** of the arguments	The **JVM at run time**, using the **actual class** of the receiver object
Return type	May differ (but cannot be the only difference)	Same or covariant
Needs inheritance?	No	Yes (class or interface)
Example	`add(int,int)`, `add(double,double)`	`Circle.area()` overriding `Shape.area()`

How it works: overload resolution

The compiler picks an overload in three phases and stops at the first phase that finds a match:

1. Exact match or **widening** (automatic conversion to a bigger or more general type) of primitives/references (`int` → `long` → `double`, `Circle` → `Shape`), no boxing, no varargs.
2. Allow **boxing/unboxing** (`int` ↔ `Integer`: wrapping a primitive value in its object form, and back).
3. Allow **varargs** (`int...`: a parameter that accepts any number of arguments). If several candidates remain in a phase, the **most specific** wins; if none is most specific, it is a compile error (ambiguous call).

Not polymorphic: fields (resolved by the static type; a child field with the same name **hides** the parent's), `static` methods (hidden, chosen by the static type), and `private` methods.

Java example

```java
// File: code/lld/ch02/polymorphism/Calculator.java
package lld.ch02.polymorphism;

/** OVERLOADING: same name, different parameter lists. Chosen by the COMPILER from static types. */
public class Calculator {
    public String add(int a, int b)       { return "add(int,int) = " + (a + b); }
    public String add(long a, long b)     { return "add(long,long) = " + (a + b); }
    public String add(double a, double b) { return "add(double,double) = " + (a + b); }
    public String add(int... xs)          { int s = 0; for (int x : xs) s += x; return "add(int...) = " + s; }

    public String greet(Shape s)  { return "greet(Shape)"; }
    public String greet(Circle c) { return "greet(Circle)"; }
}
```

```java
// File: code/lld/ch02/polymorphism/Circle.java
package lld.ch02.polymorphism;

public class Circle extends Shape {
    public String kind = "circle";                              // HIDES Shape.kind, does not override it
    private final double r;

    public Circle(double r) {
        super();                                                // implicit anyway; parent constructed first
        this.r = r;
    }

    @Override public double area() { return Math.PI * r * r; }  // OVERRIDE: same signature

    @Override public Circle copy() { return new Circle(r); }    // covariant return type is allowed

    public static String describe() { return "static Circle.describe"; }

    @Override public String who() { return super.who() + " (radius " + r + ")"; }  // super.method() reuses parent
code
}
```

```java
// File: code/lld/ch02/polymorphism/Shape.java
package lld.ch02.polymorphism;

public class Shape {
    public String kind = "shape";                               // fields are NOT polymorphic

    public double area() { return 0; }

    public Shape copy() { return new Shape(); }

    public static String describe() { return "static Shape.describe"; }   // static: hidden, not overridden

    public String who() { return "I am a " + kind + " with area " + String.format("%.2f", area()); }
}
```

```java
// File: code/lld/ch02/polymorphism/Main.java
package lld.ch02.polymorphism;

import java.util.List;

public class Main {
    public static void main(String[] args) {
        Calculator calc = new Calculator();
        System.out.println(calc.add(2, 3));           // exact match int,int
        System.out.println(calc.add(2L, 3));          // widening to long,long
        System.out.println(calc.add(2.5, 3));         // widening to double,double
        System.out.println(calc.add(1, 2, 3));        // varargs, chosen last

        Shape s = new Circle(1.0);                    // static type Shape, runtime type Circle
        System.out.println("s.area() -> " + String.format("%.2f", s.area()) + "  (runtime override: dynamic
dispatch)");
        System.out.println("calc.greet(s) -> " + calc.greet(s) + "  (overload picked at compile time from static
type)");
        System.out.println("s.kind -> " + s.kind + "  (fields use the static type)");
        System.out.println("((Circle) s).kind -> " + ((Circle) s).kind);
        System.out.println("Shape.describe() -> " + Shape.describe() + ", Circle.describe() -> " +
Circle.describe());
        System.out.println("s.copy() class -> " + s.copy().getClass().getSimpleName());
        System.out.println(s.who());

        List<Shape> shapes = List.of(new Shape(), new Circle(2), new Circle(0.5));
        double total = 0;
        for (Shape sh : shapes) total += sh.area();     // one call site, many behaviours
        System.out.println("total area = " + String.format("%.2f", total));

        if (s instanceof Circle c) {                    // pattern matching instanceof (Java 16+)
            System.out.println("pattern-matched a circle: " + c.who());
        }
    }
}
```

Output:

```
add(int,int) = 5
add(long,long) = 5
add(double,double) = 5.5
add(int...) = 6
s.area() -> 3.14  (runtime override: dynamic dispatch)
calc.greet(s) -> greet(Shape)  (overload picked at compile time from static type)
s.kind -> shape  (fields use the static type)
((Circle) s).kind -> circle
Shape.describe() -> static Shape.describe, Circle.describe() -> static Circle.describe
s.copy() class -> Circle
I am a shape with area 3.14 (radius 1.0)
total area = 13.35
pattern-matched a circle: I am a shape with area 3.14 (radius 1.0)
```

Explaining each part:

- `add(2L, 3)`: no `(long,int)` overload, so `3` widens to `long` (phase 1).
- `s.area()` runs `Circle.area()` although `s` is declared `Shape`: **dynamic dispatch**.
- `calc.greet(s)` prints `greet(Shape)`, not `greet(Circle)`: overloads are chosen **at compile time from the declared type** of `s`. This surprises many people and is a favourite interview question.
- `s.kind` is `"shape"`: fields are not polymorphic. Inside `Shape.who()`, `kind` also means `Shape.kind`, which is why the output says "I am a shape". Lesson: **never hide fields**; use private fields plus overridable methods.
- `Circle copy()` overrides `Shape copy()` with a **covariant return type**.
- `super.who()` reuses the parent's text and appends the radius.
- `s instanceof Circle c` is **pattern matching for instanceof** (Java 16+): test and cast (treat the value as the more specific type) in one step.

Common mistakes

- Expecting overloads to be picked by runtime type (they are not; that would require double dispatch, choosing a method by the runtime types of two objects; see the Visitor pattern in Chapter 11).
- Writing `public boolean equals(Point p)`: an **overload**, not an override of `equals(Object)`, so collections (Java's built-in containers such as `List`, `Set` and `Map`) never call it. `@Override` would have caught it.

In the interview

> **30-second answer:** "Overloading is compile-time: same name, different parameters, chosen by declared types. Overriding is runtime: a subclass re-implements the same signature and the JVM dispatches on the actual object. Fields and static methods are not polymorphic."

- *"Why does `greet(s)` call `greet(Shape)`?"* — Overload resolution uses the static type of `s`, which is `Shape`.

Self-check

- **Q:** Can two methods differ only in return type? **A:** No; that is a compile error.
- **Q:** Which phase allows varargs? **A:** The third (last).

TL;DR

Overloading = compiler picks by declared types. Overriding = JVM picks by actual object. Fields and statics never dispatch dynamically.

2.8 Interfaces (default, static, private methods, functional interfaces)

What it is

An **interface** is a **contract**: a named list of methods a class promises to provide, without (necessarily) saying how. `class EmailNotifier implements Notifier`. Analogy: a wall socket standard. Any appliance with the right plug works with any socket, whoever made them.

Key facts:

- Abstract methods are implicitly `public abstract`; fields are implicitly `public static final` (constants).
- A class can **implement many interfaces** (but extend only one class).
- **Default methods** (Java 8+): a method with a body that implementers inherit and may override. Added so interfaces can evolve without breaking every implementer (for example `Collection.stream()`, `Iterable.forEach`).
- **Static methods** (Java 8+): belong to the interface; called as `Notifier.console()`; **not inherited** by implementing classes.
- **Private methods** (Java 9+): helpers shared by default methods, invisible to implementers.
- A **functional interface** has **exactly one abstract method** (methods inherited from `Object`, like `equals`, do not count; default and static methods do not count). It can be implemented by a **lambda** (a short unnamed function written inline, such as `(to, msg) -> ...`) or **method reference** (a pointer to an existing method, such as `String::isBlank`). `@FunctionalInterface` asks the compiler to enforce the rule.

The problem it solves

Callers depend on **what** can be done, not on a concrete class. New implementations can be added without touching callers (open/closed: open to extension, closed to modification), and tests can pass fakes, simple stand-in objects (dependency inversion: depend on interfaces, not concrete classes; both are covered in Chapter 4). Interfaces also give Java a safe form of multiple inheritance (one class inheriting from several parents; here of **type**, not state).

How it works

1. Define the interface with the smallest set of methods a caller needs.
2. Implement it in one or more classes (or with a lambda if it is functional).
3. Callers declare variables and parameters of the interface type.

4. If two interfaces supply the same default method, the class **must** override it and may pick one with `A.super.method()`. If a superclass declares the method, **the class wins** over interface defaults.

Java example

```java
// File: code/lld/ch02/interfaces/DiscountRule.java
package lld.ch02.interfaces;

/** A FUNCTIONAL interface has exactly one abstract method, so a lambda can implement it. */
@FunctionalInterface
public interface DiscountRule {
    long apply(long priceCents);

    default DiscountRule then(DiscountRule next) { return p -> next.apply(apply(p)); }  // defaults are allowed
}
```

```java
// File: code/lld/ch02/interfaces/EmailNotifier.java
package lld.ch02.interfaces;

public class EmailNotifier implements Notifier {
    @Override public String send(String to, String message) { return "[email] to " + to + ": " + message; }
}
```

```java
// File: code/lld/ch02/interfaces/Notifier.java
package lld.ch02.interfaces;

/** An interface is a contract: WHAT can be done, not HOW. */
public interface Notifier {
    String send(String to, String message);        // abstract method: every implementer must provide it

    /** default method: implementers inherit it and may override it (added in Java 8). */
    default String sendAll(java.util.List<String> recipients, String message) {
        StringBuilder sb = new StringBuilder();
        for (String r : recipients) sb.append(send(r, clean(message))).append('\n');
        return sb.toString().stripTrailing();
    }

    /** static method: belongs to the interface itself; called as Notifier.console(). */
    static Notifier console() { return (to, msg) -> "[console] " + to + ": " + msg; }

    /** private method (Java 9+): a helper shared by default methods, hidden from implementers. */
    private String clean(String message) { return message.strip(); }
}
```

```java
// File: code/lld/ch02/interfaces/Report.java
package lld.ch02.interfaces;

/**
 * An ABSTRACT class can hold state and constructors, and mix finished and unfinished methods.
 * Here it fixes the skeleton of an algorithm (Template Method) and lets subclasses fill the steps.
 */
public abstract class Report {
    private final String title;                    // state: interfaces cannot have instance fields

    protected Report(String title) { this.title = title; }

    public final String render() {                 // final: subclasses cannot change the skeleton
        return header() + "\n" + body() + "\n-- end of " + title + " --";
    }

    protected String header() { return "== " + title + " =="; }   // concrete, overridable
    protected abstract String body();                              // must be supplied
}
```

```java
// File: code/lld/ch02/interfaces/SalesReport.java
package lld.ch02.interfaces;

public class SalesReport extends Report {
    private final long totalCents;
    public SalesReport(long totalCents) { super("Sales"); this.totalCents = totalCents; }
    @Override protected String body() { return "total: " + totalCents + " cents"; }
}
```

```java
// File: code/lld/ch02/interfaces/Main.java
package lld.ch02.interfaces;

import java.util.List;
import java.util.function.Predicate;

public class Main {
    public static void main(String[] args) {
        Notifier email = new EmailNotifier();                // class implementing the interface
        Notifier sms = (to, msg) -> "[sms] " + to + ": " + msg; // Notifier is functional too (one abstract method)
        for (Notifier n : List.of(email, sms, Notifier.console())) {
            System.out.println(n.send("ada", "your order shipped"));
        }
        System.out.println(email.sendAll(List.of("kai", "ravi"), "  sale starts today  "));

        DiscountRule tenPercent = p -> p * 90 / 100;
        DiscountRule minusFiveDollars = p -> Math.max(0, p - 500);
        System.out.println("10% then -$5 on 10000c = " + tenPercent.then(minusFiveDollars).apply(10_000) + "c");

        Predicate<String> blank = String::isBlank;             // JDK functional interface + method reference
        System.out.println("'  ' blank? " + blank.test("  "));

        Report r = new SalesReport(123_45);
        System.out.println(r.render());
    }
}
```

Output:

```
[email] to ada: your order shipped
[sms] ada: your order shipped
[console] ada: your order shipped
[email] to kai: sale starts today
[email] to ravi: sale starts today
10% then -$5 on 10000c = 8500c
'  ' blank? true
== Sales ==
total: 12345 cents
-- end of Sales --
```

Explaining each part: `Notifier` has one abstract method, so it is also usable with lambdas (`sms`). `sendAll` is a default method that uses the private helper `clean`. `Notifier.console()` is a static factory on the interface. `DiscountRule` is an explicit `@FunctionalInterface` with a default combinator (a method that joins two functions into one) `then` (like `Function.andThen`). `Predicate<String>` is one of the JDK's built-in functional interfaces (`java.util.function`: `Function`, `Supplier`, `Consumer`, `Predicate`, `BiFunction`, `UnaryOperator`...). `Report`/`SalesReport` show an **abstract class** (Section 2.9).

Trade-offs

Benefit	Cost
Loose coupling (classes know little about each other), easy testing, multiple implementations	One more type to read; pointless if only one implementation will ever exist
Multiple inheritance of type	Cannot hold instance state
Default methods allow evolution	Overusing defaults turns interfaces into mini base classes

When not to use it

An interface with a single implementation and no realistic second one (and no test-double need, i.e. no fake version for tests) is indirection (an extra layer between caller and code) without benefit. Add it when the second implementation appears.

Common mistakes

- **Fat interfaces** that force implementers to leave methods empty (Interface Segregation, Chapter 4).
- "Constant interfaces" used only to hold constants (use a final class or enum).

Real-world examples

`Comparable`, `Comparator`, `Runnable`, `Callable`, `Iterable`, `AutoCloseable` (enables try-with-resources, a `try (...)` block that closes files or connections automatically), `List`/`Map`; Spring's `Repository` interfaces; SLF4J's (a common Java logging library) `Logger`.

In the interview

> **30-second answer:** "An interface is a contract of methods. I make services depend on interfaces such as `PaymentGateway` or `PricingStrategy`, so I can add implementations without editing callers and test with fakes. Since Java 8 interfaces can have default and static methods, and an interface with one abstract method is functional, so a lambda can implement it."

- *"Why were default methods added?"* — To add methods to widely-implemented interfaces (like `Collection.stream`) without breaking existing implementations.
- *"Two interfaces with the same default method?"* — Compile error until the class overrides it; it can delegate with `X.super.m()`.

Self-check

- **Q:** Is `Comparator` functional although it has many methods? **A:** Yes; only `compare` is abstract (`equals` comes from `Object`, the rest are default/static).

TL;DR

Interfaces are contracts; depend on them. Defaults evolve them, statics provide factories/helpers, one abstract method = lambda-friendly.

2.9 Abstract classes vs interfaces

What it is

An **abstract class** is a class marked `abstract` that **cannot be instantiated**. It may contain fields, constructors, finished methods and **abstract methods** (declared without a body) that subclasses must implement. Analogy: a form with some fields pre-printed and some left blank for each department to fill in.

How it works

In the `interfaces` package above, `Report` holds state (`title`), has a constructor, a `final` skeleton method `render()`, a concrete overridable `header()`, and an abstract `body()`. `SalesReport` supplies only `body()`. This "fixed skeleton, variable steps" shape is the **Template Method** pattern (Chapter 11).

	Abstract class	Interface
Instantiable?	No	No
Instance fields (state)	Yes	No (only `public static final` constants)
Constructors	Yes	No
Method bodies	Any	`default`, `static`, `private` only
Access modifiers on members	Any	Abstract/default/static are public; helpers can be private
How many can a class extend/implement?	**One**	**Many**
Relationship expressed	"is a" (shared identity and state)	"can do" (capability / role)
Evolution	Add concrete methods freely	Add `default` methods
Typical use	Shared state + partial implementation for a close family	Contracts, roles, strategies, test seams (points where a test can swap in a fake)

Rule of thumb

Start with an **interface** for the contract. Add an **abstract class** underneath when several implementations share state or a fixed algorithm (JDK example: `List` interface + `AbstractList` skeleton + `ArrayList`). Callers still depend on the interface.

Common mistakes

- Using an abstract class just to share one helper method (use composition or a static helper).
- Making everything abstract "for flexibility".

In the interview

> **30-second answer:** "Interfaces define capabilities and allow multiple implementation; abstract classes share state and partial implementation but allow only one parent. I default to interfaces and add an abstract base class when implementations share real state or a template algorithm."

Self-check

- **Q:** Can an abstract class have no abstract methods? **A:** Yes; it just cannot be instantiated.
- **Q:** Can an interface have a constructor? **A:** No.

TL;DR

Interface = contract, many allowed, no state. Abstract class = partial implementation with state, one allowed. Interface first; abstract base class when sharing real code.

2.10 Enums with fields and behaviour

What it is

An **enum** (enumerated type) is a type with a **fixed set of named instances**, such as `Coin.PENNY` or `OrderStatus.SHIPPED`. In Java an enum is a full class: it can have **fields, constructors, methods, implement interfaces**, and even give each constant its own method body. Analogy: the fixed denominations of coins; you cannot invent a 7-cent coin.

The problem it solves

String or int constants (`"PAID"`, `2`) allow typos and invalid values and carry no behaviour. Enums are **type-safe** (only valid values compile), readable, and can hold the data and rules that belong to each value, which removes `switch` statements scattered around the code. In LLD, enums are the natural home for "**different data, not different behaviour**" (spot types, vehicle types, coin values, statuses).

How it works

1. Every enum implicitly extends `java.lang.Enum` and cannot extend anything else; it can implement interfaces.
2. Constructors are always private; constants are created once when the enum class is initialised.
3. Built-ins: `values()`, `valueOf(String)` (throws `IllegalArgumentException` for unknown names), `name()`, `ordinal()` (position, 0-based; do **not** persist it, i.e. save it to a database or file, since reordering changes it), `compareTo` (by ordinal).
4. Compare with `==` (each constant is a single instance).
5. Constant-specific bodies (`PAID { ... }`) let each constant override an abstract method: a tiny state machine (a fixed set of states plus the allowed moves between them) or strategy.
6. `EnumMap` / `EnumSet` are compact, fast collections keyed by enums.
7. `switch` expressions over an enum that cover every constant are **exhaustive**: no `default` needed, and adding a constant makes the compiler flag missing cases.
8. A single-element enum is the simplest thread-safe, serialization-safe (serialization turns an object into bytes to store or send) **Singleton** (a class allowed exactly one instance; Chapter 8).

Java example

```java
// File: code/lld/ch02/enums/Coin.java
package lld.ch02.enums;

/** An enum with a FIELD, a constructor and a method. Enum constructors are always private. */
public enum Coin {
    PENNY(1), NICKEL(5), DIME(10), QUARTER(25);

    private final int cents;

    Coin(int cents) { this.cents = cents; }

    public int cents() { return cents; }
}
```

```java
// File: code/lld/ch02/enums/OrderStatus.java
package lld.ch02.enums;

import java.util.Set;

/** An enum with BEHAVIOUR: each constant says which statuses it may move to (a tiny state machine). */
public enum OrderStatus {
    PLACED    { @Override Set<OrderStatus> next() { return Set.of(PAID, CANCELLED); } },
    PAID      { @Override Set<OrderStatus> next() { return Set.of(SHIPPED, CANCELLED); } },
    SHIPPED   { @Override Set<OrderStatus> next() { return Set.of(DELIVERED); } },
    DELIVERED { @Override Set<OrderStatus> next() { return Set.of(); } },
    CANCELLED { @Override Set<OrderStatus> next() { return Set.of(); } };

    abstract Set<OrderStatus> next();          // constant-specific method bodies

    public boolean canMoveTo(OrderStatus target) { return next().contains(target); }
    public boolean isFinal() { return next().isEmpty(); }
}
```

```java
// File: code/lld/ch02/enums/Main.java
package lld.ch02.enums;

import java.util.EnumMap;
import java.util.List;
import java.util.Map;

public class Main {
    public static void main(String[] args) {
        List<Coin> inserted = List.of(Coin.QUARTER, Coin.QUARTER, Coin.DIME, Coin.PENNY);
        int total = inserted.stream().mapToInt(Coin::cents).sum();
        System.out.println("inserted " + inserted + " = " + total + " cents");

        Map<Coin, Integer> counts = new EnumMap<>(Coin.class);   // compact, ordered by declaration
        for (Coin c : inserted) counts.merge(c, 1, Integer::sum);
        System.out.println("counts: " + counts);

        System.out.println("valueOf(\"DIME\") = " + Coin.valueOf("DIME") + ", ordinal " + Coin.DIME.ordinal());

        OrderStatus s = OrderStatus.PLACED;
        for (OrderStatus target : List.of(OrderStatus.SHIPPED, OrderStatus.PAID, OrderStatus.SHIPPED,
OrderStatus.DELIVERED)) {
            if (s.canMoveTo(target)) { s = target; System.out.println("moved to " + s); }
            else System.out.println("refused " + s + " -> " + target);
        }
        System.out.println(s + " is final? " + s.isFinal());

        String label = switch (s) {                          // exhaustive switch: no default needed
            case PLACED, PAID -> "in progress";
            case SHIPPED -> "on the way";
            case DELIVERED -> "done";
            case CANCELLED -> "stopped";
        };
        System.out.println("label: " + label);
    }
}
```

Output:

```
inserted [QUARTER, QUARTER, DIME, PENNY] = 61 cents
counts: {PENNY=1, DIME=1, QUARTER=2}
valueOf("DIME") = DIME, ordinal 2
refused PLACED -> SHIPPED
moved to PAID
moved to SHIPPED
moved to DELIVERED
DELIVERED is final? true
label: done
```

Explaining each part: `Coin` stores its value in a field, so summing is `Coin::cents`, with no switch. `EnumMap` prints in declaration order. `OrderStatus` gives each constant its own `next()` set, so illegal transitions (`PLACED → SHIPPED`) are refused in one method. This is the "enum plus a guarded method" alternative to the full State pattern that Chapter 1 recommends for small lifecycles.

Trade-offs

Benefit	Cost
Type-safe, self-documenting, can hold data/behaviour	Closed set: adding a value means recompiling
Great for small state machines and lookup tables	Large per-constant behaviour becomes hard to read; move to State/Strategy classes

When not to use it

When values are **open-ended or user-defined at run time** (product categories created by an admin) or when each value needs substantial, independently evolving behaviour (use classes).

Common mistakes

- Persisting `ordinal()` in a database (store `name()` or an explicit code field).
- Giant `switch` statements over an enum in many places instead of a method on the enum.

Real-world examples

`java.time.DayOfWeek` and `Month` (with methods like `plus`), `java.util.concurrent.TimeUnit` (each constant converts units: `TimeUnit.SECONDS.toMillis(5)`), `java.nio.file.StandardOpenOption`, `Thread.State`.

In the interview

> **30-second answer:** "I use enums for fixed sets like vehicle types, spot types and statuses. Java enums can carry fields and methods, so data like 'which spots fit this vehicle' or 'which statuses can follow this one' lives on the enum rather than in switches around the code."

- *"Enum or class hierarchy for vehicle types?"* — Enum if they differ only in data; classes if they behave differently.

Self-check

- **Q:** What does `Coin.valueOf("dime")` do? **A:** Throws `IllegalArgumentException` (names are case-sensitive).

TL;DR

Enums are type-safe fixed sets that can carry data and behaviour. Use them for "different data, same behaviour"; compare with `==`; never persist ordinals.

2.11 Composition over inheritance

What it is

Composition means building a class by **holding references to other objects** and delegating work to them ("has-a"), rather than inheriting from them ("is-a"). The principle **"favour composition over inheritance"** comes from the Gang of Four book and is a core idea in *Head First Design Patterns*. Analogy: a phone **has** a camera module; it is not a kind of camera. The module can be upgraded without redesigning the phone.

The problem it solves

Inheritance couples a child to the **internal implementation** of its parent (the **fragile base class problem**): a change in the parent, or a hidden detail of how it works, can silently break the child. Inheritance is also fixed at compile time and single-parent. Composition keeps classes independent, lets you **swap parts at run time**, and combine behaviours freely.

How it works

1. Identify the behaviour you want to reuse or vary.
2. Put it behind an interface (`Engine`, `Set`).
3. Hold it in a private field, received through the constructor (so it can be replaced or faked).
4. **Forward** (delegate) calls to it, adding your own logic around them.

Java example

```java
// File: code/lld/ch02/composition/Car.java
package lld.ch02.composition;

/** A car IS NOT an engine; it HAS an engine. The part can be swapped at run time. */
public class Car {
    private final String model;
    private Engine engine;

    public Car(String model, Engine engine) { this.model = model; this.engine = engine; }

    public void replaceEngine(Engine e) { this.engine = e; }

    public String drive() { return model + ": " + engine.start(); }
}
```

```java
// File: code/lld/ch02/composition/CountingSet.java
package lld.ch02.composition;

import java.util.Collection;
import java.util.Set;

/**
 * FIXED with composition: HAS-A Set and forwards to it. Works with ANY Set implementation
 * and does not care how that set implements addAll internally.
 */
public class CountingSet<E> {
    private final Set<E> inner;
    private int attempts = 0;

    public CountingSet(Set<E> inner) { this.inner = inner; }

    public boolean add(E e) { attempts++; return inner.add(e); }

    public boolean addAll(Collection<? extends E> c) {
        attempts += c.size();
        boolean changed = false;
        for (E e : c) changed |= inner.add(e);     // talk to the inner set, not to our own add()
        return changed;
    }

    public int size()     { return inner.size(); }
    public int attempts() { return attempts; }
}
```

```java
// File: code/lld/ch02/composition/Engine.java
package lld.ch02.composition;

public interface Engine {
    String start();
}
```

```java
// File: code/lld/ch02/composition/InheritingCountingSet.java
package lld.ch02.composition;

import java.io.Serial;
import java.util.Collection;
import java.util.HashSet;

/**
 * BROKEN on purpose: counts attempted additions by EXTENDING HashSet.
 * HashSet.addAll is inherited from AbstractCollection, which calls add() once per element,
 * so every element of addAll is counted twice. The subclass silently depends on how the parent
 * uses its own methods internally ("self-use"): the "fragile base class" problem.
 */
public class InheritingCountingSet<E> extends HashSet<E> {
    @Serial private static final long serialVersionUID = 1L;   // HashSet is Serializable, so subclasses should declare one

    private int attempts = 0;

    @Override public boolean add(E e) { attempts++; return super.add(e); }

    @Override public boolean addAll(Collection<? extends E> c) { attempts += c.size(); return super.addAll(c); }

    public int attempts() { return attempts; }
}
```

```java
// File: code/lld/ch02/composition/Main.java
package lld.ch02.composition;

import java.util.List;
import java.util.TreeSet;

public class Main {
    public static void main(String[] args) {
        InheritingCountingSet<String> bad = new InheritingCountingSet<>();
        bad.addAll(List.of("a", "b", "c"));
        System.out.println("inheritance: added 3, attempts counted = " + bad.attempts());

        CountingSet<String> good = new CountingSet<>(new TreeSet<>());
        good.addAll(List.of("a", "b", "c"));
        good.add("a");
        System.out.println("composition: 4 attempts counted = " + good.attempts() + ", size = " + good.size());

        Car car = new Car("City", () -> "petrol engine vroom");
        System.out.println(car.drive());
        car.replaceEngine(() -> "electric motor hum");
        System.out.println(car.drive());
    }
}
```

Output:

```
inheritance: added 3, attempts counted = 6
composition: 4 attempts counted = 4, size = 3
City: petrol engine vroom
City: electric motor hum
```

Explaining each part: `InheritingCountingSet` counts 6 for 3 elements because `HashSet` inherits `addAll` from `AbstractCollection`, which calls `add` once per element, and `add` is overridden to count again. The subclass depended on **how the parent uses its own methods internally** ("self-use"). `AbstractCollection` describes this in an implementation note, but `HashSet` does not promise to keep it, so a future version could change it and silently fix or break the count. `CountingSet` **has a** `Set`, forwards to it, and works with any `Set` implementation (here a `TreeSet`). `Car` has an `Engine`, and the engine is swapped at run time, which inheritance cannot do.

Trade-offs

	Inheritance	Composition
Relationship	is-a	has-a
Coupling	Tight (to parent internals)	Loose (to an interface)
Change at run time	No	Yes
Boilerplate (repetitive filler code)	Low	Forwarding methods
Polymorphism	Built in	Via the interface the parts implement

When not to use it

When there is a **genuine is-a relationship** designed for extension (e.g. extending an abstract template class meant to be subclassed), inheritance is fine and simpler.

Common mistakes

- Extending a concrete library class (`HashMap`, `ArrayList`) to add a feature.
- Composing but then exposing the inner object directly (`getInner()`), losing control again.

Real-world examples

`java.io.BufferedReader` wraps any `Reader` (Decorator, a wrapper that adds behaviour around an object = composition); `Collections.unmodifiableList` wraps a list; Spring beans (objects the framework creates) are composed via dependency injection (the framework hands each object the collaborators it needs); strategy objects such as `Comparator` passed into `TreeMap`.

In the interview

> **30-second answer:** "I prefer composition: a class holds an interface-typed collaborator and delegates to it. It avoids the fragile base class problem, lets me swap behaviour at run time, and most patterns such as Strategy, Decorator and State are built on it. I use inheritance only for true is-a relationships."

- *"Show a case where inheritance breaks."* — The counting set above: overriding `add` and `addAll` double counts because the parent's `addAll` calls `add`.

Self-check

- **Q:** Why does `CountingSet.addAll` call `inner.add`, not `this.add`? **A:** To avoid double counting and to depend only on the inner set's public contract.

TL;DR

Has-a + delegate beats is-a for reuse. Use inheritance only for real, designed-for-extension type families.

2.12 Object identity vs equality: the `equals` / `hashCode` contract

What it is

- **Identity:** are these two references pointing at the **same object**? Tested with `==`.
- **Equality:** do these two objects **represent the same value**? Tested with `equals`. By default `Object.equals` is identity; classes override it to mean value equality (`String`, `Integer`, `LocalDate`, records).

Analogy: two printed copies of the same book are **equal** (same content) but not **identical** (two physical objects).

The problem it solves

Hash-based collections (`HashMap`, `HashSet`) first use `hashCode()` to pick a bucket, then `equals()` to compare inside the bucket. If you get either wrong, objects "disappear" from sets and maps.

> **Key term — hash table:** A `HashMap` or `HashSet` keeps its entries in an array of slots called **buckets**. To store or find an object it computes the object's **hash code** (an `int` derived from its fields), uses that number to jump straight to one bucket, and only then compares the few objects in that bucket with `equals`. This is why lookups are fast, and why two equal objects must produce the same hash code: otherwise the search starts in the wrong bucket.

How it works: the contracts

`equals` must be:

1. **Reflexive:** `x.equals(x)` is true.
2. **Symmetric:** `x.equals(y)` ⇔ `y.equals(x)`.
3. **Transitive:** if `x.equals(y)` and `y.equals(z)` then `x.equals(z)`.
4. **Consistent:** repeated calls give the same answer if nothing used in the comparison changed.
5. **Non-null:** `x.equals(null)` is false.

`hashCode` must:

1. Return the same value on repeated calls in one run, if the fields used by `equals` do not change.
2. Return **equal hash codes for equal objects**.
3. Unequal objects **may** share a hash code (collisions are allowed, just slower).

So: whenever you override `equals`, override `hashCode` using the same fields. Records and IDE generators (the "generate equals/hashCode" command in a code editor) do this for you.

Java example

```java
// File: code/lld/ch02/equality/BrokenPoint.java
package lld.ch02.equality;

/**
 * WRONG on purpose: overrides equals but NOT hashCode, breaking the contract "equal objects -> equal hash codes".
 * javac -Xlint warns about exactly this bug ([overrides]); the warning is silenced ONLY because this class
 * exists to demonstrate the bug. In real code, treat that warning as an error and add hashCode().
 */
@SuppressWarnings("overrides")
public final class BrokenPoint {
    private final int x, y;

    public BrokenPoint(int x, int y) { this.x = x; this.y = y; }

    @Override
    public boolean equals(Object o) {
        return o instanceof BrokenPoint p && x == p.x && y == p.y;
    }
    // hashCode() inherited from Object: usually different for two distinct objects
}
```

```java
// File: code/lld/ch02/equality/Point.java
package lld.ch02.equality;

import java.util.Objects;

/** Correct value-equality: equals and hashCode are overridden TOGETHER, on the same fields. */
public final class Point {
    private final int x, y;

    public Point(int x, int y) { this.x = x; this.y = y; }

    @Override
    public boolean equals(Object o) {
        if (this == o) return true;                          // reflexive fast path
        if (!(o instanceof Point p)) return false;           // also handles null
        return x == p.x && y == p.y;
    }

    @Override public int hashCode() { return Objects.hash(x, y); }

    @Override public String toString() { return "(" + x + "," + y + ")"; }
}
```

```java
// File: code/lld/ch02/equality/Main.java
package lld.ch02.equality;

import java.util.HashSet;
import java.util.Set;

public class Main {
    public static void main(String[] args) {
        Point a = new Point(1, 2), b = new Point(1, 2);
        System.out.println("a == b (identity): " + (a == b));
        System.out.println("a.equals(b) (equality): " + a.equals(b));
        System.out.println("hash codes equal: " + (a.hashCode() == b.hashCode()));
        Set<Point> good = new HashSet<>();
        good.add(a); good.add(b);
        System.out.println("HashSet<Point> size after adding a and b: " + good.size() + ", contains (1,2)? " +
good.contains(new Point(1, 2)));

        BrokenPoint x = new BrokenPoint(1, 2), y = new BrokenPoint(1, 2);
        Set<BrokenPoint> bad = new HashSet<>();
        bad.add(x);
        System.out.println("BrokenPoint equals: " + x.equals(y) + ", but set.contains(equal one): " +
bad.contains(y));

        String s1 = "hi", s2 = new String("hi");
        System.out.println("\"hi\" == new String(\"hi\"): " + (s1 == s2) + ", equals: " + s1.equals(s2));

        Integer i1 = 1000, i2 = 1000;
        System.out.println("Integer 1000 equals: " + i1.equals(i2) + "  (never compare boxed numbers with ==)");
    }
}
```

Output:

```
a == b (identity): false
a.equals(b) (equality): true
hash codes equal: true
HashSet<Point> size after adding a and b: 1, contains (1,2)? true
BrokenPoint equals: true, but set.contains(equal one): false
"hi" == new String("hi"): false, equals: true
Integer 1000 equals: true  (never compare boxed numbers with ==)
```

Explaining each part: `Point` overrides both methods on the same fields, so the set treats `a` and `b` as one element. `BrokenPoint` overrides only `equals`; its inherited identity-based `hashCode` (almost always different for two distinct objects) sends an equal object to a different bucket, so `contains` fails. `javac -Xlint` (the compiler run with extra warnings switched on) even warns about this (`[overrides] ... overrides equals, but neither it nor any superclass overrides hashCode`); `BrokenPoint` carries `@SuppressWarnings("overrides")` only because it exists to show the bug. In real code, treat that warning as an error. Strings and boxed numbers must be compared with `equals`: `Integer` caches (keeps ready-made, reused objects for) only small values (at least −128 to 127), so `==` on boxed numbers happens to work for small values and fails for large ones.

Trade-offs / design choice

Kind of class	Equality
Value object (Money, Point, Coordinate)	Value equality on all fields; ideally immutable
Entity (User, Order, ParkingSpot)	Identity or equality by a stable **ID** only

Common mistakes

- Overriding `equals` without `hashCode` (above).
- `equals(Point p)` instead of `equals(Object o)` (an overload, never called by collections).
- Using **mutable fields** in `hashCode` and then mutating an object that is already a key in a `HashMap` (it becomes unfindable).
- Using `getClass() !=` vs `instanceof` inconsistently across a hierarchy, breaking symmetry.

Real-world examples

`String`, `Integer`, `BigDecimal` (note: `new BigDecimal("1.0").equals(new BigDecimal("1.00"))` is false because scale (the number of decimal places) is part of equality; use `compareTo` for numeric comparison), `LocalDate`, `List.equals` (element-wise).

In the interview

> **30-second answer:** "`==` compares identity, `equals` compares logical value. If I override `equals` I must override `hashCode` on the same fields, because hash collections use the hash to find the bucket and `equals` inside it. For value objects I use records; for entities I compare by ID."

- *"What happens if only `equals` is overridden?"* — Equal objects can land in different buckets; `HashSet.contains` and `HashMap.get` fail.

Self-check

- **Q:** Can two unequal objects have the same hash code? **A:** Yes; that is a collision and is allowed.
- **Q:** Can two equal objects have different hash codes? **A:** No; that breaks the contract.

TL;DR

`==` = same object; `equals` = same value. Override `equals` and `hashCode` together, on the same (preferably immutable) fields.

2.13 Immutability and records

What it is

An **immutable** object cannot change after construction. "Changes" produce **new** objects. A **record** (Java 16+) is a concise way to declare an immutable **data carrier**: `record Order(String id, List<String> items, Money total) {}`. Analogy: a printed receipt. To correct it, you print a new receipt; you do not edit the old one.

The problem it solves

Mutable shared objects cause bugs when one part of the program changes something another part relies on, and they need locking when shared between threads. Immutable objects (all fields `final`, `this` not leaked during

construction) are **thread-safe without locks**, safe as `HashMap` keys and `HashSet` elements, easy to cache and share, and easy to reason about.

How it works

Hand-written immutable class (checklist):

1. Make the class `final` (or give it private constructors and static factories) so no subclass can add mutability.
2. Make all fields `private final`.
3. Provide no setters; methods that "modify" return a new object (`plus`, `withItem`).
4. **Defensive copies:** copy mutable inputs in the constructor and never hand out internal mutable objects (return copies or unmodifiable views).
5. Do not let `this` escape during construction.

Records generate: `private final` fields for each component, a canonical constructor, accessors named after the components (`id()`, not `getId()`), and `equals`, `hashCode`, `toString` based on all components. Records are implicitly `final`, extend `java.lang.Record`, cannot declare extra **instance** fields (static fields and extra methods are fine), and can implement interfaces. A **compact constructor** (`public Order { ... }`) validates or normalises the parameters before they are assigned.

Records are only shallowly immutable: if a component is a mutable `List`, the list can still change unless you copy it (`List.copyOf`).

Java example

```java
// File: code/lld/ch02/immutability/Money.java
package lld.ch02.immutability;

import java.math.BigDecimal;
import java.math.RoundingMode;
import java.util.Objects;

/**
 * A hand-written immutable VALUE OBJECT: final class, private final fields, no setters,
 * "changes" return NEW objects. The amount is a BigDecimal (exact decimal arithmetic, never double),
 * normalised to 2 decimal places so that 5 and 5.00 are the same Money.
 */
public final class Money {
    private final BigDecimal amount;
    private final String currency;

    private Money(BigDecimal amount, String currency) {
        this.currency = Objects.requireNonNull(currency);
        // UNNECESSARY = refuse (ArithmeticException) anything finer than a cent instead of silently rounding it
        this.amount = amount.setScale(2, RoundingMode.UNNECESSARY);
    }

    public static Money of(String amount, String currency) { return new Money(new BigDecimal(amount), currency); }

    public Money plus(Money other) {
        if (!currency.equals(other.currency)) throw new IllegalArgumentException("currency mismatch");
        return new Money(amount.add(other.amount), currency);   // new object; 'this' is untouched
    }

    public BigDecimal amount() { return amount; }

    @Override public boolean equals(Object o) {        // safe: the scale is always 2, so equals == numeric
equality
        return o instanceof Money m && amount.equals(m.amount) && currency.equals(m.currency);
    }
    @Override public int hashCode() { return Objects.hash(amount, currency); }
    @Override public String toString() { return amount.toPlainString() + " " + currency; }
}
```

```java
// File: code/lld/ch02/immutability/Order.java
package lld.ch02.immutability;

import java.util.List;

/**
 * A RECORD: the compiler generates the private final fields, canonical constructor, accessors,
 * equals, hashCode and toString. The compact constructor validates and makes a DEFENSIVE COPY,
 * because a record is only shallowly immutable.
 */
public record Order(String id, List<String> items, Money total) {
    public Order {
        if (id == null || id.isBlank()) throw new IllegalArgumentException("id required");
        items = List.copyOf(items);                // unmodifiable copy: caller's list cannot leak in
    }

    public Order withItem(String item, Money price) {  // "wither": returns a modified copy
        var more = new java.util.ArrayList<>(items);
        more.add(item);
        return new Order(id, more, total.plus(price));
    }
}
```

```java
// File: code/lld/ch02/immutability/Main.java
package lld.ch02.immutability;

import java.util.ArrayList;
import java.util.List;

public class Main {
    public static void main(String[] args) {
        Money five = Money.of("5.00", "USD");
        Money seven = five.plus(Money.of("2.00", "USD"));
        System.out.println("five = " + five + ", seven = " + seven + "  (five unchanged)");
        System.out.println("Money.of(\"5\") equals Money.of(\"5.00\")? " + Money.of("5", "USD").equals(five) + "
(scale normalised)");

        List<String> callerList = new ArrayList<>(List.of("pen"));
        Order o1 = new Order("O-1", callerList, five);
        callerList.add("SNEAKY");                          // does not reach the record
        System.out.println("o1 = " + o1);

        Order o2 = o1.withItem("ink", Money.of("1.50", "USD"));
        System.out.println("o2 = " + o2);
        System.out.println("o1 still = " + o1.items() + ", equals copy? " + o1.equals(new Order("O-1",
List.of("pen"), Money.of("5.00", "USD"))));

        try {
            o1.items().add("hack");
        } catch (UnsupportedOperationException e) {
            System.out.println("items() is unmodifiable: " + e.getClass().getSimpleName());
        }
    }
}
```

Output:

```
five = 5.00 USD, seven = 7.00 USD  (five unchanged)
Money.of("5") equals Money.of("5.00")? true  (scale normalised)
o1 = Order[id=O-1, items=[pen], total=5.00 USD]
o2 = Order[id=O-1, items=[pen, ink], total=6.50 USD]
o1 still = [pen], equals copy? true
items() is unmodifiable: UnsupportedOperationException
```

Explaining each part: `Money.plus` returns a new object; `five` stays 5.00. The amount is a `BigDecimal` (exact decimal arithmetic; `double` cannot represent 0.10 exactly, so money in `double` drifts). The constructor fixes the **scale** (number of decimal places) at 2, because `BigDecimal.equals` compares scale too (`5` and `5.00` would otherwise be unequal, see Section 2.12); `RoundingMode.UNNECESSARY` makes it throw instead of silently rounding away a fraction of a cent. The constructor is private and `Money.of(...)` is a **static factory**, one of the options in the checklist above. The record's compact constructor copies the caller's list with `List.copyOf`, so adding `"SNEAKY"` to the caller's list later has no effect, and `items()` is unmodifiable. `withItem` is a "wither" returning a changed copy. Two records with equal components are `equals`.

Trade-offs

Benefit	Cost
Thread-safe without locks; safe hash keys; no defensive reasoning needed	New object per change (usually cheap; can matter in hot loops, i.e. code that runs millions of times)
Records remove boilerplate	Records cannot hide their components or extend classes

When not to use it

Entities whose identity persists while state changes (a `ParkingSpot` becoming occupied, an `Account` balance) are naturally **mutable**, with encapsulated changes. Make them immutable only if you adopt an event-sourced (state rebuilt from a stored list of past events) or copy-on-write (every change makes a new copy) style deliberately.

Common mistakes

- Forgetting defensive copies (a "final" list field whose contents anyone can change).
- Assuming `final` makes the referenced object immutable (it only fixes the reference).
- Using records for entities that need controlled mutation.

Real-world examples

`String`, boxed primitives (`Integer`, `Long`), `BigDecimal`, `BigInteger`, all of `java.time` (`LocalDate`, `Instant`, `Duration`), `List.of`/`Map.of` collections; Kafka (a widely used message-streaming system) messages and event-sourcing events are treated as immutable facts.

In the interview

> **30-second answer:** "For value objects like Money, Coordinate or Ticket I use immutable records: final fields, no setters, validation in the compact constructor, and defensive copies of collections. They are thread-safe and safe as map keys. Entities whose state changes stay mutable but encapsulated."

- *"Is a record fully immutable?"* — Shallowly. Mutable components must be copied.

Self-check

- **Q:** What does `final List<String> items` guarantee? **A:** The reference never changes; the list contents still can.

TL;DR

Immutable = final class, private final fields, no setters, defensive copies. Records give you this (shallowly) in one line. Use for value objects; keep entities mutable but encapsulated.

2.14 Access modifiers and packages

What it is

A **package** is a named group of related classes (a namespace and a folder), e.g. `lld.ch02.access.core`. **Access modifiers** control who can see a class or member.

Modifier	Same class	Same package	Subclass in another package	Everyone
`private`	✔	✘	✘	✘
(none) package-private	✔	✔	✘	✘
`protected`	✔	✔	✔ (through inheritance)	✘
`public`	✔	✔	✔	✔

Top-level classes can only be `public` or package-private. Analogy: rooms in an office: your desk drawer (private), the team room (package), the company floor accessible to affiliated teams (protected), the lobby (public).

The problem it solves

Access modifiers make encapsulation **enforceable by the compiler**. Packages group classes by feature and let you hide implementation classes, exposing only a small public API.

How it works

1. Start everything as `private`; widen only when needed.
2. Group by **feature** (`parking`, `payment`) rather than by layer only.
3. Keep helper classes package-private; expose a small `public` facade (one simple front class that hides the others).
4. `protected` is for members designed for subclasses; note that it **also** grants access to the whole package.
5. Since Java 9, **modules** (`module-info.java`) add a further level: only exported packages are visible to other modules.

Java example

```java
// File: code/lld/ch02/access/client/PremiumWallet.java
package lld.ch02.access.client;

import lld.ch02.access.core.Wallet;

/** A subclass in ANOTHER package: may use protected members, not package-private or private ones. */
public class PremiumWallet extends Wallet {
    public PremiumWallet(String owner) { super(owner); }

    public void grantBonus(long cents) {
        bonusCents += cents;                    // OK: protected, accessed through inheritance
        // auditCount++;                        // would NOT compile: package-private in another package
        // balanceCents += cents;               // would NOT compile: private
    }

    @Override public String describe() {       // may WIDEN protected -> public when overriding
        return "[premium] " + super.describe();
    }
}
```

```java
// File: code/lld/ch02/access/client/Main.java
package lld.ch02.access.client;

import lld.ch02.access.core.Audits;
import lld.ch02.access.core.Wallet;

public class Main {
    public static void main(String[] args) {
        Wallet basic = new Wallet("Ada");
        basic.add(1_000);
        PremiumWallet premium = new PremiumWallet("Kai");
        premium.add(2_000);
        premium.add(500);
        premium.grantBonus(300);

        System.out.println("public field owner: " + basic.owner + ", public method balance: " +
basic.balanceCents());
        System.out.println(premium.describe());
        System.out.println("audit lines: " + Audits.all());
        System.out.println("audits for Kai: " + Audits.countFor(premium));
        // new lld.ch02.access.core.AuditLog();  // would NOT compile: class is package-private
    }
}
```

```java
// File: code/lld/ch02/access/core/AuditLog.java
package lld.ch02.access.core;

import java.util.ArrayList;
import java.util.List;

/** Package-private CLASS: an implementation detail of the core package. */
final class AuditLog {
    private static final List<String> LINES = new ArrayList<>();

    private AuditLog() { }

    static void record(Wallet w, String what) {
        w.auditCount++;                          // allowed: same package
        LINES.add(w.owner + ": " + what);
    }

    static List<String> lines() { return List.copyOf(LINES); }
}
```

```java
// File: code/lld/ch02/access/core/Audits.java
package lld.ch02.access.core;

import java.util.List;

/** The PUBLIC face of the package: exposes only what outsiders are allowed to read. */
public final class Audits {
    private Audits() { }
    public static List<String> all() { return AuditLog.lines(); }
    public static long countFor(Wallet w) { return w.auditCount; }
}
```

```java
// File: code/lld/ch02/access/core/Wallet.java
package lld.ch02.access.core;

/** Shows all four access levels on one class. */
public class Wallet {
    public final String owner;                // public: visible everywhere
    protected long bonusCents;                // protected: same package + subclasses anywhere
    long auditCount;                          // package-private (no keyword): same package only
    private long balanceCents;                // private: this class only

    public Wallet(String owner) { this.owner = owner; }

    public void add(long cents) {
        if (cents <= 0) throw new IllegalArgumentException("positive only");
        balanceCents += cents;
        AuditLog.record(this, "add " + cents);   // package-private helper class, invisible outside core
    }

    public long balanceCents() { return balanceCents; }

    protected String describe() { return owner + " has " + balanceCents + "c (+" + bonusCents + "c bonus)"; }
}
```

(`Main` is in `lld.ch02.access.client`; run `java -cp /tmp/lld_02 lld.ch02.access.client.Main`.)

Output:

```
public field owner: Ada, public method balance: 1000
[premium] Kai has 2500c (+300c bonus)
audit lines: [Ada: add 1000, Kai: add 2000, Kai: add 500]
audits for Kai: 2
```

Explaining each part: `AuditLog` is a package-private class and `auditCount` a package-private field, so only code in `core` touches them; outsiders read audit data only through the public `Audits` facade. `PremiumWallet` in another package can update `protected bonusCents` but the commented lines (package-private and private access) would not compile. The override of `describe()` widens `protected` to `public`, which overriding allows.

Common mistakes

- Making everything `public` "to be safe".
- Using `protected` fields as a shortcut instead of protected methods (subclasses then break invariants).
- Putting every class of a machine-coding solution in one package.

In the interview

30-second answer: "Fields are private by default, collaborators within a feature package can be package-private, protected is only for members designed for subclassing, and public is the deliberate API. I organise machine-coding solutions into packages such as model, repository, service and strategy."

Self-check

- **Q:** Can a class in another package, which is not a subclass, read a `protected` field? **A:** No.

TL;DR

private < package-private < protected < public. Default to private; expose a small public API per package.

2.15 Generics basics for LLD

What it is

Generics let a class, interface or method work with **any type while keeping compile-time type safety**. `List<String>` holds only strings; `Repository<String, User>` stores only users. The letters in angle brackets (`T`,

`ID`, `E`, `K`, `V`) are **type parameters**. Analogy: a labelled storage box: "SHOES ONLY". The label is checked when you put things in, so you never need to check when you take them out.

The problem it solves

Without generics you store `Object` (the root type of every class) and cast on every read, discovering mistakes at run time (`ClassCastException`). With generics, mistakes are **compile errors**, and one class (`Repository<ID, T>`) serves every entity, which is extremely handy in machine-coding rounds.

How it works

1. **Generic class/interface:** `class Repository<ID, T extends Identifiable<ID>>`.
2. **Bounded type parameter:** `T extends X` means T must be X or a subtype, so you can call X's methods on T.
3. **Generic method:** `static <T extends Comparable<? super T>> T max(List<? extends T> items)`.
4. **Wildcards:** `? extends T` (read-only producer), `? super T` (write-capable consumer), `?` (unknown). Mnemonic **PECS**: *Producer Extends, Consumer Super* (from *Effective Java*, Joshua Bloch's well-known Java best-practice book).
5. **Diamond operator:** `new Repository<>()` infers the type arguments.
6. **Type erasure:** type arguments exist only at compile time; at run time `List<String>` and `List<Integer>` are the same class. Consequences: no `new T()`, no `instanceof List<String>`, no primitive type arguments (use `Integer`, not `int`).
7. **Avoid raw types** (`List` without `<...>`); they switch the checks off.

Java example

```java
// File: code/lld/ch02/generics/Identifiable.java
package lld.ch02.generics;

/** Generic interface: ID is a TYPE PARAMETER filled in by each implementer. */
public interface Identifiable<ID> {
    ID id();
}
```

```java
// File: code/lld/ch02/generics/Product.java
package lld.ch02.generics;

public record Product(Integer id, String title, long priceCents)
        implements Identifiable<Integer>, Comparable<Product> {
    @Override public int compareTo(Product o) { return Long.compare(priceCents, o.priceCents); }
}
```

```java
// File: code/lld/ch02/generics/Repository.java
package lld.ch02.generics;

import java.util.*;

/**
 * A generic in-memory repository, a very common helper in machine-coding rounds.
 * T is BOUNDED: it must be Identifiable by the same ID type.
 */
public class Repository<ID, T extends Identifiable<ID>> {
    private final Map<ID, T> store = new LinkedHashMap<>();

    public void save(T item)            { store.put(item.id(), item); }
    public Optional<T> findById(ID id)  { return Optional.ofNullable(store.get(id)); }
    public List<T> findAll()            { return List.copyOf(store.values()); }
}
```

```java
// File: code/lld/ch02/generics/User.java
package lld.ch02.generics;

public record User(String id, String name) implements Identifiable<String> { }
```

```java
// File: code/lld/ch02/generics/Main.java
package lld.ch02.generics;

import java.util.ArrayList;
import java.util.List;

public class Main {
    /** Generic METHOD with a bounded type parameter. */
    static <T extends Comparable<? super T>> T max(List<? extends T> items) {
        T best = items.get(0);
        for (T t : items) if (t.compareTo(best) > 0) best = t;
        return best;
    }

    /** PECS: Producer Extends (we read from src), Consumer Super (we write into dst). */
    static <T> void copy(List<? extends T> src, List<? super T> dst) {
        dst.addAll(src);
    }

    public static void main(String[] args) {
        Repository<String, User> users = new Repository<>();
        users.save(new User("u1", "Ada"));
        users.save(new User("u2", "Kai"));
        System.out.println("user u2: " + users.findById("u2").map(User::name).orElse("none"));
        System.out.println("user u9: " + users.findById("u9").map(User::name).orElse("none"));

        Repository<Integer, Product> products = new Repository<>();
        products.save(new Product(1, "pen", 150));
        products.save(new Product(2, "lamp", 2_500));
        products.save(new Product(3, "mug", 800));
        System.out.println("most expensive: " + max(products.findAll()).title());

        List<Integer> ints = List.of(3, 1, 2);
        List<Number> numbers = new ArrayList<>();
        copy(ints, numbers);                            // Integer list into a Number list
        System.out.println("copied into List<Number>: " + numbers + ", max int = " + max(ints));

        // users.save(new Product(4, "x", 1));          // would NOT compile: type safety at compile time
        List<String> a = new ArrayList<>();
        List<Integer> b = new ArrayList<>();
        System.out.println("same runtime class (type erasure)? " + (a.getClass() == b.getClass()));
    }
}
```

Output:

```
user u2: Kai
user u9: none
most expensive: lamp
copied into List<Number>: [3, 1, 2], max int = 3
same runtime class (type erasure)? true
```

Explaining each part: one `Repository` class stores `User`s keyed by `String` and `Product`s keyed by `Integer`; `findById` returns `Optional` (a box that either holds a value or is empty, used instead of `null`) for a normal "not found". `max` works for any comparable type (`Product` compares by price). `copy` accepts a `List<Integer>` as a producer and a `List<Number>` as a consumer (PECS). The final line demonstrates erasure.

Common mistakes

- Raw types and unchecked casts.
- Thinking `List<Integer>` is a subtype of `List<Number>` (it is not; use `List<? extends Number>`).
- Over-generic designs with five type parameters nobody can read.

Real-world examples

The entire Collections framework (`List<E>`, `Map<K,V>`), `Optional<T>`, `CompletableFuture<T>` (a result that will arrive later from background work), `Comparator<T>`, Spring Data's `CrudRepository<T, ID>` (the same idea as our `Repository`).

In the interview

> **30-second answer:** "I use generics for reusable infrastructure like an in-memory `Repository<ID, T>` or an `EventBus<E>`, so type errors are caught at compile time. I know bounded types, wildcards with PECS, and that erasure removes type arguments at run time."

Self-check

- **Q:** Why can't you write `new T()`? **A:** Type erasure: the runtime does not know T; pass a `Supplier<T>` instead.

TL;DR

Generics = type-safe reuse. Bounds let you call methods on T; PECS for wildcards; erasure means no runtime type info.

2.16 Coupling and cohesion (the yardsticks)

- **Cohesion** — how closely the responsibilities **inside** one class belong together. **High cohesion is good**: every method works on the same data toward one purpose (the "one sentence, no 'and'" test from Chapter 1).
- **Coupling** — how much one class **depends on** others' details. **Low coupling is good**: classes talk through small interfaces, so a change in one does not ripple through many.

Every idea in this chapter pushes toward **high cohesion, low coupling**: encapsulation and access modifiers reduce coupling; single-responsibility classes raise cohesion; interfaces and composition decouple callers from implementations. Chapters 4–5 turn these yardsticks into named principles (SOLID, Law of Demeter, GRASP).

2.17 Object-oriented analysis and design (OOA / OOD / OOP)

What it is

Object-oriented analysis and design (OOAD) is a long-established, standard method for converting a written description of a system into objects plus the links between them. Most of the vocabulary used in an LLD interview originates here. The name covers two separate activities, analysis and design, followed by implementation; each asks a different question and produces a different result:

Activity	Question it answers	What exists at the end	Talks about
Analysis (OOA)	What does the system consist of, and what is it required to do?	The things in the problem, named in **business (domain) terms**	books, members, loans
Design (OOD)	Which objects, with which responsibilities, will provide that behaviour?	Classes, what each is responsible for, and how they relate	`Book`, `Member`, `Loan` and who holds whom
Implementation (OOP)	How do we express it in a programming language?	Running code	`ArrayList`, `HashMap`, `synchronized`

If you are talking about a `HashMap` two minutes in, you have leapt straight to implementation and **left out the two activities the interviewer wanted to watch**.

The problem it solves

Blending the activities is the classic time sink: if you pick operations before the objects are settled, operations end up on the wrong class, and moving them later is expensive.

How it works: the four steps

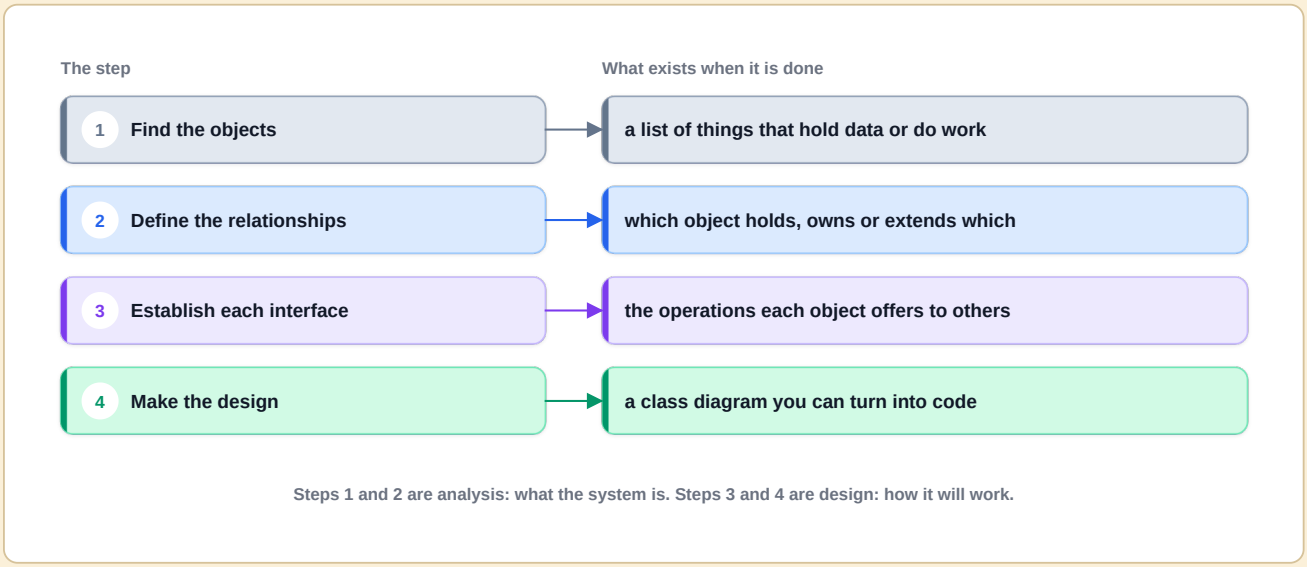


Figure — The four OOAD steps and what exists after each; steps 1–2 are analysis and steps 3–4 are design (course diagram)

1. **Find the objects.** Go through the description and note everything that **stores information or performs work**; most candidates are nouns. Anything that carries only a single value (a colour, a date) becomes a **field** of some object, not an object itself.
2. **Define the relationships.** For every pair of objects mentioned together, answer three questions: which one holds a reference to the other, does it **own** it, and **how many** of each are involved? (E.g. a library holds many books; a loan points at one book and one member.)
3. **Establish each interface.** Here *interface* means the set of operations an object makes available **to other objects**. Write that set down per object. Whatever is left off becomes **private**, so this step is where encapsulation really gets decided.
4. **Make the design.** Put classes, fields, operations and relationships into a single drawing (a UML class diagram) and verify it against the description you began with. That drawing is the design; the code is derived from it.

In the figure, steps 1–2 form the analysis (what the system is) and steps 3–4 form the design (how it will work). **The order is fixed because each step consumes the output of the one before.**

Worked example: "library members borrow books; each book on loan must be returned by a due date"

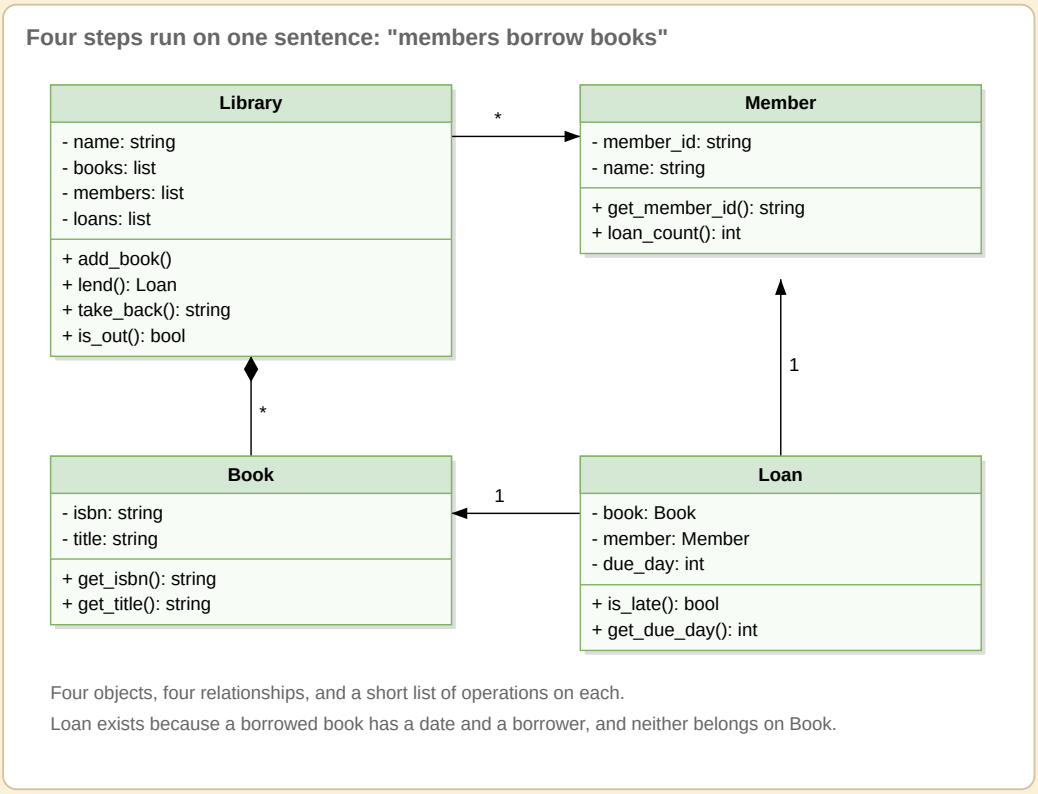

Figure — The four steps applied to one sentence: Library, Member, Book and the connection object Loan (course diagram)

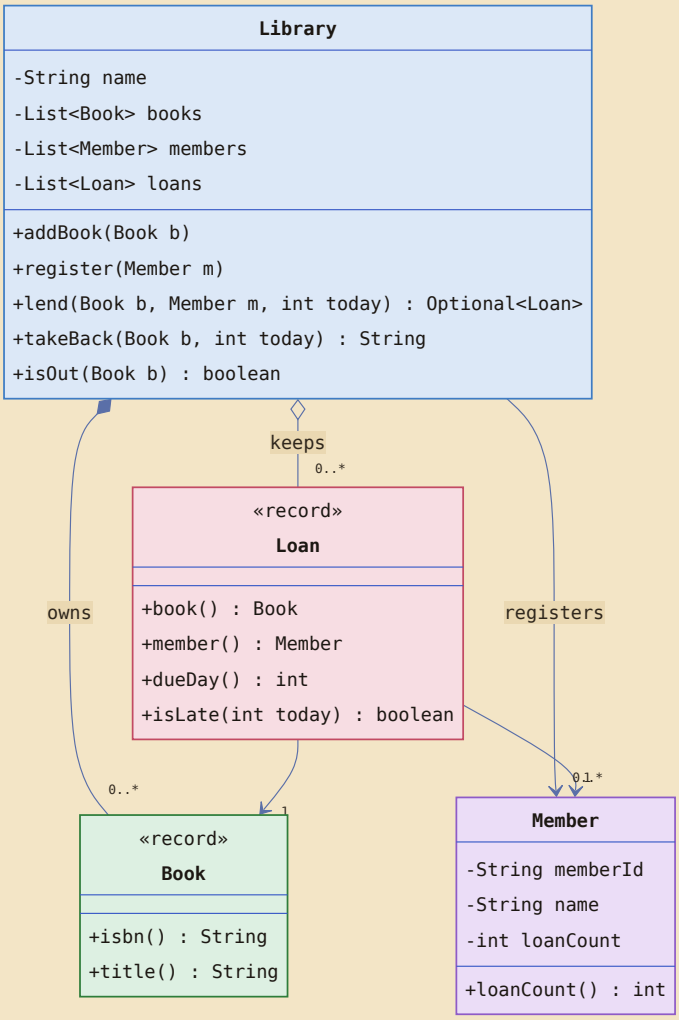
Step 1, objects. Candidate nouns: member, library, book, date, borrowed book. A *date* is one value, so it becomes a field. That leaves four objects: `Library`, `Member`, `Book`, and the borrowed book, which reads better as **`Loan`**. `Loan` is the one candidates overlook most often, since the sentence never uses it as a noun.

> **General rule:** if two objects are linked and **the link has data of its own**, model the link as an object. A lent book comes with someone who borrowed it and a date it must be back by; neither can live on `Book`, because a book sitting on the shelf has neither. Other examples: `Reservation` in a hotel, `Ticket` in a parking lot, `Enrollment` between student and course.

Step 2, relationships. The library **owns** its many book records in the strong sense (delete the library and its book records disappear with it): that is **composition**, drawn as the filled diamond. The library also **registers** many members without owning them (people go on existing without the library): a plain **association** arrow. Each loan **points to** a single book and a single member, owning neither.

Step 3, interfaces. Library: lend a book, accept a return, report whether a copy is currently out. Book: expose its title and ISBN (the International Standard Book Number printed on every book). Member: report its number of loans. Loan: report whether it is overdue. All other members, every field included, stay private. Pay attention to **which class answers "is this book out?"**: `Book` cannot, since it has no knowledge of loans; `Library` keeps the loans, so only it can answer.

Step 4, design. The figure fully answers the original sentence in four steps without a line of code. Our Java version (which adds a `register` operation so members can be checked):



```java
// File: code/lld/ch02/ooad/Book.java
package lld.ch02.ooad;

/** A book on the shelf: knows its ISBN and title, and nothing about who borrowed it. */
public record Book(String isbn, String title) { }
```

```java
// File: code/lld/ch02/ooad/Library.java
package lld.ch02.ooad;

import java.util.ArrayList;
import java.util.List;
import java.util.Optional;

/** Owns its books (composition), refers to members (association), and keeps the loans. */
public final class Library {
    public static final int LOAN_DAYS = 14;
    public static final int MAX_LOANS_PER_MEMBER = 5;

    private final String name;
    private final List<Book> books = new ArrayList<>();
    private final List<Member> members = new ArrayList<>();
    private final List<Loan> loans = new ArrayList<>();

    public Library(String name) { this.name = name; }

    public void addBook(Book b)     { books.add(b); }
    public void register(Member m)  { members.add(m); }

    /** Only the library can answer this: a Book does not know about loans. */
    public boolean isOut(Book b) { return loans.stream().anyMatch(l -> l.book().equals(b)); }

    public Optional<Loan> lend(Book b, Member m, int today) {
        if (!books.contains(b) || !members.contains(m)) return Optional.empty();
        if (isOut(b) || m.loanCount() >= MAX_LOANS_PER_MEMBER) return Optional.empty();
        Loan loan = new Loan(b, m, today + LOAN_DAYS);
        loans.add(loan);
        m.loanStarted();
        return Optional.of(loan);
    }

    public String takeBack(Book b, int today) {
        for (Loan l : loans) {
            if (l.book().equals(b)) {
                loans.remove(l);
                l.member().loanEnded();
                return b.title() + " returned " + (l.isLate(today) ? "LATE" : "on time");
            }
        }
        return b.title() + " was not on loan";
    }

    public String name() { return name; }
}
```

```java
// File: code/lld/ch02/ooad/Loan.java
package lld.ch02.ooad;

/**
 * The CONNECTION OBJECT: "a borrowed book" carries its own data (borrower, due day),
 * which belongs neither on Book nor on Member.
 */
public record Loan(Book book, Member member, int dueDay) {
    public boolean isLate(int today) { return today > dueDay; }
}
```

```java
// File: code/lld/ch02/ooad/Member.java
package lld.ch02.ooad;

/** A member exists independently of the library (the library refers to it, it does not own it). */
public final class Member {
    private final String memberId;
    private final String name;
    private int loanCount;

    public Member(String memberId, String name) { this.memberId = memberId; this.name = name; }

    public String memberId() { return memberId; }
    public String name()     { return name; }
    public int loanCount()   { return loanCount; }

    void loanStarted() { loanCount++; }        // package-private: only Library changes it
    void loanEnded()   { loanCount--; }
}
```

```java
// File: code/lld/ch02/ooad/Main.java
package lld.ch02.ooad;

public class Main {
    public static void main(String[] args) {
        Library lib = new Library("City Library");
        Book ddd = new Book("978-0321125217", "Domain-Driven Design");
        Book gof = new Book("978-0201633610", "Design Patterns");
        lib.addBook(ddd);
        lib.addBook(gof);
        Member ada = new Member("M1", "Ada");
        Member kai = new Member("M2", "Kai");
        lib.register(ada);
        lib.register(kai);

        System.out.println("Ada borrows DDD on day 1: " + lib.lend(ddd, ada, 1).map(l -> "due day " +
l.dueDay()).orElse("refused"));
        System.out.println("Kai borrows DDD on day 2: " + lib.lend(ddd, kai, 2).map(l -> "due day " +
l.dueDay()).orElse("refused (already out)"));
        System.out.println("Kai borrows GoF on day 2: " + lib.lend(gof, kai, 2).map(l -> "due day " +
l.dueDay()).orElse("refused"));
        System.out.println("is DDD out? " + lib.isOut(ddd) + ", Ada's loans: " + ada.loanCount());
        System.out.println(lib.takeBack(ddd, 10));
        System.out.println(lib.takeBack(gof, 20));
        System.out.println(lib.takeBack(gof, 21));
        System.out.println("is DDD out? " + lib.isOut(ddd));
    }
}
```

Output:

```
Ada borrows DDD on day 1: due day 15
Kai borrows DDD on day 2: refused (already out)
Kai borrows GoF on day 2: due day 16
is DDD out? true, Ada's loans: 1
Domain-Driven Design returned on time
Design Patterns returned LATE
Design Patterns was not on loan
is DDD out? false
```

Explaining each part: limits from the requirements became constants (`LOAN_DAYS = 14`, `MAX_LOANS_PER_MEMBER = 5`). `Loan` is an immutable record holding the connection data. `Member.loanStarted/loanEnded` are package-private so only `Library` changes loan counts. `isOut` lives on `Library`, the only object with the information.

Why UML

A design only helps if another engineer can read it. **UML (Unified Modeling Language)** is the standard drawing notation for that; it displaced several rival notations decades ago because it can express exactly the OOAD ideas above: a **filled diamond** marks ownership (composition), a **plain arrow** marks one object referring to another, and **+ / −** mark public / private. No symbol is decorative; each records a design decision. That is also why the concepts are taught before the notation: a shape means nothing until you know the decision behind it. Chapter 3 teaches UML in full.

Three ways this goes wrong

1. **Naming classes after tables** (`UserRow`, `OrderTable`, `BookData`). That is a database schema (the layout of tables and columns) wearing OO clothes. An object pairs data with the behaviour that modifies it, so a class holding only fields and getters should prompt the question: what is it for, what does it **do**?
2. **Missing the connection object** (`Loan`, `Reservation`, `Ticket`). If `borrower` and `dueDate` are drifting onto `Book`, that is the signal that a connection class is missing.
3. **Listing every operation you can imagine.** Step 3 is about what an object provides **to other objects**, not every conceivable action. Long method lists on every class show that no decisions were made.

In the interview

30-second answer: "I separate analysis from design. First I find the objects from the nouns, dropping single values into fields, and define relationships with ownership and multiplicity. Then I decide each object's public operations, which also decides what is private, and draw the class diagram. When the link between two objects has data of its own, like a loan's due date, that link becomes a class."

- *"Where does `isOut(book)` belong?"* — On `Library`, because it owns the loans; a `Book` does not know about loans.
- *"Why is `date` not a class?"* — It holds a single value with no behaviour of its own in this problem; it is a field.

Self-check

- **Q:** Which OOAD steps are analysis? **A:** Find the objects, define the relationships.
- **Q:** What is the connection object in a parking lot? **A:** The parking ticket (vehicle + spot + entry time).
- **Q:** When is encapsulation actually decided? **A:** In step 3, when you list each object's public operations; everything unlisted is private.

TL;DR

Analysis = what the system is (objects, relationships). Design = how objects deliver it (interfaces, class diagram). Implementation = code. Connections with data become objects. Don't name a `HashMap` in minute two.

Chapter summary: in the interview

30-second answer (to "Explain the pillars of OOP"): "Encapsulation hides data and gathers the rules about it into the class that owns it. Abstraction exposes only what callers need. Inheritance lets a child reuse a parent when 'child is a parent' is truly correct. Polymorphism lets one call behave differently per object, which removes type switches. In design I prefer interfaces and composition over deep inheritance, use enums for fixed sets, records for immutable values, and I keep equals and hashCode consistent."

Common follow-ups:

- *"Abstract class or interface?"* — Interface for the contract (many allowed, no state); abstract class when implementations share state or a template algorithm.
- *"Overloading vs overriding?"* — Compile-time by declared parameter types vs run-time by actual object.
- *"Why composition over inheritance?"* — Avoids fragile base classes, allows run-time swapping, keeps coupling low.
- *"What breaks if `hashCode` is not overridden with `equals`?"* — Hash collections fail to find equal objects.

- *"How do you make a class immutable?"* — Final class, private final fields, no setters, defensive copies; or a record with a compact constructor that copies collections.

Self-check (whole chapter)

- **Q:** Class vs object? **A:** Blueprint vs one instance with real values.
- **Q:** What does `this(...)` do? **A:** Calls another constructor of the same class (constructor chaining).
- **Q:** Encapsulation vs abstraction? **A:** Hiding data behind rule-enforcing methods vs hiding complexity behind a minimal set of operations.
- **Q:** What is dynamic dispatch? **A:** The JVM choosing an overridden method's implementation from the object's actual class at run time.
- **Q:** Are static methods overridden? **A:** No, hidden.
- **Q:** Can an interface have a method with a body? **A:** Yes: default, static and private methods.
- **Q:** Where should "which spot types fit a truck" live? **A:** As data on the `VehicleType` enum.
- **Q:** State the hashCode rule in one line. **A:** Equal objects must have equal hash codes.
- **Q:** Are records deeply immutable? **A:** No, shallowly; copy mutable components.
- **Q:** Who can see a package-private member? **A:** Only classes in the same package.
- **Q:** What does PECS stand for? **A:** Producer `extends`, consumer `super`.
- **Q:** Name the OOAD steps. **A:** Find objects, define relationships, establish interfaces, make the design.

TL;DR

- OOP = data bundled with the only code allowed to modify it.
- Class = blueprint; object = instance. Constructors create valid objects; `this` = current object; `static` = one per class.
- Four pillars: encapsulation (who may change data), abstraction (what callers need), inheritance (true is-a only), polymorphism (one call, many behaviours; kills type switches).
- Overloading is compile-time; overriding is run-time; fields and statics are not polymorphic.
- Interfaces = contracts (default/static/private methods, functional interfaces for lambdas); abstract classes = shared state and templates.
- Enums hold data and behaviour for fixed sets; composition beats inheritance for reuse.
- `==` identity vs `equals` value; override `hashCode` with `equals`.
- Immutable value objects (records + defensive copies); mutable but encapsulated entities.
- Default to `private`; group by feature packages; generics for type-safe reusable infrastructure.
- OOA (what) → OOD (how, with objects) → OOP (code). Connections that carry data become objects.

Chapter 3 — Class Relationships & UML

> **What you will learn.** How two classes can be connected (association, aggregation, composition, dependency, generalization, realization), how each connection looks in Java, how to pick the right one in ten seconds, and how to *draw* a design with UML (Unified Modeling Language, the standard picture notation for software designs; Section 3.9): use-case, class, sequence, activity and state machine diagrams. The chapter ends with how much UML you should actually draw in a 45-minute interview.

How this chapter is organised

Part	Topics	Java package
A. Relationships	3.1 Big picture · 3.2 Association (uni/bi, multiplicity) · 3.3 Aggregation · 3.4 Composition · 3.5 Dependency · 3.6 Generalization · 3.7 Realization · 3.8 Decision guide	`lld.ch03.association`, `aggregation`, `composition`, `dependency`, `generalization`, `realization`
B. UML	3.9 What UML is · 3.10 Use-case · 3.11 Class · 3.12 Sequence · 3.13 Activity · 3.14 State machine	`lld.ch03.library` (use case → class → sequence → activity), `lld.ch03.statemachine`
C. Interview	3.15 How much UML to draw · 3.16 Chapter self-check · 3.17 TL;DR	—

Every package has a `Main` that you can run (`javac` is the Java compiler, which turns `.java` files into runnable `.class` files; `java` runs them, and `-cp` says where the compiled classes are):

```
cd chapters/03-relationships-and-uml/code
javac --release 21 -d /tmp/lld_03 $(find . -name '*.java')
java -cp /tmp/lld_03 lld.ch03.association.Main     # or aggregation, composition, dependency,
                                                   # generalization, realization, statemachine, library
```

Part A — Class Relationships

3.1 The big picture: what a "relationship" really claims

What it is

A **relationship** is a line between two classes on a class diagram. It says that objects of one class are connected to objects of the other. That is all a beginner usually hears. But the line actually makes two precise claims:

1. **A claim about lifetime.** If object A is destroyed, is object B destroyed too? ("Lifetime" = the time between an object being created and it no longer being used.)
2. **A claim about substitution.** Can an object of class B be used anywhere an object of class A is expected? ("Substitution" = handing a B to code that asked for an A and having everything still work.)

Everyday analogy: your **body** and your **heart** share a lifetime (composition). A **car** and its **driver** do not — the driver walks away after parking (association). A **sports car** *is a* car and can go anywhere a car can (generalization).

There are six relationships you must know. Three of them are "has-a", one is "uses-a", and two are "is-a":

Family	Relationship	One-line meaning	Coupling (rough order)
uses-a	**Dependency**	A uses B briefly (parameter, local variable, return type)	weakest
has-a	**Association**	A holds a reference to B and can call it; nobody owns anybody	↓
has-a	**Aggregation**	A is a whole holding parts B; the parts can outlive A	↓
has-a	**Composition**	A is a whole *owning* parts B; the parts die with A	↓
is-a	**Realization**	class A implements interface B	↓
is-a	**Generalization**	class A extends class B (inheritance)	strongest coupling

"Coupling" means how much one class must change when the other changes. Inheritance couples a subclass to every detail of its parent, which is why it is at the bottom of the list. The order is a rule of thumb for discussion, not something the UML standard defines.

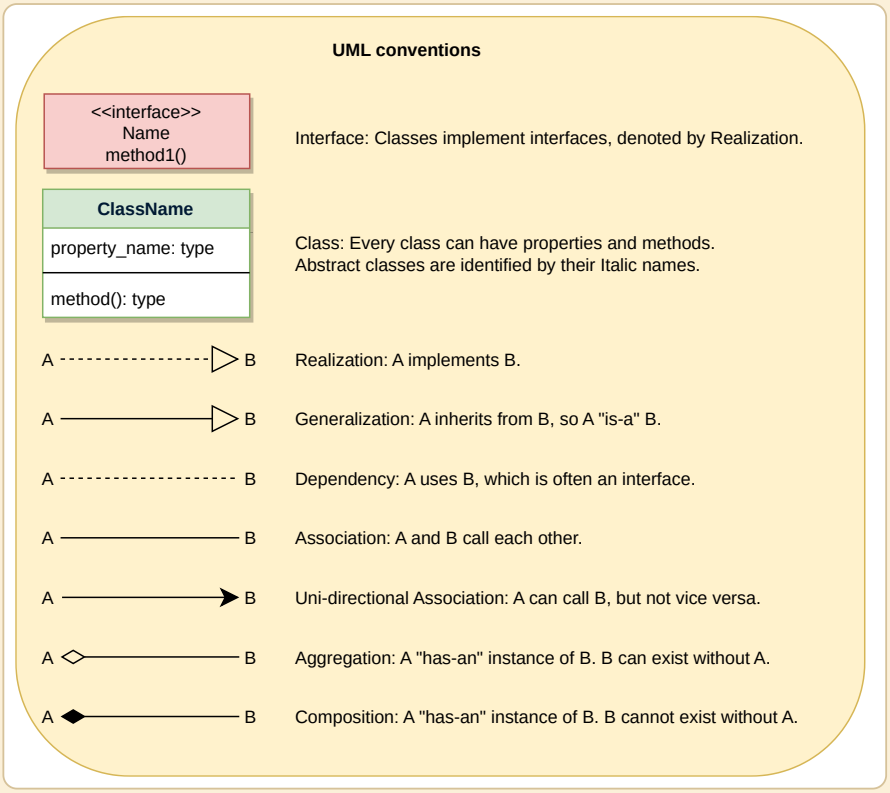


Figure — The UML conventions legend used throughout this book: class and interface boxes, and the line style for realization, generalization, dependency, association, uni-directional association, aggregation and composition (course diagram)

In the figure above, look at the *ends* of each line. The shape at the end (triangle, diamond, arrowhead) and whether the line is solid or dashed is the entire vocabulary. The rest of Part A goes through each line one at a time.

Two small differences between this legend and strict UML, so you are not confused later: the legend draws the **uni-directional association** with a *filled* arrowhead and the **dependency** as a dashed line with *no* head. Standard UML (and this book's Mermaid diagrams; Mermaid is a text-based diagram language that renders into pictures) uses an **open** arrowhead (`→`) for both — solid line for association, dashed line for dependency. Either drawing is understood in an interview if you say what you mean.

The problem it solves

Without a precise vocabulary, "Order has a Customer" and "ParkingFloor has ParkingSpots" sound the same. In code they are very different: one only points at an object that lives elsewhere, the other creates, owns and deletes its parts. If you mix them up you get bugs such as deleting data you did not own, or leaking objects nobody is responsible for. In an interview the mistake is visible on the whiteboard before a single line of code is written.

TL;DR

A relationship line is a claim about **who owns whom (lifetime)** and **who can stand in for whom (substitution)**. Learn the six lines and the one question that separates each.

3.2 Association (uni-directional, bi-directional, multiplicity)

What it is

An **association** means one class keeps a *reference* (a field) to another class and can call its methods over a long period — longer than one method call. Neither side owns the other. Destroy one and the other is unaffected.

Analogy: a **ticket** refers to a **parking spot**. Throw the ticket away and the spot is still in the building.

Three sub-ideas come with it:

- **Direction (navigability).** "Navigable" means "can be reached from". In a **uni-directional** association only one side has a field pointing at the other. In a **bi-directional** association both sides have fields pointing at each other.
- **Multiplicity.** How many objects take part at each end: `1`, `0..1` (optional), `*` or `0..*` (any number), `1..*` (at least one), `2` (exactly two), `2..4` (a range).
- **Role name / association name.** An optional label on the line such as `assigned to` or `borrower`.

The problem it solves

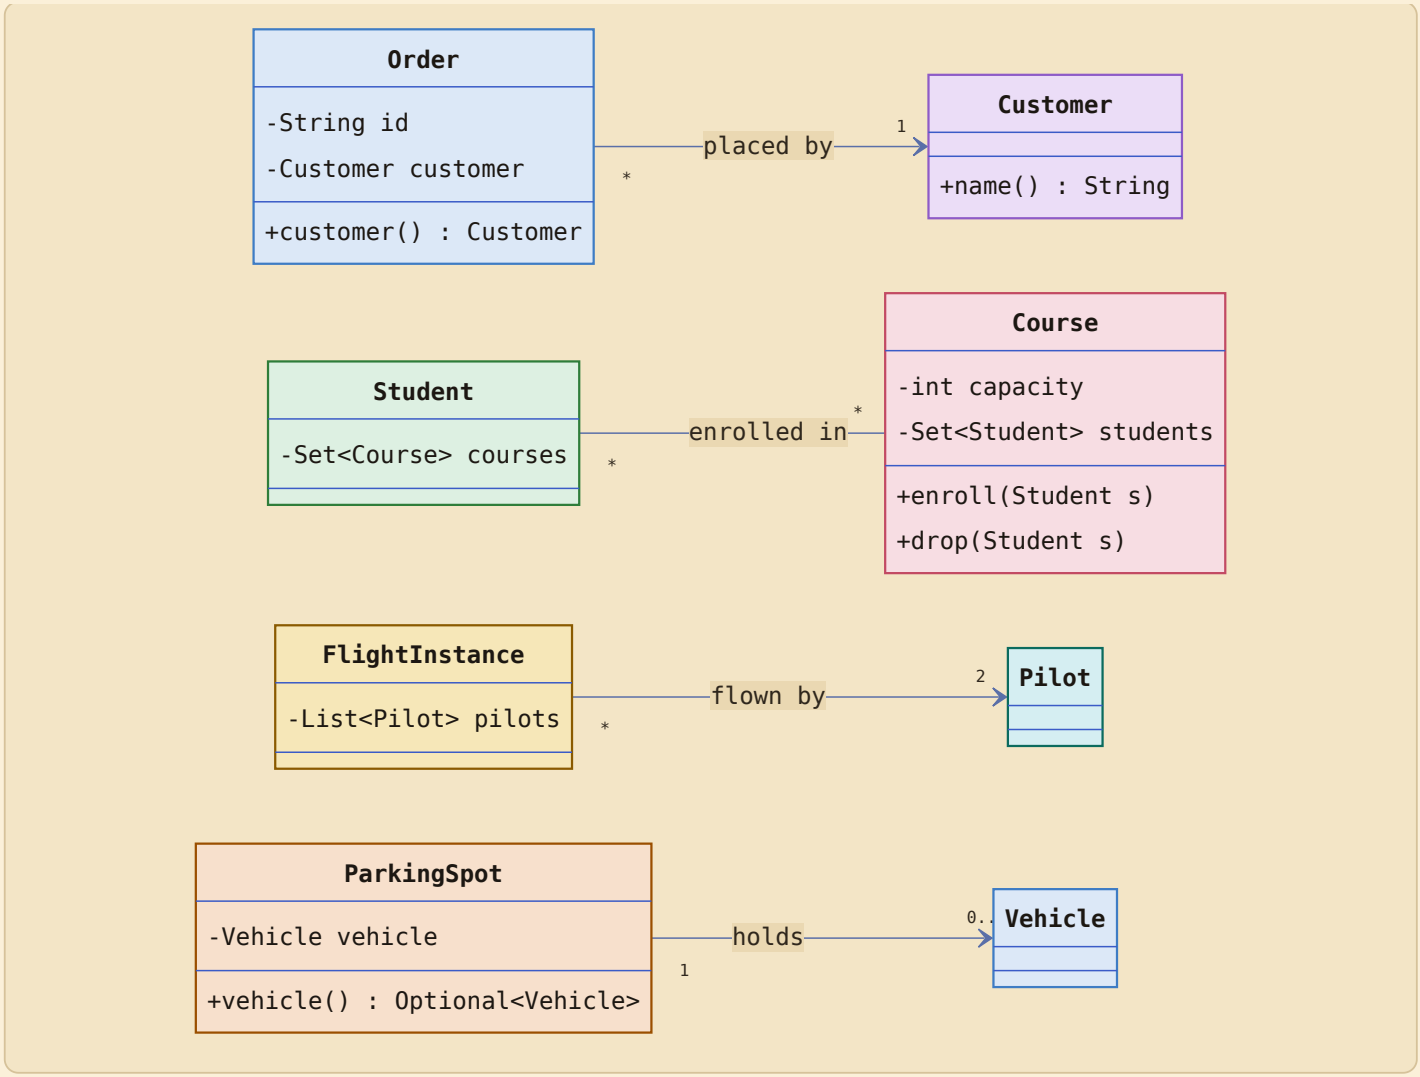
Objects need to collaborate over time. An `Order` must always know which `Customer` placed it. Association is the plain, honest way to record "A knows B" without claiming ownership. It is the most common relationship in a real design, and that is correct.

How it works

1. Decide who needs to call whom. If only `Order` ever asks for its customer, make it **uni-directional**: put a `customer` field in `Order` only.
2. Only make it **bi-directional** if *both* directions are needed by real use cases (e.g. "list a student's courses" *and* "list a course's students").
3. For a bi-directional link, choose **one side to own the update** and make it update both fields in one method, so the two ends can never disagree.
4. Write the **multiplicity** at each end of the line, and then **enforce it in code**:
    - `1` → the field is required: `Objects.requireNonNull` (throws an error if the value is `null`, i.e. no object) in the constructor.
    - `0..1` → the field may be empty: expose it as `Optional<T>` (a box that either holds one value or is empty, so callers must check).
    - `*` → a collection; `1..*` → a collection that must never be empty.
    - exact numbers like `2` → check the size in the constructor.

UML notation

- Plain solid line = association (UML reads a plain line as "navigability unspecified"; in interviews it is read as "both know each other").
- Solid line with an **open arrowhead** = uni-directional; the class at the tail knows the class at the head.
- An **×** at an end (rarely drawn) = explicitly not navigable in that direction.
- Numbers at each end = multiplicity. The number sits next to the class it counts. `Order "*" --> "1" Customer` reads "many orders, each with exactly one customer".



Java example

```java
// File: code/lld/ch03/association/Customer.java
package lld.ch03.association;

/** Knows nothing about orders: the association Order -> Customer is one-way. */
public record Customer(String name) { }
```

```java
// File: code/lld/ch03/association/Order.java
package lld.ch03.association;

import java.util.Objects;

/**
 * Uni-directional association, multiplicity "many orders to exactly 1 customer".
 * Order holds a reference to Customer; Customer has no field pointing back.
 */
public final class Order {
    private final String id;
    private final Customer customer;   // "1" end: never null

    public Order(String id, Customer customer) {
        this.id = id;
        this.customer = Objects.requireNonNull(customer, "an order needs exactly one customer");
    }

    public String id() { return id; }
    public Customer customer() { return customer; }
}
```

```java
// File: code/lld/ch03/association/Student.java
package lld.ch03.association;

import java.util.Collections;
import java.util.LinkedHashSet;
import java.util.Set;

/** One side of a bi-directional many-to-many association (Student * -- * Course). */
public final class Student {
    private final String name;
    private final Set<Course> courses = new LinkedHashSet<>();

    public Student(String name) { this.name = name; }

    public String name() { return name; }
    public Set<Course> courses() { return Collections.unmodifiableSet(courses); }

    /** Package-private: only Course.enroll/drop may touch this side, so both ends stay in sync. */
    void linkCourse(Course c)   { courses.add(c); }
    void unlinkCourse(Course c) { courses.remove(c); }

    @Override public String toString() { return name; }
}
```

```java
// File: code/lld/ch03/association/Course.java
package lld.ch03.association;

import java.util.Collections;
import java.util.LinkedHashSet;
import java.util.Set;

/**
 * Other side of the bi-directional association. Course is the "owner" of the link:
 * enroll/drop update BOTH ends in one place, which is the main rule for two-way links.
 * Multiplicity on this end: a course holds 0..capacity students.
 */
public final class Course {
    private final String code;
    private final int capacity;
    private final Set<Student> students = new LinkedHashSet<>();

    public Course(String code, int capacity) {
        this.code = code;
        this.capacity = capacity;
    }

    public void enroll(Student s) {
        if (students.contains(s)) return;
        if (students.size() == capacity) {
            throw new IllegalStateException(code + " is full (max " + capacity + ")");
        }
        students.add(s);
        s.linkCourse(this);
    }

    public void drop(Student s) {
        if (students.remove(s)) s.unlinkCourse(this);
    }

    public Set<Student> students() { return Collections.unmodifiableSet(students); }
    public String code() { return code; }

    @Override public String toString() { return code; }
}
```

```java
// File: code/lld/ch03/association/Pilot.java
package lld.ch03.association;

public record Pilot(String name) { }
```

```java
// File: code/lld/ch03/association/FlightInstance.java
package lld.ch03.association;

import java.util.List;

/** Multiplicity "exactly 2": the constructor enforces the number written on the diagram. */
public final class FlightInstance {
    private final String flightNo;
    private final List<Pilot> pilots;

    public FlightInstance(String flightNo, List<Pilot> pilots) {
        if (pilots.size() != 2) {
            throw new IllegalArgumentException("a flight needs exactly 2 pilots, got " + pilots.size());
        }
        this.flightNo = flightNo;
        this.pilots = List.copyOf(pilots);
    }

    public List<Pilot> pilots() { return pilots; }
    public String flightNo() { return flightNo; }
}
```

```java
// File: code/lld/ch03/association/Vehicle.java
package lld.ch03.association;

public record Vehicle(String plate) { }
```

```java
// File: code/lld/ch03/association/ParkingSpot.java
package lld.ch03.association;

import java.util.Optional;

/** Multiplicity "0..1": the field may be empty, so the getter returns Optional and callers must check. */
public final class ParkingSpot {
    private final int number;
    private Vehicle vehicle;   // null means "0" of 0..1

    public ParkingSpot(int number) { this.number = number; }

    public void park(Vehicle v) {
        if (vehicle != null) throw new IllegalStateException("spot " + number + " is taken");
        vehicle = v;
    }

    public void leave() { vehicle = null; }

    public Optional<Vehicle> vehicle() { return Optional.ofNullable(vehicle); }
    public int number() { return number; }
}
```

```java
// File: code/lld/ch03/association/Main.java
package lld.ch03.association;

import java.util.List;

public class Main {
    public static void main(String[] args) {
        System.out.println("== Uni-directional: Order -> Customer ==");
        Customer asha = new Customer("Asha");
        Order o1 = new Order("O-1", asha);
        Order o2 = new Order("O-2", asha);
        System.out.println(o1.id() + " belongs to " + o1.customer().name());
        System.out.println(o2.id() + " belongs to " + o2.customer().name());
        System.out.println("Customer has no way to list its orders (one-way link).");

        System.out.println("\n== Bi-directional many-to-many: Student <-> Course ==");
        Student ravi = new Student("Ravi");
        Student meera = new Student("Meera");
        Course java = new Course("JAVA101", 2);
        Course uml = new Course("UML201", 30);
        java.enroll(ravi);
        java.enroll(meera);
        uml.enroll(ravi);
        System.out.println("JAVA101 students: " + java.students());
        System.out.println("Ravi's courses:   " + ravi.courses());
        try {
            java.enroll(new Student("Kiran"));
        } catch (IllegalStateException e) {
            System.out.println("Multiplicity 0..2 enforced: " + e.getMessage());
        }
        java.drop(ravi);
        System.out.println("After drop, JAVA101: " + java.students() + ", Ravi: " + ravi.courses());

        System.out.println("\n== Multiplicity 2 and 0..1 ==");
        FlightInstance f = new FlightInstance("AI-202", List.of(new Pilot("Capt. Rao"), new Pilot("F/O Das")));
        System.out.println(f.flightNo() + " pilots: " + f.pilots());
        try {
            new FlightInstance("AI-303", List.of(new Pilot("Solo")));
        } catch (IllegalArgumentException e) {
            System.out.println("Rejected: " + e.getMessage());
        }
        ParkingSpot spot = new ParkingSpot(7);
        System.out.println("Spot 7 vehicle: " + spot.vehicle().map(Vehicle::plate).orElse("<empty>"));
        spot.park(new Vehicle("KA-01-1234"));
        System.out.println("Spot 7 vehicle: " + spot.vehicle().map(Vehicle::plate).orElse("<empty>"));
    }
}
```

What each part shows:

- `Order` has a `final Customer customer` field and `Customer` has nothing pointing back → **uni-directional**, multiplicity `1` enforced with `requireNonNull`.
- `Student` and `Course` each hold a `Set` of the other → **bi-directional many-to-many**. Only `Course.enroll/drop` may change the link; `Student.linkCourse` is package-private (no access keyword, so only classes in the same Java package can call it). This single "owning side" rule is what keeps both ends consistent.
- `Course(capacity)` turns multiplicity `0..capacity` into a runtime check.
- `FlightInstance` rejects anything but exactly **2** pilots; `ParkingSpot` exposes **0..1** as `Optional<Vehicle>`.
- Lifetimes: every object here is created by `Main` and merely *referenced* by the others. Dropping a course does not delete the student.

Output:

```
== Uni-directional: Order -> Customer ==
O-1 belongs to Asha
O-2 belongs to Asha
Customer has no way to list its orders (one-way link).

== Bi-directional many-to-many: Student <-> Course ==
JAVA101 students: [Ravi, Meera]
Ravi's courses:   [JAVA101, UML201]
Multiplicity 0..2 enforced: JAVA101 is full (max 2)
After drop, JAVA101: [Meera], Ravi: [UML201]

== Multiplicity 2 and 0..1 ==
AI-202 pilots: [Pilot[name=Capt. Rao], Pilot[name=F/O Das]]
Rejected: a flight needs exactly 2 pilots, got 1
Spot 7 vehicle: <empty>
Spot 7 vehicle: KA-01-1234
```

Trade-offs

Choice	Pros	Cons
Uni-directional	Simple; one field; no sync bugs; lower coupling	Reverse question ("which orders does this customer have?") needs a query or repository (a class that stores and looks up objects)
Bi-directional	Fast navigation both ways	Two fields to keep in sync; tighter coupling; risk of infinite loops in `toString` / `equals` /JSON serialisation (turning objects into JSON, a common text data format)
Strict multiplicity checks	Invalid states cannot be created	A little more constructor code

When not to use it

- Do not store a long-lived field if you only need the object inside one method — that is a **dependency** (3.5), which couples less.
- Do not default to bi-directional. Most associations should be uni-directional.

Common mistakes

- Making every line bi-directional "just in case".
- Updating only one side of a bi-directional link (`student.courses.add(c)` without `course.students.add(s)`).
- Forgetting multiplicity on the line, then forgetting the null-check / non-empty check in the code.
- Including both sides in `toString()` or `equals()` → stack overflow from infinite recursion (each object's method calls the other's, forever, until Java runs out of room to track the calls).

Real-world examples

- **JPA / Hibernate** (Java's standard API for saving objects into SQL database tables, and its most popular implementation): `@ManyToOne` on `Order.customer` is a uni-directional association. A bi-directional `@OneToMany(mappedBy = "customer")` needs an *owning side* (the side with the foreign key, the column that stores the other row's ID) and helper methods that set both ends — exactly the `Course.enroll` rule above.
- **Spring** (a popular Java application framework): a service with a constructor-injected repository (one handed in through the constructor) holds an association to it; the Spring container (the part of Spring that creates and wires objects), not the service, creates and destroys the repository.
- **E-commerce:** an order row stores `customer_id` (Order → Customer); a customer does not store a list of order ids.

In the interview

30-second answer: "Association means one class holds a reference to another and can call it, with no ownership. I make it uni-directional unless both directions are needed, and I write multiplicity on every

line because it changes the code: `1` is a required field, `0..1` is an Optional, `1..*` is a non-empty collection."

Follow-ups:

- *Q: How do you keep a bi-directional association consistent?* — A: Pick one owning side and put a single method there (`enroll`) that updates both ends; make the other side's mutators (methods that change state) package-private.
- *Q: What changes if a parking spot can hold two motorbikes?* — A: The multiplicity changes from `0..1` to `0..2`, so the field becomes a small collection with a size check instead of an `Optional`.
- *Q: Why not make everything bi-directional?* — A: It doubles the places that must change together and increases coupling; the reverse direction can usually be answered by a repository query.

Self-check

- *Q: `Order "*" --> "1" Customer` — which class has the field?* → A: `Order`; the arrow points at the class being referenced.
- *Q: What Java type fits multiplicity `0..1`?* → A: A nullable field exposed as `Optional<T>`.
- *Q: Is a many-to-many association always bi-directional?* → A: No. "Many-to-many" is about counts; direction is a separate choice.

TL;DR

Association = "A knows B", no ownership. Prefer one-way. Put multiplicity on every line and enforce it in the constructor/types.

3.3 Aggregation

What it is

Aggregation is a special association that says "A is a *whole* made of parts B, but the parts have their own life". The parts exist before the whole, can move to another whole, and survive when the whole is destroyed. It is sometimes called *shared aggregation* because a part may even belong to several wholes.

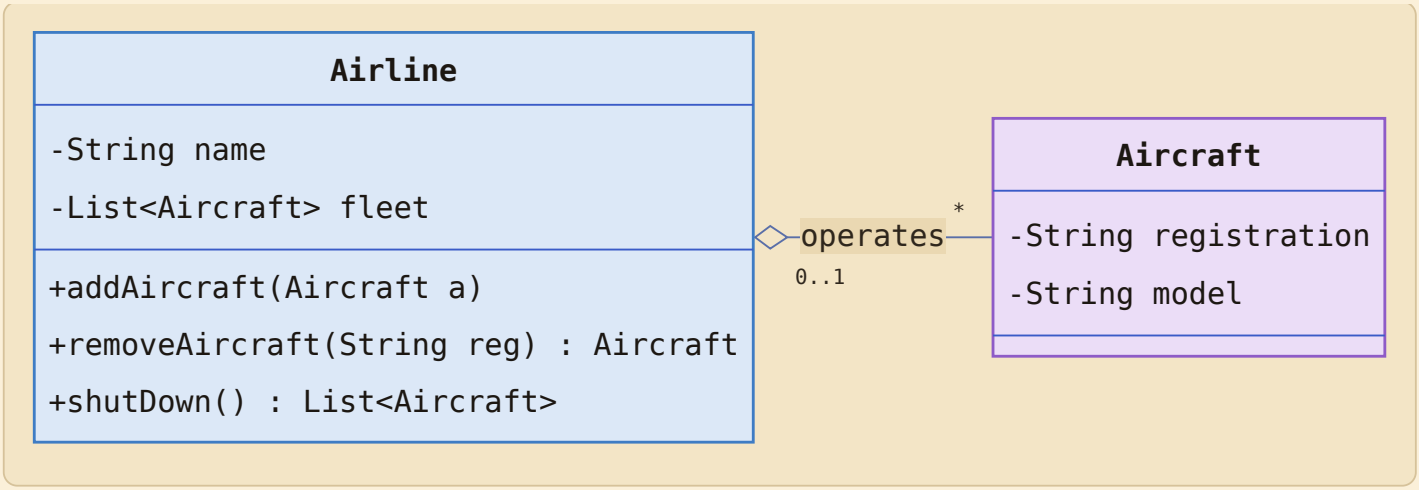
Analogy: an **airline** and its **aircraft**. If the airline shuts down, the planes are sold to another airline — they are not scrapped. A **team** and its **players** is another: disband the team and the players still exist.

The problem it solves

It lets you say "these objects form a group" (a whole–part meaning, stronger than a plain association) while making clear that the group does **not** control their lifetime. That tells readers: "do not delete the parts when you delete the whole".

How it works

1. The part is **created outside** the whole (by the caller, a factory, or a repository).
2. The part is **passed in** (`addAircraft(a)`), and the whole stores a reference.
3. Removing the part from the whole **returns it alive**; destroying the whole **releases** its parts.
4. In UML, draw a **hollow diamond at the whole's end** of the line.



Java example

```java
// File: code/lld/ch03/aggregation/Aircraft.java
package lld.ch03.aggregation;

/** A part that has its own life: it is created outside any airline and can move between airlines. */
public final class Aircraft {
    private final String registration;
    private final String model;

    public Aircraft(String registration, String model) {
        this.registration = registration;
        this.model = model;
    }

    public String registration() { return registration; }

    @Override public String toString() { return registration + " (" + model + ")"; }
}
```

```java
// File: code/lld/ch03/aggregation/Airline.java
package lld.ch03.aggregation;

import java.util.ArrayList;
import java.util.Collections;
import java.util.List;

/**
 * Aggregation (hollow diamond at Airline): Airline 0..1 o-- * Aircraft
 * (an aircraft belongs to at most one airline at a time and may belong to none).
 * The airline HOLDS aircraft that were created elsewhere and handed in.
 * It never creates them and never destroys them.
 */
public final class Airline {
    private final String name;
    private final List<Aircraft> fleet = new ArrayList<>();

    public Airline(String name) { this.name = name; }

    public void addAircraft(Aircraft a) { fleet.add(a); }        // part is passed in

    public Aircraft removeAircraft(String registration) {         // part is handed back, still alive
        for (var it = fleet.iterator(); it.hasNext(); ) {
            Aircraft a = it.next();
            if (a.registration().equals(registration)) { it.remove(); return a; }
        }
        throw new IllegalArgumentException("no aircraft " + registration + " in " + name);
    }

    /** Shutting down the airline releases the parts instead of destroying them. */
    public List<Aircraft> shutDown() {
        List<Aircraft> released = List.copyOf(fleet);
        fleet.clear();
        return released;
    }

    public List<Aircraft> fleet() { return Collections.unmodifiableList(fleet); }
    public String name() { return name; }
}
```

```java
// File: code/lld/ch03/aggregation/Main.java
package lld.ch03.aggregation;

import java.util.List;

public class Main {
    public static void main(String[] args) {
        // The parts exist BEFORE any whole.
        Aircraft a1 = new Aircraft("VT-AAA", "A320");
        Aircraft a2 = new Aircraft("VT-BBB", "B737");
        Aircraft a3 = new Aircraft("VT-CCC", "ATR72");

        Airline skyways = new Airline("Skyways");
        skyways.addAircraft(a1);
        skyways.addAircraft(a2);
        Airline blueJet = new Airline("BlueJet");
        blueJet.addAircraft(a3);

        System.out.println(skyways.name() + " fleet: " + skyways.fleet());
        System.out.println(blueJet.name() + " fleet: " + blueJet.fleet());

        // Transfer one part between wholes.
        blueJet.addAircraft(skyways.removeAircraft("VT-BBB"));
        System.out.println("After transfer, BlueJet fleet: " + blueJet.fleet());

        // Destroy a whole: its parts survive and can join another whole.
        List<Aircraft> released = skyways.shutDown();
        skyways = null;   // the Airline object is now unreachable
        System.out.println("Skyways shut down. Released aircraft still exist: " + released);
        released.forEach(blueJet::addAircraft);
        System.out.println("BlueJet fleet now: " + blueJet.fleet());
    }
}
```

What each part shows: `Aircraft` objects are built in `Main` *before* any airline exists. `Airline.addAircraft` receives them; `removeAircraft` and `shutDown` hand them back. After `skyways = null` the airline is garbage (nothing points to it any more, so Java's garbage collector, which frees the memory of unreachable objects, will reclaim it), but its aircraft are still referenced and join `BlueJet`.

Output:

```
Skyways fleet: [VT-AAA (A320), VT-BBB (B737)]
BlueJet fleet: [VT-CCC (ATR72)]
After transfer, BlueJet fleet: [VT-CCC (ATR72), VT-BBB (B737)]
Skyways shut down. Released aircraft still exist: [VT-AAA (A320)]
BlueJet fleet now: [VT-CCC (ATR72), VT-BBB (B737), VT-AAA (A320)]
```

Trade-offs

	Aggregation	Plain association
Extra meaning	"whole–part" grouping	just "knows"
Lifetime claim	parts outlive whole	none
Code difference	usually **none** — both are a field holding a reference	—

The honest trade-off: aggregation adds meaning for the reader but almost nothing in code. The UML specification itself leaves the precise meaning of shared aggregation to the modeller, and several well-known UML authors (Martin Fowler's *UML Distilled* among them) advise using it sparingly. In interviews, it is still expected when there is a clear whole–part grouping.

When not to use it

- If there is no "whole made of parts" idea (a ticket and a spot), use plain association.
- If the parts are created by and die with the whole, it is composition.

Common mistakes

- Putting the diamond at the **part's** end. The diamond always sits at the **whole**.
- Choosing aggregation vs composition at random. Use the test: *imagine the whole is gone — is the part still meaningful by itself?* Yes → aggregation.
- Deleting parts in the whole's "close/delete" method even though the diagram says aggregation.

Real-world examples

- A `java.util.List<Customer>`: clearing the list does not destroy the customers; they are still referenced elsewhere.
- A Slack/Teams **channel** and its **members**: archiving a channel does not delete user accounts.
- A **playlist** and **songs** (Spotify): deleting your playlist does not delete the songs from the catalogue.
- A **department** and its **professors** in a university model.

In the interview

> **30-second answer:** "Aggregation is a whole–part association where the parts can outlive the whole — hollow diamond at the whole. An airline aggregates aircraft: shut the airline down and the aircraft still exist. In Java the parts are created outside and passed in, and the whole never destroys them."

Follow-ups:

- *Q: Can an airline exist without aircraft?* — A: That is a multiplicity question, not an aggregation question. If the business says an airline must have at least one aircraft, write `1..*` on the aircraft end; it is still aggregation because the aircraft survive the airline.
- *Q: How is aggregation different in code from association?* — A: Usually it is not; the difference is the modelling intent (whole–part). That is why you say the lifetime test out loud.

Self-check

- *Q: Where does the hollow diamond go?* → A: At the whole (`Airline`).
- *Q: A library closes; do its members disappear?* → A: No — a person exists either way, so Library ◇— Member is aggregation.

TL;DR

Aggregation = "has-a, parts live on". Parts are passed in, never destroyed by the whole. Hollow diamond at the whole.

3.4 Composition

What it is

Composition is the strongest has-a relationship: the whole **owns** its parts. A part belongs to **exactly one** whole at a time, is usually **created by** the whole, and is **destroyed with** it. (UML also allows a part to be explicitly removed from the whole *before* the whole is deleted.)

Analogy: a **house** and its **rooms**. Demolish the house and the rooms are gone — a "room of a house that does not exist" means nothing. Likewise a **parking floor** and its **spots**, a **parking lot** and its **floors**, a **flight** and its **weekly schedule**.

The problem it solves

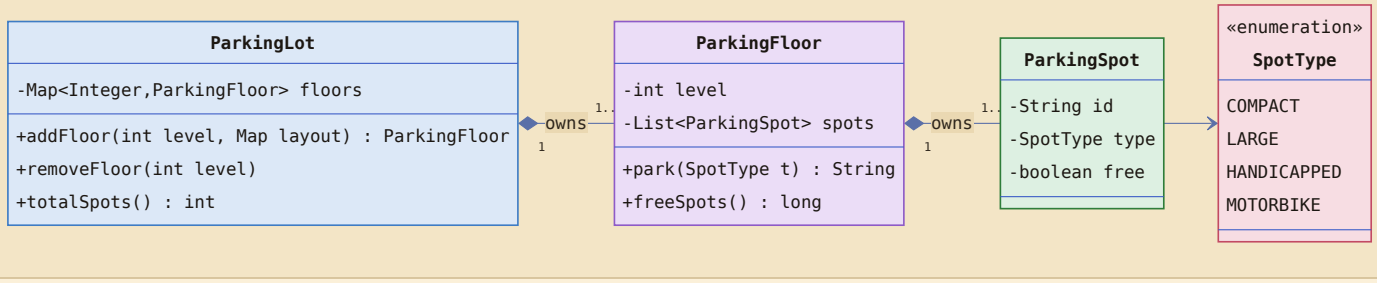
Some objects make no sense on their own, and letting outsiders create or share them causes bugs (two floors pointing at the same spot, orphan spots after a floor is removed). Composition makes the owner responsible for the parts' full life cycle, so there is one place that creates, changes and removes them.

How it works

1. The whole **creates** the parts itself (in its constructor or an `addX(...)` method that takes *data*, not a ready-made part).

2. The part's constructor is **not public** (package-private or a private nested class, i.e. a class declared inside the whole's class) so nobody else can make one.
3. The whole **never hands out** its internal collection — only read-only views or copies.
4. **Removing** the whole (or removing a part from it) drops the only reference, so the part becomes garbage.
5. In UML, draw a **filled (black) diamond at the whole's end**.

A note on Java: Java has no destructors (methods that run automatically when an object is destroyed, as in C++). "The part dies with the whole" means *logically*: nobody else holds a reference, so when the whole is removed the part becomes unreachable and the garbage collector reclaims it. If you need clean-up (closing files, sockets, i.e. open network connections), the whole's `close()` must close its parts too — for example, closing a `BufferedReader` also closes the `FileReader` it wraps.



Java example

```java
// File: code/lld/ch03/composition/SpotType.java
package lld.ch03.composition;

/** A spot "kind" is a value, not a subclass (see the generalization chapter section). */
public enum SpotType { COMPACT, LARGE, HANDICAPPED, MOTORBIKE }
```

```java
// File: code/lld/ch03/composition/ParkingSpot.java
package lld.ch03.composition;

/**
 * A part of a composition. The constructor is package-private, so only ParkingFloor
 * (same package) can create a spot. Outside code can read a spot but never make one.
 */
public final class ParkingSpot {
    private final String id;
    private final SpotType type;
    private boolean free = true;

    ParkingSpot(String id, SpotType type) {
        this.id = id;
        this.type = type;
    }

    public String id() { return id; }
    public SpotType type() { return type; }
    public boolean isFree() { return free; }
    void occupy() { free = false; }

    @Override public String toString() { return id + ":" + type; }
}
```

```java
// File: code/lld/ch03/composition/ParkingFloor.java
package lld.ch03.composition;

import java.util.ArrayList;
import java.util.Collections;
import java.util.List;
import java.util.Map;

/**
 * Composition (filled diamond at ParkingFloor): ParkingFloor 1 *-- 1..* ParkingSpot.
 * The floor CREATES its spots in its own constructor, never shares them with another floor,
 * and when the floor is removed the spots go with it.
 */
public final class ParkingFloor {
    private final int level;
    private final List<ParkingSpot> spots = new ArrayList<>();

    ParkingFloor(int level, Map<SpotType, Integer> layout) {
        this.level = level;
        int n = 1;
        for (var e : layout.entrySet()) {
            for (int i = 0; i < e.getValue(); i++) {
                spots.add(new ParkingSpot("L" + level + "-" + n++, e.getKey()));
            }
        }
        if (spots.isEmpty()) throw new IllegalArgumentException("a floor needs 1..* spots");
    }

    public int level() { return level; }
    public List<ParkingSpot> spots() { return Collections.unmodifiableList(spots); }

    public long freeSpots() { return spots.stream().filter(ParkingSpot::isFree).count(); }

    /** Parks in the first free spot of the type; the spot itself never leaves the floor. */
    public String park(SpotType type) {
        for (ParkingSpot s : spots) {
            if (s.isFree() && s.type() == type) { s.occupy(); return s.id(); }
        }
        return null;
    }
}
```

```java
// File: code/lld/ch03/composition/ParkingLot.java
package lld.ch03.composition;

import java.util.Collections;
import java.util.Map;
import java.util.TreeMap;

/** Composition again: ParkingLot 1 *-- 1..* ParkingFloor. The lot builds and removes its floors. */
public final class ParkingLot {
    private final String name;
    private final Map<Integer, ParkingFloor> floors = new TreeMap<>();

    public ParkingLot(String name) { this.name = name; }

    /** The caller describes the floor; the lot constructs it. No ParkingFloor object is passed in. */
    public ParkingFloor addFloor(int level, Map<SpotType, Integer> layout) {
        ParkingFloor f = new ParkingFloor(level, layout);
        floors.put(level, f);
        return f;
    }

    /** Removing the whole removes its parts: no one else holds the spots, so they become garbage. */
    public void removeFloor(int level) { floors.remove(level); }

    public int totalSpots() {
        return floors.values().stream().mapToInt(f -> f.spots().size()).sum();
    }

    public Map<Integer, ParkingFloor> floors() { return Collections.unmodifiableMap(floors); }
    public String name() { return name; }
}
```

```java
// File: code/lld/ch03/composition/Main.java
package lld.ch03.composition;

import java.util.LinkedHashMap;
import java.util.Map;

public class Main {
    public static void main(String[] args) {
        ParkingLot lot = new ParkingLot("City Centre");
        Map<SpotType, Integer> layout = new LinkedHashMap<>();
        layout.put(SpotType.COMPACT, 3);
        layout.put(SpotType.LARGE, 1);

        ParkingFloor ground = lot.addFloor(0, layout);
        lot.addFloor(1, Map.of(SpotType.MOTORBIKE, 4));

        System.out.println("Floor 0 spots: " + ground.spots());
        System.out.println("Total spots in lot: " + lot.totalSpots());
        System.out.println("Parked compact car at " + ground.park(SpotType.COMPACT));
        System.out.println("Free spots on floor 0: " + ground.freeSpots());

        try {
            ground.spots().clear();
        } catch (UnsupportedOperationException e) {
            System.out.println("Outsiders cannot change the parts: spots() is read-only");
        }

        lot.removeFloor(1);
        System.out.println("After removing floor 1, total spots: " + lot.totalSpots()
                + " (its 4 spots are gone with it)");
        System.out.println("Floors left: " + lot.floors().keySet());
    }
}
```

What each part shows: `ParkingLot.addFloor` receives a *layout description* and builds the `ParkingFloor` itself. `ParkingFloor`'s constructor builds its `ParkingSpot`s; `ParkingSpot`'s constructor is package-private, so code outside the package cannot create a spot. `spots()` returns an unmodifiable view, so outsiders cannot add or remove parts. `removeFloor(1)` drops the floor and, with it, its four spots.

Output:

```
Floor 0 spots: [L0-1:COMPACT, L0-2:COMPACT, L0-3:COMPACT, L0-4:LARGE]
Total spots in lot: 8
Parked compact car at L0-1
Free spots on floor 0: 3
Outsiders cannot change the parts: spots() is read-only
After removing floor 1, total spots: 4 (its 4 spots are gone with it)
Floors left: [0]
```

Trade-offs

	Composition	Aggregation
Who creates the part	the whole	someone else
Can the part be shared?	no (one owner at a time)	yes
Part outlives whole?	no	yes
Encapsulation	strong — whole controls all changes	weaker
Flexibility	lower — parts cannot be reused elsewhere	higher

When not to use it

- When the part has an independent identity the business cares about (a *person*, an *aircraft*, a *song*) — use aggregation/association.
- When the part must be shared between wholes.

Common mistakes

- Accepting a ready-made part from outside (`addSpot(ParkingSpot s)`) and calling it composition — the caller may still hold and share it.
- Returning the internal mutable list (`return spots;`) — outsiders can now add/remove parts behind the owner's back.
- Mixing up composition (object design) with "favour composition over inheritance" (3.6): in that slogan "composition" means *holding* an object instead of extending its class, and it covers association/aggregation too.

Real-world examples

- `java.util.HashMap` creates and manages its internal `Node` entries (a package-private nested class); they are never shared with another map and go away with it.
- **JPA:** `@OneToMany(cascade = CascadeType.ALL, orphanRemoval = true)` models composition — delete the `Order` and its `OrderLine` rows are deleted too.
- **Documents:** deleting a Google Doc deletes its comments and revision history.
- **Operating systems:** killing a process (a running program) frees its threads (its parallel lines of execution) and memory pages (the blocks of memory the OS gave it).

In the interview

30-second answer: "Composition means the whole owns the parts: it creates them, they belong to only it, and they die with it — filled diamond at the whole. A parking floor composes its spots: remove the floor and the spots are gone. In Java I build the parts inside the owner, hide their constructor, and only expose read-only views."

Follow-ups:

- *Q: Java has garbage collection — how can a part 'die'?* — A: It dies logically: the whole holds the only reference, so removing the whole makes the part unreachable. If the part holds resources, the whole's `close()` closes it.
- *Q: Is `Flight` → `WeeklySchedule` composition?* — A: Yes; a schedule of a flight that no longer exists is meaningless.

Self-check

- *Q: The test that separates aggregation from composition?* → A: Imagine the whole is gone — is the part still meaningful by itself? No → composition.
- *Q: Why is `ParkingSpot`'s constructor package-private?* → A: So only the owning floor can create spots.

TL;DR

Composition = "owns, parts die with it". Whole creates parts, never shares them, exposes read-only views. Filled diamond at the whole.

3.5 Dependency

What it is

A **dependency** means class A *uses* class B for a short time — inside one method — without keeping a field that points at B. B appears as a **method parameter**, a **local variable**, a **return type**, or a **static method call**. When the method returns, the relationship is over.

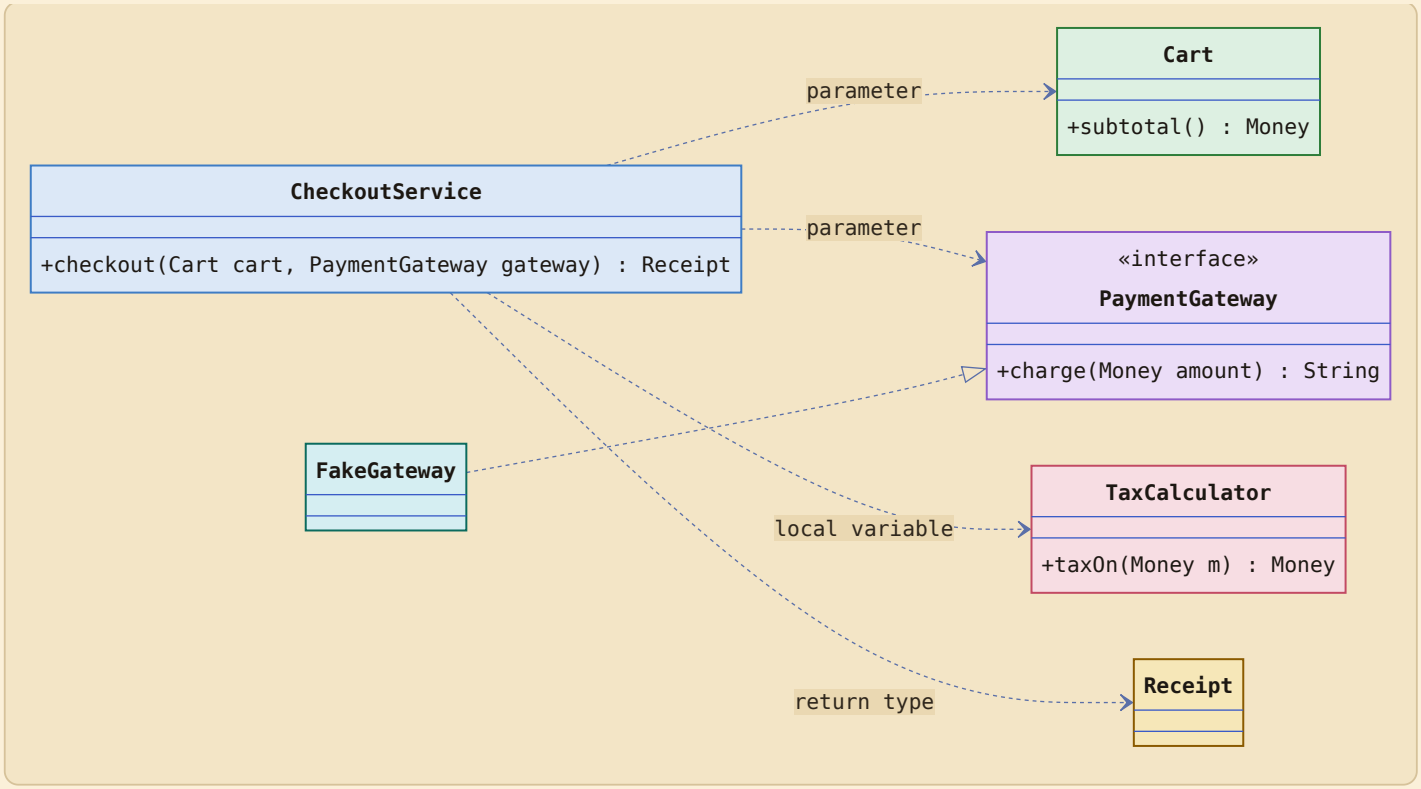
Analogy: a **chef** *uses* a **delivery van** to receive groceries this morning. The chef does not own the van and does not keep it in the kitchen; tomorrow it may be a different van.

The problem it solves

It records the weakest possible link: "if B's interface changes, A may have to change", nothing more. Recognising a dependency (instead of an association) keeps classes stateless (holding no data between calls) and loosely coupled — the caller can pass in a different collaborator on every call.

How it works

1. A method receives B as a parameter (`checkout(Cart cart, PaymentGateway gateway)`), or
2. creates B as a local variable (`new TaxCalculator()`), or
3. returns a B (`Receipt`), or calls a static method on B.
4. No field of type B exists in A.
5. In UML, draw a **dashed line with an open arrowhead** from the user (A) to the used class (B). You may add a keyword such as `«use»` or `«create»`.



Java example

```java
// File: code/lld/ch03/dependency/Money.java
package lld.ch03.dependency;

import java.math.BigDecimal;
import java.math.RoundingMode;

/** A small value type. Anything that returns or accepts Money depends on it. */
public record Money(BigDecimal amount) {
    public static Money of(String s) { return new Money(new BigDecimal(s).setScale(2, RoundingMode.HALF_UP)); }
    public Money plus(Money o) { return new Money(amount.add(o.amount)); }
    public Money times(BigDecimal f) { return new Money(amount.multiply(f).setScale(2, RoundingMode.HALF_UP)); }
    @Override public String toString() { return "Rs " + amount.toPlainString(); }
}
```

```java
// File: code/lld/ch03/dependency/Cart.java
package lld.ch03.dependency;

import java.util.List;

public record Cart(List<Money> itemPrices) {
    public Money subtotal() {
        return itemPrices.stream().reduce(Money.of("0"), Money::plus);
    }
}
```

```java
// File: code/lld/ch03/dependency/PaymentGateway.java
package lld.ch03.dependency;

public interface PaymentGateway {
    String charge(Money amount);   // returns a transaction id
}
```

```java
// File: code/lld/ch03/dependency/FakeGateway.java
package lld.ch03.dependency;

public final class FakeGateway implements PaymentGateway {
    private int next = 1;
    @Override public String charge(Money amount) {
        System.out.println("  [gateway] charging " + amount);
        return "TXN-" + next++;
    }
}
```

```java
// File: code/lld/ch03/dependency/TaxCalculator.java
package lld.ch03.dependency;

import java.math.BigDecimal;

public final class TaxCalculator {
    private static final BigDecimal GST = new BigDecimal("0.18");
    public Money taxOn(Money m) { return m.times(GST); }
}
```

```java
// File: code/lld/ch03/dependency/CheckoutService.java
package lld.ch03.dependency;

/**
 * Dependency (dashed arrow, "uses"): CheckoutService has NO fields pointing at
 * Cart, PaymentGateway, TaxCalculator or Receipt. It only touches them for the
 * duration of one method call:
 *   - Cart and PaymentGateway arrive as PARAMETERS,
 *   - TaxCalculator is a LOCAL variable,
 *   - Receipt is the RETURN type.
 * When checkout() returns, the relationship is over.
 */
public final class CheckoutService {

    public Receipt checkout(Cart cart, PaymentGateway gateway) {
        TaxCalculator tax = new TaxCalculator();            // local-variable dependency
        Money subtotal = cart.subtotal();                   // parameter dependency
        Money total = subtotal.plus(tax.taxOn(subtotal));
        String txn = gateway.charge(total);                 // parameter dependency (interface)
        return new Receipt(txn, subtotal, total);           // return-type dependency
    }

    public record Receipt(String txnId, Money subtotal, Money total) { }
}
```

```java
// File: code/lld/ch03/dependency/Main.java
package lld.ch03.dependency;

import java.util.List;

public class Main {
    public static void main(String[] args) {
        CheckoutService service = new CheckoutService();   // holds no collaborators at all
        Cart cart = new Cart(List.of(Money.of("250"), Money.of("99.50")));

        // The caller decides which gateway to use on every call.
        CheckoutService.Receipt r = service.checkout(cart, new FakeGateway());
        System.out.println("Receipt: " + r);

        PaymentGateway loggingGateway = amount -> {
            System.out.println("  [lambda gateway] charging " + amount);
            return "LMB-42";
        };
        System.out.println("Receipt: " + service.checkout(cart, loggingGateway));
    }
}
```

What each part shows: `CheckoutService` has **no fields at all**. It depends on `Cart` and `PaymentGateway` through parameters, on `TaxCalculator` through a local variable, and on `Receipt` through its return type. `Main` passes a different gateway (even a lambda, a short unnamed function written inline) on each call — something you cannot do as easily with a stored field. `Money` uses `BigDecimal` (Java's exact decimal-number type), not `double` (a binary floating-point number that cannot hold values like 0.10 exactly), because currency needs exact decimal arithmetic.

Output:

```
  [gateway] charging Rs 412.41
Receipt: Receipt[txnId=TXN-1, subtotal=Rs 349.50, total=Rs 412.41]
  [lambda gateway] charging Rs 412.41
Receipt: Receipt[txnId=LMB-42, subtotal=Rs 349.50, total=Rs 412.41]
```

Trade-offs

	Dependency (parameter)	Association (field)
Coupling	lowest	higher
Object state	can be stateless	holds state
Swapping collaborator	per call	per object (or via setter)
Call-site noise	caller passes B every time	caller passes B once

When not to use it

If A needs B across many methods and many calls (e.g. a service always uses the same repository), a stored field (association via constructor injection, where the collaborator is passed into the constructor once) is cleaner than passing B to every method.

Common mistakes

- Drawing a solid association line for something that is only a parameter — it overstates coupling.
- Drawing *every* dependency: a real class depends on `String`, `List`, `LocalDate`… Draw only the ones that matter to the design.
- Hiding a dependency with `new ConcreteThing()` deep inside a method when the caller should decide (this blocks testing). Prefer taking an interface as a parameter.

Real-world examples

- `Collections.sort(list, comparator)` depends on the `Comparator` only during the call.

- A Spring MVC controller method (the code that answers one web request) `handle(HttpServletRequest req)` depends on the request only for that call.
- `LocalDate.now(Clock clock)` depends on a `Clock` parameter — the JDK's way to make time testable.
- In build tools (Maven/Gradle, programs that download libraries and compile a Java project) a "dependency" is the same idea at package level: your code uses a library's classes.

In the interview

> **30-second answer:** "Dependency is 'uses briefly': B is a parameter, local variable or return type of A's method, and A keeps no field for it. Dashed arrow from A to B. It is the loosest coupling, so when a collaborator is only needed in one method I pass it in rather than store it."

Follow-ups:

- *Q: `FlightReservation` takes a `Payment` in `pay(Payment p)` — association or dependency?* — A: Dependency, unless the reservation stores the payment in a field; then it becomes an association.
- *Q: How is this related to Dependency Injection?* — A: DI is about *who supplies* the collaborator (from outside, not `new` inside). The supplied object may be stored (association) or passed per call (dependency). The Dependency Inversion Principle adds: depend on interfaces, not concrete classes (Chapter 4).

Self-check

- *Q: Which UML line: dashed + open arrow, or dashed + hollow triangle?* → A: Dashed + open arrow is dependency; dashed + hollow triangle is realization.
- *Q: A method returns a `Receipt`. Does that create a relationship?* → A: Yes, a dependency on `Receipt`.

TL;DR

Dependency = "uses for one call". Parameter, local variable, return type or static call; no field. Dashed arrow.

3.6 Generalization (inheritance)

What it is

Generalization is UML's word for **inheritance**: class B `extends` class A, so B *is a kind of* A. A is the **parent** (superclass, general); B is the **child** (subclass, specialised). B inherits A's fields and methods and may override them.

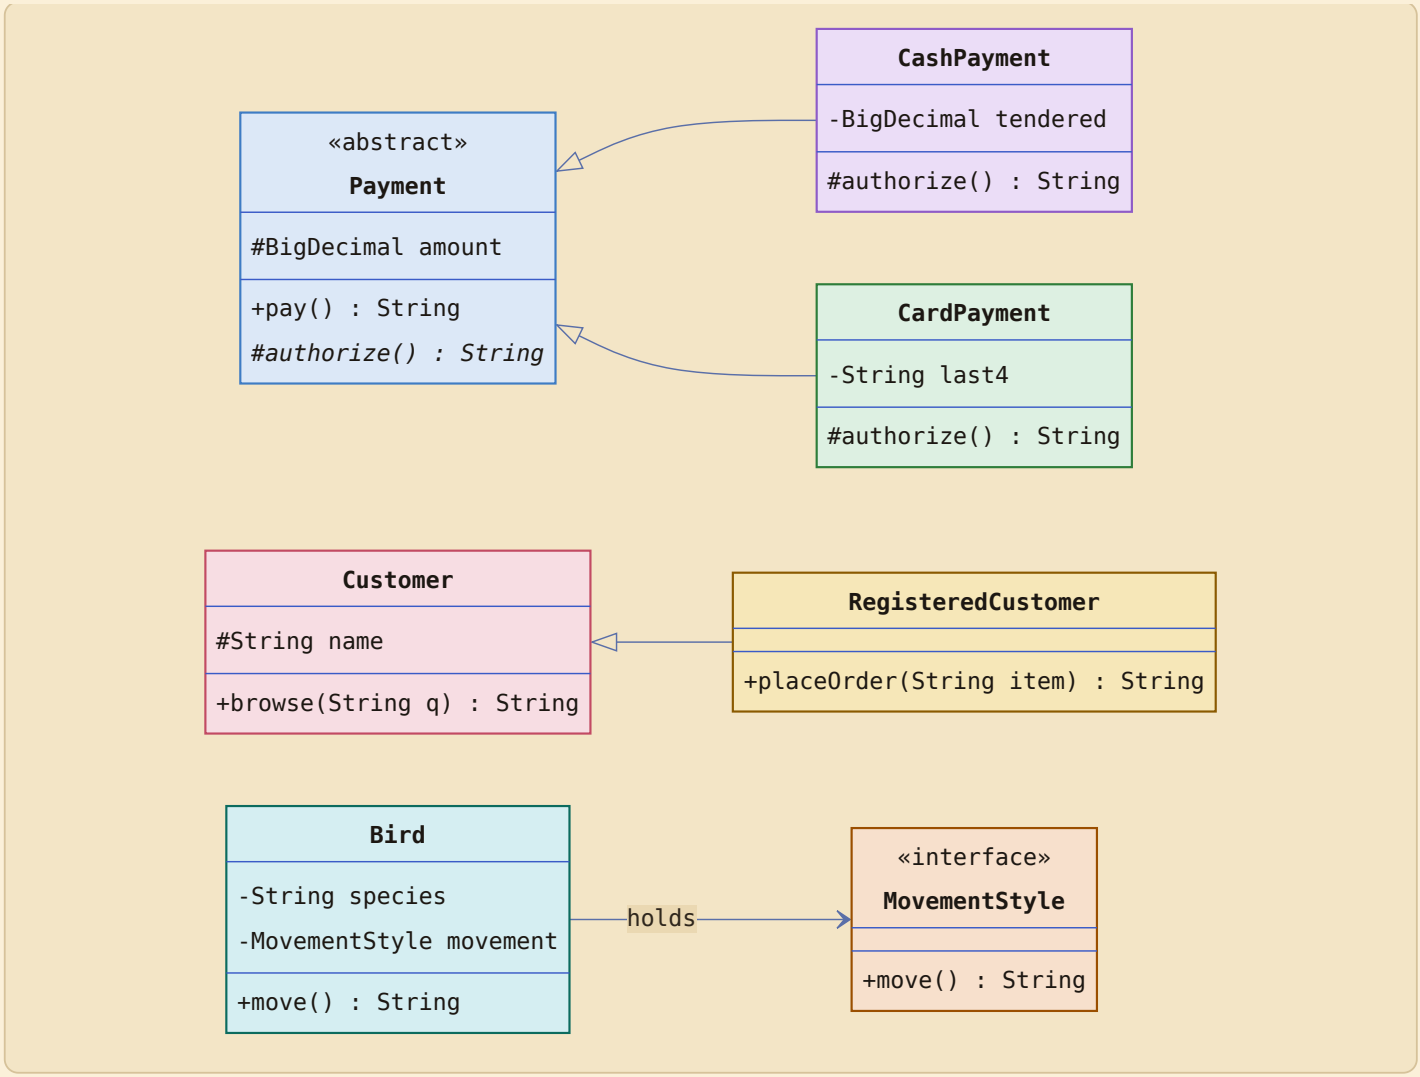
Analogy: a **credit-card payment** *is a* **payment**. Anywhere the shop's code can handle "a payment", it can handle a credit-card payment.

The problem it solves

When several classes truly share a contract **and** some behaviour, inheritance puts the shared parts in one place and lets calling code work with the general type (`Payment`) without knowing the specific one (**polymorphism** — one call, different behaviour depending on the actual object).

How it works

1. Before extending, run the **substitution test**: *can B be used anywhere A is expected, with no surprises?* If there is any method of A that B would have to refuse or break, the answer is no. (This is the Liskov Substitution Principle — Chapter 4.)
2. If yes, put the shared state and workflow in A (often `abstract`: a class that cannot be instantiated and may leave some methods for subclasses to fill in), and let subclasses override only the varying steps.
3. If no, **hold instead of extend**: give A a field of an interface type and plug in different behaviour objects.
4. In UML, draw a **solid line with a hollow triangle pointing at the parent**. An abstract class is shown with its name in *italics* (or `{abstract}` / `«abstract»`); abstract operations are italic too.



Java example

```java
// File: code/lld/ch03/generalization/Payment.java
package lld.ch03.generalization;

import java.math.BigDecimal;

/**
 * Generalization parent (abstract, drawn in italics or with {abstract}).
 * Every subclass genuinely "is a" Payment: each one really can take money, in its own way.
 * Money is BigDecimal, never double: double cannot represent amounts like 0.10 exactly.
 */
public abstract class Payment {
    protected final BigDecimal amount;   // '#' protected: visible to subclasses

    protected Payment(BigDecimal amount) {
        if (amount.signum() <= 0) throw new IllegalArgumentException("amount must be positive");
        this.amount = amount;
    }

    /** Shared, final workflow; the varying step is abstract. */
    public final String pay() {
        String ref = authorize();
        return getClass().getSimpleName() + " of " + amount + " -> " + ref;
    }

    protected abstract String authorize();   // abstract operation (italics in UML)
}
```

```java
// File: code/lld/ch03/generalization/CashPayment.java
package lld.ch03.generalization;

import java.math.BigDecimal;

public final class CashPayment extends Payment {
    private final BigDecimal tendered;

    public CashPayment(BigDecimal amount, BigDecimal tendered) {
        super(amount);
        this.tendered = tendered;
    }

    @Override protected String authorize() {
        if (tendered.compareTo(amount) < 0) return "DECLINED (short by " + amount.subtract(tendered) + ")";
        return "OK, change " + tendered.subtract(amount);
    }
}
```

```java
// File: code/lld/ch03/generalization/CardPayment.java
package lld.ch03.generalization;

import java.math.BigDecimal;

public final class CardPayment extends Payment {
    private final String last4;

    public CardPayment(BigDecimal amount, String last4) {
        super(amount);
        this.last4 = last4;
    }

    @Override protected String authorize() { return "OK, card ****" + last4 + " approved"; }
}
```

```java
// File: code/lld/ch03/generalization/Customer.java
package lld.ch03.generalization;

/** Base class holds only what EVERY customer can do, so no subclass must refuse anything. */
public class Customer {
    protected final String name;
    public Customer(String name) { this.name = name; }
    public String browse(String query) { return name + " browses '" + query + "'"; }
}
```

```java
// File: code/lld/ch03/generalization/RegisteredCustomer.java
package lld.ch03.generalization;

/** Ordering lives here, not on Customer, because a guest may not order. */
public class RegisteredCustomer extends Customer {
    public RegisteredCustomer(String name) { super(name); }
    public String placeOrder(String item) { return name + " orders " + item; }
}
```

```java
// File: code/lld/ch03/generalization/MovementStyle.java
package lld.ch03.generalization;

/** "Prefer holding over extending": behaviour that varies is held, not inherited. */
public interface MovementStyle {
    String move();

    MovementStyle FLY = () -> "flies";
    MovementStyle SWIM = () -> "swims";
    MovementStyle WALK = () -> "walks";
}
```

```java
// File: code/lld/ch03/generalization/Bird.java
package lld.ch03.generalization;

public final class Bird {
    private final String species;
    private MovementStyle movement;   // held, so it can be swapped at run time

    public Bird(String species, MovementStyle movement) {
        this.species = species;
        this.movement = movement;
    }

    public void setMovement(MovementStyle m) { this.movement = m; }
    public String move() { return species + " " + movement.move(); }
}
```

```java
// File: code/lld/ch03/generalization/Main.java
package lld.ch03.generalization;

import java.math.BigDecimal;
import java.util.List;

public class Main {
    public static void main(String[] args) {
        System.out.println("== Good hierarchy: substitution works ==");
        List<Payment> payments = List.of(
                new CashPayment(new BigDecimal("500.00"), new BigDecimal("600.00")),
                new CardPayment(new BigDecimal("1200.00"), "4242"),
                new CashPayment(new BigDecimal("300.00"), new BigDecimal("200.00")));
        for (Payment p : payments) System.out.println(p.pay());   // caller only knows Payment

        System.out.println("\n== Guest vs registered customer ==");
        Customer guest = new Customer("Guest-17");
        RegisteredCustomer reg = new RegisteredCustomer("Asha");
        List<Customer> visitors = List.of(guest, reg);   // a RegisteredCustomer IS a Customer
        visitors.forEach(c -> System.out.println(c.browse("headphones")));
        System.out.println(reg.placeOrder("headphones"));
        System.out.println("guest.placeOrder(...) does not compile: guests never inherit ordering");

        System.out.println("\n== Holding instead of extending ==");
        Bird eagle = new Bird("Eagle", MovementStyle.FLY);
        Bird penguin = new Bird("Penguin", MovementStyle.SWIM);
        System.out.println(eagle.move());
        System.out.println(penguin.move());
        penguin.setMovement(MovementStyle.WALK);   // impossible with a subclass
        System.out.println(penguin.move() + " (behaviour swapped at run time)");
    }
}
```

What each part shows:

- `Payment` is abstract, its `pay()` is `final` (the shared workflow), and `authorize()` is abstract (the step that varies). Both subclasses honour every promise of `Payment`, so `Main` loops over `List<Payment>` without caring

which is which. Amounts are `BigDecimal` and compared with `compareTo`, because `double` cannot store values such as `0.10` exactly and money must not drift.

- **Wrong-inheritance fix #1 — the subclass that must refuse something.** If `Guest extends Customer` and `Customer` can place orders, a guest could order, which the requirement forbids. The fix: `Customer` only has what *every* customer can do (browse); ordering moves down to `RegisteredCustomer`.
- **Wrong-inheritance fix #2 — the subclass that only carries a constant.** `CompactSpot`, `LargeSpot`, `HandicappedSpot` whose constructors only pass a different value up are three classes with no new behaviour. That is a field: see the `SpotType` enum in the composition example. A fourth type becomes one enum constant, not a new class.
- **Prefer holding over extending.** `FlyingBird` / `Penguin` subclasses break when a penguin arrives (penguins don't fly). `Bird` *holds* a `MovementStyle` instead, and it can even be swapped at run time — impossible with `extends`.

Output:

```
== Good hierarchy: substitution works ==
CashPayment of 500.00 -> OK, change 100.00
CardPayment of 1200.00 -> OK, card ****4242 approved
CashPayment of 300.00 -> DECLINED (short by 100.00)

== Guest vs registered customer ==
Guest-17 browses 'headphones'
Asha browses 'headphones'
Asha orders headphones
guest.placeOrder(...) does not compile: guests never inherit ordering

== Holding instead of extending ==
Eagle flies
Penguin swims
Penguin walks (behaviour swapped at run time)
```

Trade-offs

	Inheritance (extends)	Holding an object (composition/association)
Reuse	automatic	explicit delegation
Change at run time	no — fixed at compile time	yes — swap the held object
Coupling	tight: subclass sees parent internals ("fragile base class")	loose: only the interface
Number of parents in Java	one class	many interfaces / many fields
Best for	true is-a with different behaviour	varying behaviour, features that combine

When not to use it

- To share a few fields or a helper method ("code reuse" alone is not a reason).
- When a subclass would have to throw `UnsupportedOperationException` (Java's standard "this operation is not supported" error) for an inherited method.
- When the variation is just data (use a field or enum).
- When behaviours need to be mixed (fly + swim + walk) — the class count explodes.

Common mistakes

- Deep hierarchies (more than 2–3 levels) that nobody can follow.
- `Stack extends Vector` style mistakes: the child inherits methods that break its own rules (a JDK `Stack` lets you insert in the middle).
- Arrow direction: the triangle points **at the parent**, not the child.
- Using inheritance between two classes when one can do what the other does only in *some* situations. Generalization needs "always"; for "sometimes", hold a shared interface or a role object instead.

Real-world examples

- `java.util.ArrayList extends AbstractList` (reuses the skeleton implementation).
- `java.io.FileInputStream extends InputStream`; any code taking an `InputStream` accepts it.
- Every Java exception: `IOException extends Exception extends Throwable`, which is why `catch (Exception e)` catches an `IOException`.
- **Counter-example in the JDK:** `java.util.Stack extends Vector` and `java.util.Properties extends Hashtable` are widely cited as inheritance that should have been composition.

In the interview

> **30-second answer:** "Generalization is inheritance — solid line with a hollow triangle at the parent. I use it only when the child passes the substitution test: it can go anywhere the parent goes and never refuses a parent method. A subclass that only passes a constant up becomes an enum field; varying behaviour I hold as an interface instead of extending."

Follow-ups:

- *Q: Why not `CompactSpot extends ParkingSpot`?* — A: It adds no behaviour; a `SpotType` field does the same job and new types are one enum constant.
- *Q: When is inheritance right?* — A: When subclasses behave differently but all keep the parent's promises, like `Payment` → cash/card: both really take money, differently.
- *Q: Can a Java class have two parents?* — A: It can extend only one class but implement many interfaces.

Self-check

- *Q: Which way does the hollow triangle point?* → A: At the parent (general class).
- *Q: Guest cannot order, but `Guest extends Customer` and `Customer.placeOrder()` exists. What principle is broken and how do you fix it?* → A: Substitution (LSP). Move `placeOrder` to `RegisteredCustomer`.

TL;DR

Generalization = "is-a", `extends`. Only after the substitution test. Constants → fields; varying behaviour → hold an interface. Triangle points at the parent.

3.7 Realization (interface implementation)

What it is

Realization means a class *implements* an **interface**. An interface is a named list of operations (a contract) with no instance state. The class promises to provide those operations. In Java: `class EmailNotifier implements Notifier`.

Analogy: a **wall socket standard**. Any appliance whose plug "realizes" the standard works in any socket; the socket does not care who made the appliance.

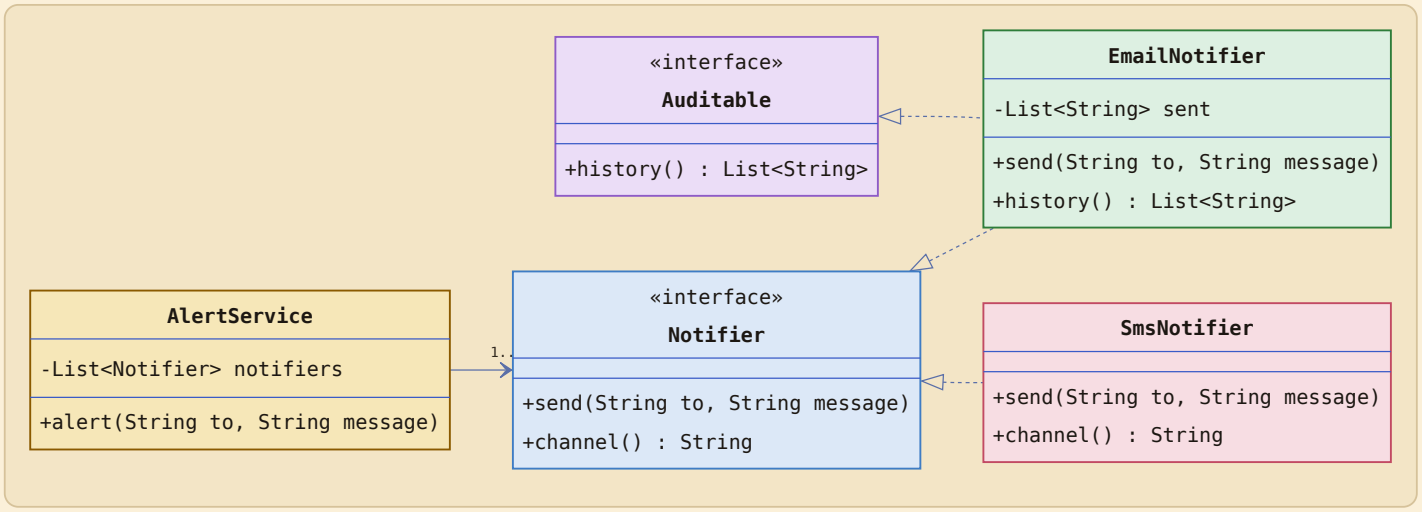
The problem it solves

Callers can depend on the **contract**, not the concrete class. You can add new implementations (SMS, push, WhatsApp) without changing the caller, test with fakes, and give one class several roles (a class may implement many interfaces but extend only one class).

How it works

1. Define an interface with the operations callers need (`send(to, message)`).
2. Each concrete class `implements` it and provides the method bodies.
3. Callers hold / receive the **interface type** (`List<Notifier>`).
4. Since Java 8 an interface may have `default` methods (with a body) and `static` methods; implementers may override defaults.
5. In UML, draw a **dashed line with a hollow triangle pointing at the interface**, and mark the interface with `«interface»`. (A compact alternative is the "lollipop": a small circle on a stick labelled with the interface name.)

Realization looks like generalization on purpose: it is the same "is-a" idea, but nothing but the contract is inherited.



Java example

```java
// File: code/lld/ch03/realization/Notifier.java
package lld.ch03.realization;

/** An interface: a contract of operations with no state. Drawn as <<interface>>. */
public interface Notifier {
    void send(String to, String message);

    /** Java 8+ default method: implementers inherit this unless they override it. */
    default String channel() {
        String n = getClass().getSimpleName();
        return n.contains("$$Lambda") ? "lambda" : n;   // lambdas get generated class names
    }
}
```

```java
// File: code/lld/ch03/realization/Auditable.java
package lld.ch03.realization;

import java.util.List;

public interface Auditable {
    List<String> history();
}
```

```java
// File: code/lld/ch03/realization/EmailNotifier.java
package lld.ch03.realization;

import java.util.ArrayList;
import java.util.List;

/** Realizes TWO interfaces. A class may implement many interfaces but extend only one class. */
public final class EmailNotifier implements Notifier, Auditable {
    private final List<String> sent = new ArrayList<>();

    @Override public void send(String to, String message) {
        String line = "EMAIL to " + to + ": " + message;
        sent.add(line);
        System.out.println("  " + line);
    }

    @Override public List<String> history() { return List.copyOf(sent); }
}
```

```java
// File: code/lld/ch03/realization/SmsNotifier.java
package lld.ch03.realization;

public final class SmsNotifier implements Notifier {
    @Override public void send(String to, String message) {
        String text = message.length() > 20 ? message.substring(0, 20) + "..." : message;
        System.out.println("  SMS to " + to + ": " + text);
    }

    @Override public String channel() { return "SMS"; }   // overrides the default
}
```

```java
// File: code/lld/ch03/realization/AlertService.java
package lld.ch03.realization;

import java.util.List;

/**
 * AlertService is associated with the INTERFACE, not with any concrete class.
 * Adding a PushNotifier later needs no change here.
 */
public final class AlertService {
    private final List<Notifier> notifiers;

    public AlertService(List<Notifier> notifiers) { this.notifiers = List.copyOf(notifiers); }

    public void alert(String to, String message) {
        for (Notifier n : notifiers) {
            System.out.println("via " + n.channel());
            n.send(to, message);
        }
    }
}
```

```java
// File: code/lld/ch03/realization/Main.java
package lld.ch03.realization;

import java.util.List;

public class Main {
    public static void main(String[] args) {
        EmailNotifier email = new EmailNotifier();
        Notifier sms = new SmsNotifier();
        Notifier console = (to, msg) -> System.out.println("  CONSOLE " + to + ": " + msg); // lambda realizes it
too

        AlertService alerts = new AlertService(List.of(email, sms, console));
        alerts.alert("ops@shop.example", "Disk usage above 90 percent on db-1");

        Auditable audit = email;   // same object, seen through its other interface
        System.out.println("Email audit trail: " + audit.history());
    }
}
```

What each part shows: `EmailNotifier` realizes **two** interfaces; `SmsNotifier` realizes one and overrides the `default` method; a **lambda** also realizes `Notifier`, because it has exactly one abstract method (a *functional interface*). `AlertService` holds `List<Notifier>` — an association to the interface — so a new channel needs no change in it. The same `email` object is seen as a `Notifier` by `AlertService` and as an `Auditable` by `Main`.

Output:

```
via EmailNotifier
  EMAIL to ops@shop.example: Disk usage above 90 percent on db-1
via SMS
  SMS to ops@shop.example: Disk usage above 90 ...
via lambda
  CONSOLE ops@shop.example: Disk usage above 90 percent on db-1
Email audit trail: [EMAIL to ops@shop.example: Disk usage above 90 percent on db-1]
```

Trade-offs

	Interface + realization	Abstract class + generalization
Multiple per class	yes	no (single inheritance)
Instance fields	no	yes
Shared code	`default` methods only	any methods, constructors
Best for	roles/capabilities, plug-ins, test seams	a family sharing state and a workflow

When not to use it

- An interface with exactly one implementation that will never vary, and no testing need, is ceremony. Add it when a second implementation or a test double (a fake stand-in used in tests) appears (YAGNI: "you aren't gonna need it", so don't build things before they are needed).
- "Marker" interfaces with no methods are rarely needed now; annotations (`@` tags such as `@Override` that attach information to code) usually serve better.

Common mistakes

- Solid line instead of dashed (that would mean class inheritance).
- Fat interfaces that force implementers to stub (write empty placeholder versions of) methods they do not need (breaks the Interface Segregation Principle, Chapter 4).
- Callers declaring variables with the concrete type (`EmailNotifier n = ...`) and losing the benefit.

Real-world examples

- `java.util.List` realized by `ArrayList` and `LinkedList`; `Comparable`, `Runnable`, `AutoCloseable`.
- **JDBC** (Java Database Connectivity, Java's standard way to talk to SQL databases): `java.sql.Connection` is an interface; each database vendor's driver realizes it, and your code never names the vendor class.
- **Spring:** you inject `PaymentGateway`; the bean (an object Spring creates) may be a Stripe, Razorpay (online payment providers) or mock (fake, for testing) implementation.
- **SLF4J** (logging facade, i.e. one simple front for several logging libraries): your code calls the `Logger` interface; Logback or Log4j (two logging libraries) realizes it.

In the interview

30-second answer: "Realization is a class implementing an interface — dashed line, hollow triangle at the interface. I put an interface wherever behaviour can vary or I need a test double (payment gateway, notifier, pricing strategy), and the rest of the design depends on the interface only."

Follow-ups:

- *Q: Interface or abstract class?* — A: Interface for a capability many unrelated classes can have, or when a class needs several; abstract class when subclasses share state and a fixed workflow. They combine well: interface on top, abstract skeleton class below (like `List` → `AbstractList` → `ArrayList`).
- *Q: Is a lambda a realization?* — A: Yes; a lambda is an instance of a functional interface.

Self-check

- *Q: Draw the difference between generalization and realization.* → A: Same hollow triangle; generalization has a solid line, realization a dashed line.
- *Q: How many interfaces can a Java class implement?* → A: Any number.

TL;DR

Realization = "implements". Dashed line + hollow triangle at the `«interface»`. Depend on the interface, plug in implementations.

3.8 Decision guide: choosing the relationship between two classes

Ask these questions **in order** and stop at the first "yes":

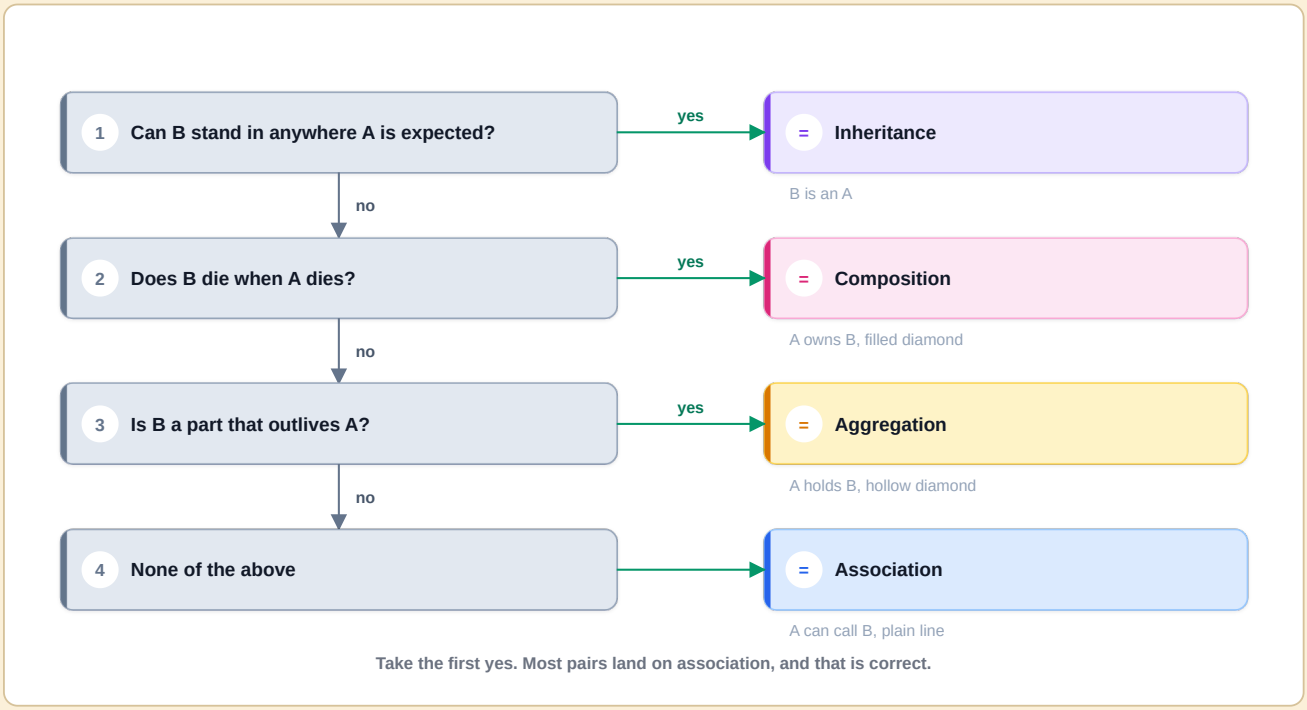


Figure — The four-question decision: inheritance, then composition, then aggregation, else association (course diagram)

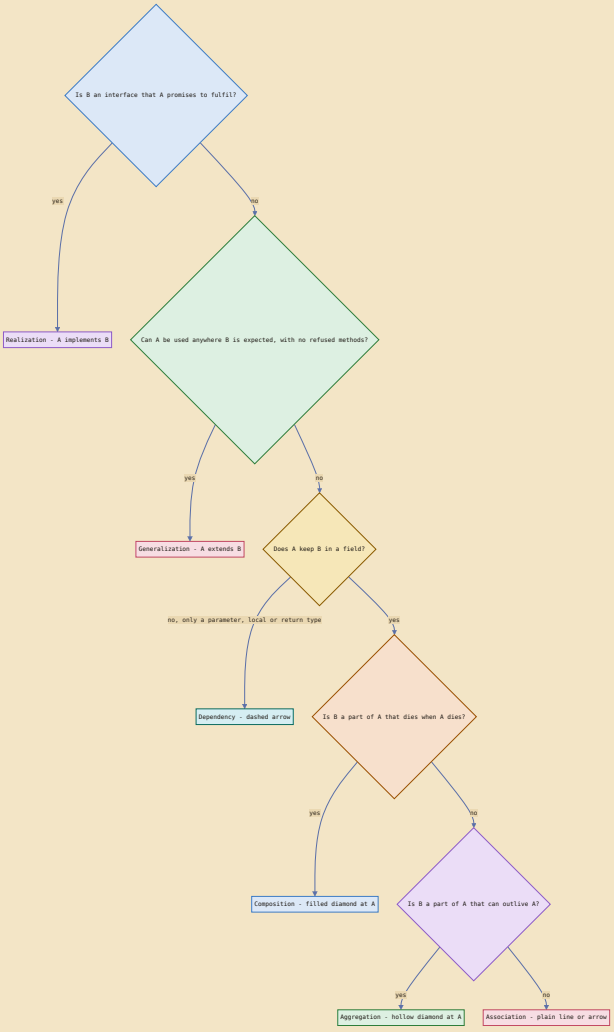
As the figure above shows, inheritance is asked first only because it is the easiest to *rule out*: it needs a strict yes to the substitution test, and most pairs fail it. Most pairs end up as plain association, which is healthy. If nearly every box in your diagram extends another, the design needs another look.

The full guide including the two "light" relationships:



Summary table (keep this one)

Relationship	Phrase	UML line	Java shape	Lifetime	Example
Dependency	A *uses* B	dashed, open arrow → B	B as parameter / local / return / static call	none	`CheckoutService` uses `PaymentGateway`
Association	A *knows* B	solid line (arrow for one-way)	field of type B, B created elsewhere	independent	`Order` → `Customer`
Aggregation	A *has* B (parts live on)	solid, hollow ◇ at A	field/collection, parts passed in	B outlives A	`Airline` ◇— `Aircraft`
Composition	A *owns* B	solid, filled ◆ at A	A creates B, hides it, B not shared	B dies with A	`ParkingFloor` ◆— `ParkingSpot`
Realization	A *implements* B	dashed, hollow △ at B	`implements`	—	`EmailNotifier` ⇢ `Notifier`
Generalization	A *is a* B	solid, hollow △ at B	`extends`	—	`CardPayment` → `Payment`

Mermaid cheat-sheet for these lines (used in all later chapters):

Mermaid	Meaning
`A ..> B`	A depends on B
`A --> B`	A associated with B, navigable A to B
`A -- B`	association (both ways / unspecified)
`A o-- B`	aggregation, A is the whole
`A *-- B`	composition, A is the whole
`B <|.. A`	A realizes interface B
`B <|-- A`	A extends B
`A "1" *-- "1..*" B`	with multiplicities

Common mistakes (all relationships)

- Diamond at the wrong end (it goes at the **whole**).
- Triangle at the wrong end (it goes at the **parent / interface**).
- Lines without multiplicity. A line with no type or count means the design question behind it is still open. Candidates who write the numbers on every line from the very first box report that the interviewer simply stops asking about them — it is cheap to add and removes a whole class of follow-up questions.
- Inheritance used to share data.

In the interview

Say the test **out loud** as you draw each line, e.g. *"When a floor is removed its spots go too, so this is composition"* or *"Cash and card can both be asked to take money, so inheriting from Payment is honest."* If you spot a subclass that only carries a constant, say so and collapse it into a field yourself. Expect two follow-ups: "why not inheritance here?" (answer with the substitution test) and "what if a spot can hold two motorbikes?" (change the multiplicity, then say what it does to the code).

Self-check

- *Q: `Library` and `Member` — which relationship?* → A: Aggregation (or plain association): members exist whether or not the library does.
- *Q: `Flight` and `WeeklySchedule`?* → A: Composition.
- *Q: `ParkingTicket` and `ParkingSpot`?* → A: Association: the ticket refers to the spot but is not a whole made of spots.
- *Q: `Report.render(Formatter f)`?* → A: Dependency.

TL;DR

Realization/generalization for "is-a" (only after the substitution test), composition when parts die with the whole, aggregation when they live on, association when one just knows the other, dependency when it is only used inside a method.

Part B — UML

3.9 What UML is (structural vs behavioural diagrams)

What it is

UML (Unified Modeling Language) is a standard set of symbols for drawing software designs. Because everybody uses the same symbols, a diagram drawn by one engineer can be read by another without a legend. It is maintained by the OMG (Object Management Group); the current version is UML 2.5.1.

UML is **not** a programming language. It does not run and you do not need a tool to use it — a whiteboard is enough. It is an agreement about what, for example, "a line with a filled diamond on one end" means.

A little history explains its size: in the 1990s three competing object-oriented methods (Grady Booch's, James Rumbaugh's OMT and Ivar Jacobson's OOSE) each had their own notation. They were merged into UML so that the industry had one language. Because it had to satisfy three groups of users, UML is large — and every team uses only the subset it needs.

The problem it solves

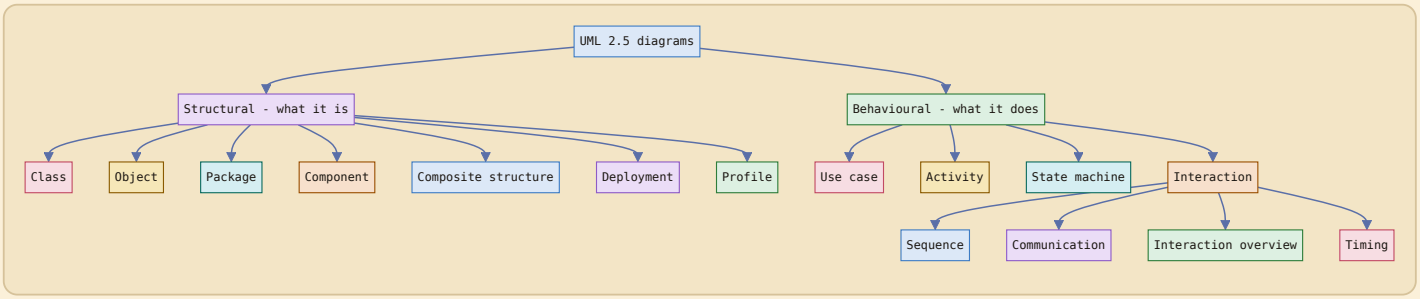
1. **It makes a design visible.** Twelve classes in sentences are hard to hold in your head; twelve boxes with lines are readable in seconds.
2. **It makes decisions explicit.** In a sentence you can stay vague about whether A owns B. On a diagram you must pick a diamond — filled or hollow.
3. **It makes disagreement cheap.** The interviewer can put a finger on one line and ask "why composition here?". That kind of back-and-forth is exactly what a good interview looks like.

How it works — the 14 diagram types

UML 2.5 defines **14 diagram types** in two families:

- **Structural diagrams** show what the system *is made of* — the static parts that exist at any moment.
- **Behavioural diagrams** show what the system *does* over time. A subgroup of behavioural diagrams, **interaction diagrams**, focus on messages between objects.

Family	Diagram	Shows	Interview use
Structural	**Class**	classes, attributes, operations, relationships	**always**
Structural	Object	a snapshot of real objects and their links	rarely (to explain an example)
Structural	Package	how classes group into packages/modules	rarely
Structural	Component	deployable parts and their interfaces	system design rounds
Structural	Composite structure	internal parts of one class	rarely
Structural	Deployment	software on hardware nodes (machines)	system design rounds
Structural	Profile	extensions to UML itself	never
Behavioural	**Use case**	actors and what they can achieve	early, often spoken
Behavioural	**Activity**	steps of one flow with branches	one per key flow
Behavioural	**State machine**	states of one object and allowed transitions	when an object has a lifecycle
Behavioural → interaction	**Sequence**	who calls whom, in time order	on request
Behavioural → interaction	Communication	same messages, drawn on a network of objects	rarely
Behavioural → interaction	Interaction overview	an activity diagram whose nodes are interactions	rarely
Behavioural → interaction	Timing	state changes against a time axis	embedded (software inside devices) / hardware



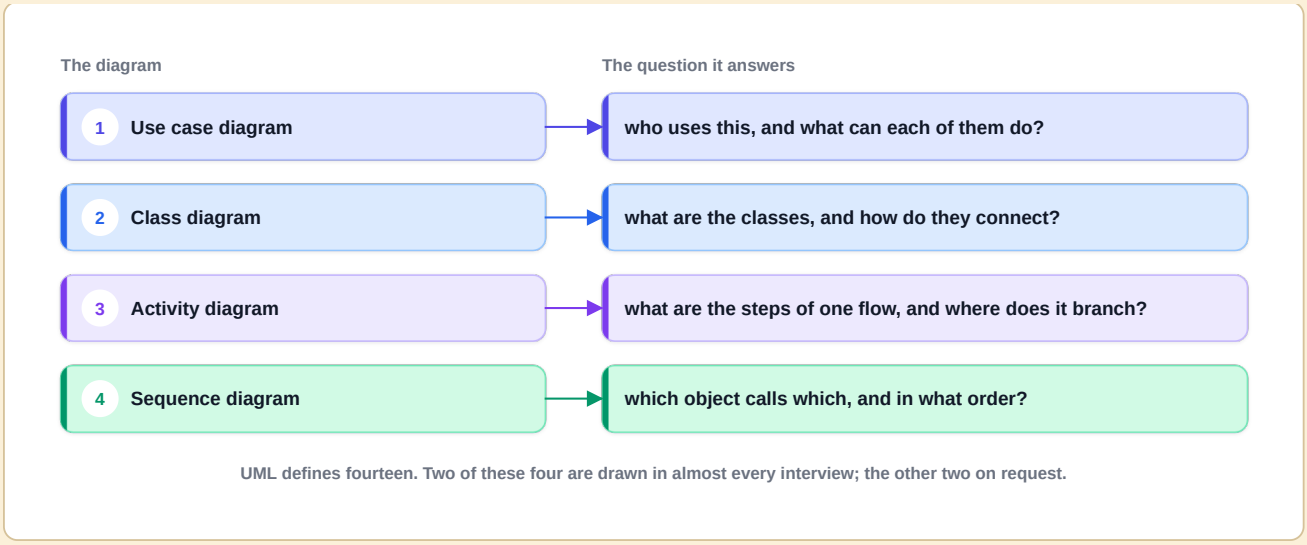


Figure — The four diagrams an OOD interview uses and the question each answers (course diagram)

As the figure above shows, four diagrams carry an object-oriented design interview, and this book adds a fifth that often helps:

1. **Use-case diagram** — who uses the system and what can each of them do? Drawn first, before any class exists.
2. **Class diagram** — what are the classes and how do they connect? *The* answer; the only one that maps directly to code.
3. **Activity diagram** — what are the steps of one flow and where does it branch?
4. **Sequence diagram** — which object calls which, in what order?
5. **State machine diagram** — what states can one object be in, and what moves it between them? (Parking spot, order, elevator, vending machine…)

Trade-offs

Benefit	Cost
Shared vocabulary, no legend needed	Large spec; easy to over-draw
Forces explicit decisions	Takes whiteboard time from code/discussion
Tool support (PlantUML, Mermaid, draw.io, StarUML: diagram-drawing tools)	Diagrams go stale if not kept with code

When not to use it

As documentation that nobody maintains, or in full formal detail on a whiteboard. Many teams today use lightweight "sketch" UML, the C4 model for architecture (a simple style that draws a system at four zoom levels), or text-based tools (Mermaid/PlantUML) kept next to the code. For an interview, UML-lite is exactly right.

Common mistakes

- Thinking the interviewer grades notation. They grade whether your **diagram and your words agree**. If you forget the realization arrow, say "this one implements that one" and draw something. If you draw a hollow diamond where you meant a filled one and then say which you meant, that is a discussion, not a lost point.
- Drawing a line you cannot justify. It hurts more than a missing line.

Real-world examples

- Mermaid diagrams render natively in GitHub and GitLab Markdown (a plain-text formatting language), which is why many design docs (RFCs, written design proposals; ADRs, Architecture Decision Records) embed sequence and class diagrams as text.
- PlantUML is widely used in enterprise wikis (Confluence, a company wiki tool, via plug-ins) for sequence diagrams of service calls.

In the interview

> **30-second answer:** "UML is a standard notation for designs. It has 14 diagrams: structural ones (class, object, component…) describe what the system is made of; behavioural ones (use case, activity, state machine, and the interaction diagrams such as sequence) describe what it does. In an OOD round I use a quick use-case list, one class diagram, and an activity or sequence diagram for the key flow."

Follow-ups:

- *Q: Is UML outdated?* — A: The full formal UML is rarely used, but its core notations (class, sequence, state) remain the shared language of design discussions and appear in Mermaid/PlantUML in modern repos (code repositories). You only need the subset.
- *Q: Which diagram maps to code?* — A: The class diagram.

Self-check

- *Q: Structural or behavioural: sequence diagram?* → A: Behavioural (an interaction diagram).
- *Q: How many UML diagram types exist?* → A: 14 (7 structural, 7 behavioural).

TL;DR

UML = standard symbols, not a language that runs. 14 diagrams: structural (what it is) vs behavioural (what it does). Interviews use class (always), use case, activity, sequence, and state machine when an object has a lifecycle.

3.10 Use-case diagrams

What it is

A **use-case diagram** shows **who** uses the system and **what** each of them can achieve. It has no classes, no methods, no data and no ordering.

- An **actor** is a *role* that interacts with the system, drawn as a stick figure outside the system. Roles, not people: one person can be both a Member and a Librarian; one actor can stand for thousands of users. An actor need not be human — a payment gateway, an email service or a timer ("System") is an actor too.
- A **use case** is one goal an actor can achieve that produces a result the actor cares about, drawn as an oval with a verb phrase: "Borrow a book". "Click the search button" is not a use case; it is a step inside one.
- The **system boundary** is a rectangle around all use cases, labelled with the system's name. Inside = what you build. Outside = everything else.

Analogy: the menu board at a restaurant. It lists what customers can order (use cases) and who can order what (a kids' menu for children), without saying anything about the kitchen.

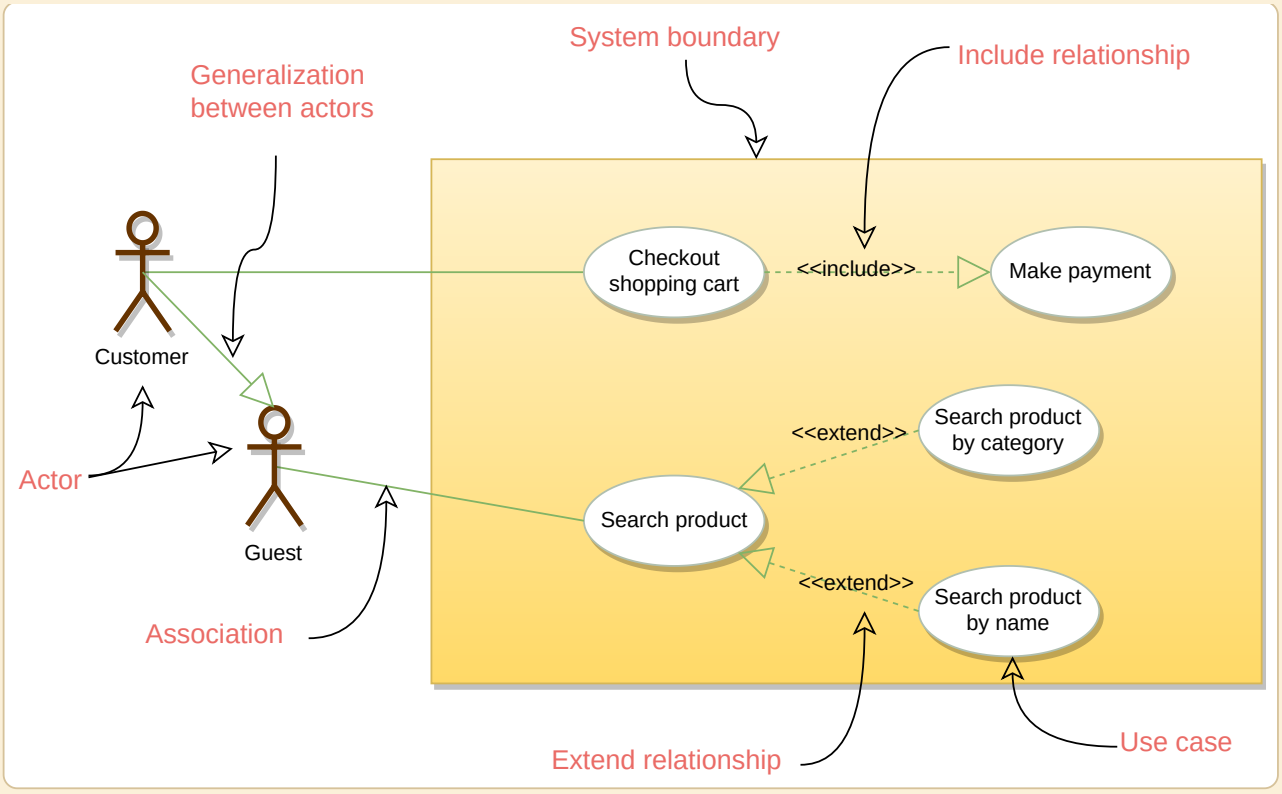

Figure — The parts of a use-case diagram for online shopping: actors (Customer, Guest), use cases, system boundary, generalization between actors, and «include» / «extend» relationships (course diagram)

The problem it solves

It turns a vague one-line question ("design a library") into an **agreed scope**. Drawing the boundary lets you say "these nine things are in; refunds, seasonal pricing and reporting are out" — and the interviewer, who judges whether your answer is complete, has agreed to that list. It also hands you your first classes: **actors usually become classes and use cases usually become methods**.

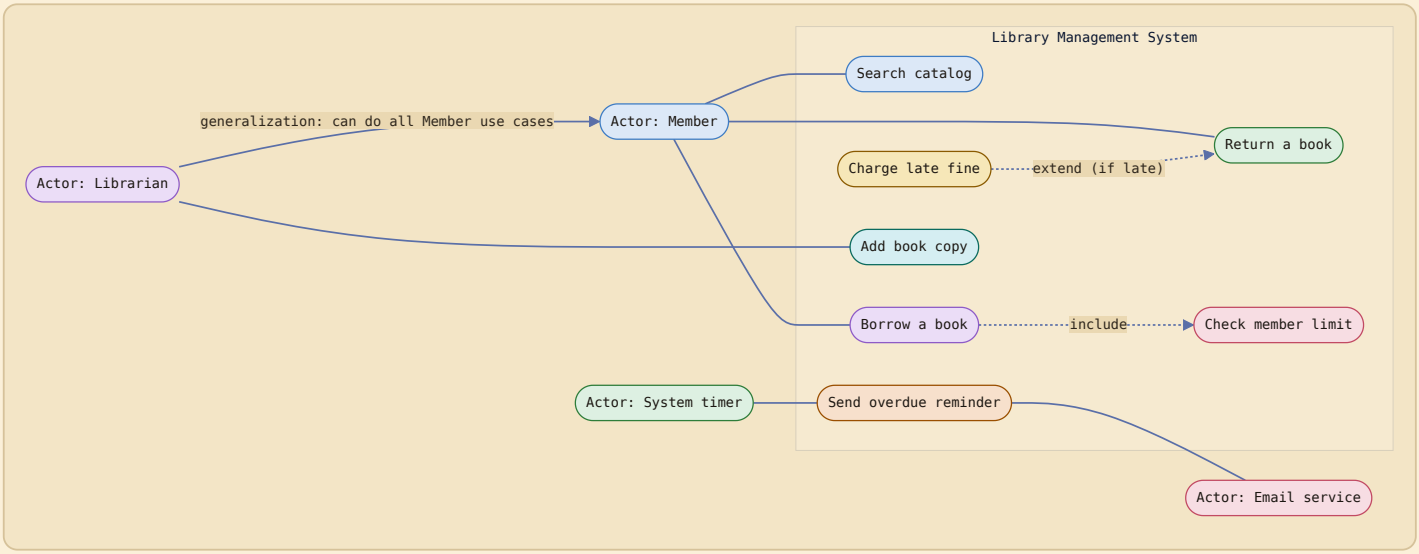
How it works

1. **Find the actors** with four questions:
   - *Who starts something?* (customer, member, player)
   - *Who administers it?* (adds books, sets rates, blocks accounts — the most-forgotten actor, and it brings a whole column of use cases)
   - *Who gets told?* (anyone receiving notifications)
   - *What acts with nobody present?* (timers, background jobs, external services — draw as "System")
2. Put **primary actors** (who start use cases) on the left and **secondary/supporting actors** (whom the system calls, e.g. payment gateway) on the right.
3. Draw the **system boundary** and put each **use case** (verb phrase) inside.
4. Connect actors to their use cases with **plain lines (associations)**.
5. Add relationships between use cases only where they help:
   - **«include»** — *always*. The base use case always performs the included one. Dashed arrow **from the base to the included** case. E.g. *Borrow a book* «include» *Check member's limit*. In code: one method always calls another.
   - **«extend»** — *sometimes*. An optional behaviour that is inserted into the base under a condition, at a named **extension point**. Dashed arrow **from the extending case back to the base**. E.g. *Charge fine* «extend» *Return a book* (only if late). Test: can the base use case complete without it? Yes → extend; no → include.
   - **Generalization** — solid line with a hollow triangle: between actors (a Librarian can do everything a Member can) or between use cases (*Pay by card* is a kind of *Make payment*).
6. Spell the keywords singular: «include», «extend». Older material uses «includes», «extends» or «uses»; «uses» was replaced by «include» long ago.

Reading the course figure above: the Customer→Guest line has its hollow triangle at **Guest**, so it reads "a Customer is a kind of Guest — a Customer can do everything a Guest can, plus check out". The figure also puts

hollow triangles on its «include»/«extend» arrows; strict UML draws both as a dashed line with an **open** arrowhead (the triangle is reserved for generalization). What matters is the direction and the label: «include» points *Checkout shopping cart → Make payment*; both «extend» arrows point from the search variants back to *Search product*.

Mermaid has no native use-case diagram, so this book draws them as flowcharts (stadium shapes = use cases, a subgraph = the boundary):



From use cases to code (see `lld.ch03.library`)

Use-case element	Becomes in Java
Actor *Member*	class `Member`
Actor *Librarian* (generalizes Member)	`class Librarian extends Member`
Borrow a book	`Member.checkout(BookItem, LocalDate)`
«include» *Check member limit*	private `checkLimit()` called on **every** checkout
Return a book	`Member.returnBook(BookItem, LocalDate)`
«extend» *Charge late fine*	`chargeFine(...)` called **only if** the book is late
Add book copy	`Librarian.addCopy(...)`

This is a starting point, not a rule: a use-case method sometimes belongs on a service class instead of the actor class.

Trade-offs

Pro	Con
Fast scope agreement; finds forgotten actors	No ordering, no data — it cannot show *how*
Maps to classes and methods	Easy to bloat with UI (user interface) steps

When not to use it

When the interviewer has already given precise requirements — then a spoken list of actors and their use cases is enough.

Common mistakes

- **Use cases that are UI steps.** Typing a password, pressing submit and seeing a confirmation are all part of a single use case, "Log in". A diagram with dozens of ovals is usually a list of screens, not goals.
- **One actor per person.** A librarian who also borrows is *two roles*. Draw two actors, linked by generalization if one can do everything the other can.
- Reversing the «extend» arrow (it points from the optional case to the base).

- Using «include» for something that only happens sometimes.
- Leaving off the system boundary — the most useful part.

Real-world examples

- **An e-commerce checkout (Amazon-style), modelled:** *Place order* always «include»s *Make payment*; *Apply gift card* «extend»s it only when the customer has one.
- **BookMyShow:** Customer, Theatre admin, Payment gateway and a timer that releases held seats are the actors.

In the interview

> **30-second answer:** "Before classes, I list actors and what each can do, and draw a boundary to agree scope. Actors are roles — including admins, external services and timers. «include» is always, «extend» is sometimes. Actors become my first classes and use cases become methods."

Follow-ups:

- *Q: Is 'make payment' an include or an extend of 'checkout'?* — A: If every checkout requires payment, it is «include». Something like "apply coupon", which checkout can complete without, is «extend».
- *Q: How long should this take?* — A: Three to five minutes, early.

Self-check

- *Q: Which direction does the «include» arrow point?* → A: From the base use case to the included one.
- *Q: Is a payment gateway an actor?* → A: Yes — an external system that interacts with ours (a secondary actor).
- *Q: "Search product by name" and "by category" relate to "Search product" how?* → A: As in the course diagram: optional variants, drawn as «extend» (some modellers draw them as use-case generalization — both are defensible if explained).

TL;DR

Actors (roles, outside) + use cases (goals, inside) + boundary (scope). «include» = always, arrow base→included; «extend» = sometimes, arrow extension→base. Actors → classes, use cases → methods.

3.11 Class diagrams

What it is

A **class diagram** shows the **static structure** of a design: which classes exist, what each holds (attributes), what each can do (operations), and how they connect (relationships with multiplicity). It is the answer to an OOD question and the only UML diagram that maps directly to code.

The problem it solves

It captures the whole design on one page so it can be reviewed, challenged and turned into code. Every other diagram exists either to get you to it (use case) or to check/explain it (activity, sequence, state).

How it works — the class box

A class is a rectangle with three compartments: **name** / **attributes** / **operations**.

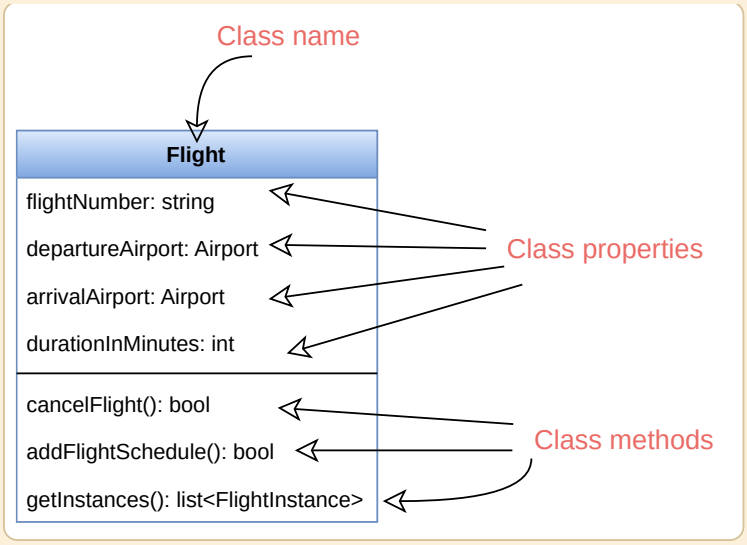


Figure — A class box: name on top, properties (attributes) in the middle, methods (operations) at the bottom, using a Flight class (course diagram)

As in the figure above, attributes are written `name: Type` and operations `name(params): ReturnType`. The full UML syntax is:

```
visibility name : Type [multiplicity] = default      e.g.  - spots : ParkingSpot [1..*]
visibility name(param : Type, ...) : ReturnType      e.g.  + park(v : Vehicle) : Ticket
```

Visibility markers (mapped to Java):

UML	Meaning	Java
`+`	public — anyone	`public`
`-`	private — only this class	`private`
`#`	protected — this class and subclasses	`protected` (Java also allows the same package)
`~`	package — same package only	no modifier (package-private)

Other notation:

Notation	Meaning	Java
Italic name, or `{abstract}` / `«abstract»`	abstract class (one you never create objects of directly) / abstract operation (no body)	`abstract`
`«interface»` above the name	interface	`interface`
`«enumeration»` + literals	enum	`enum`
underlined member	static (class-level)	`static`
`{readOnly}`	cannot change after creation	`final` field
`List<T>` / `T[*]`	collection attribute	`List<T>`

You do **not** have to fill all three compartments. Early in an interview a box with only a name is a perfectly good class. Attributes and operations arrive as the design settles.

In Mermaid, visibility uses the same symbols; `*` after a method means abstract and `$` means static; `<<interface>>`, `<<abstract>>`, `<<enumeration>>` are annotations; generics are written `List~T~`.

How it works — the relationships (all arrow types)

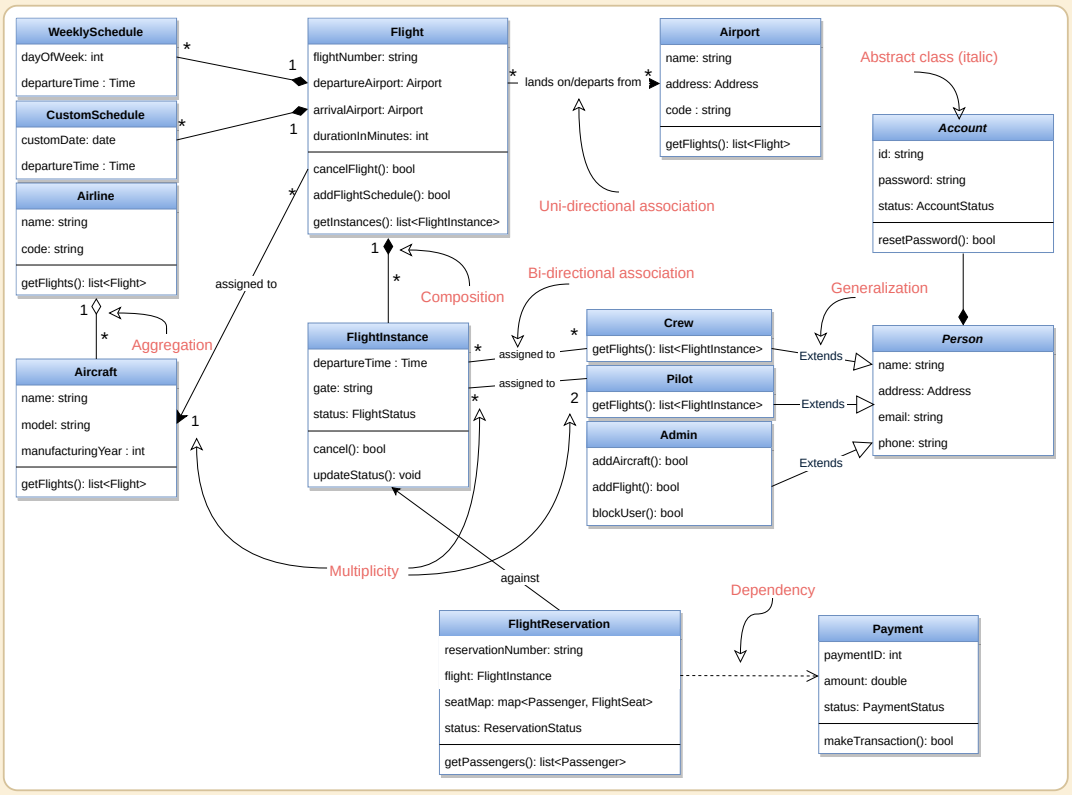

Figure — An airline-system class diagram using every relationship: associations (e.g. Flight to Aircraft, uni-directional), multiplicities (FlightInstance has 2 Pilots), aggregation (Airline–Aircraft), composition (Flight–WeeklySchedule), generalization (Person to Crew/Pilot/Admin) and dependency (course diagram)

The figure above uses the complete vocabulary: the six relationships of Part A (association appearing in both its two-way and one-way form) plus multiplicity. Those are the only symbols a class diagram needs:

Line	Drawn as	Read as	Example from the figure
Association (bi-directional)	solid line	"A and B know each other"	FlightInstance — Pilot, FlightInstance — Crew ("assigned to")
Uni-directional association	solid line, arrowhead at B	"A can call B, not vice versa"	Flight → Airport ("lands on/departs from"), Flight → Aircraft ("assigned to")
Multiplicity	numbers at the line ends: `1`, `*`, `0..1`, `2..4` (a range)	"how many"	FlightInstance `*` — `2` Pilot: each flight instance has exactly 2 pilots, each pilot flies many instances
Aggregation	hollow diamond at the whole	"has-a, part lives on"	Airline `1` ◇— `*` Aircraft
Composition	filled diamond at the whole	"owns, part dies with it"	Flight ◆— WeeklySchedule, Flight ◆— CustomSchedule, Flight ◆— FlightInstance
Generalization	solid line, hollow triangle at parent	"is-a"	Pilot, Crew, Admin → Person
Realization	dashed line, hollow triangle at interface	"implements"	(any `«interface»`)
Dependency	dashed line, open arrowhead	"uses"	FlightReservation ⇢ Payment

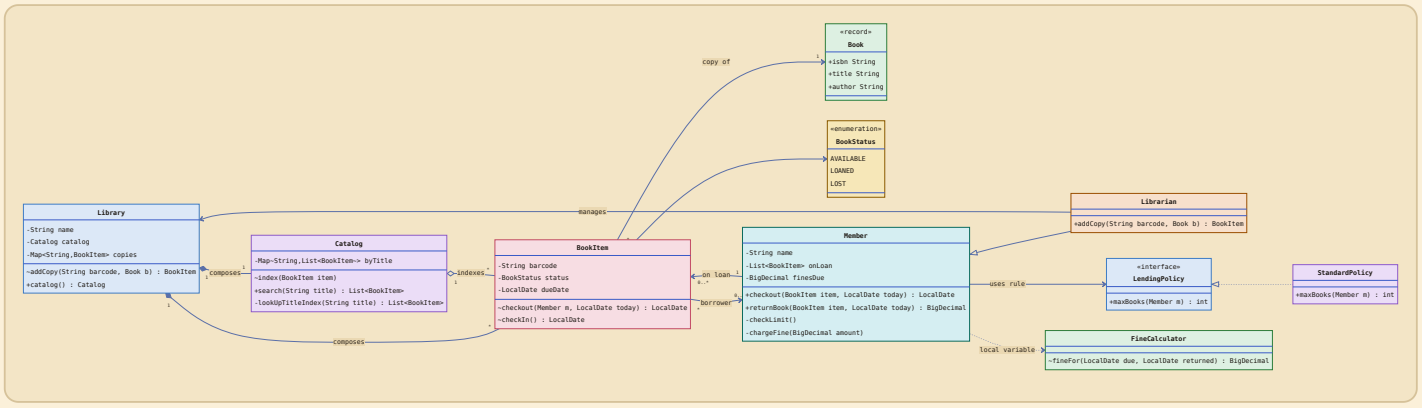
(The figure draws its one-way arrowheads filled; strict UML uses an open arrowhead — see the legend note in 3.1.)

A note on reading the figure: some of its classes carry getters for the "other" direction (e.g. `Aircraft.getFlights()`) even though the line is drawn one-way. Strictly, such a getter makes the association navigable both ways; treat the arrow as "the primary direction", and in your own diagrams keep arrows and fields consistent.

Two extra notations worth recognising:

- **Association class** — a class hanging off an association by a dashed line, holding data about the *link itself* (e.g. `Enrollment{grade}` on Student–Course).
- **Qualified association** — a small box on one end with a key (e.g. `Library [isbn] → Book`), meaning "look up by this key" — in Java a `Map<Isbn, Book>`.

Worked example — the library design (code in `lld.ch03.library`)



Every line type appears: composition (Library ◆ Catalog, Library ◆ BookItem), aggregation (Catalog ◇ BookItem — the index points at copies it does not own), associations with multiplicity, generalization (Librarian → Member), realization (StandardPolicy ⇢ LendingPolicy) and dependency (Member ⇢ FineCalculator). Visibility `~` marks package-private methods such as `BookItem.checkout`, which only `Member` (same package) may call. The Java code is listed in full in 3.12.

How much detail to draw

- **Every class gets a box and a name.** 10–15 boxes is a full answer.
- **Attributes only where they matter** — the two or three fields that carry the design.
- **Operations only where they are interesting** — the methods that appear in your flows.
- **Every line gets a relationship type and a multiplicity.** This is the part not to skip.
- If short of time, **drop attributes before relationships**. Boxes with only names but precise, labelled lines already describe a design; richly detailed boxes joined by vague lines do not.

Trade-offs

Detailed diagram	Sketch diagram
Near code-ready; fewer surprises later	Faster; easier to change during discussion
Takes 10+ minutes	Leaves details for the coding phase

When not to use it

It does not show *order* or *time* — use sequence/activity/state diagrams for behaviour.

Common mistakes

- Unlabelled lines (no type, no multiplicity).
- Diamonds/triangles at the wrong end.
- Listing every getter/setter and `String` field.
- Associations drawn in the diagram that do not exist as fields in the code (or vice versa).

Real-world examples

- IntelliJ IDEA (Ultimate), a popular Java IDE (code editor with build and run tools), can generate class diagrams from code; many teams use them to explore unfamiliar modules.
- JPA entity diagrams (ER-style, i.e. entity-relationship pictures of database tables) are essentially class diagrams with multiplicities (`@OneToMany` = `1..*`).

In the interview

> **30-second answer:** "I start with named boxes from the nouns and actors, then draw every line with a type and multiplicity, saying the lifetime/substitution test aloud. I add only the attributes and methods that drive the key flows. `+ - # ~` for visibility, italics or «abstract» for abstract, «interface» for interfaces."

Follow-ups:

- *Q: What does `#` mean and what is the Java nuance?* — A: Protected. In Java, protected is also visible to classes in the same package, which UML's `#` does not imply.
- *Q: How do you show a static method?* — A: Underline it (Mermaid: `$` suffix).

Self-check

- *Q: `~` means?* → A: Package visibility (Java's default, no modifier).
- *Q: What is the one test for aggregation vs composition?* → A: Imagine the whole is gone — is the part still meaningful by itself?

TL;DR

Box = name / attributes / operations with `+ - # ~`. Seven lines: association (± arrow), aggregation ◇, composition ◆, generalization (solid △), realization (dashed △), dependency (dashed arrow), plus multiplicity on every line.

3.12 Sequence diagrams

What it is

A **sequence diagram** shows **which object calls which, and in what order**, for one scenario. Objects run across the top; **time runs down the page**.

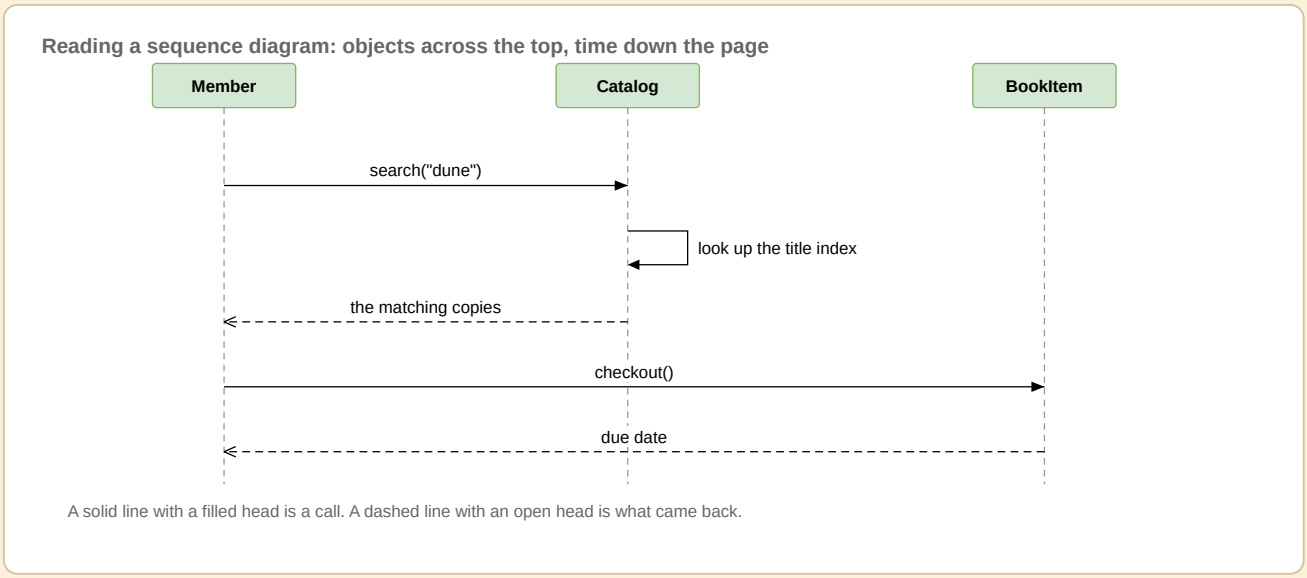


Figure — A member searches the catalog for "dune" and borrows a copy: lifelines, a self-call on Catalog, calls with filled arrowheads and dashed returns (course diagram)

The problem it solves

A class diagram says objects *can* talk; a sequence diagram shows what they *actually say* and in which order. It is the right diagram when the order is easy to get wrong (reserve seat → take payment → confirm — any other order is a bug, and the diagram is the argument for this one), when several objects take part in one flow (two objects need no diagram; five usually do), or when you are explaining a class diagram you have already drawn.

How it works — the notation

Element	Drawn as	Meaning
Participant / lifeline	box at top + dashed vertical line	one *object* (strictly `catalog : Catalog`; most people just write the class name)
Actor	stick figure at top	a user or external system starting the flow
Synchronous message	solid line, **filled** arrowhead	a call; the caller waits for it to finish
Asynchronous message	solid line, **open** arrowhead	fire-and-forget; the caller continues (events, queues: lists of messages waiting to be processed)
Return (reply)	dashed line, open arrowhead	the value coming back — draw only when it matters
Self-message	arrow looping back to the same lifeline	the object calls its own method
Activation bar (execution specification)	thin rectangle on a lifeline	the object is busy executing
Create message	dashed arrow to the new object's box, often labelled «create»	the object is created at that moment
Destruction	**X** at the end of a lifeline	the object is destroyed
Combined fragment	labelled box around messages	control logic: see below

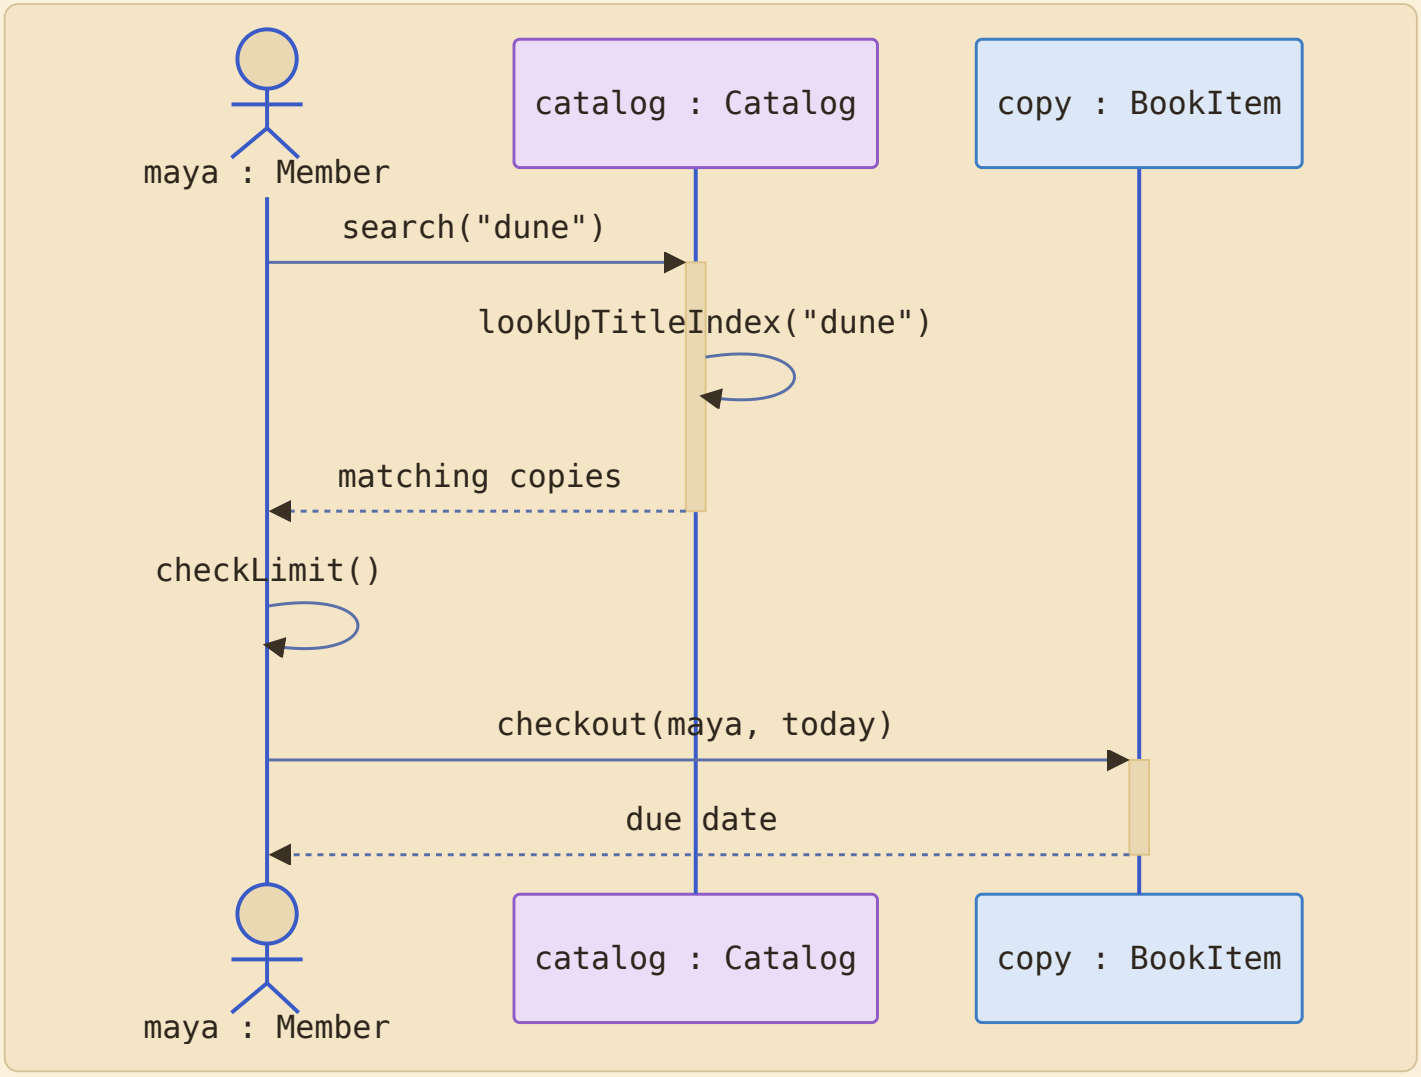
Combined fragments (the box's top-left label is the *operator*; conditions called *guards* are in `[ ]`):

Operator	Meaning	Java equivalent
`alt`	alternatives, one runs (sections split by dashed lines, each with a guard, last can be `[else]`)	`if / else if / else`
`opt`	optional, runs only if the guard is true	`if` without `else`
`loop`	repeats while the guard holds (`loop [for each item]`)	`for` / `while`
`par`	sections run in parallel	threads (independent lines of execution) / `CompletableFuture` (a result that arrives later from background work)
`break`	if guard true, run this and leave the enclosing fragment	early `return` / `break`
`critical`	atomic region (runs as one indivisible step), no interleaving	`synchronized` (Java keyword: one thread at a time) / lock
`ref`	reference to another diagram	calling a helper flow

(UML also has `neg`, `strict`, `seq`, `assert`, `ignore` and `consider`; you will not need them in an interview.)

On a whiteboard, activation bars and fragments are both optional and usually skipped: lifelines, calls, the returns that matter and self-calls are enough. They are shown in full here so you can read them when you meet them.

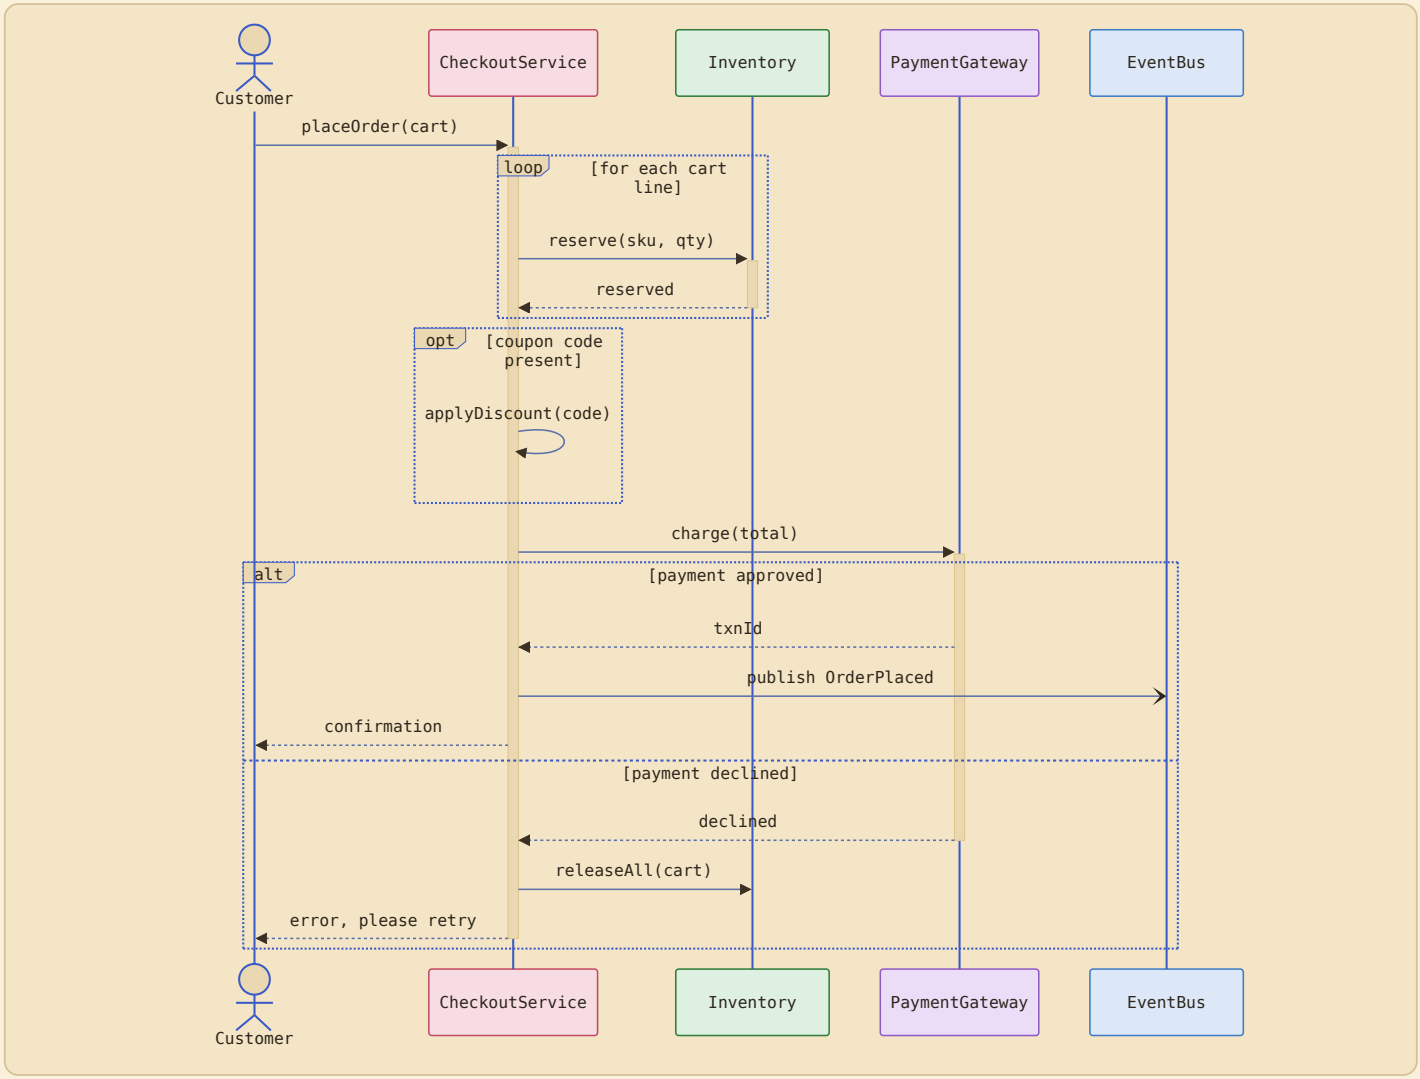
Example 1 — the library checkout, matching the Java code



Four things are worth noticing (the same as in the course figure above):

1. **The first message starts the flow** — a flow is always kicked off from outside the objects shown; here the member calls `search`.
2. **The catalog calls itself** — looking up the title index needs no other object, so the arrow loops back.
3. **Only two returns are drawn** — the copies and the due date; other calls return nothing worth naming.
4. **The member talks to the copy directly** — borrowing goes straight to `BookItem`, not back through `Catalog`. No other diagram shows this choice, and an interviewer can question it simply by tapping that arrow.

Example 2 — all fragments and async messages (checkout with payment)



Here `->>` is a synchronous call, `-->>` a reply, and `-)` an **asynchronous** message: publishing an event does not wait for subscribers. (An `EventBus` is an object that delivers each published event to everyone subscribed to it; `sku` is a stock-keeping unit, a product's ID. Queues and asynchronous messaging are explained in System Design Fundamentals.) The order is the point of the diagram: reserve stock *before* charging, and release it if the charge fails.

Java code for Example 1 (`lld.ch03.library`)

```java
// File: code/lld/ch03/library/Book.java
package lld.ch03.library;

/** The title (one per ISBN). Many physical copies (BookItem) point at one Book. */
public record Book(String isbn, String title, String author) { }
```

```java
// File: code/lld/ch03/library/BookStatus.java
package lld.ch03.library;

public enum BookStatus { AVAILABLE, LOANED, LOST }
```

```java
// File: code/lld/ch03/library/BookItem.java
package lld.ch03.library;

import java.time.LocalDate;
import java.util.Optional;

/** One physical copy. Association BookItem * --> 1 Book, and 0..1 borrower. */
public final class BookItem {
    static final int LOAN_DAYS = 14;

    private final String barcode;
    private final Book book;
    private BookStatus status = BookStatus.AVAILABLE;
    private Member borrower;      // 0..1
    private LocalDate dueDate;    // set only while LOANED

    public BookItem(String barcode, Book book) {
        this.barcode = barcode;
        this.book = book;
    }

    /** Called by Member. Returns the due date: the one return the sequence diagram draws. */
    LocalDate checkout(Member m, LocalDate today) {
        if (status != BookStatus.AVAILABLE) {
            throw new IllegalStateException(barcode + " is " + status);
        }
        status = BookStatus.LOANED;
        borrower = m;
        dueDate = today.plusDays(LOAN_DAYS);
        return dueDate;
    }

    LocalDate checkIn() {
        if (status != BookStatus.LOANED) throw new IllegalStateException(barcode + " is not on loan");
        LocalDate due = dueDate;
        status = BookStatus.AVAILABLE;
        borrower = null;
        dueDate = null;
        return due;
    }

    public String barcode() { return barcode; }
    public Book book() { return book; }
    public BookStatus status() { return status; }
    public Optional<Member> borrower() { return Optional.ofNullable(borrower); }

    @Override public String toString() { return barcode + "[" + book.title() + ", " + status + "]"; }
}
```

```java
// File: code/lld/ch03/library/Catalog.java
package lld.ch03.library;

import java.util.ArrayList;
import java.util.HashMap;
import java.util.List;
import java.util.Locale;
import java.util.Map;

/** An index over copies. It aggregates BookItems: it points at them but does not create or own them. */
public final class Catalog {
    private final Map<String, List<BookItem>> byTitle = new HashMap<>();

    void index(BookItem item) {
        byTitle.computeIfAbsent(key(item.book().title()), k -> new ArrayList<>()).add(item);
    }

    public List<BookItem> search(String title) {
        List<BookItem> hits = lookUpTitleIndex(title);   // self-call in the sequence diagram
        return List.copyOf(hits);
    }

    private List<BookItem> lookUpTitleIndex(String title) {
        return byTitle.getOrDefault(key(title), List.of());
    }

    private static String key(String title) { return title.toLowerCase(Locale.ROOT); }
}
```

```java
// File: code/lld/ch03/library/LendingPolicy.java
package lld.ch03.library;

/** Realized by concrete policies. Member depends on this interface, not on a class. */
public interface LendingPolicy {
    int maxBooks(Member m);
}
```

```java
// File: code/lld/ch03/library/StandardPolicy.java
package lld.ch03.library;

public final class StandardPolicy implements LendingPolicy {
    @Override public int maxBooks(Member m) { return m instanceof Librarian ? 10 : 2; }
}
```

```java
// File: code/lld/ch03/library/FineCalculator.java
package lld.ch03.library;

import java.math.BigDecimal;
import java.time.LocalDate;
import java.time.temporal.ChronoUnit;

/** Used as a local helper inside Member.returnBook: a dependency, not a field. */
final class FineCalculator {
    private static final BigDecimal PER_DAY = new BigDecimal("5.00");

    BigDecimal fineFor(LocalDate due, LocalDate returned) {
        long late = ChronoUnit.DAYS.between(due, returned);
        return late > 0 ? PER_DAY.multiply(BigDecimal.valueOf(late)) : BigDecimal.ZERO.setScale(2);
    }
}
```

```java
// File: code/lld/ch03/library/Member.java
package lld.ch03.library;

import java.math.BigDecimal;
import java.time.LocalDate;
import java.util.ArrayList;
import java.util.Collections;
import java.util.List;

/**
 * Actor "Member" becomes a class; its use cases become methods:
 *   Borrow a book  -> checkout(...)  which always <<include>>s the limit check
 *   Return a book  -> returnBook(...) which is sometimes <<extend>>ed by "charge a fine"
 */
public class Member {
    private final String name;
    private final LendingPolicy policy;             // association to an interface
    private final List<BookItem> onLoan = new ArrayList<>();

// File: code/lld/ch03/library/Librarian.java
package lld.ch03.library;

/** Generalization between actors: a librarian can do everything a member can, plus more. */
public final class Librarian extends Member {
    private final Library library;

    public Librarian(String name, LendingPolicy policy, Library library) {
        super(name, policy);
        this.library = library;
    }

    public BookItem addCopy(String barcode, Book book) { return library.addCopy(barcode, book); }
}
```

```java
// File: code/lld/ch03/library/Library.java
package lld.ch03.library;

import java.util.LinkedHashMap;
import java.util.Map;

/**
 * The system boundary made concrete. Library composes its Catalog (created here,
 * never shared) and composes its copies (only a Library creates a BookItem it registers).
 */
public final class Library {
    private final String name;
    private final Catalog catalog = new Catalog();                  // composition
    private final Map<String, BookItem> copies = new LinkedHashMap<>();

    public Library(String name) { this.name = name; }

    BookItem addCopy(String barcode, Book book) {
        BookItem item = new BookItem(barcode, book);
        copies.put(barcode, item);
        catalog.index(item);
        return item;
    }

    public Catalog catalog() { return catalog; }
    public String name() { return name; }
}
```

```java
// File: code/lld/ch03/library/Main.java
package lld.ch03.library;

import java.math.BigDecimal;
import java.time.LocalDate;
import java.util.List;

public class Main {
    public static void main(String[] args) {
        LendingPolicy policy = new StandardPolicy();
        Library lib = new Library("Town Library");
        Librarian lee = new Librarian("Lee", policy, lib);

        Book dune = new Book("978-0441013593", "Dune", "Frank Herbert");
        Book hobbit = new Book("978-0547928227", "The Hobbit", "J.R.R. Tolkien");
        lee.addCopy("B-1", dune);
        lee.addCopy("B-2", dune);
        lee.addCopy("B-3", hobbit);
        lee.addCopy("B-4", hobbit);

        Member maya = new Member("Maya", policy);
        LocalDate day1 = LocalDate.of(2026, 3, 1);

        // Sequence: member -> catalog.search -> (self) lookUpTitleIndex -> copies; member -> copy.checkout -> due
        List<BookItem> hits = lib.catalog().search("dune");
        System.out.println("search(\"dune\") -> " + hits);
        LocalDate due = maya.checkout(hits.get(0), day1);
        System.out.println("Maya borrowed B-1, due " + due);
        maya.checkout(lib.catalog().search("the hobbit").get(0), day1);
        System.out.println("Maya on loan: " + maya.onLoan());

        try {
            maya.checkout(hits.get(1), day1);   // <<include>> limit check fires
        } catch (IllegalStateException e) {
            System.out.println("Blocked: " + e.getMessage());
        }

        try {
            new Member("Omar", policy).checkout(hits.get(0), day1);   // copy already LOANED
        } catch (IllegalStateException e) {
            System.out.println("Blocked: " + e.getMessage());
        }

        BigDecimal onTime = maya.returnBook(hits.get(0), day1.plusDays(10));
        System.out.println("Returned B-1 on time, fine = " + onTime);
        BookItem hobbitCopy = maya.onLoan().get(0);
        BigDecimal late = maya.returnBook(hobbitCopy, day1.plusDays(17));   // <<extend>> fine applies
        System.out.println("Returned " + hobbitCopy.barcode() + " 3 days late, fine = " + late
                + ", Maya owes " + maya.finesDue());
        System.out.println("Librarian limit: " + policy.maxBooks(lee) + ", member limit: " +
policy.maxBooks(maya));
    }
}
```

Output:

```
search("dune") -> [B-1[Dune, AVAILABLE], B-2[Dune, AVAILABLE]]
Maya borrowed B-1, due 2026-03-15
Maya on loan: [B-1[Dune, LOANED], B-3[The Hobbit, LOANED]]
Blocked: Maya already has 2 books (limit)
Blocked: B-1 is LOANED
Returned B-1 on time, fine = 0.00
Returned B-3 3 days late, fine = 15.00, Maya owes 15.00
Librarian limit: 10, member limit: 2
```

Check the diagram against the code: every arrow is a real method — `Catalog.search`, `Catalog.lookUpTitleIndex`, `Member.checkLimit`, `BookItem.checkout`. **If a message has no method, your class diagram is missing one** — the same check the activity diagram does, from another direction.

Trade-offs

Good at	Poor at
Order of calls, who talks to whom	Branch-heavy flows (nested `alt` becomes unreadable)
Showing sync vs async	Showing the whole design
Spotting missing methods	Being quick to draw — each message is a line

When not to use it

- For a flow with three or more decisions: use an **activity diagram**. A second `alt`/`opt` box on the same diagram is the warning sign.
- Unprompted in most OOD interviews — it costs time you need for the class diagram.

Common mistakes

- Drawing a return for every call — the diagram doubles in height and says nothing more.
- Messages that are not methods on the receiving class.
- Mixing up arrowheads: filled = sync call, open solid = async, dashed = reply.
- Drawing classes instead of the specific objects when two objects of the same class take part (e.g. `from : Account`, `to : Account`).

Real-world examples

- **OAuth 2.0 / OpenID Connect** (standard protocols for "log in with another account") login flows (browser → app → authorization server → token endpoint) are almost always documented as sequence diagrams.
- **Payment integrations** (Stripe, Razorpay) document "create order → redirect → webhook" (a webhook is an HTTP call the provider makes to your server when something happens) as sequence diagrams, with the webhook as an asynchronous message.
- **Microservice sagas** (microservices are small, separately deployed services; a saga is a multi-step transaction in which every step has an "undo"; e.g. a travel booking that reserves a flight, a hotel and a car) are usually explained with sequence diagrams that show the compensating "undo" calls when one step fails.

In the interview

> **30-second answer:** "A sequence diagram shows one scenario: objects across the top, time downwards. Solid filled arrows are sync calls, open arrows async, dashed arrows returns. `alt` / `opt` / `loop` fragments show if/else, if, and loops. I keep it to three or four objects and six to eight messages, and check that every arrow is a method on my class diagram."

Follow-ups:

- *Q: Sync vs async message?* — A: Sync: caller blocks until the callee returns (a normal method call). Async: caller continues immediately (a queue message, event, `CompletableFuture`).
- *Q: When would you use a sequence diagram over an activity diagram?* — A: When the interesting part is *who calls whom* in what order; activity when the interesting part is branching.

Self-check

- *Q: What does a thin rectangle on a lifeline mean?* → A: An activation bar — the object is executing.
- *Q: Which fragment models "retry up to 3 times"?* → A: `loop [attempt <= 3]`.
- *Q: How do you show that `Order` creates a `Payment` mid-flow?* → A: A create message (dashed arrow, «create») pointing to the new lifeline's box, which starts lower on the page.

TL;DR

Objects across, time down. Filled = sync call, open = async, dashed = return. `alt` = if/else, `opt` = if, `loop` = loop, `par` = parallel. Keep it small and check each arrow is a real method.

3.13 Activity diagrams

What it is

An **activity diagram** traces **a single flow end to end**, marking each point where it **branches** (and any steps that run in parallel). Where a class diagram captures the design at rest, an activity diagram follows one route through it. Among UML diagrams it is the closest thing to a flowchart, so nearly everyone can follow it — which also makes a careless one easy to produce.

The problem it solves

It makes the business logic of a flow — every `if`, `unless`, `otherwise` in the requirements — visible and checkable. Its best interview use is as a **test of your class diagram**: walk the flow action by action and ask *which class does this?* If an action has no home, you have found a missing class — on the whiteboard, not in the code.

How it works — the symbols

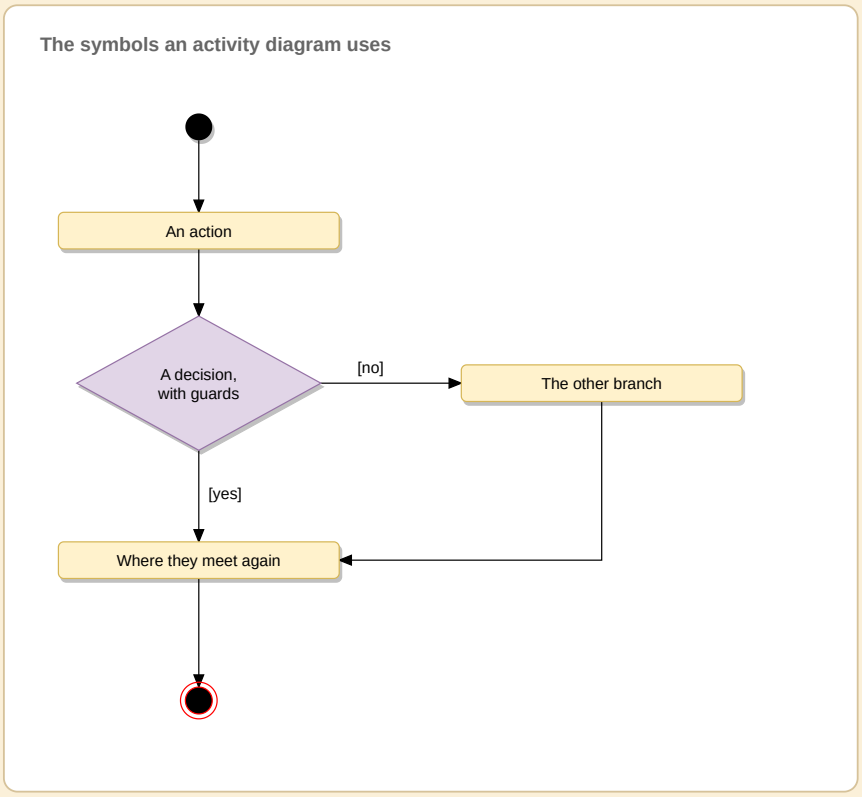

Figure — The core activity-diagram symbols: start, action, a decision with [yes]/[no] guards, the other branch, where the branches meet again, and the end (course diagram)

Symbol	Drawn as	Meaning
Initial node (start)	filled black circle	where the flow begins (draw exactly one; UML technically allows several, but one keeps the diagram readable)
Action	rounded rectangle with a verb phrase	one step: "System calculates the parking fee"
Control flow	arrow	time runs along the arrows
Decision	diamond, each outgoing arrow has a **guard** `[condition]`	a branch; guards must cover every case (use `[else]`)
Merge	diamond (or arrows meeting one node)	branches come back together
Fork	thick bar, one arrow in, many out	the following actions run **in parallel**
Join	thick bar, many in, one out	wait until **all** parallel actions finish
Activity final (end)	filled circle inside a ring (bullseye)	the whole activity stops; there may be several ("payment failed", "gate opened")
Flow final	circle with an X	only *this* branch stops; others continue
Swimlane (partition)	vertical or horizontal lanes labelled with an actor/class	*who* performs each action
Object node	rectangle	data passed between actions (e.g. `[Ticket]`)
Send / receive signal	convex / concave pentagon	sending or waiting for an event

Steps to draw one:

1. Pick **one** flow, ideally the one with an interesting branch. A requirement containing "if", "unless" or "otherwise" describes a branch — draw that.
2. Start node → actions in the language of the problem ("The system calculates the fee", **not** "call `calculateFee()`").
3. At each decision, draw every outcome with a guard.
4. Use fork/join only when steps really happen at the same time. Most interview flows do not need them.
5. Add swimlanes if it helps to show which actor/class does each step.
6. End node(s).

Example 1 — online shopping (course)

Every activity diagram has the shape of the small symbols figure above, and it reads as a single sentence: *begin, perform an action, ask a question, follow one of two paths, merge, end.* Here is a bigger example:

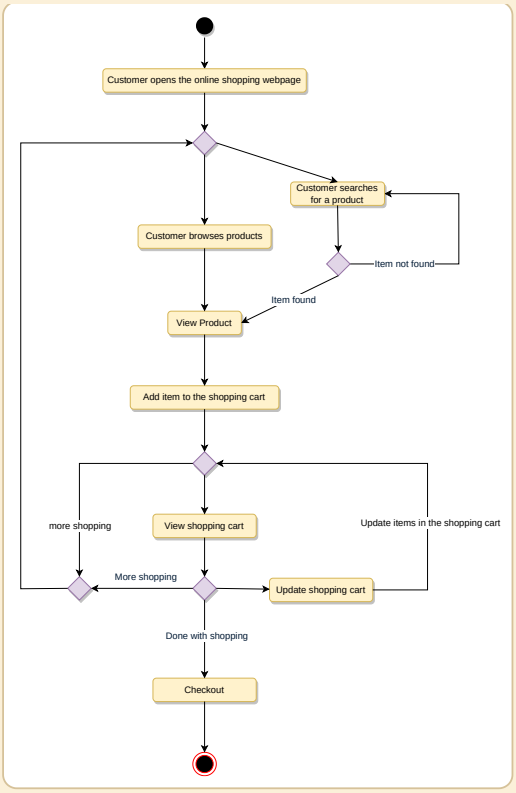

Figure — A customer shopping online: search, item found or not found, add to cart, view/update the cart, more shopping or checkout (course diagram)

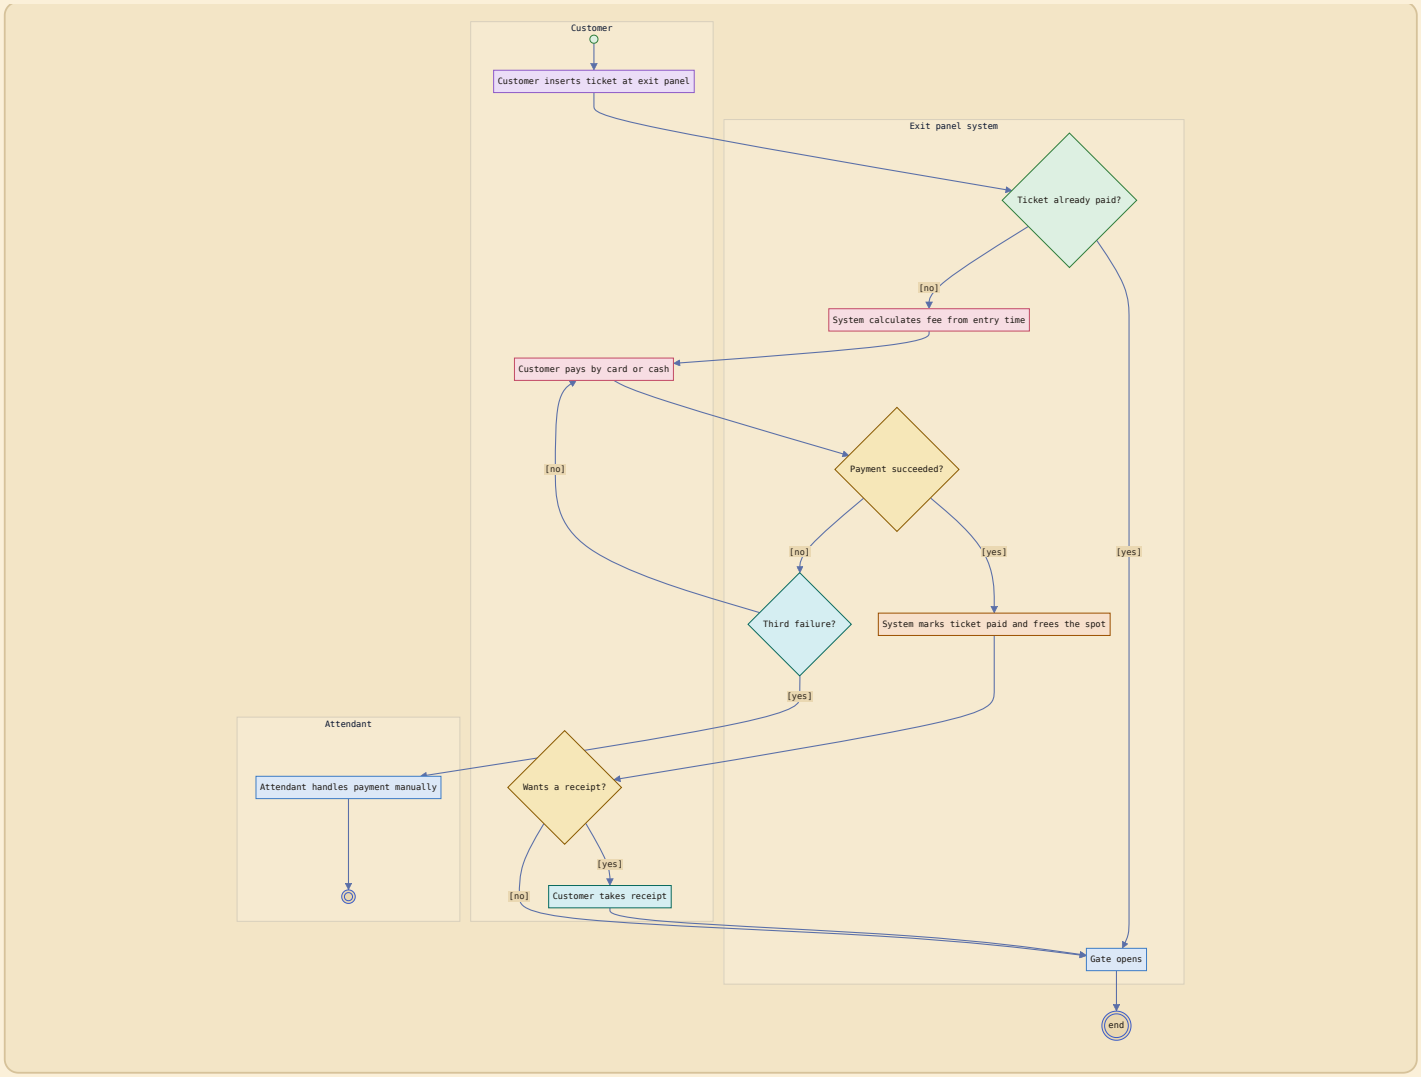
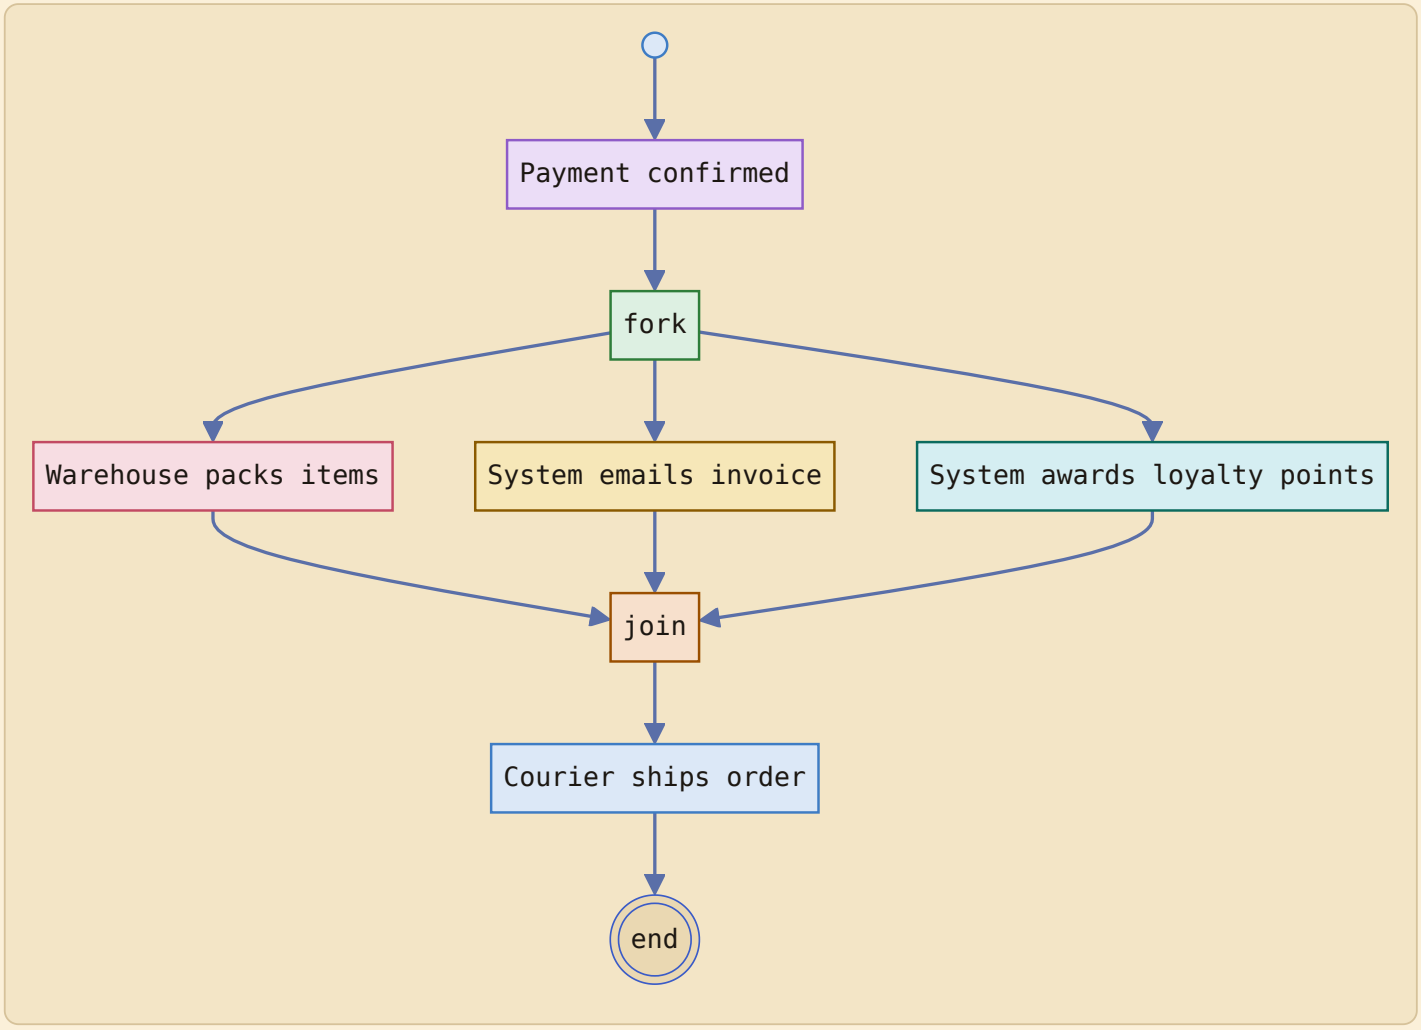
Example 2 — pay at the parking exit (three decisions, with swimlanes)

Three decisions appear in the Parking Lot case study (Chapter 14): *is the ticket paid already?*, *did payment go through?* and *does the customer ask for a receipt?* Every one traces back to a requirement. Below it is drawn with swimlanes (subgraphs), a retry loop, and a hand-off to an attendant once three attempts fail:



Customer
Customer inserts ticket at exit panel
Exit panel system
Ticket already paid?
[no]
System calculates fee from entry time
Customer pays by card or cash
[no]
Payment succeeded?
[no]
[yes]
[yes]
Third failure?
System marks ticket paid and frees the spot
[yes]
Attendant
Attendant handles payment manually
Wants a receipt?
[yes]
[no]
Customer takes receipt
Gate opens
end

Example 3 — fork and join (order fulfilment)



After the **fork** bar the three actions happen in parallel; the **join** waits for all three before shipping.

Activity vs sequence diagram

	Activity diagram	Sequence diagram
Shows	a process as a series of steps	objects sending messages to each other
Branches	natural: decisions with guards	awkward: nested `alt` fragments
Names	actions, in business language	objects and method calls
Use when	the flow has interesting branches	the order of calls is the interesting part
Answers	"what happens?"	"who calls whom?"

Rule of thumb: a flow with **three branches** calls for an activity diagram; **four objects** whose call order is easy to confuse call for a sequence diagram.

Trade-offs

Pro	Con
Anyone (including non-engineers) can read it	Does not show which object does what unless you add swimlanes
Great at branches and parallelism	Big flows sprawl quickly

When not to use it

For a straight-line flow ("customer pays and leaves") — there is nothing to decide, so the picture adds nothing. For object-to-object call order, use a sequence diagram.

Common mistakes

- **A diamond with only one exit.** If only one outcome is possible, nothing is being decided — draw the missing branch or remove the diamond.
- **Actions written as code** ("call `calculateFee()`"). Keep it in the language of the problem so it can be checked against the requirements.
- Guards that do not cover every case (`[amount > 100]` and `[amount < 100]` — what about exactly 100?).
- Using fork/join for steps that are merely sequential.

Real-world examples

- **BPMN** (Business Process Model and Notation), used by workflow engines (software that runs business processes step by step) such as Camunda, is a close cousin of UML activity diagrams, with lanes and gateways.
- **CI/CD pipelines** (Continuous Integration / Continuous Delivery: automatically building, testing and deploying code on every change; e.g. GitHub Actions, Jenkins) are activity diagrams in practice: parallel jobs (fork), a job that `needs:` several others (join), conditional steps (guards).
- Food-delivery apps (Swiggy, Zomato, DoorDash) typically let the restaurant prepare the food while a delivery partner is being assigned — two parallel branches that join at "order picked up".

In the interview

> **30-second answer:** "An activity diagram walks one flow: start, actions, decisions with guards covering every case, merges, optional fork/join for parallel steps, swimlanes for who does what, and one or more ends. I draw the flow with the interesting branch, then check that every action has a class to live in."

Follow-ups:

- *Q: Activity final vs flow final?* — A: Activity final ends the whole activity; flow final ends only that one path while other parallel paths continue.
- *Q: Which flow do you draw?* — A: The one whose requirement contains "if/unless/otherwise" — e.g. payment failure and retry.

Self-check

- *Q: What must every arrow leaving a decision have?* → A: A guard in square brackets; together they must cover all cases.
- *Q: How do you show two steps that happen at the same time?* → A: A fork bar before them and a join bar after them.

TL;DR

One flow, start → actions → decisions with guards → merge → end. Fork/join for parallel, swimlanes for who. Draw the branching flow and use it to test your class diagram.

3.14 State machine diagrams

What it is

A **state machine diagram** (also called a *statechart* or *state diagram*) shows the **states one object can be in** during its life and the **transitions** that move it from one state to another in response to **events**.

- **State** — a condition during which the object behaves in a certain way or waits (rounded rectangle): `CREATED`, `PAID`, `SHIPPED`.
- **Initial pseudostate** — filled circle, arrow to the first state.
- **Final state** — bullseye; the object's life (in this machine) is over.
- **Transition** — arrow labelled `event [guard] / action`:
  - **event (trigger)** — what happens: `pay(amount)`.
  - **guard** — boolean condition that must be true for the transition to fire: `[amount == total]`.
  - **action (effect)** — what the object does while transitioning: `/ refund()`.

- **Internal activities** inside a state: `entry / ...` (on entering), `exit / ...` (on leaving), `do / ...` (while in the state).
- **Self-transition** — an arrow from a state back to itself (exit and re-entry actions run).
- **Choice pseudostate** — a small diamond that picks the next state based on guards.
- **Composite state** — a state containing sub-states (e.g. `Active` containing `Idle` and `Moving`); **history** `(H)` remembers the last sub-state.
- **Orthogonal regions** — a state split by dashed lines into parts that are active at the same time.

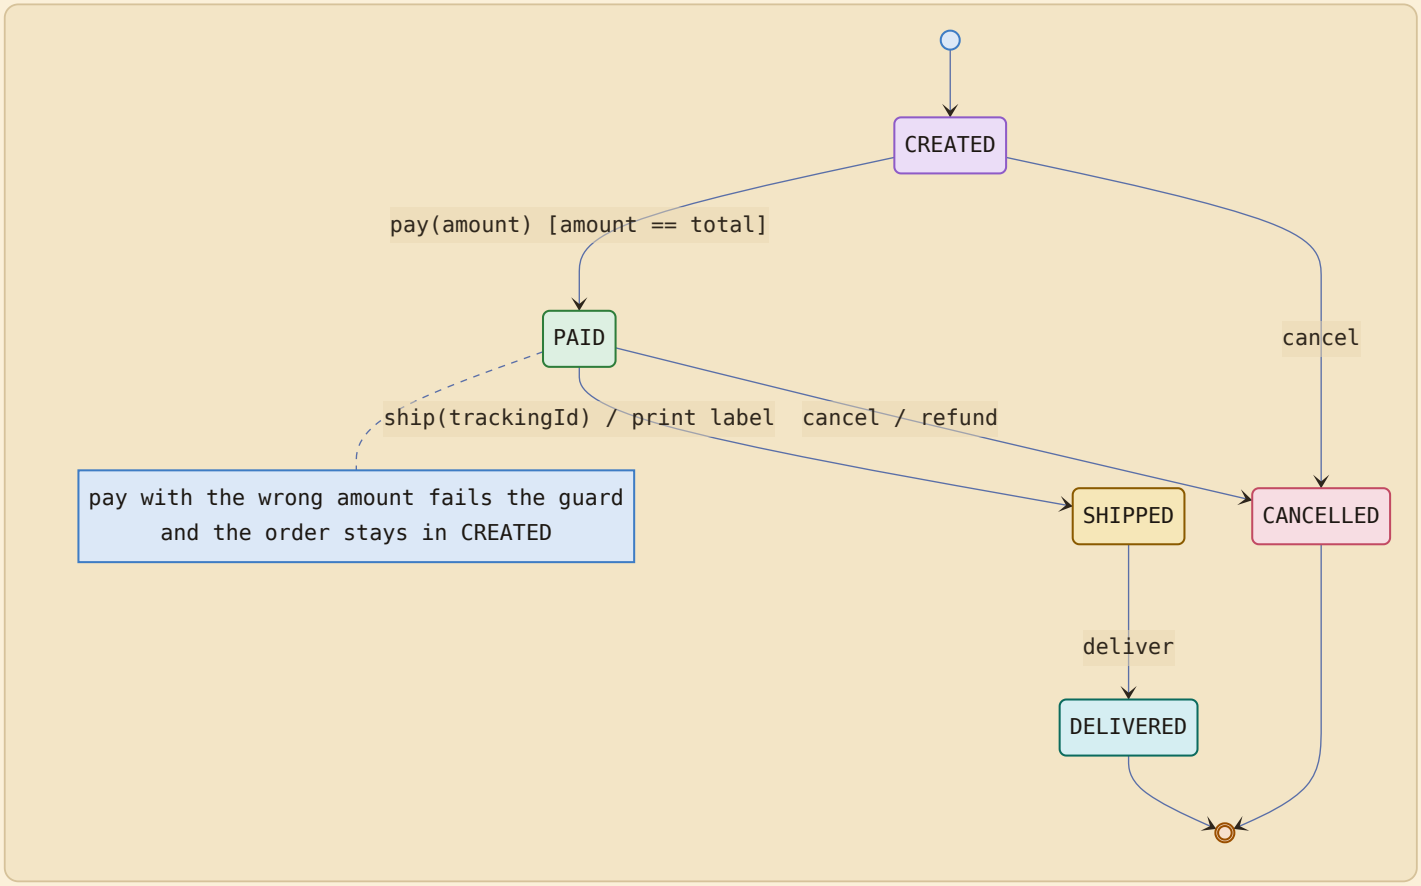
Analogy: a **traffic light**. It is always in exactly one state (red, green, yellow), a timer event moves it on, and the allowed order is fixed — it never goes straight from green to red.

The problem it solves

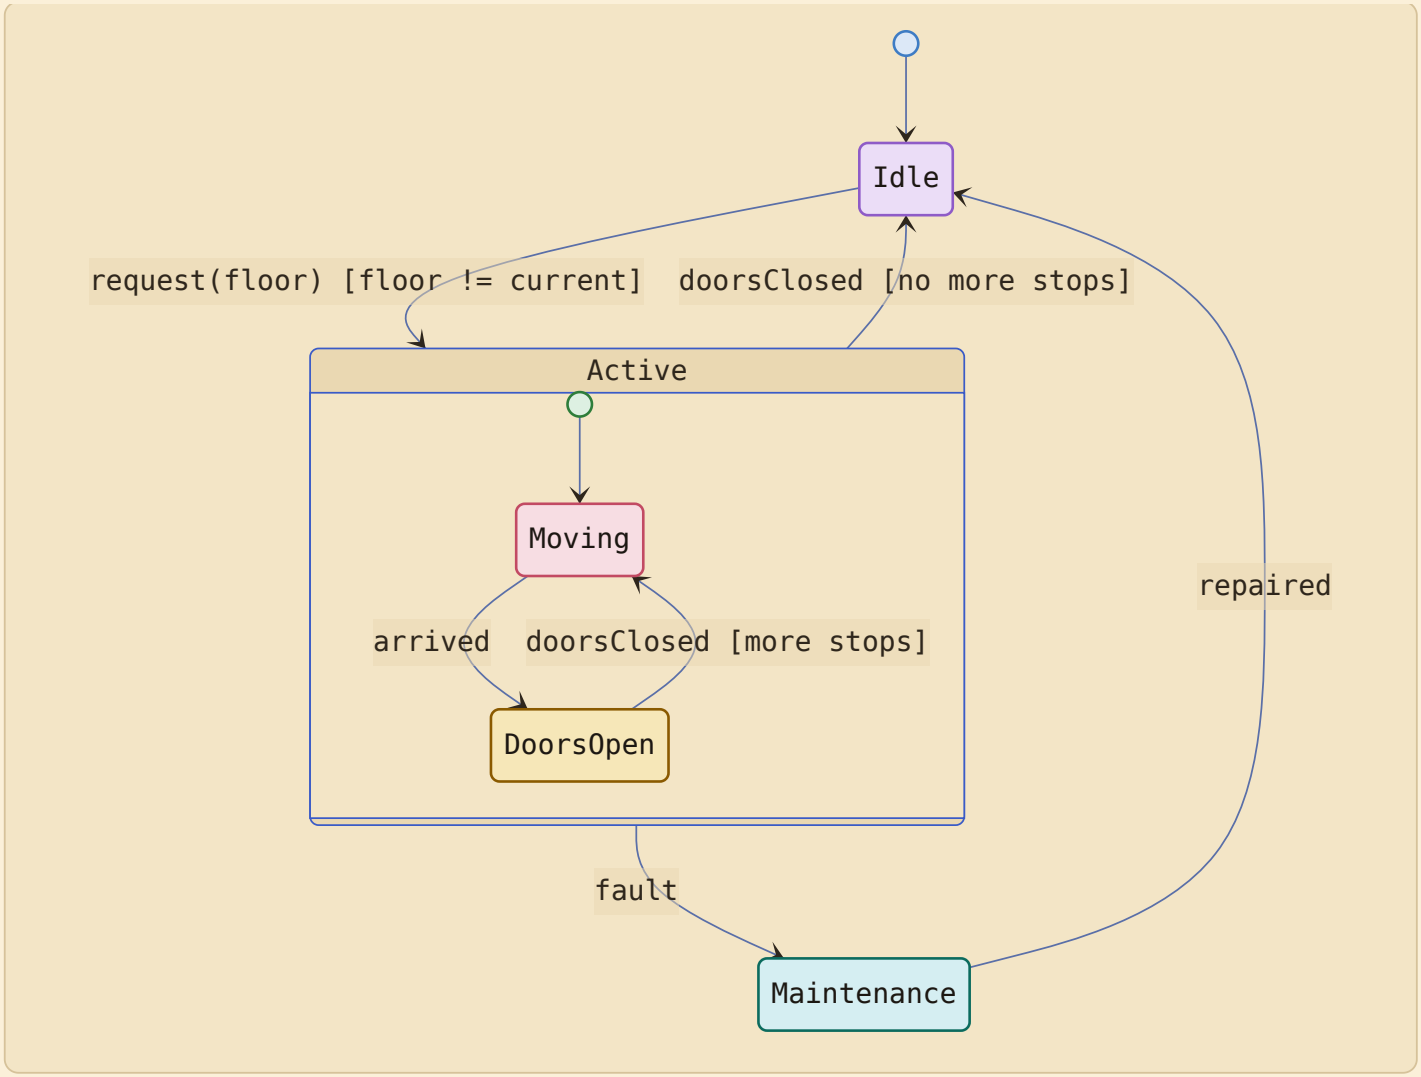
Objects with a lifecycle (orders, tickets, elevators, vending machines, parking spots, TCP connections, TCP being the network protocol for reliable connections, see System Design Fundamentals) are the source of many bugs: shipping a cancelled order, paying twice, refunding an undelivered item. A state diagram lists **every legal transition** so that everything else can be rejected. It also maps directly to code (an `enum` of states plus a transition method, or the **State pattern**, Chapter 11).

How it works

1. Pick **one** class with a lifecycle.
2. List its states (usually an `enum`).
3. For each state, list the events it accepts, the guard (if any), the target state and the action.
4. Everything not listed is **illegal** — the code must reject it.
5. Mark the initial and final states.



A composite-state example (an elevator car) for recognition:



Java example (`lld.ch03.statemachine`)

```java
// File: code/lld/ch03/statemachine/OrderState.java
package lld.ch03.statemachine;

public enum OrderState { CREATED, PAID, SHIPPED, DELIVERED, CANCELLED;
    public boolean isFinal() { return this == DELIVERED || this == CANCELLED; }
}
```

```java
// File: code/lld/ch03/statemachine/OrderEvent.java
package lld.ch03.statemachine;

import java.math.BigDecimal;

/** Events that can trigger transitions. Sealed, so the switch in Order is checked for completeness. */
public sealed interface OrderEvent {
    record Pay(BigDecimal amount) implements OrderEvent { }
    record Ship(String trackingId) implements OrderEvent { }
    record Deliver() implements OrderEvent { }
    record Cancel(String reason) implements OrderEvent { }
}
```

```java
// File: code/lld/ch03/statemachine/Order.java
package lld.ch03.statemachine;

import java.math.BigDecimal;
import java.util.ArrayList;
import java.util.List;

/**
 * Code for the state machine diagram. Each transition is written as
 *   event [guard] / action
 * An event that has no transition from the current state is rejected.
 */
public final class Order {
    private final String id;
    private final BigDecimal total;   // money: BigDecimal, not double
    private OrderState state = OrderState.CREATED;   // initial pseudostate -> CREATED
    private final List<String> log = new ArrayList<>();

    public Order(String id, BigDecimal total) {
        this.id = id;
        this.total = total;
        log.add("[*] -> CREATED");
    }

    public OrderState state() { return state; }
    public List<String> log() { return List.copyOf(log); }

    public void handle(OrderEvent event) {
        OrderState from = state;
        OrderState to = switch (event) {
            case OrderEvent.Pay p when state == OrderState.CREATED && p.amount().compareTo(total) == 0 ->
OrderState.PAID;
            case OrderEvent.Pay p when state == OrderState.CREATED ->
                    reject(event, "guard failed: paid " + p.amount() + " but total is " + total);
            case OrderEvent.Ship s when state == OrderState.PAID -> {
                log.add("  action: print label " + s.trackingId());
                yield OrderState.SHIPPED;
            }
            case OrderEvent.Deliver d when state == OrderState.SHIPPED -> OrderState.DELIVERED;
            case OrderEvent.Cancel c when state == OrderState.CREATED -> OrderState.CANCELLED;
            case OrderEvent.Cancel c when state == OrderState.PAID -> {
                log.add("  action: refund " + total);
                yield OrderState.CANCELLED;
            }
            default -> reject(event, "no transition from " + state);
        };
        state = to;
        log.add(from + " --" + event.getClass().getSimpleName() + "--> " + to);
    }

    private OrderState reject(OrderEvent e, String why) {
        throw new IllegalStateException(id + ": " + e.getClass().getSimpleName() + " rejected, " + why);
    }
}
```

```java
// File: code/lld/ch03/statemachine/Main.java
package lld.ch03.statemachine;

import java.math.BigDecimal;

public class Main {
    public static void main(String[] args) {
        Order happy = new Order("ORD-1", new BigDecimal("499.00"));
        happy.handle(new OrderEvent.Pay(new BigDecimal("499.00")));
        happy.handle(new OrderEvent.Ship("TRK-77"));
        happy.handle(new OrderEvent.Deliver());
        System.out.println("ORD-1 path:");
        happy.log().forEach(l -> System.out.println("  " + l));
        System.out.println("  final? " + happy.state().isFinal());

        Order refund = new Order("ORD-2", new BigDecimal("120.00"));
        tryEvent(refund, new OrderEvent.Pay(new BigDecimal("100.00")));   // guard fails
        tryEvent(refund, new OrderEvent.Pay(new BigDecimal("120.00")));
        tryEvent(refund, new OrderEvent.Cancel("changed mind"));
        tryEvent(refund, new OrderEvent.Ship("TRK-99"));                        // no transition from CANCELLED
        System.out.println("ORD-2 path:");
        refund.log().forEach(l -> System.out.println("  " + l));
    }

    private static void tryEvent(Order o, OrderEvent e) {
        try {
            o.handle(e);
        } catch (IllegalStateException ex) {
            System.out.println("Rejected: " + ex.getMessage());
        }
    }
}
```

What each part shows: `OrderState` is the list of states. Amounts are `BigDecimal` (never `double` for money), so the guard `[amount == total]` is written `p.amount().compareTo(total) == 0` — `BigDecimal.equals` would treat `120.0` and `120.00` as different because it also compares scale. `OrderEvent` is a **sealed** interface (only the types listed inside it may implement it) of event records, so the `switch` in `Order.handle` uses Java 21 **pattern matching with `when` guards** — each `case` line is literally one arrow of the diagram: `event [guard] -> target` with its action. The `default` branch rejects every transition that is not on the diagram.

Output:

```
ORD-1 path:
  [*] -> CREATED
  CREATED --Pay--> PAID
    action: print label TRK-77
  PAID --Ship--> SHIPPED
  SHIPPED --Deliver--> DELIVERED
  final? true
Rejected: ORD-2: Pay rejected, guard failed: paid 100.00 but total is 120.00
Rejected: ORD-2: Ship rejected, no transition from CANCELLED
ORD-2 path:
  [*] -> CREATED
  CREATED --Pay--> PAID
    action: refund 120.00
  PAID --Cancel--> CANCELLED
```

Trade-offs

enum + switch (this example)	State pattern (class per state, Ch. 11)
All transitions visible in one place	Each state's behaviour in its own class
Best for few states, simple actions	Best when states have lots of different behaviour
Adding a state edits the switch	Adding a state adds a class (Open/Closed)

When not to use it

For objects with only a flag or two and no real lifecycle (`active/inactive`). For flows that span many objects, use an activity diagram instead — a state machine describes **one** object.

Common mistakes

- Confusing states with actions: "Paying" (an action) vs "PAID" (a state).
- Missing transitions (e.g. forgetting that a paid order can be cancelled with a refund) or allowing illegal ones by default.
- Guards that overlap, so two transitions could fire for the same event.
- Drawing a state machine for the *system* rather than for one object.

Real-world examples

- `java.lang.Thread.State`: `NEW`, `RUNNABLE`, `BLOCKED`, `WAITING`, `TIMED_WAITING`, `TERMINATED`.
- **TCP** connection states (`LISTEN`, `SYN_SENT`, `ESTABLISHED`, `FIN_WAIT_1`, …) — the classic protocol state machine.
- **Amazon / Flipkart order tracking** (ordered → packed → shipped → out for delivery → delivered; cancel allowed only before shipping).
- **Uber trip** (requested → driver assigned → driver arrived → in progress → completed / cancelled).
- **Spring Statemachine** and AWS Step Functions (Amazon's cloud workflow service) are libraries/services built around state machines.

In the interview

> **30-second answer:** "When an object has a lifecycle — order, ticket, elevator, vending machine — I draw its states with transitions labelled `event [guard] / action`. Anything not on the diagram is illegal and the code rejects it. In Java it is an enum of states with one transition method, or the State pattern if each state has a lot of behaviour."

Follow-ups:

- *Q: What is a guard?* — A: A boolean condition in `[ ]` that must be true for the transition to fire, e.g. `[amount == total]`.
- *Q: State machine vs activity diagram?* — A: A state machine is about one object's states over its lifetime; an activity diagram is about the steps of a process, possibly across many objects.
- *Q: How do you make transitions thread-safe?* — A: Make the transition method `synchronized` (or use a lock / compare-and-set on an `AtomicReference<State>`; compare-and-set changes a value only if it still equals what you last read, in one atomic step), so two events cannot both read the old state and both move on.

Self-check

- *Q: Read `PAID --> CANCELLED : cancel / refund`.* → A: In PAID, the event `cancel` moves to CANCELLED and performs the action `refund`.
- *Q: What happens to an event that has no transition from the current state?* → A: It is ignored or rejected — in our code, rejected with an exception.

TL;DR

One object, its states, and `event [guard] / action` arrows. Initial dot, final bullseye. Everything not drawn is illegal. Code: enum + guarded switch, or the State pattern.

Part C — UML in the interview

3.15 How much UML to draw in an interview

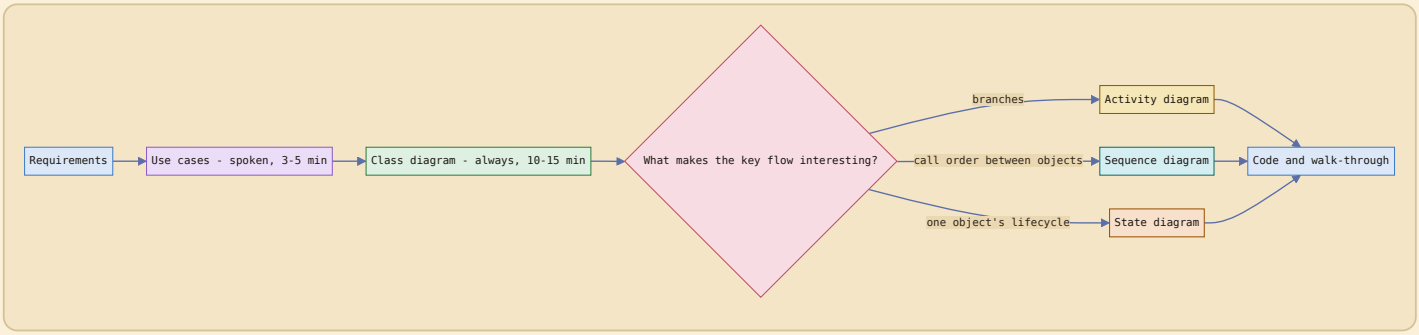
The interviewer is not marking your arrowheads. What is checked is whether **your diagram and your words agree**. Leaving a line out costs you less than drawing one you cannot justify.

Suggested budget for a 45-minute OOD round:

Minute	Diagram	Depth
0–5	**Use case**	Usually *spoken* or a quick list: actors + what each does + what is out of scope (the boundary). Draw it only if asked.
5–20	**Class diagram**	*Always drawn.* 10–15 boxes, every line typed with multiplicity; key attributes and methods only.
20–25	**Activity** *or* **sequence** *or* **state**	One diagram for the one flow that carries the design: activity if it branches, sequence if call order matters, state if one object has a lifecycle.
25–45	Code + discussion	Code the core classes; walk the flow against your diagrams.

Rules of thumb

1. **If you only have one picture, make it the class diagram.** It is the answer.
2. **Drop attributes before relationships** when short of time.
3. **Never leave a line unlabelled** — type + multiplicity.
4. **Say the test aloud** for every diamond and triangle.
5. **Use the other diagrams as tests:** every action in the activity diagram and every arrow in the sequence diagram must be a method on a class in the class diagram.
6. **Keep sequence diagrams small:** 3–4 objects, 6–8 messages, no branches.
7. **Machine-coding rounds** (90–120 min, working code expected): a 2-minute class sketch is enough — spend the time on code.
8. If you forget a symbol, **say what you mean** ("this implements that") and move on.



In the interview

> **30-second answer:** "I list use cases verbally to fix scope, spend most of my diagram time on one class diagram with typed, multiplicity-labelled lines, then draw one behaviour diagram for the key flow and use it to check that every step has a class and method."

3.16 Chapter self-check

1. *Q: Name the six relationships from weakest to strongest coupling.* → A: Dependency, association, aggregation, composition, realization, generalization.
2. *Q: Where does the diamond go, and what does filled vs hollow mean?* → A: At the whole; filled = composition (parts die with it), hollow = aggregation (parts live on).
3. *Q: Code smell (a surface sign of a likely design problem):* `CompactSpot`, `LargeSpot` *subclasses that only pass a constant to* `super`*. Fix?* → A: One `ParkingSpot` with a `SpotType` enum field.
4. *Q: Java type for multiplicity* `0..1` *and* `1..*`*?* → A: `Optional<T>` (nullable field); a non-empty collection checked in the constructor.
5. *Q: «include» vs «extend»?* → A: Include = always, arrow from base to included; extend = sometimes (conditional), arrow from extension to base.
6. *Q:* `+ - # ~`*?* → A: public, private, protected, package.
7. *Q: Arrowheads in sequence diagrams?* → A: Solid + filled = sync call; solid + open = async; dashed + open = return.

8. *Q: `alt` vs `opt`?* → A: `alt` = if/else with several guarded sections; `opt` = a single guarded section (if without else).
9. *Q: Fork/join?* → A: Fork splits one flow into parallel flows; join waits for all of them.
10. *Q: Transition label syntax in a state machine?* → A: `event [guard] / action`.
11. *Q: 14 UML diagrams split how?* → A: 7 structural (class, object, package, component, composite structure, deployment, profile) and 7 behavioural (use case, activity, state machine, sequence, communication, interaction overview, timing).
12. *Q: If you can draw only one diagram?* → A: The class diagram.

3.17 TL;DR

- **Relationships are claims about lifetime and substitution.** Dependency (uses, dashed arrow) · Association (knows, line/arrow) · Aggregation (has, parts live on, ◇ at whole) · Composition (owns, parts die, ◆ at whole) · Realization (implements, dashed △) · Generalization (extends, solid △).
- **Choose in order:** substitution test → dies with whole? → part that outlives? → else association; parameter-only → dependency. Inheritance last.
- **Multiplicity changes code:** `1` required, `0..1` Optional, `1..*` non-empty collection, exact numbers checked in constructors.
- **UML:** 14 diagrams, structural vs behavioural. Interviews: use case (scope), class (the answer), activity (branches), sequence (call order), state machine (lifecycle).
- **Draw little, label everything, say the test out loud,** and use behaviour diagrams to test the class diagram.

Chapter 4 — SOLID Principles

> **What you will learn.** The five SOLID principles, one at a time and then all together. For each one you get a plain definition, an everyday analogy, a broken Java example, the refactored Java example, the rules behind it, the cost of applying it, and how to talk about it in a design interview. Along the way you also learn the ideas SOLID is built on: **cohesion**, **coupling** and **separation of concerns**.
>
> **How to use this chapter.** Read 4.1 first. Then read the principles in order, because each one sets up the next. Section 4.11 runs one class through all five principles, and it is the best single thing to rehearse before an interview. Sections 4.13 and 4.14 are about saying all this out loud.

Run the code. All code for this chapter is under `chapters/04-solid-principles/code/`, one package per topic. From that folder (`javac` is the Java compiler; `java` runs the compiled classes, and `-cp` tells it where they are):

```
javac --release 21 -d /tmp/lld_04 $(find . -name '*.java')
java -cp /tmp/lld_04 lld.ch04.srp.Main        # also: cohesion, coupling, soc, ocp, lsp, isp, dip, checkout
```

Package	What it shows
`lld.ch04.srp`	SRP: an `Employee` class split by actor
`lld.ch04.cohesion`	Low cohesion vs high cohesion
`lld.ch04.coupling`	Tight coupling vs loose coupling, in three steps
`lld.ch04.soc`	Separation of concerns: rules vs storage
`lld.ch04.ocp`	OCP: invoice formats behind an interface
`lld.ch04.lsp`	LSP: cars, the four contract rules, the history rule, birds and composition
`lld.ch04.isp`	ISP: fat printer interface, over-splitting, role interfaces
`lld.ch04.dip`	DIP: notifications, dependency injection, service locator, plug-ins
`lld.ch04.checkout`	One checkout class refactored through all five principles

A note on money. Every amount of money in this chapter's code (pay, invoice totals, prices, balances, order totals) is a `java.math.BigDecimal` (Java's exact decimal-number type) created from a string (`new BigDecimal("19.99")`), and every result that could gain extra decimal places (a multiplication by a rate) is rounded explicitly with `setScale(2, RoundingMode.HALF_EVEN)` (two decimal places, "banker's rounding": a value exactly halfway, such as 2.345, goes to the neighbour whose last digit is even, 2.34, so rounding errors do not all lean one way). Adding or subtracting two-decimal amounts stays at two decimals on its own. Never use `double` for money: binary floating point cannot store values such as 0.1 exactly, so `0.1 + 0.2` prints `0.30000000000000004`, and those tiny errors add up in totals. `BigDecimal` also has one trap: `equals` compares the scale (the number of decimal places) too (`2.0` is not equal to `2.00`), so compare amounts with `compareTo` or `signum()`, as the code here does.

4.1 What SOLID is and why you should learn it

What it is

SOLID is a set of five design guidelines for object-oriented code. Each letter names one principle:

Letter	Principle	The one-line rule
S	Single Responsibility Principle (SRP)	A class should have one reason to change.
O	Open/Closed Principle (OCP)	Add new behaviour by adding code, not by editing working code.
L	Liskov Substitution Principle (LSP)	A subtype must be usable anywhere its parent type is expected.
I	Interface Segregation Principle (ISP)	No client should be forced to depend on methods it does not use.
D	Dependency Inversion Principle (DIP)	Depend on abstractions, not on concrete details.

A few terms first, because the rest of the chapter uses them:

- A **class** is a blueprint for objects. A **module** is a bigger unit: a package, a library, a service.
- A **client** (or **caller**) is any code that uses another piece of code.
- An **interface** is a list of methods a class promises to provide, with no bodies. In Java it is the `interface` keyword. In general design talk it also means "the set of methods a caller can see".
- An **abstraction** is an interface or abstract class (a class marked `abstract` that cannot be created directly and may leave some methods for subclasses to write): something that says *what* is done without saying *how*.
- A **concrete class** is a class you can actually create with `new`.
- A **subtype** is a class that extends another class or implements an interface; the type it extends or implements is its **parent** (or base) type.

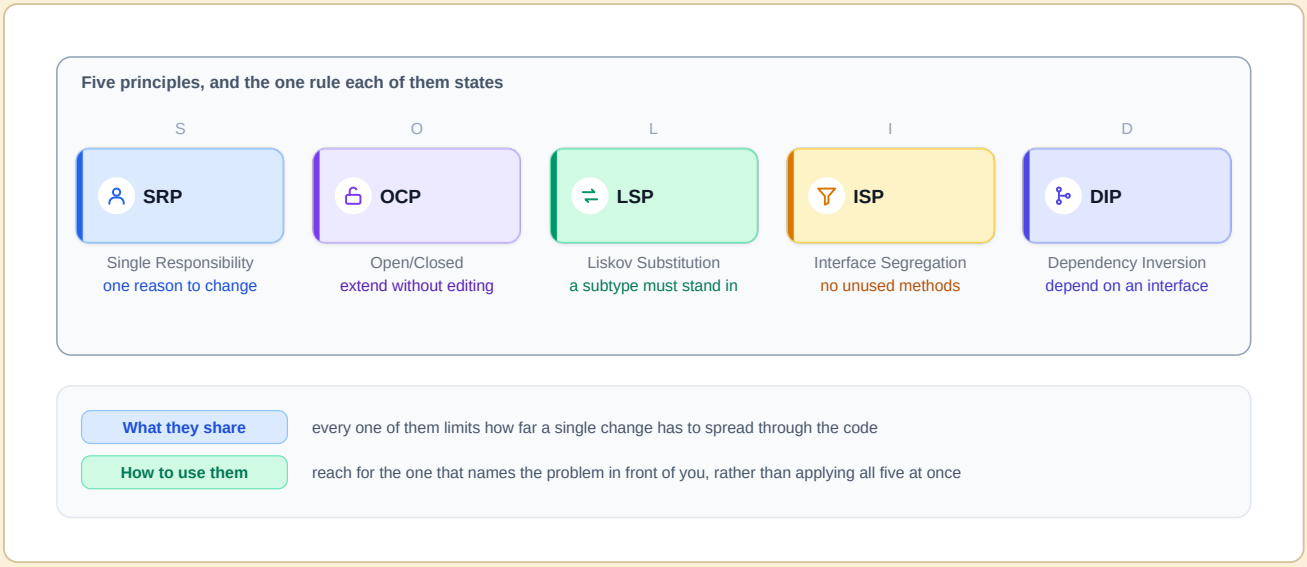


Figure — the five principles and the single rule each one states (course diagram)

In the figure above, look at the bottom line: every principle **limits how far one change spreads through the code**. That is the common thread. SRP limits it by giving each class one owner. OCP limits it by letting you add instead of edit. LSP makes sure a new subclass does not break old callers. ISP stops a change in one method from reaching callers that never use it. DIP stops a change in a low-level detail (a technical part such as a database driver) from reaching business logic (the rules the application exists for, such as pricing).

A little history. Robert C. Martin ("Uncle Bob") collected these principles in his writing around 2000, most fully in the paper *Design Principles and Design Patterns* and the book *Agile Software Development: Principles, Patterns, and Practices* (2002). Michael Feathers noticed the initials spelled SOLID. Two of the ideas are older: the Open/Closed Principle comes from Bertrand Meyer (1988), and the Substitution Principle from Barbara Liskov (1987).

The problem it solves

Code that works today still has to change tomorrow. Without guidelines, classes grow by small additions until one edit breaks three unrelated features. SOLID gives you:

- **Cleaner code.** Small, focused classes are easier to read and to hand to a teammate.
- **Flexibility.** New features plug in without breaking old ones.
- **Fewer bugs.** Less code is touched per change, so there is less to break.
- **Reuse.** A class with one job can be used in places its author never imagined.
- **Easier change.** When requirements shift, the change lands in one place.

- **A shared vocabulary.** This is the benefit people forget. When a teammate says "this class breaks ISP", everybody knows what the problem is, and a disagreement about design can be decided by an argument rather than by personal preference.

How to use SOLID (the honest version)

1. Treat each principle as a **name for a problem**, not a rule to obey everywhere.
2. When code is painful to change, find the principle that names the pain.
3. Apply the fix **when a real change asks for it**, not in advance.
4. Always say what the fix costs (more classes, more interfaces, more wiring, i.e. code that creates objects and connects them).

Applied without judgement, SOLID produces a maze of interfaces that each have one implementation. This chapter shows the cost of every recommendation along with its benefit.

> **TL;DR**
>
> SOLID = five guidelines that keep one change from spreading. Use them to **diagnose** code, apply them when a real change needs them, and always state the cost.

4.2 Single Responsibility Principle (SRP)

What it is

Robert C. Martin's first wording was roughly: **a class should have only one reason to change.** Later (in *Clean Architecture*, 2017) he sharpened it to: **a module should be responsible to one, and only one, actor.** An **actor** is a person or group who can ask for a change to the code.

The everyday version you will often hear is "every component should have one job". That version is a useful start, but it is hard to measure, as we will see.

> **Analogy: army knife vs kitchen knife.** A Swiss army knife has scissors, a bottle opener and a screwdriver. It does many jobs and is not the best tool for any of them. A kitchen knife has one job, cutting, and it is excellent at it.

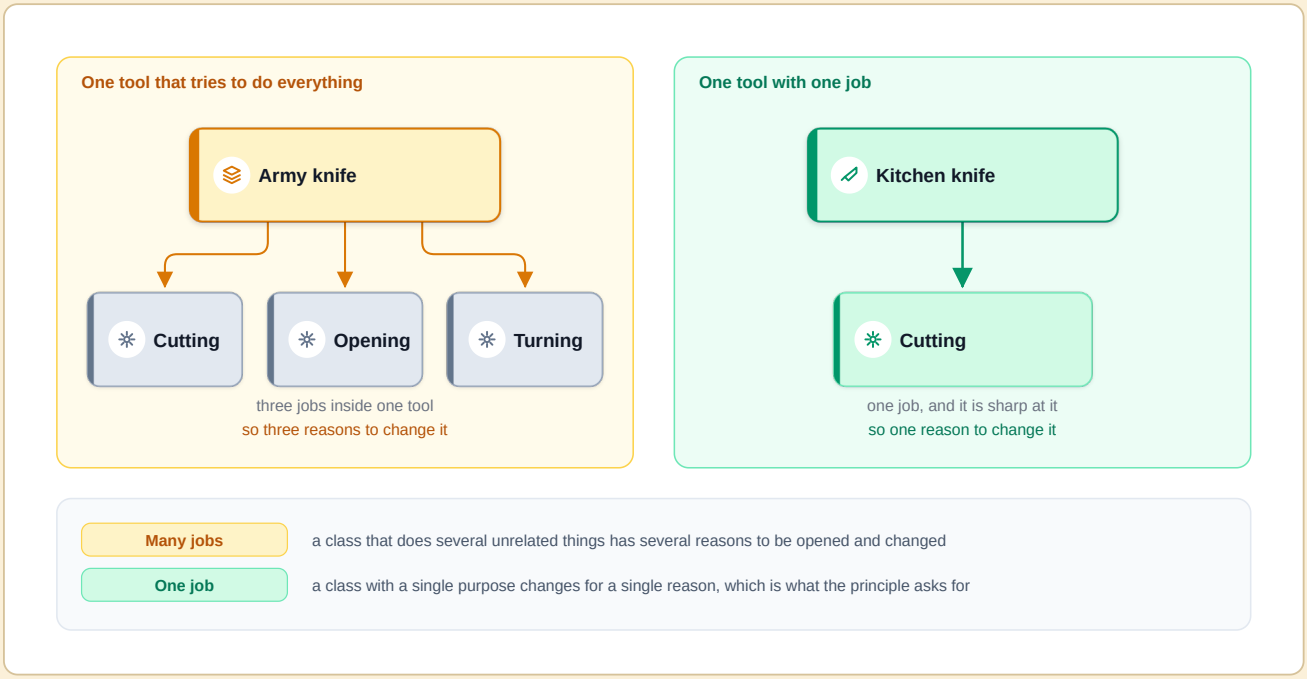

Figure — an army knife with three jobs (three reasons to change) next to a knife with one job (course diagram)

In the figure above, the army knife is the class that breaks SRP: three jobs, three reasons to open it and change it. The kitchen knife follows SRP.

The "one job" idea is often applied at every size of code:

- a **method** should perform one action,
- a **class** should serve one purpose,
- a **module** should cover one area of functionality.

Be precise about the names, though. Martin's SRP is a rule about **classes and modules** and their reasons to change. "A function should do one thing" is a separate (good) rule about functions from *Clean Code*. Both push in the same direction, but only the first is SRP.

The problem it solves

When one class serves several groups, every edit made for one group ships inside code that the other groups rely on, so a payroll tweak can break an operations report. Unrelated logic is also mixed together, which makes it slow to find the right place for a change. With one responsibility per class, you know exactly which class to open.

What counts as one responsibility?

"Do one thing" has no fixed size. Is "register a user" one thing? Is checking the email address part of it, or a job of its own? Reasonable people can debate that without end, because the phrase offers no yardstick.

The **actor** view gives you something to measure. A reason to change always comes from someone. So ask: **who can send me a change request for this code?** If two different groups can, the class has two responsibilities, however small it looks.

Here is an `Employee` class. Every method is "about employees", so the "one thing" test passes. Now ask who can demand a change to each method:

Method	Who asks for the change	Example request
`calculatePay`	Finance	"Overtime starts after 38 hours, not 40."
`reportHours`	Operations	"Show the week-ending date in the report."
`save`	Database team	"Move from SQL (table database) to a document store (stores JSON-like documents)."

So one class has three owners and three independent reasons to change. A new overtime rule from finance means editing `Employee`, which also ships the report code and the storage code again, although neither of those teams wanted anything. If the edit accidentally breaks the report layout, operations pays for a decision it had no part in.

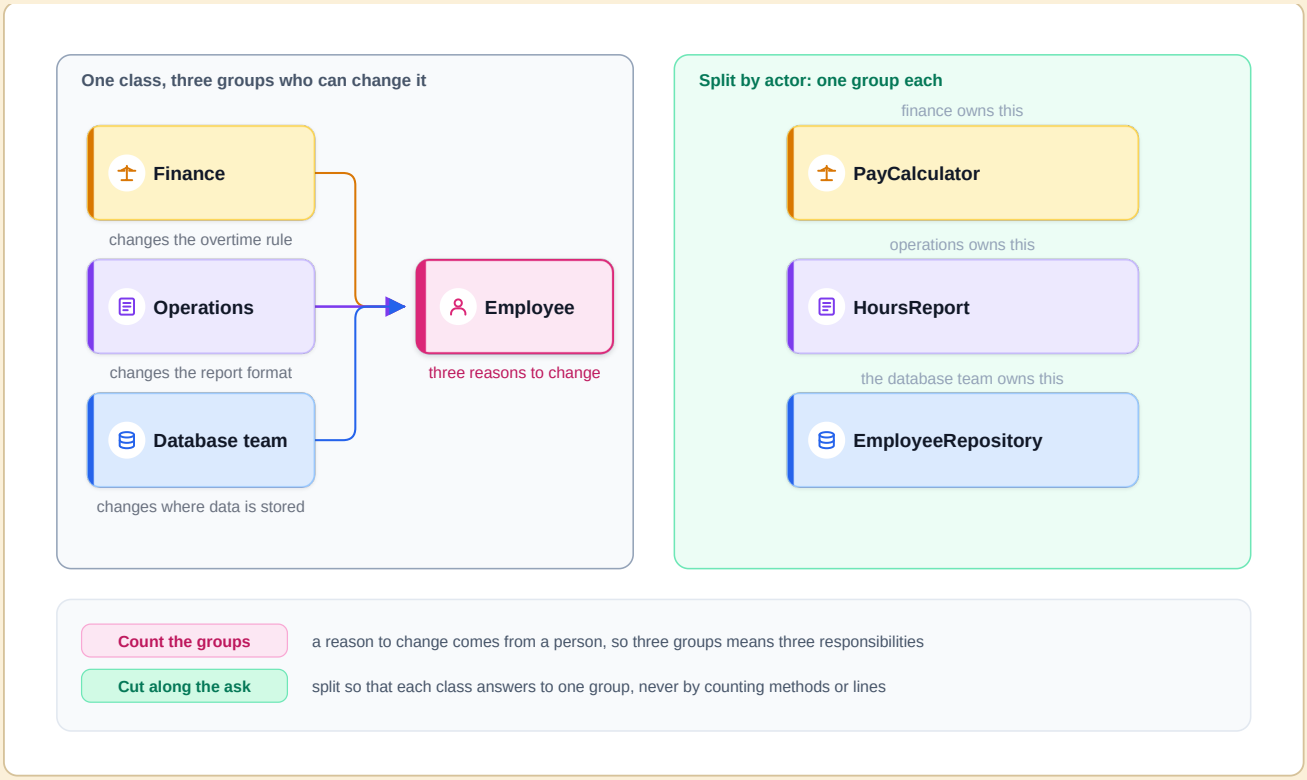

Figure — finance, operations and the database team all reach into one Employee class; splitting by actor gives each group its own class (course diagram)

Martin tells a sharper version of this story in *Clean Architecture*. Suppose `calculatePay` and `reportHours` both call a shared private helper, `regularHours()`, because the two calculations happen to match today. Finance changes the helper for its own reasons. The operations report now shows wrong numbers, and nobody on the operations side was told. The code looked like good reuse, but the two uses belonged to different actors. That is **accidental duplication**: two pieces of code that look the same but change for different reasons should not be merged.

How it works

1. List the methods of the class.
2. For each one, name **who** would ask for it to change.
3. Group the methods by actor.
4. Move each group into its own class, named after its job.
5. Keep plain data in a simple data class (a Java `record` is ideal: a compact class that only holds a fixed set of fields).
6. Check the split with the three checks below.

Java example: splitting `Employee` by actor

The violation. Three actors share one class:

```java
// File: code/lld/ch04/srp/before/Employee.java
package lld.ch04.srp.before;

import java.math.BigDecimal;
import java.math.RoundingMode;

/**
 * VIOLATION: three different groups (actors) can each demand a change here.
 * Finance owns the pay rule, operations owns the report, the database team owns storage.
 */
public class Employee {
    private final String name;
    private final int hoursWorked;
    private final BigDecimal hourlyRate; // money: BigDecimal, never double

    public Employee(String name, int hoursWorked, BigDecimal hourlyRate) {
        this.name = name;
        this.hoursWorked = hoursWorked;
        this.hourlyRate = hourlyRate;
    }

    // Actor 1: Finance -- "overtime should start after 38 hours, not 40"
    public BigDecimal calculatePay() {
        int overtime = Math.max(0, hoursWorked - 40);
        int normal = hoursWorked - overtime;
        BigDecimal normalPay = hourlyRate.multiply(BigDecimal.valueOf(normal));
        BigDecimal overtimePay = hourlyRate.multiply(new BigDecimal("1.5"))
                .multiply(BigDecimal.valueOf(overtime));
        return normalPay.add(overtimePay).setScale(2, RoundingMode.HALF_EVEN);
    }

    // Actor 2: Operations -- "show the week-ending date in the report"
    public String reportHours() {
        return name + " worked " + hoursWorked + " hours";
    }

    // Actor 3: Database team -- "move from SQL to a document store"
    public void save() {
        System.out.println("INSERT INTO employees VALUES ('" + name + "')");
    }
}
```

The refactor. `Employee` keeps only the data. Each actor gets its own class:

```java
// File: code/lld/ch04/srp/after/Employee.java
package lld.ch04.srp.after;

import java.math.BigDecimal;

/** Just the data. No group owns a business rule in here. */
public record Employee(String name, int hoursWorked, BigDecimal hourlyRate) { }
```

```java
// File: code/lld/ch04/srp/after/PayCalculator.java
package lld.ch04.srp.after;

import java.math.BigDecimal;
import java.math.RoundingMode;

/** Only Finance asks for changes to this class. */
public class PayCalculator {
    private static final int OVERTIME_THRESHOLD = 40;
    private static final BigDecimal OVERTIME_MULTIPLIER = new BigDecimal("1.5");

    public BigDecimal calculatePay(Employee e) {
        int overtime = Math.max(0, e.hoursWorked() - OVERTIME_THRESHOLD);
        int normal = e.hoursWorked() - overtime;
        BigDecimal normalPay = e.hourlyRate().multiply(BigDecimal.valueOf(normal));
        BigDecimal overtimePay = e.hourlyRate().multiply(OVERTIME_MULTIPLIER)
                .multiply(BigDecimal.valueOf(overtime));
        return normalPay.add(overtimePay).setScale(2, RoundingMode.HALF_EVEN); // cents
    }
}
```

```java
// File: code/lld/ch04/srp/after/HoursReport.java
package lld.ch04.srp.after;

/** Only Operations asks for changes to this class. */
public class HoursReport {
    public String format(Employee e) {
        return e.name() + " worked " + e.hoursWorked() + " hours";
    }
}
```

```java
// File: code/lld/ch04/srp/after/EmployeeRepository.java
package lld.ch04.srp.after;

/** Only the database team asks for changes to this class. */
public class EmployeeRepository {
    public void save(Employee e) {
        System.out.println("INSERT INTO employees VALUES ('" + e.name() + "')");
    }
}
```

```java
// File: code/lld/ch04/srp/Main.java
package lld.ch04.srp;

import java.math.BigDecimal;
import lld.ch04.srp.after.EmployeeRepository;
import lld.ch04.srp.after.HoursReport;
import lld.ch04.srp.after.PayCalculator;

public class Main {
    public static void main(String[] args) {
        System.out.println("--- Before: one class, three actors ---");
        var before = new lld.ch04.srp.before.Employee("Ada", 45, new BigDecimal("20.00"));
        System.out.println("Pay: " + before.calculatePay());
        System.out.println(before.reportHours());
        before.save();

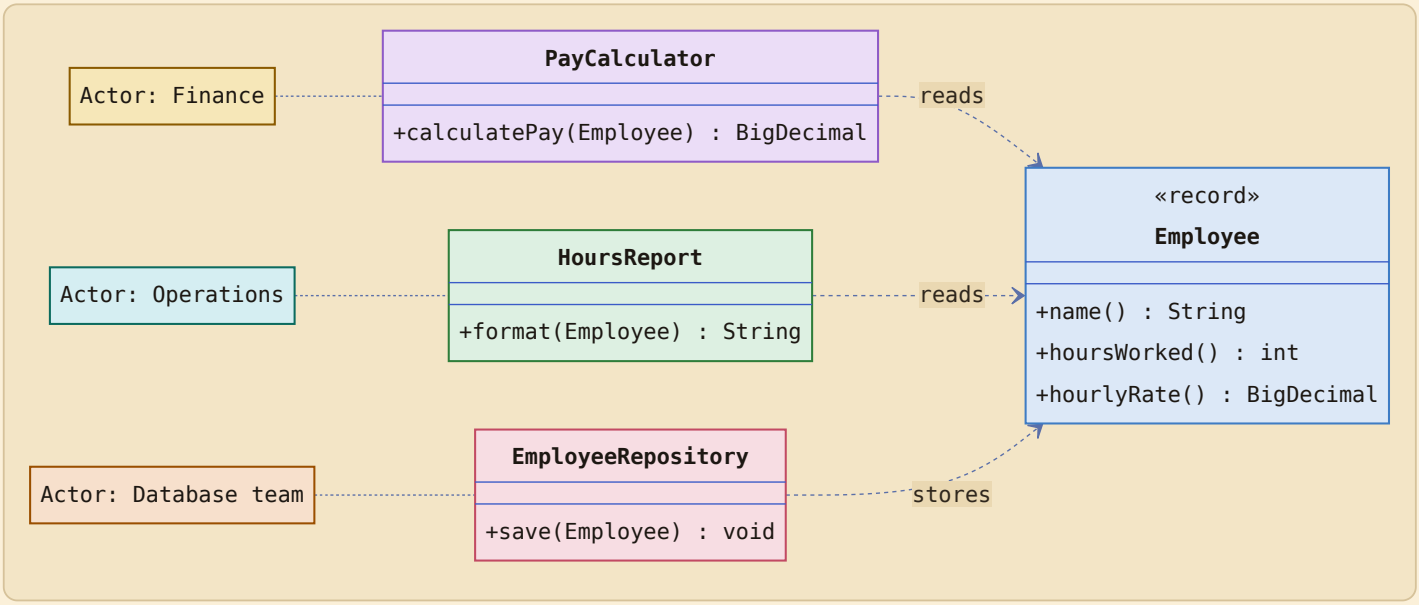
        System.out.println("--- After: split by actor ---");
        var ada = new lld.ch04.srp.after.Employee("Ada", 45, new BigDecimal("20.00"));
        System.out.println("Pay: " + new PayCalculator().calculatePay(ada));
        System.out.println(new HoursReport().format(ada));
        new EmployeeRepository().save(ada);
    }
}
```

Output:

```
--- Before: one class, three actors ---
Pay: 950.00
Ada worked 45 hours
INSERT INTO employees VALUES ('Ada')
--- After: split by actor ---
Pay: 950.00
Ada worked 45 hours
INSERT INTO employees VALUES ('Ada')
```

What each part does:

- `Employee` is a `record`: an immutable (cannot change after creation) data carrier. No business rule lives there, so no actor needs to edit it for a rule change.
- `PayCalculator` belongs to finance. The overtime threshold and multiplier are named constants, so the next finance request is a one-line change in one class.
- `HoursReport` belongs to operations. `EmployeeRepository` belongs to the database team.
- The output is **identical** before and after. Behaviour did not change. What changed is who must be consulted before an edit. Finance can now change the overtime rule without anyone touching the report or the database code.



Where splitting goes wrong

A badly applied SRP leaves the code in a **worse** state than no SRP at all. The typical mistake: a large class is chopped up by verb, one class per method or per step, without asking who owns what. The cuts fall in arbitrary places, and the result is a handful of tiny classes that must always be edited as a group, so each change now spreads over half a dozen files. Three checks catch this:

1. **Do the pieces change together?** After a few months, read the version-control log (the history kept by a tool such as Git, where each **commit** is one saved change). Two classes that show up in nearly every commit side by side were really one responsibility that got cut in two.
2. **Does each new class have a name that stands on its own?** `EmployeePayCalculator` describes a job. `EmployeeHelper` and `EmployeeUtils` describe nothing. If the name is meaningless without the original class next to it, the class usually is too.
3. **Could the new class be used from somewhere else?** A pay calculator could serve a payroll export, a quote for a contractor, or a unit test (a small automated test of one class on its own). If you cannot imagine any second caller, question why you split it off.

Splitting does not automatically reduce dependencies. After an extraction the two classes still call each other. If the extracted class was designed around the precise needs of the class it came from, every change to one will drag the other along. So the split is only step one; step two is deciding what each class is allowed to know about the other. Those two questions have names: **cohesion** (4.3) and **coupling** (4.4). SRP usually helps both, but promises neither.

Why SRP is important

- **Simpler maintenance.** A class with one job is easy to understand, debug and change.
- **Reuse.** A focused class fits in more places.
- **Scales with the codebase.** New features add classes instead of bloating old ones.
- **High cohesion.** Everything in the class serves one purpose.
- **Opens the door to low coupling, but does not finish the job.** Separating responsibilities gives you a seam (a boundary where one side can be swapped without editing the other). Coupling drops only when the dependency across that seam points at an abstraction (see 4.4).

Trade-offs

You gain	You pay
A change requested by one group touches only that group's code	More classes and files to navigate
Smaller classes are easier to test in isolation	The caller now wires several objects together
Clear ownership (who reviews what)	Risk of over-splitting into classes that always change together

When not to use it

- When you cannot name two different actors. If you cannot name the groups, you do not yet know where the seam is.
- In short-lived code such as a one-off script.
- When the pieces would always change together anyway.

Common mistakes

- **Splitting by counting methods or verbs** instead of by actor.
- **Helper/Utils classes** that exist only because something had to be moved somewhere.
- **Merging "duplicate" code that belongs to different actors** (the `regularHours()` trap).
- **Thinking SRP means "a class has one method".** A class can have ten methods and one responsibility.
- **Confusing SRP with "a function should do one thing".** That is a separate (good) rule about functions from *Clean Code*. SRP is about reasons to change.

Code smells that point to SRP (from *Refactoring*)

A **code smell** is a surface sign that the design is probably wrong somewhere; *Refactoring* is Martin Fowler's book that names the common smells and the step-by-step fixes (called refactorings) for each.

- **Divergent Change** — one class is edited for many different kinds of reasons. This is SRP broken.
- **Large Class** — too many fields and methods, often a sign of several jobs.
- **Shotgun Surgery** — one change forces small edits in many classes. This is often the result of **over-splitting**, the opposite mistake.
- The usual fix is the **Extract Class** refactoring (and **Move Function**/**Move Field**).

Real-world examples

- **Spring layers** (Spring is a popular Java application framework): `@Controller` handles HTTP (the web's request/response protocol, see System Design Fundamentals), `@Service` holds business rules, `@Repository` handles persistence (saving data permanently, usually in a database). Each layer answers to a different kind of change.
- **JDK**: `java.time.format.DateTimeFormatter` formats and parses dates; `LocalDate` holds the date. Formatting rules can change without touching the date value type.
- **Logging frameworks** (Logback, Log4j 2: libraries that write a program's log messages) split the *logger* (what to log), the *appender* (where it goes) and the *layout* (how it looks). A new output format does not touch the destination code.

In the interview

> **30-second answer:** "SRP says a class should have one reason to change. The sharp version is: one actor, one group of people who can request changes. I find the actors by asking who would ask for each method to change. If finance, operations and the DBAs (database administrators) can all ask for edits to `Employee`, I split it into `PayCalculator`, `HoursReport` and `EmployeeRepository`, and keep `Employee` as data. The cost is more classes and some wiring, so I only split when I can name the different groups."

Follow-ups:

- *"Would you always split?"* — No. If the two halves always change together, I have turned one file into two for nothing. I split when two different people can ask for two different changes.
- *"How do you know you split too far?"* — The pieces show up in the same commits, their names only make sense next to each other (`XHelper`), and nothing else could use them.
- *"Is SRP about methods?"* — It applies to methods, classes and modules, but the test is always reasons to change, not the number of methods.

Self-check

1. **Q:** What is an "actor" in SRP? **A:** A person or group who can request a change to the code, for example finance or the database team.
2. **Q:** A `ReportService` formats a report and emails it. Is that an SRP problem? **A:** Yes, if different people own the wording and the delivery. Formatting and delivery change for different reasons.
3. **Q:** Name the three checks for a good split. **A:** Do the pieces change together? Does each name stand alone? Could each piece be used elsewhere?
4. **Q:** Does splitting a class always lower coupling? **A:** No. If the new class names a concrete collaborator, the dependency just moved. Point it at an abstraction to loosen it.

TL;DR

One class, one actor. Find the actors, split along them, keep data in a record, check the split, and do not split what always changes together.

4.3 Cohesion

What it is

Cohesion is how closely the contents of one class (or module, or method) belong together. **High cohesion**: every method works toward the same purpose. **Low cohesion**: unrelated jobs are bundled into one place.

> **Analogy: a garbage dump vs sorted bins.** A dump holds plastic, paper and food waste in one pile. Nothing in it has a clear purpose, and finding anything is hard. Separate bins, one per material, each have one job.

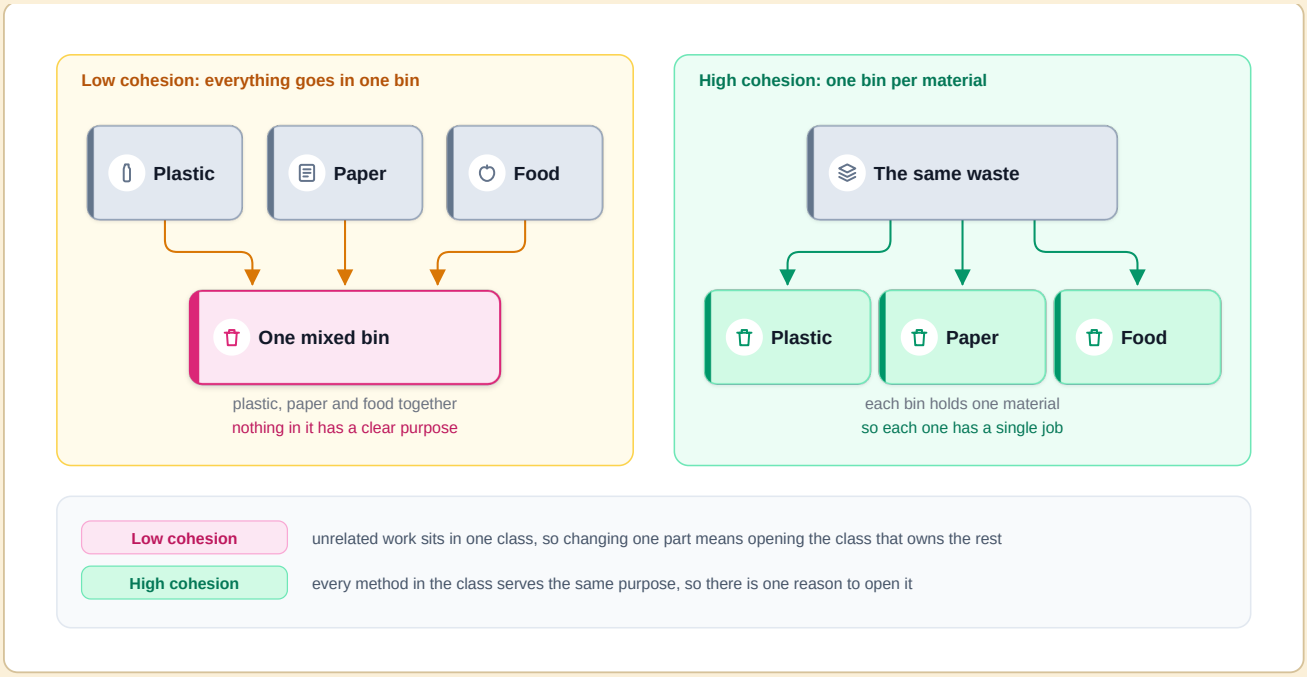


Figure — one mixed bin (low cohesion) next to one bin per material (high cohesion) (course diagram)

In the figure above, the mixed bin is a class whose methods have nothing to do with each other. The sorted bins are classes where every method serves the same purpose, so each one has a single reason to change.

The problem it solves

In a low-cohesion class, someone who wants to change one job has to open, read and redeploy (release to production again) a class that also owns other jobs. Low cohesion also works in the other direction: if the code for **one** job is **scattered** over several classes (say `addUser` in one class and `deleteUser` in another), a change to that job has to hunt for all the pieces. Both are cohesion problems: the first mixes unrelated things, the second separates related things.

The classic types of cohesion

Structured-design authors (Larry Constantine, Ed Yourdon, Glenford Myers, 1970s) ranked cohesion from worst to best. The names are still useful for describing what you see:

Type (worst → best)	What groups the code	Java-flavoured example
Coincidental	Nothing, it just ended up together	`Utils` with `formatDate`, `sendEmail`, `parseCsv`
Logical	Same category, chosen by a flag	`handle(type)` with a big `switch` over unrelated actions
Temporal	Things that run at the same time	`startup()` that opens the DB, warms caches (fills fast temporary copies of data) and prints a banner
Procedural	Steps that follow an order	A method that validates, then logs, then retries
Communicational	Work on the same data	`ReportBuilder` methods that all read the same `Order` list
Sequential	Output of one step is input to the next	`parse → validate → transform` pipeline in one class
Functional (best)	Everything contributes to one well-defined task	`PayCalculator`

You do not need to memorise the list. Aim for **functional** cohesion and recognise **coincidental** cohesion (the "Utils" class) as a warning sign.

How it works

1. Look at each method in the class. Which fields does it use?
2. If the methods fall into groups that use **different** fields for **different** purposes, the class has low cohesion.

3. Move each group into its own class.
4. If the code for one job is scattered over several classes, gather it into one.

Java example

Before: user bookkeeping and audit-file work share a class. `addUser` / `deleteUser` use `users`; `writeToFile` / `readFromFile` use `auditLines`. Two disjoint groups:

```java
// File: code/lld/ch04/cohesion/before/UserManager.java
package lld.ch04.cohesion.before;

import java.util.ArrayList;
import java.util.List;

/** LOW cohesion: user bookkeeping and audit-file work share one class but not one purpose. */
public class UserManager {
    private final List<String> users = new ArrayList<>();
    private final List<String> auditLines = new ArrayList<>();

    // --- user work ---
    public void addUser(String user) {
        users.add(user);
        System.out.println("user added: " + user);
    }

    public void deleteUser(String user) {
        users.remove(user);
        System.out.println("user deleted: " + user);
    }

    // --- file work, unrelated to the two methods above ---
    public void writeToFile(String line) {
        auditLines.add(line);
        System.out.println("wrote a line to the audit file: " + line);
    }

    public List<String> readFromFile() {
        System.out.println("read " + auditLines.size() + " line(s) back from the audit file");
        return List.copyOf(auditLines);
    }
}
```

After: two classes, each with one purpose:

```java
// File: code/lld/ch04/cohesion/after/UserManager.java
package lld.ch04.cohesion.after;

import java.util.ArrayList;
import java.util.List;

/** HIGH cohesion: every method works on the same field for the same purpose. */
public class UserManager {
    private final List<String> users = new ArrayList<>();

    public void addUser(String user) {
        users.add(user);
        System.out.println("user added: " + user);
    }

    public void deleteUser(String user) {
        users.remove(user);
        System.out.println("user deleted: " + user);
    }
}
```

```java
// File: code/lld/ch04/cohesion/after/AuditFile.java
package lld.ch04.cohesion.after;

import java.util.ArrayList;
import java.util.List;

/** HIGH cohesion: only audit-log work lives here. */
public class AuditFile {
    private final List<String> lines = new ArrayList<>();

    public void writeLine(String line) {
        lines.add(line);
        System.out.println("wrote a line to the audit file: " + line);
    }

    public List<String> readAll() {
        System.out.println("read " + lines.size() + " line(s) back from the audit file");
        return List.copyOf(lines);
    }
}
```

```java
// File: code/lld/ch04/cohesion/Main.java
package lld.ch04.cohesion;

import lld.ch04.cohesion.after.AuditFile;
import lld.ch04.cohesion.after.UserManager;

public class Main {
    public static void main(String[] args) {
        System.out.println("--- Before: one class, two unrelated jobs ---");
        var manager = new lld.ch04.cohesion.before.UserManager();
        manager.addUser("ada");
        manager.writeToFile("created ada");
        manager.deleteUser("ada");
        manager.readFromFile();

        System.out.println("--- After: two classes, one job each ---");
        var users = new UserManager();
        var audit = new AuditFile();
        users.addUser("ada");
        audit.writeLine("created ada");
        users.deleteUser("ada");
        audit.readAll();
    }
}
```

Output:

```
--- Before: one class, two unrelated jobs ---
user added: ada
wrote a line to the audit file: created ada
user deleted: ada
read 1 line(s) back from the audit file
--- After: two classes, one job each ---
user added: ada
wrote a line to the audit file: created ada
user deleted: ada
read 1 line(s) back from the audit file
```

Both halves of the output are identical. The difference is structural: each class now has a single purpose, so a new audit-log format is an edit to `AuditFile` alone and never touches user management. The **cost** is that the caller must create and hold two objects instead of one, which becomes worth it as soon as the two jobs change for different reasons.

Cohesion and SRP

- Low cohesion usually means several unrelated jobs in one class, which breaks SRP.
- High cohesion means the class is built around one job, which is what SRP asks for.
- So aiming for high cohesion tends to give you SRP for free.

Trade-offs

High cohesion gains	Costs
Easy to name, read and test each class	More classes to wire
A change lands in one class	Callers may hold several objects

When not to use it

Do not split a class that already has functional cohesion just to make it smaller. Five tiny classes can be harder to follow than one clear one.

Common mistakes

- Calling every mixed class a "coupling problem". A single class mixing jobs is a **cohesion** problem; coupling needs two classes.
- Creating a `Utils` dumping ground (coincidental cohesion).

Real-world examples

- `java.lang.Math` is a set of static math functions: functional cohesion around "numeric calculations".
- `java.util.Collections` is looser: sorting, searching, wrapping and synchronising collections all live together. It is still "operations on collections", but it shows how a utility class drifts toward logical cohesion.

In the interview

> **30-second answer:** "Cohesion is how much the things inside one class belong together. I check which fields each method uses. If the methods split into two groups that touch different fields for different reasons, the class has low cohesion and I split it. High cohesion is basically SRP seen from inside the class."

Follow-up: *"Is a big class always low-cohesion?"* — No. If every method serves one task, it is cohesive even if it is large. Size is a hint, not the measure.

Self-check

1. **Q:** What is the worst kind of cohesion? **A:** Coincidental: code grouped for no reason, like a `Utils` class.
2. **Q:** Is "the code for one job is spread over three classes" a cohesion problem? **A:** Yes. Related code should live together.

TL;DR

Cohesion = do the parts of this class belong together? Aim for one purpose per class; split disjoint groups; gather scattered pieces.

4.4 Coupling

What it is

Coupling is how much one class depends on another. It always describes a pair: a lone class cannot be "tightly coupled", because there is nothing else in the picture for it to depend on.

- **Low (loose) coupling**: you can change, replace or test one class without changing the other.
- **High (tight) coupling**: a change to one forces a change to the other.

> **Analogy: TV and remote.** A remote that controls only one specific TV, and a TV that accepts only that remote, are tightly coupled: replace one and you must replace both. A universal remote and a TV that accepts any remote are loosely coupled: each follows a shared standard (the infrared signal), and each can be swapped on its own.

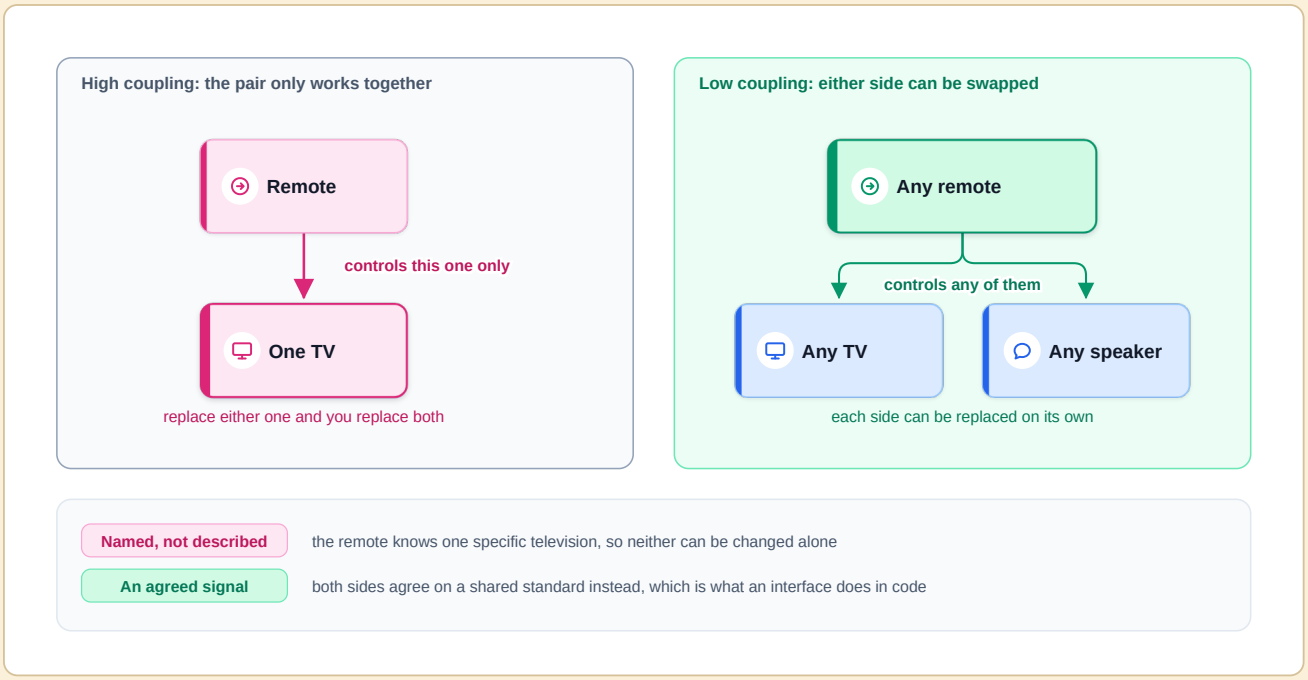

Figure — a remote tied to one TV (high coupling) vs any remote working with any device through an agreed signal (low coupling) (course diagram)

In the figure above, the "agreed signal" on the right is exactly what an **interface** does in code: both sides agree on a contract instead of knowing each other.

The problem it solves

With tight coupling:

- you cannot swap an implementation (MySQL → Postgres, two popular SQL databases) without editing the caller,
- you cannot unit-test the caller without the real dependency (a running database),
- a change in how the dependency is **constructed** ripples into every class that builds it.

The classic types of coupling

From structured design again, from worst to best:

Type (worst → best)	What A knows about B	Java-flavoured example
Content	A reaches into B's internals	Reflection (Java's ability to inspect and change classes while running) that sets B's private field
Common	A and B share global mutable data	Both read/write a `public static Map`
External	Both depend on an external format or device	Both parse the same hand-rolled file format
Control	A passes a flag telling B *how* to work	`print(doc, boolean asPdf)`
Stamp	A passes a whole structure when B needs one field	`sendInvoice(Customer c)` that only reads `c.email()`
Data	A passes only the values B needs	`sendInvoice(String email, Money total)`
Message (lowest)	A sends a message through an interface	`notifier.send(message)` on an interface

In object-oriented design, the practical goal is: **depend on interfaces, pass only what is needed, never share mutable globals.**

How it works

1. Find where class A **names** class B (a field type, a `new B()`, a static call `B.x()`).
2. Ask: does A need *this particular* B, or just *something that does the job*?
3. If the latter, describe the job as an interface.
4. Let A accept any object that implements the interface, usually through its constructor.
5. Let the caller (or the program's entry point, the `main` method where it starts) choose which implementation to pass.

Java example: three steps with `Student`

Start: one class, two jobs. `Student` holds data *and* talks to MySQL. With a single class in play this is a **cohesion** problem; coupling needs a second class:

```java
// File: code/lld/ch04/coupling/start/Student.java
package lld.ch04.coupling.start;

/** Starting point: ONE class, two jobs. A cohesion problem -- nothing to be coupled to yet. */
public class Student {
    private final String studentId;

    public Student(String studentId) {
        this.studentId = studentId;
    }

    public String studentId() {
        return studentId;
    }

    // Student holds the data AND knows how to store it
    public void save() {
        System.out.println("Connecting to MySQL...");
        System.out.println("Saving student with ID: " + studentId);
    }
}
```

Step 1: extract the database work. Cohesion is fixed. But now there are two classes, and the coupling is **tight**: `Student` names `MySqlDatabase` directly.

```java
// File: code/lld/ch04/coupling/extracted/MySqlDatabase.java
package lld.ch04.coupling.extracted;

public class MySqlDatabase {
    public void saveStudent(String studentId) {
        System.out.println("Connecting to MySQL...");
        System.out.println("Saving student with ID: " + studentId);
    }
}
```

```java
// File: code/lld/ch04/coupling/extracted/Student.java
package lld.ch04.coupling.extracted;

/** Step 1: cohesion fixed, but Student now names one concrete class -> TIGHT coupling. */
public class Student {
    private final String studentId;
    private final MySqlDatabase database = new MySqlDatabase(); // hard-wired

    public Student(String studentId) {
        this.studentId = studentId;
    }

    public void save() {
        database.saveStudent(studentId);
    }
}
```

Three costs follow: storing students in any other place requires editing `Student`; every test of `Student` needs a live MySQL server; and if `MySqlDatabase` ever needs constructor arguments, `Student` must change too. The extraction relocated the database code, but `Student` still **depends** on it just as much as before.

Step 2: depend on an interface. Describe what `Student` needs as `StudentRepository`, and let the caller choose the implementation:

```java
// File: code/lld/ch04/coupling/decoupled/StudentRepository.java
package lld.ch04.coupling.decoupled;

/** What Student needs, described as a contract rather than a working class. */
public interface StudentRepository {
    void save(String studentId);
}
```

```java
// File: code/lld/ch04/coupling/decoupled/MySqlStudentRepository.java
package lld.ch04.coupling.decoupled;

public class MySqlStudentRepository implements StudentRepository {
    @Override
    public void save(String studentId) {
        System.out.println("Saving student " + studentId + " to MySQL");
    }
}
```

```java
// File: code/lld/ch04/coupling/decoupled/InMemoryStudentRepository.java
package lld.ch04.coupling.decoupled;

import java.util.ArrayList;
import java.util.List;

/** A stand-in that a unit test can use -- no database server needed. */
public class InMemoryStudentRepository implements StudentRepository {
    private final List<String> saved = new ArrayList<>();

    @Override
    public void save(String studentId) {
        saved.add(studentId);
        System.out.println("Keeping student " + studentId + " in memory for a test");
    }

    public List<String> saved() {
        return List.copyOf(saved);
    }
}
```

```java
// File: code/lld/ch04/coupling/decoupled/Student.java
package lld.ch04.coupling.decoupled;

import java.util.Objects;

/** Step 2: Student names no database at all -> LOOSE coupling. */
public class Student {
    private final String studentId;
    private final StudentRepository repository;

    public Student(String studentId, StudentRepository repository) {
        this.studentId = studentId;
        this.repository = Objects.requireNonNull(repository);
    }

    public void save() {
        repository.save(studentId);
    }
}
```

```java
// File: code/lld/ch04/coupling/Main.java
package lld.ch04.coupling;

import lld.ch04.coupling.decoupled.InMemoryStudentRepository;
import lld.ch04.coupling.decoupled.MySqlStudentRepository;
import lld.ch04.coupling.decoupled.Student;

public class Main {
    public static void main(String[] args) {
        System.out.println("--- Start: one class holds data and SQL ---");
        new lld.ch04.coupling.start.Student("S-1024").save();

        System.out.println("--- Step 1: extracted, but tightly coupled to MySqlDatabase ---");
        new lld.ch04.coupling.extracted.Student("S-1024").save();

        System.out.println("--- Step 2: depends on the StudentRepository interface ---");
        new Student("S-1024", new MySqlStudentRepository()).save();
        var fake = new InMemoryStudentRepository();
        new Student("S-2048", fake).save();
        System.out.println("test double recorded: " + fake.saved());
    }
}
```

Output:

```
--- Start: one class holds data and SQL ---
Connecting to MySQL...
Saving student with ID: S-1024
--- Step 1: extracted, but tightly coupled to MySqlDatabase ---
Connecting to MySQL...
Saving student with ID: S-1024
--- Step 2: depends on the StudentRepository interface ---
Saving student S-1024 to MySQL
Keeping student S-2048 in memory for a test
test double recorded: [S-2048]
```

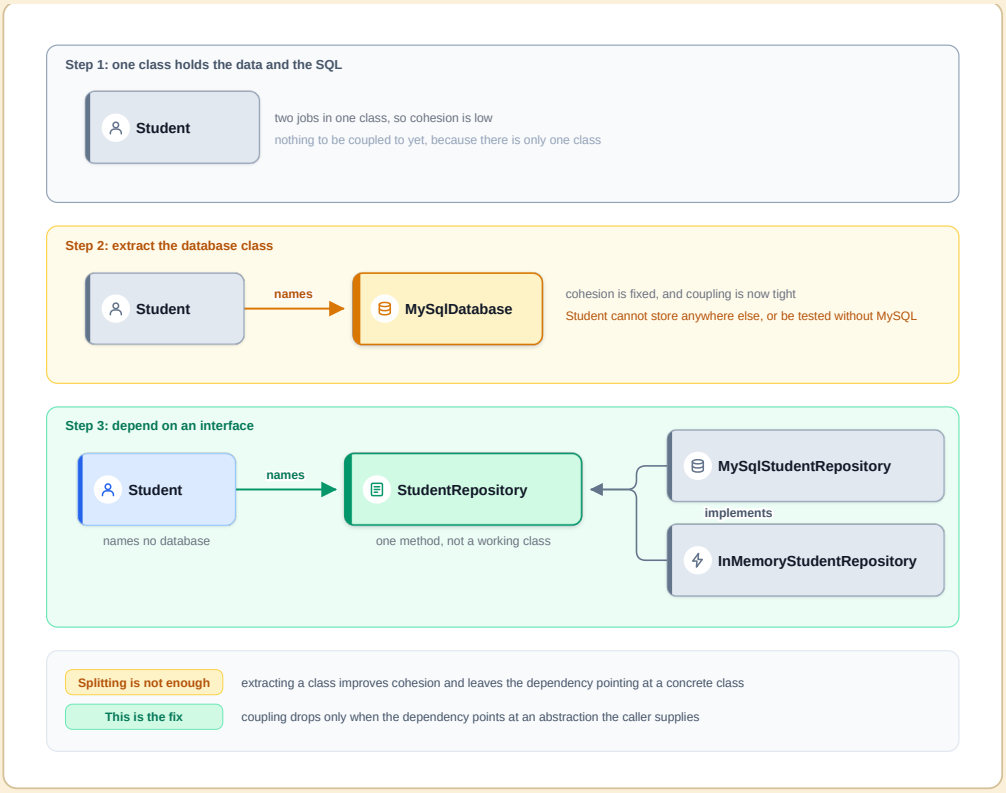

Figure — the three steps: one class with two jobs, an extracted but tightly coupled class, and a class that depends on an interface (course diagram)

In the figure above, follow the arrows. In the middle panel `Student` *names* `MySqlDatabase`. In the last panel it names only `StudentRepository`, a one-method contract, and the concrete repositories point *toward* that contract. Moving to Postgres is now a new repository class handed in by the caller, with no edit to `Student`, and a unit test simply hands in the in-memory version.

This final move is the rule **depend on abstractions, not on concrete classes**, the D in SOLID (4.10). DIP is, in effect, the standard cure for tight coupling.

Coupling and SRP

- **Separating the jobs** (SRP) repaired cohesion, yet by itself it left `Student` bound tightly to `MySqlDatabase`.
- **Aiming the dependency at an interface** is what repaired coupling, and SRP alone never requires that step.
- Hence SRP *usually* reduces coupling (a single-job class needs fewer collaborators) without *guaranteeing* it. After each split, inspect what the two resulting classes depend on; a class carved out to serve its parent's exact needs can remain welded to it.

Trade-offs

Loose coupling gains	Costs
Swap implementations without editing callers	An extra interface and a constructor parameter
Unit tests with in-memory fakes (simple stand-ins that keep data in a list instead of a database)	Someone must do the wiring (the entry point or a framework)
Changes stop rippling	"Go to definition" lands on an interface, one more hop to the real code

When not to use it

- Do not put an interface in front of a **stable** class that will never vary and never needs faking (`String`, `LocalDate`, a pure calculation). Coupling to stable things is harmless.
- An interface with one implementation and no test double (a fake stand-in object used in tests) is usually just an extra file.

Common mistakes

- Thinking "I extracted a class, so coupling is lower". Only depending on an abstraction lowers it.

- Hiding `new ConcreteThing()` inside a constructor. The dependency is still hard-wired.
- Passing whole objects when only one field is needed (stamp coupling).

Real-world examples

- **JDBC** (Java Database Connectivity, Java's standard way to talk to SQL databases): your code talks to `java.sql.Connection`, `Statement` and `ResultSet`, which are interfaces. The MySQL or Postgres driver (the library that speaks one database's protocol) supplies the implementation.
- **SLF4J** (a common Java logging facade, i.e. one front for several logging libraries): code logs through the `org.slf4j.Logger` interface; Logback or Log4j is plugged in at deployment (when the program is installed and started).
- **USB, HTTP, SQL** themselves are "agreed signals", the real-world version of an interface.

In the interview

> **30-second answer:** "Coupling is how much one class depends on another. I check where a class names a concrete collaborator. If it only needs something that does the job, I describe the job as an interface and pass the implementation in. That lets me swap MySQL for Postgres and test with an in-memory fake. I do not add interfaces in front of stable things like `String`."

Follow-up: *"Can SRP increase coupling?"* — It can. Extract a class built around the old class's exact needs and the two are tightly bound. Check the dependencies after every split.

Self-check

1. **Q:** Can a single class be "tightly coupled"? **A:** Not to anything inside itself. Coupling is between two things. A single class with two jobs has a cohesion problem.
2. **Q:** `Student` does `new MySqlDatabase()` in its constructor. Tight or loose? **A:** Tight. It names a concrete class and creates it.
3. **Q:** What is "control coupling"? **A:** Passing a flag that tells the other code how to behave, e.g. `print(doc, asPdf)`.

TL;DR

Coupling = how much A must know about B. Loosen it by depending on an interface and passing the implementation in. Extracting a class alone is not enough.

4.5 Separation of Concerns (SoC)

What it is

Separation of Concerns means splitting a program into parts where each part handles one **concern**. A concern is one area of the work: storing data is one concern, deciding whether an email address is acceptable is another, drawing the screen is a third. The term comes from Edsger Dijkstra (1974).

> **Analogy:** in a restaurant, the kitchen cooks, the waiters serve, and the cashier takes payment. A new menu does not change how payment works.

The problem it solves

When concerns are mixed, one change forces you to read and edit code about other concerns. When they are separate, each change lands in one module.

Benefits:

- **Modularity** — each part covers one area, so the system is easier to follow.
- **Maintainability** — a change in one part rarely affects the others.
- **Reusability** — a well-defined module can be reused elsewhere.
- **Testability** — test one concern with the others replaced by simple stand-ins.

How it works

1. List the concerns in the feature (for registration: storage, business rules).
2. Give each concern its own module.
3. Let modules talk only through small, clear methods.
4. Test the result: for each likely requirement change, **count the modules you would have to edit**. The ideal answer is one.

Java example: user registration

Two concerns. **Storage** keeps users and never judges whether a user is valid. **Business rules** decide what is acceptable and ask storage to save it, without knowing how storage works.

```java
// File: code/lld/ch04/soc/UserStore.java
package lld.ch04.soc;

import java.util.ArrayList;
import java.util.List;

/** Storage concern only. It has no opinion about what a valid user is. */
public class UserStore {
    public record User(String username, String email) { }

    private final List<User> users = new ArrayList<>();

    public void addUser(String username, String email) {
        users.add(new User(username, email));
        System.out.println("Stored user: " + username);
    }

    public int count() {
        return users.size();
    }
}
```

```java
// File: code/lld/ch04/soc/UserService.java
package lld.ch04.soc;

/** Business-rules concern only. Storage is somebody else's job. */
public class UserService {
    private final UserStore store;

    public UserService(UserStore store) {
        this.store = store;
    }

    boolean isValidUsername(String username) {
        return username.length() >= 3;
    }

    boolean isValidEmail(String email) {
        return email.contains("@") && email.contains(".");
    }

    public boolean registerUser(String username, String email) {
        if (!isValidUsername(username)) {
            System.out.println("Rejected: " + username + " is too short");
            return false;
        }
        if (!isValidEmail(email)) {
            System.out.println("Rejected: " + email + " is not an email address");
            return false;
        }
        store.addUser(username, email);
        return true;
    }
}
```

```java
// File: code/lld/ch04/soc/Main.java
package lld.ch04.soc;

public class Main {
    public static void main(String[] args) {
        UserStore store = new UserStore();
        UserService service = new UserService(store);
        service.registerUser("ada", "ada@example.com");
        service.registerUser("jo", "jo@example.com");
        service.registerUser("grace", "grace-at-example");
        System.out.println("Users in store: " + store.count());
    }
}
```

Output:

```
Stored user: ada
Rejected: jo is too short
Rejected: grace-at-example is not an email address
Users in store: 1
```

Of the three attempts, only `ada` made it into storage: `jo` failed the length rule and `grace-at-example` failed the email rule. Every accept/reject decision was made by `UserService`, which never touched the list itself; `UserStore` simply kept whatever it was handed, without judging it.

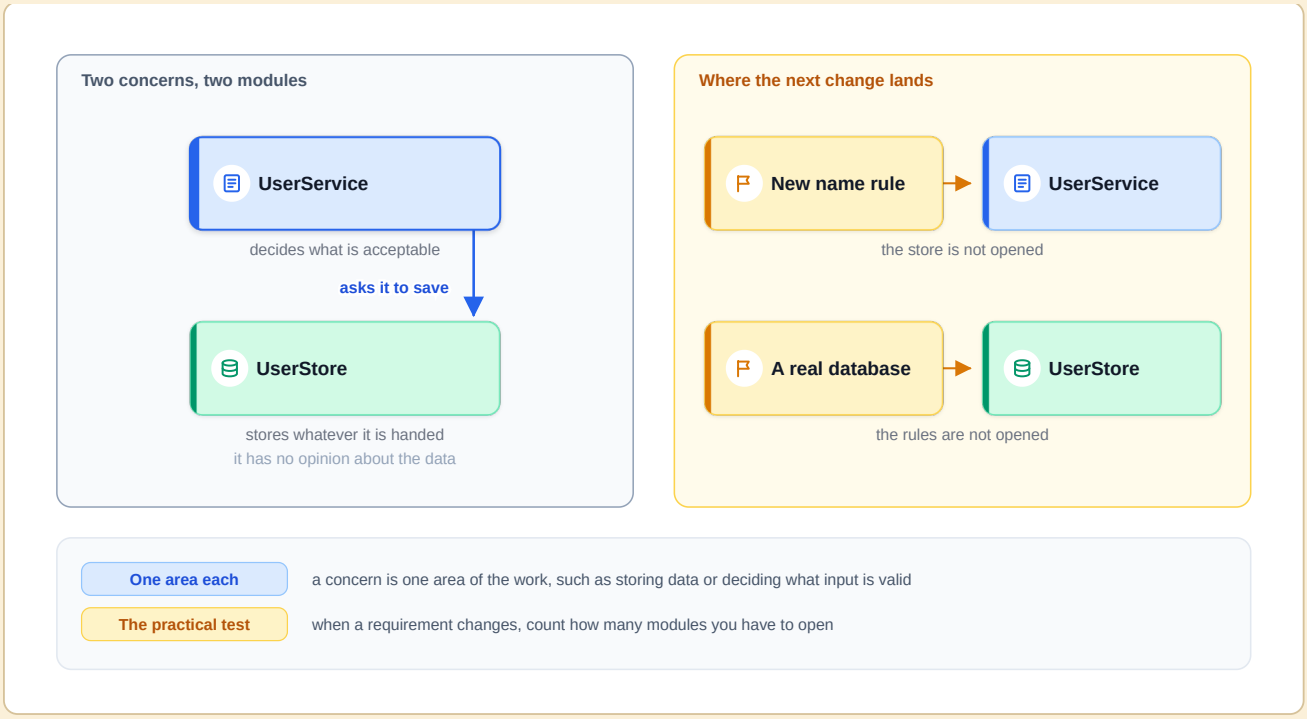

Figure — UserService decides what is acceptable and asks UserStore to save it; each change lands in one module (course diagram)

As the figure above shows, each likely change lands in exactly one place:

Change	Module you open
Move from an in-memory list to a real database	`UserStore` only
Require usernames of at least eight characters	`UserService` only
Test the rules without a database	Pass `UserService` a stand-in store

(In a bigger system you would also put `UserStore` behind an interface, which is the coupling fix from 4.4.)

SoC and SRP

The two are the same instinct applied at different scales. **SRP** is normally discussed for a single class; **SoC** for modules, layers and whole subsystems. Giving every class in a module a single responsibility is one route to well-separated concerns.

Trade-offs

Gains	Costs
Changes stay local	More modules and boundaries to design
Each concern tested alone	Cross-cutting concerns (logging, security, transactions, i.e. groups of database changes that succeed or fail together) still touch many modules; they need special tools such as aspects (code woven automatically around many methods) or decorators (wrappers that add behaviour)

When not to use it

A 50-line script does not need layers. Separate concerns when they change for different reasons or at different speeds.

Common mistakes

- Validation that quietly happens inside the storage class ("the DAO also checks the email"; a DAO, Data Access Object, is a class that reads and writes one kind of data in the database).
- Layers that exist on paper but call each other in every direction.

Real-world examples

- **MVC** (Model–View–Controller): model = data and rules, view = display, controller = input handling. Spring MVC and most web frameworks (libraries that handle the plumbing of web applications) follow it.
- **HTML / CSS / JavaScript**: structure, style and behaviour are three concerns in three languages.
- **Layered architecture**: controller → service → repository.
- **Spring** `@Transactional`: transaction handling (a cross-cutting concern) is separated from business code by a proxy (a stand-in object that wraps the real one and adds behaviour before and after each call).

In the interview

> **30-second answer:** "Separation of concerns means each module handles one area of the work, like storage vs business rules. My test is: when a requirement changes, how many modules do I open? Ideally one. It is SRP at module size."

Self-check

1. **Q:** What is a "concern"? **A:** One area of the work, such as storage, validation or presentation.
2. **Q:** How do SoC and SRP differ? **A:** Mostly in size: SRP is about a class, SoC about modules and layers.

TL;DR

One module per area of work; measure it by how many modules a change forces you to open.

4.6 SRP vs cohesion vs coupling vs SoC — one table

Idea	Question it asks	Scope	How it relates to SRP
SRP	How many actors can ask this class to change?	Class / module	—
Cohesion	Do the parts of this class belong together?	Inside one unit	Applying SRP usually raises cohesion, because one job means related parts.
Coupling	How much does A depend on B?	Between two units	SRP tends to lower coupling but does not guarantee it; you still need to depend on abstractions.
SoC	Is each area of work in its own module?	Modules, layers	SRP applied to every class is one way to achieve SoC.

The rule of thumb every textbook repeats, **"high cohesion, low coupling"**, is the goal. SRP is the tool that gets you the first half; depending on abstractions (DIP) gets you the second.

4.7 Open/Closed Principle (OCP)

What it is

Software entities (classes, modules, functions) should be open for extension but closed for modification. In plain words: you should be able to add new behaviour **by adding new code**, without editing code that already works.

- **Closed for modification**: once a class is written and tested, adding the next variation should not require opening it. Every edit to working code risks breaking it.
- **Open for extension**: new behaviour arrives as new parts, usually through **interfaces**, **polymorphism** (one call, many implementations) or **inheritance**.

Where it comes from. Bertrand Meyer stated the principle in 1988 (*Object-Oriented Software Construction*). In **Meyer's OCP** a class is *closed* once it is compiled, published and used by clients (it is changed only to fix bugs), and it stays *open* because a new class can **inherit** from it and add or redefine features. That is extension by implementation inheritance. Robert C. Martin's 1996 article restated it as the **polymorphic OCP**: the stable code depends on an **abstract interface**, and new behaviour arrives as new implementations of that interface, which

can be swapped for one another. The polymorphic version is the one people usually mean today, and it is the one used in this chapter.

> **Analogy: a game console and its accessories.** You buy a console with a standard controller. Later you add a racing wheel, a motion controller and a VR headset. Nobody opens the console and rewires it. The console is **closed** (its internals stay sealed) and **open** (it offers a standard port that new accessories plug into).

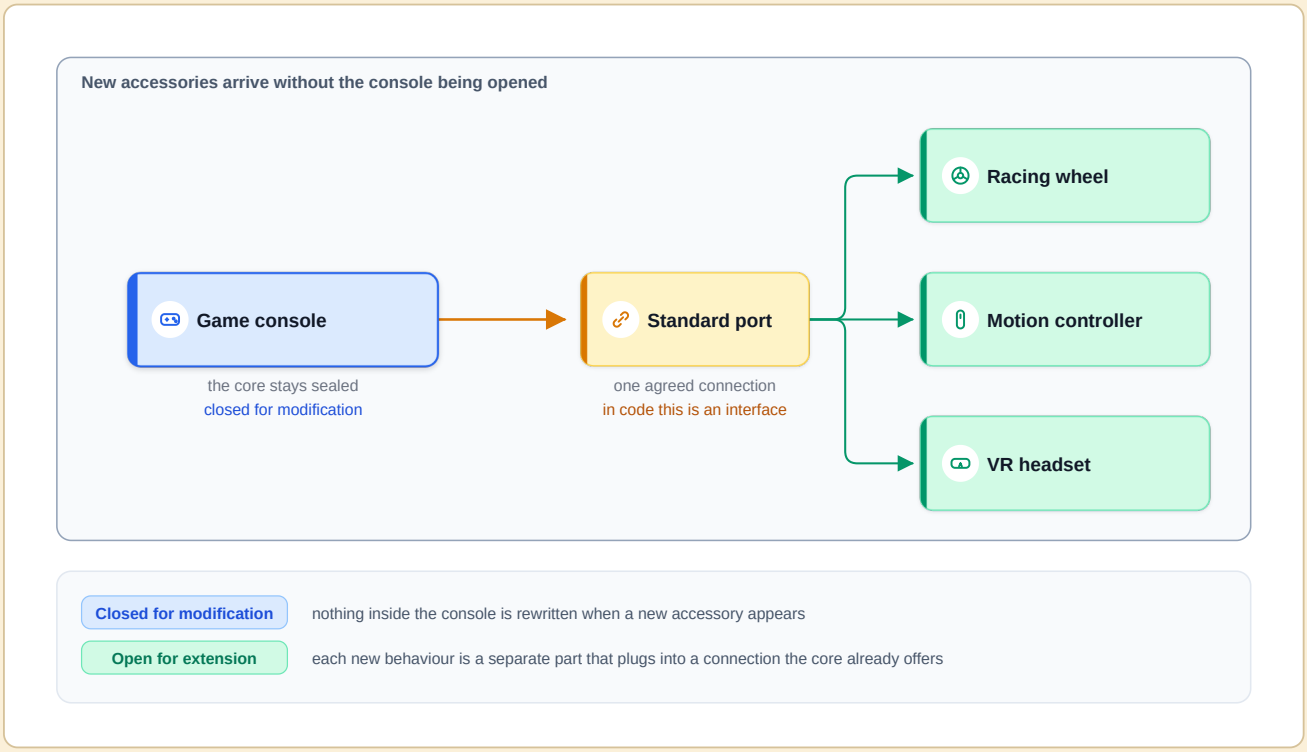

Figure — new accessories plug into a standard port; the console itself is never opened (course diagram)

In the figure above, the **standard port** is the interface. The accessories are new classes that implement it.

The problem it solves

The textbook symptom is an `if/else` chain or `switch` on a type code that keeps growing. Each new case is an edit to a tested, working method, and each edit can break the cases that were fine. Often the same `switch` also appears in several places, and one copy gets missed.

Quick test: *can I add the next case without opening this file?* If not, the class is not closed against that kind of change.

How it works

1. Wait until you have seen the variation happen (at least a second case).
2. Identify **the part that varies** (here: the invoice format).
3. Describe it as an interface.
4. Move each variant into its own class that implements the interface.
5. Make the stable class **delegate** (hand the work over) to the interface instead of branching.
6. Add the next variant as a new class. Nothing existing is opened.
7. Choose the variant in one place, at the edge of the program (the entry point, a factory, i.e. a method or class whose job is creating objects, a map, or configuration).

Java example: invoice formats

Before. While `Invoice` had a single format, there was nothing to fix: OCP only matters for code that actually receives new variations. The trouble starts when sales wants **international invoices** and the quickest route is a type parameter and a branch:

```java
// File: code/lld/ch04/ocp/before/Invoice.java
package lld.ch04.ocp.before;

import java.math.BigDecimal;

/** VIOLATION: every new invoice type means opening this working, tested method. */
public class Invoice {
    private final BigDecimal amount;

    public Invoice(BigDecimal amount) {
        this.amount = amount;
    }

    public void generate(String invoiceType) {
        if (invoiceType.equals("basic")) {
            System.out.println("Generating basic invoice for amount: " + amount);
        } else if (invoiceType.equals("international")) {
            System.out.println("Generating international invoice for amount: " + amount);
        } else {
            throw new IllegalArgumentException("Unknown invoice type: " + invoiceType);
        }
    }

    public void applyDiscount() {
        System.out.println("Applying discount on invoice: " + amount);
    }
}
```

Note exactly what is wrong. Doing two jobs would be an SRP complaint; the OCP complaint is that **each new invoice type forces an edit to code that already works**.

After. Step 1: turn the part that varies into an interface. Step 2: give each format its own class. These classes *produce* invoices, so they are named *generators*; a name like `BasicInvoice` would falsely imply a subtype of invoice. Step 3: `Invoice` hands the work to its generator. Step 4: a third format costs one new class plus one line at the place where formats are chosen.

```java
// File: code/lld/ch04/ocp/after/InvoiceGenerator.java
package lld.ch04.ocp.after;

import java.math.BigDecimal;

/** Step 1: the part that varies (the invoice format) gets its own abstraction. */
@FunctionalInterface
public interface InvoiceGenerator {
    void generate(BigDecimal amount);
}
```

```java
// File: code/lld/ch04/ocp/after/BasicInvoiceGenerator.java
package lld.ch04.ocp.after;

import java.math.BigDecimal;

public class BasicInvoiceGenerator implements InvoiceGenerator {
    @Override
    public void generate(BigDecimal amount) {
        System.out.println("Generating basic invoice for amount: " + amount);
    }
}
```

```java
// File: code/lld/ch04/ocp/after/InternationalInvoiceGenerator.java
package lld.ch04.ocp.after;

import java.math.BigDecimal;

public class InternationalInvoiceGenerator implements InvoiceGenerator {
    @Override
    public void generate(BigDecimal amount) {
        System.out.println("Generating international invoice for amount: " + amount);
        System.out.println("  including customs declaration and currency conversion");
    }
}
```

```java
// File: code/lld/ch04/ocp/after/DetailedInvoiceGenerator.java
package lld.ch04.ocp.after;

import java.math.BigDecimal;

/** Step 4: the ONLY new code for a third format. No existing class was opened. */
public class DetailedInvoiceGenerator implements InvoiceGenerator {
    @Override
    public void generate(BigDecimal amount) {
        System.out.println("Generating detailed invoice for amount: " + amount);
        System.out.println("  line items, tax breakdown and payment terms");
    }
}
```

```java
// File: code/lld/ch04/ocp/after/Invoice.java
package lld.ch04.ocp.after;

import java.math.BigDecimal;
import java.util.Objects;

/** Step 3: Invoice delegates. It no longer knows how many formats exist. */
public class Invoice {
    private final BigDecimal amount;
    private final InvoiceGenerator generator;

    public Invoice(BigDecimal amount, InvoiceGenerator generator) {
        this.amount = Objects.requireNonNull(amount);
        this.generator = Objects.requireNonNull(generator);
    }

    public void generate() {
        generator.generate(amount); // no branching
    }

    // Still closed? No -- a new discount rule would still edit this class.
    // That is fine until discounts actually start to vary.
    public void applyDiscount() {
        System.out.println("Applying discount on invoice: " + amount);
    }
}
```

```java
// File: code/lld/ch04/ocp/Main.java
package lld.ch04.ocp;

import java.math.BigDecimal;
import java.util.List;
import lld.ch04.ocp.after.BasicInvoiceGenerator;
import lld.ch04.ocp.after.DetailedInvoiceGenerator;
import lld.ch04.ocp.after.InternationalInvoiceGenerator;
import lld.ch04.ocp.after.Invoice;
import lld.ch04.ocp.after.InvoiceGenerator;

public class Main {
    public static void main(String[] args) {
        BigDecimal amount = new BigDecimal("120.00"); // money: BigDecimal with 2 decimals

        System.out.println("--- Before: branch per type ---");
        var old = new lld.ch04.ocp.before.Invoice(amount);
        old.generate("basic");
        old.generate("international");

        System.out.println("--- After: one class per format ---");
        List<InvoiceGenerator> generators = List.of(
                new BasicInvoiceGenerator(),
                new InternationalInvoiceGenerator(),
                new DetailedInvoiceGenerator(),
                // A lambda is also an extension: no new file, no edited file.
                a -> System.out.println("Generating pro-forma invoice for amount: " + a));
        for (InvoiceGenerator g : generators) {
            new Invoice(amount, g).generate();
        }
    }
}
```

Output:

```
--- Before: branch per type ---
Generating basic invoice for amount: 120.00
Generating international invoice for amount: 120.00
--- After: one class per format ---
Generating basic invoice for amount: 120.00
Generating international invoice for amount: 120.00
  including customs declaration and currency conversion
Generating detailed invoice for amount: 120.00
  line items, tax breakdown and payment terms
Generating pro-forma invoice for amount: 120.00
```

What to notice:

- `Invoice` has **no branch**. It does not know how many formats exist.
- `DetailedInvoiceGenerator` is the only new code for format three. `Invoice`, `BasicInvoiceGenerator` and `InternationalInvoiceGenerator` were not opened.
- `InvoiceGenerator` is a `@FunctionalInterface` (an interface with exactly one abstract method), so in Java a **lambda** (a short unnamed function written inline, such as `a -> ...`) is also an extension (the pro-forma line in `Main`). That is OCP with zero new files.

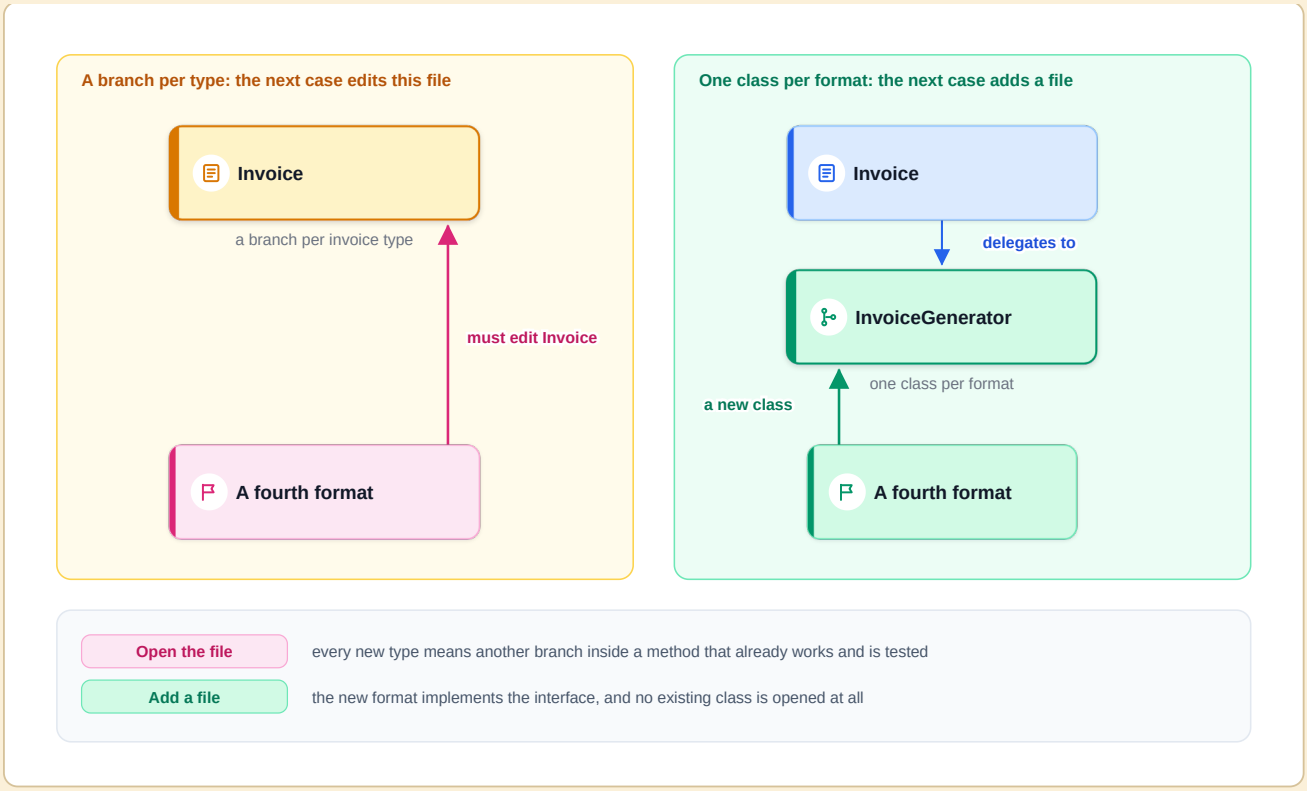

Figure — a branch per type forces an edit to Invoice; one class per format lets a new format be added as a file (course diagram)

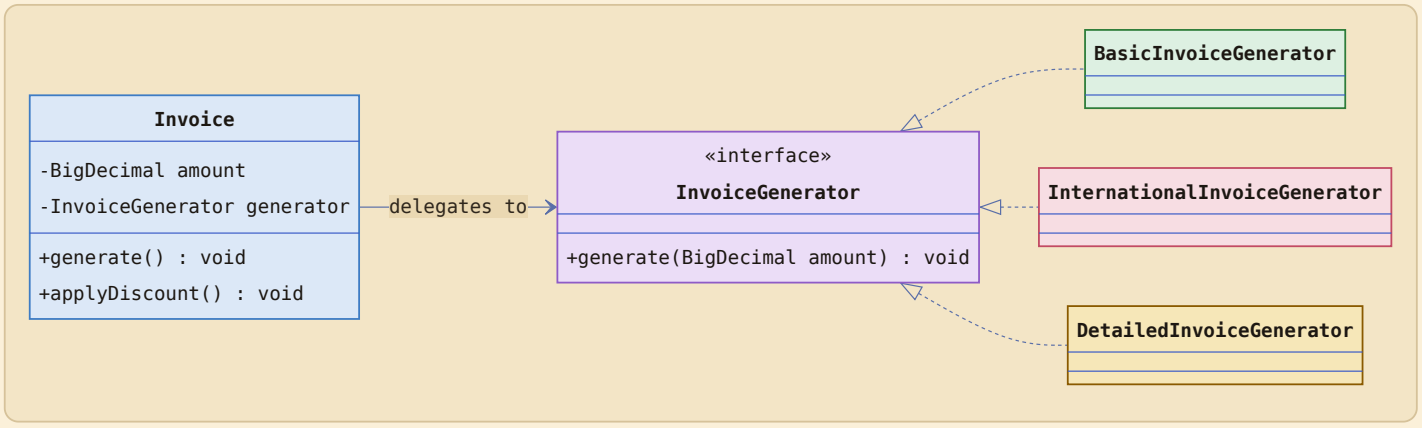

This shape (a context object holding an interface-typed field, with interchangeable implementations) is the **Strategy pattern** (a design pattern, i.e. a named reusable design; Chapters 8–11 cover them all). Strategy is OCP applied to an algorithm that varies.

Why not just subclass `Invoice`?

Most readers ask this. Writing `class InternationalInvoice extends Invoice` and overriding `generate()` is also OCP-compliant (it is Meyer's original style): a class is added, nothing is edited. In a small program that is perfectly acceptable. Delegation wins as the system grows, for two reasons:

- **A second dimension of change.** If invoices differ by format **and** by currency, subclassing needs a class for every pairing (3 formats × 4 currencies = 12 classes), while delegation combines two independent objects (3 + 4 = 7 classes).
- **Deciding while the program runs.** An object's class is fixed at `new`. A generator can be picked once the customer's country is known, and even replaced later on the same invoice.

Inheritance is therefore a legitimate option; delegation simply copes with more situations. (*Head First Design Patterns*, a popular introductory book, calls this "favour composition over inheritance".)

What is still not closed

Only invoice *generation* was opened up. `applyDiscount` still lives inside `Invoice`, so a new kind of discount still means an edit there, and that is fine. **"Closed" is never absolute: a class is closed against a specific**

kind of change, normally one you have already watched happen. Discount rules have not varied yet, so there is no reason to abstract them yet. Martin's term for this is **strategic closure**: since no real program can be closed against every possible change, the designer picks which kinds of change to close against, guided by experience.

Approaches to OCP

Approach	How it extends	Pattern / Java feature	Good when
Interface + delegation	New class implements the interface	Strategy, `Comparator`	The algorithm varies, choose at run time
Inheritance + overriding	Subclass overrides a hook method (an overridable step the parent calls)	Template Method, abstract classes	Fixed skeleton, a few steps vary
Wrapping	New class wraps the old and adds behaviour	Decorator (`BufferedInputStream`)	Add features around existing behaviour
Listening	New subscriber registers	Observer, event listeners	New reactions to existing events
Plug-ins / registry	New implementation registers itself in a map or via `ServiceLoader` (Java's built-in way to discover implementations at start-up)	Plug-in architecture	Third parties add features
Functions	Pass a lambda	`java.util.function`, `@FunctionalInterface`	Small, one-method variations
Data / configuration	New entry in a table or config file	Rules engines, feature flags (on/off switches kept in configuration)	Variations that are just different numbers

The `switch` does not always disappear. It moves to **one** place at the edge of the program, often a factory or a `Map<String, InvoiceGenerator>`, instead of being repeated inside business logic.

Importance of OCP

- **Extensibility** — features are added without touching the tested core.
- **Faster testing** — you test the new class, and the core's tests stay valid.
- **Fewer regressions** (old features that break after a change) — working code is not edited, so it is not broken.
- **Adaptability** — the software absorbs new requirements without rewrites.

Caution: do not over-engineer

- **Start simple.** Write the `if` first. Introduce the interface when the second or third case actually arrives (the "rule of three").
- **Balance.** Too many abstraction layers make the code harder to read, which defeats the purpose.
- **Think about real needs.** Extension points for futures that never arrive are wasted effort. *Refactoring* calls this smell **Speculative Generality**.

How OCP relates to SRP

The SOLID principles reinforce one another. OCP pulls the parts that change away from the core that stays put, and each changing part ends up in a class with a single job, which is SRP. In practice SRP usually has to happen first, because the extension point stays hidden until the class is down to one job.

Trade-offs

You gain	You pay
New variants without editing old code	An interface plus one class per variant
Each variant tested on its own	Behaviour is spread over files; reading the whole flow takes more hops
Variants selectable at run time	Someone must choose the variant (factory, map, DI, i.e. dependency injection, Section 4.10)

When not to use it

- Nothing has varied yet.
- The "variants" are just different numbers (use data, not classes).
- The set of cases is fixed and small and will not grow (e.g. the two values of a boolean). Java 21's **sealed interfaces with pattern-matching** `switch` (a sealed interface lists the only types allowed to implement it, so a `switch` can check it has covered them all) are a good fit here: the compiler checks every case is handled, which is the opposite trade (easy to add operations, hard to add types).

Common mistakes

- Thinking OCP means "never edit a file". Bug fixes, refactoring and changes to the extension point itself all involve editing.
- Building plug-in systems for one implementation.
- Replacing a `switch` in business logic with a `switch` in five factories.

Refactorings and smells

- Smell: **Repeated Switches** (called *Switch Statements* in the first edition of *Refactoring*).
- Fix: **Replace Conditional with Polymorphism**; also **Replace Type Code with Subclasses**.

Real-world examples

- **`Comparator`**: `list.sort(comparator)` never changes; you pass a new comparator for a new ordering.
- **Java I/O decorators**: `new BufferedInputStream(new FileInputStream(f))` adds buffering without editing `FileInputStream`.
- **Servlet filters / Spring `HandlerInterceptor`** (code that runs before and after every web request in a Java web server): new cross-cutting behaviour is a new filter registered in a chain.
- **JDBC drivers** via `ServiceLoader`: a new database is supported by adding a driver JAR (a zipped bundle of compiled Java classes), not by editing `DriverManager`.
- **IDE plug-ins** (IntelliJ, VS Code extensions) and **browser extensions**: the core is closed, the plug-in API is the port.

In the interview

> **30-second answer:** "OCP says you should be able to add the next variation by adding code, not editing working code. When I see a `switch` over a type that keeps growing, I put the varying behaviour behind an interface, one class per variant, and the stable class delegates to it. That is Strategy. I only do it once the variation has actually appeared, and I say that a class is closed against a specific kind of change, not against everything."

Follow-ups:

- *"Does OCP mean you never edit a class?"* — No. It means the next variation of a known kind is an addition. Bug fixes and refactoring still edit.
- *"Inheritance or delegation?"* — Both satisfy OCP. Delegation handles several axes of variation and run-time choice better.
- *"Would you add an interface for pricing up front?"* — Only if pricing has already varied or is clearly about to. Otherwise I leave the `if` and refactor when the second case shows up.
- *"The interviewer adds: 'trucks are charged a different rate'."* — A design that answers "add a class" beats one that answers "add a branch in this switch".

Self-check

1. **Q:** What does "closed for modification" mean? **A:** Adding the next variation does not require editing tested code.
2. **Q:** After the refactor, is `Invoice` closed against new discount rules? **A:** No, only against new formats. That is fine until discounts vary.
3. **Q:** Which pattern is "OCP for an algorithm"? **A:** Strategy.
4. **Q:** Give a quick OCP test. **A:** "To add the next case, must I open this file?"

TL;DR

Put the part that varies behind an interface, add variants as new classes, choose them at the edge. Do it when variation is real, and remember closure is always against a specific kind of change.

4.8 Liskov Substitution Principle (LSP)

What it is

Objects of a subtype must be usable wherever objects of the parent type are expected, without making the program incorrect. Barbara Liskov introduced the idea in a 1987 keynote; with Jeannette Wing she later (1994) defined it precisely as *behavioural subtyping*. Robert C. Martin's short form is: **subtypes must be substitutable for their base types.**

"Substitutable" means more than "it compiles". Code written against the parent type must still get **correct results** when handed a child.

> **Analogy:** a hire-car company promises "a car that takes petrol". If they hand you an electric car and you drive to a petrol station, the promise was broken, even though an electric car is certainly a car.

The problem it solves

Polymorphism only works if callers can trust the base type. If some subclass secretly behaves differently, every caller has to check which subclass it got (`instanceof`), and the benefit of polymorphism, and of OCP, is gone.

Example 1: `Car` and `ElectricCar`

`Car` has `start()`, `stop()` and `refuel()`. `ElectricCar extends Car`. An electric car starts and stops fine, but `refuel()` makes no sense, so it throws. It also adds its own `recharge()`.

```java
// File: code/lld/ch04/lsp/car/before/Car.java
package lld.ch04.lsp.car.before;

public class Car {
    public void start() {
        System.out.println("Car is starting");
    }

    public void stop() {
        System.out.println("Car is stopping");
    }

    /** Names a MECHANISM (liquid fuel) instead of a goal. */
    public void refuel() {
        System.out.println("Car is refueling");
    }
}
```

```java
// File: code/lld/ch04/lsp/car/before/ElectricCar.java
package lld.ch04.lsp.car.before;

/** VIOLATION: inherits a promise (refuel) it cannot keep. */
public class ElectricCar extends Car {
    @Override
    public void refuel() {
        throw new UnsupportedOperationException("Electric cars don't need refueling");
    }

    public void recharge() {
        System.out.println("Electric car is recharging");
    }
}
```

Code that *knows* it holds an `ElectricCar` can call `recharge()` and never notice a problem. But the new method does not make `refuel()` go away; the broken method is still part of the object's public face. LSP is tested by code that does **not** know the subclass, such as `service(Car car)` in `Main` below: it calls `start`, `refuel` and `stop` on whatever `Car` it receives, and it crashes when that car is electric.

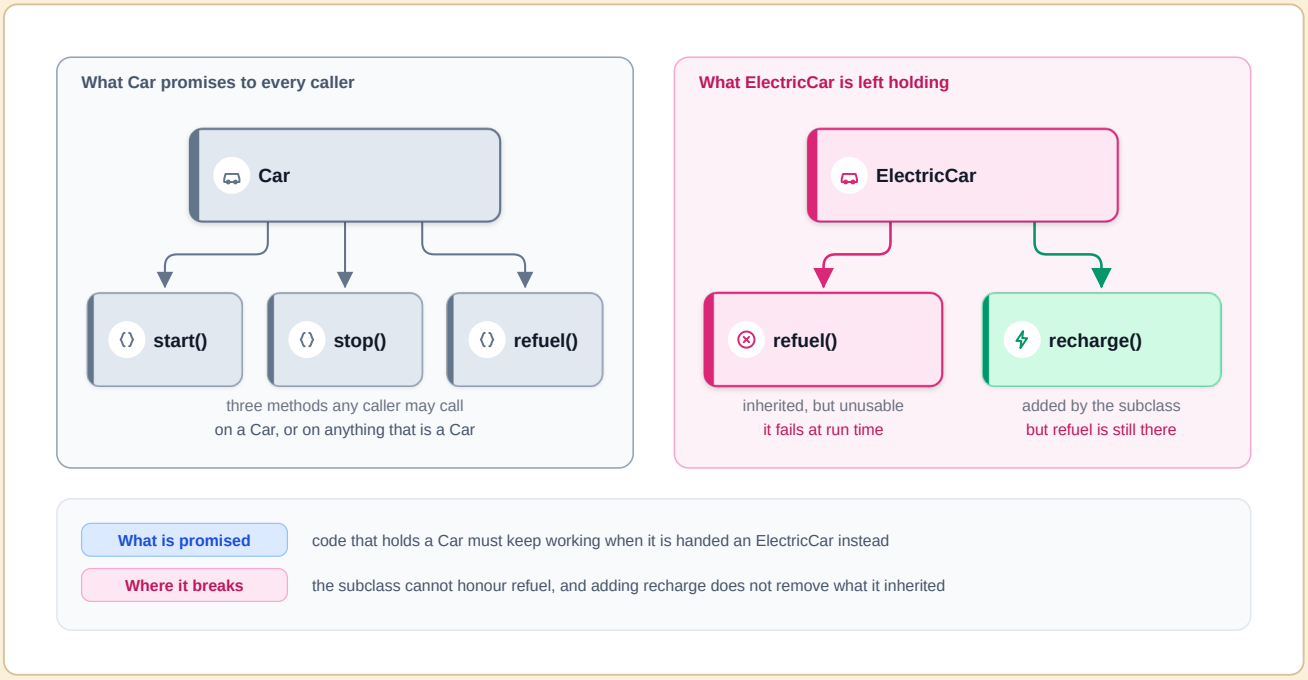

Figure — what Car promises every caller, and the unusable refuel() that ElectricCar is left holding (course diagram)

As the figure above shows, `ElectricCar` cannot fulfil the contract of `Car`, so it is not a valid substitute.

Name the real mistake. "`ElectricCar` should not extend `Car`" is only half the diagnosis. The root cause is the method itself: `refuel()` describes one **mechanism** (pouring in liquid fuel) that only some vehicles use. A method on a base class should describe the **goal** that all subclasses have in common. Every vehicle must take on energy before driving, so the common goal is `replenishEnergy()`.

The fix: raise a general parent. `Vehicle` declares the goal. `Car` and `ElectricCar` both extend `Vehicle`, and **neither extends the other**:

```java
// File: code/lld/ch04/lsp/car/after/Vehicle.java
package lld.ch04.lsp.car.after;

/** The base type promises the GOAL every vehicle shares, not one mechanism. */
public abstract class Vehicle {
    public void start() {
        System.out.println(getClass().getSimpleName() + " is starting");
    }

    public void stop() {
        System.out.println(getClass().getSimpleName() + " is stopping");
    }

    public abstract void replenishEnergy();
}
```

```java
// File: code/lld/ch04/lsp/car/after/Car.java
package lld.ch04.lsp.car.after;

public class Car extends Vehicle {
    @Override
    public void replenishEnergy() {
        System.out.println("Car is pumping gasoline");
    }
}
```

```java
// File: code/lld/ch04/lsp/car/after/ElectricCar.java
package lld.ch04.lsp.car.after;

/** A sibling of Car, not a child of it. Both can stand in for Vehicle. */
public class ElectricCar extends Vehicle {
    @Override
    public void replenishEnergy() {
        System.out.println("Electric car is charging its battery");
    }
}
```

Three points worth stating carefully:

- **The easy workaround is still wrong.** You could keep `refuel()` and have `ElectricCar.refuel()` secretly charge the battery. The exception disappears, but the method name keeps telling callers something untrue about half the fleet. Renaming fixes the promise itself rather than disguising it.
- **Why not just add `recharge()` to `ElectricCar`?** Code typed as `Vehicle` has no way to call it. A caller may depend only on what the base type declares, never on extras one subclass happens to offer.
- **Substitution goes from child to parent, never between siblings.** `Car` and `ElectricCar` can each replace a `Vehicle`. An `ElectricCar` was never meant to replace a `Car`; the two are siblings.

When to break a hierarchy, watch for:

- a subclass that **cannot implement** a parent method (it throws or does nothing),
- a base method that describes a **mechanism** rather than a goal,
- callers that **test the type** (`if (v instanceof ElectricCar)`), a sign that the base type promises too little or promises the wrong thing,
- subclasses with almost nothing in common, where the shared parent invents a relationship that is not really there.

The fix is usually one of two moves: **raise a general parent** (as above) or **take the varying behaviour out of the hierarchy** with composition (next).

Example 2: birds, and composition instead of inheritance

Here `fly()` is declared on `Bird`, so penguins inherit it and have to reject it. The fault is not the penguin; it is that `Bird` made a promise only part of its family can keep. (In *Refactoring*, a subclass that does not want what it inherits is the **Refused Bequest** smell.)

Two ways to connect classes:

- **Inheritance is an is-a relationship.** `Sparrow extends Bird`: a sparrow is a bird and receives **every** method of `Bird`, whether it suits it or not.
- **Composition is a has-a relationship.** `Bird` holds a field of type `MovementStyle`: a bird *has* a way of moving and calls it. It inherits nothing from it.

The fix: turn the varying behaviour (how a bird moves) into its own small type, and give each bird one through its constructor. There are **no bird subclasses** at all. A sparrow and a penguin are both `Bird`, built with a different `MovementStyle`.

```java
// File: code/lld/ch04/lsp/birds/inheritance/Bird.java
package lld.ch04.lsp.birds.inheritance;

/** Promises fly() to EVERY bird -- a promise only some birds can keep. */
public class Bird {
    public void fly() {
        System.out.println(getClass().getSimpleName() + " is flying");
    }
}
```

```java
// File: code/lld/ch04/lsp/birds/inheritance/Sparrow.java
package lld.ch04.lsp.birds.inheritance;

public class Sparrow extends Bird { }
```

```java
// File: code/lld/ch04/lsp/birds/inheritance/Penguin.java
package lld.ch04.lsp.birds.inheritance;

/** VIOLATION ("refused bequest"): inherits fly() and has to refuse it. */
public class Penguin extends Bird {
    @Override
    public void fly() {
        throw new UnsupportedOperationException("Penguins can't fly");
    }
}
```

```java
// File: code/lld/ch04/lsp/birds/composition/MovementStyle.java
package lld.ch04.lsp.birds.composition;

/** The behaviour that varies, pulled out into its own small type. */
@FunctionalInterface
public interface MovementStyle {
    void move(String birdName);
}
```

```java
// File: code/lld/ch04/lsp/birds/composition/Flying.java
package lld.ch04.lsp.birds.composition;

public class Flying implements MovementStyle {
    @Override
    public void move(String birdName) {
        System.out.println(birdName + " is flying through the air");
    }
}
```

```java
// File: code/lld/ch04/lsp/birds/composition/Swimming.java
package lld.ch04.lsp.birds.composition;

public class Swimming implements MovementStyle {
    @Override
    public void move(String birdName) {
        System.out.println(birdName + " is swimming through the water");
    }
}
```

```java
// File: code/lld/ch04/lsp/birds/composition/Running.java
package lld.ch04.lsp.birds.composition;

public class Running implements MovementStyle {
    @Override
    public void move(String birdName) {
        System.out.println(birdName + " is running along the ground");
    }
}
```

```java
// File: code/lld/ch04/lsp/birds/composition/Bird.java
package lld.ch04.lsp.birds.composition;

import java.util.Objects;

/** A bird HAS-A movement style. No subclasses, so nothing is inherited and refused. */
public final class Bird {
    private final String name;
    private MovementStyle movement;

    public Bird(String name, MovementStyle movement) {
        this.name = name;
        this.movement = Objects.requireNonNull(movement);
    }

    public void eat() {
        System.out.println(name + " is eating");
    }

    /** Tell, don't ask: callers say "travel", the bird decides how. */
    public void travel() {
        movement.move(name);
    }

    /** Composition can change behaviour at run time (e.g. an injured bird). */
    public void changeMovement(MovementStyle movement) {
        this.movement = Objects.requireNonNull(movement);
    }
}
```

Why this satisfies LSP: `Bird` now promises only what every bird can do (`eat()` and `travel()`), so there is nothing any bird must refuse. Flight has become one optional object that some birds are given, not a promise to all of them. Supporting the ostrich took one new movement style instead of an `Ostrich` subclass stuck with a meaningless `fly()`. And since the style is just a field, it can be replaced while the program runs (`changeMovement`).

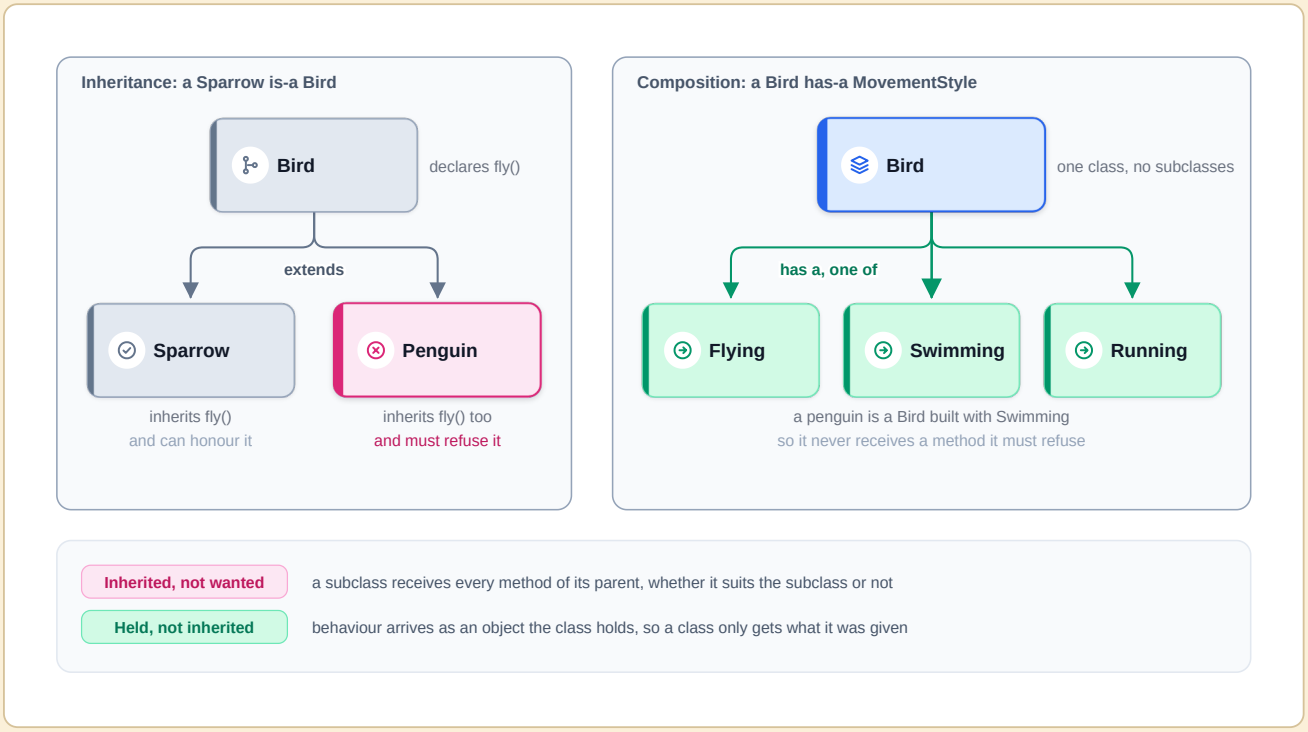

Figure — inheritance (Penguin inherits fly() and refuses it) vs composition (a Bird has a MovementStyle) (course diagram)

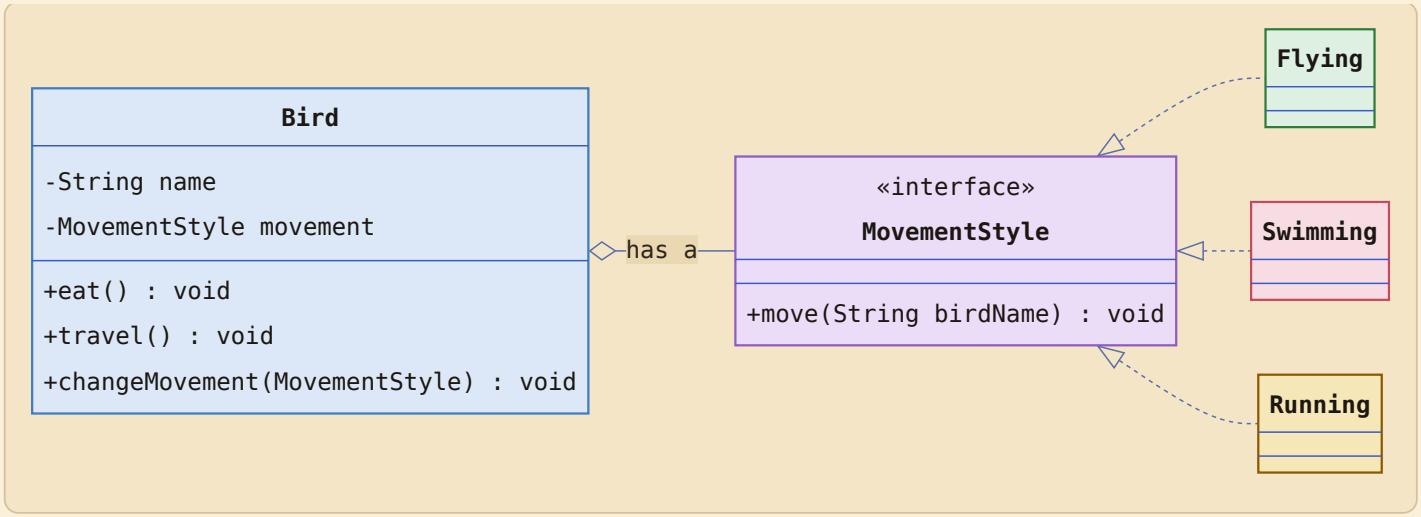
In the figure above, the left side is the inheritance tree where the penguin receives a method it does not want. The right side is composition: one `Bird` class holding one of `Flying`, `Swimming`, `Running`.



Is-a and has-a side by side:

	Inheritance	Composition
Kind of link	Penguin **is a** Bird	Bird **has a** MovementStyle
In code	`class Penguin extends Bird`	`Bird` holds a `MovementStyle` field
What it gets	all of the parent's methods	just the object handed to it
To change behaviour	add another subclass	supply another object
Change while running?	no, fixed at creation	yes, replace the field
LSP risk	high: inherited methods may not suit	low: nothing is inherited

When to use which. Choose **inheritance** when the child genuinely is a kind of the parent *and* can keep every inherited promise. Choose **composition** when what differs between objects is a behaviour, or the moment you find a subclass rejecting something it inherited. That rejection is the tell: an overridden method that throws, silently does nothing, or carries a "never call this on X" comment should become a separate object.

Tell, Don't Ask

The composition design above follows a related guideline, popularised by Andy Hunt and Dave Thomas (*The Pragmatic Programmer* authors): **tell an object what to do; do not ask it about its state and then decide for it.**

```
// Asking: the caller inspects the object and makes the decision.
if (bird instanceof Penguin) { swim(bird); } else { fly(bird); }

// Telling: the caller states the goal, the object decides how.
bird.travel();
```

Asking code has to know every subtype, so it breaks OCP and hides LSP problems behind `instanceof` checks. Telling code works with any substitute. In the composition design, `bird.travel()` is the "tell". A caller that needs `instanceof` on a base type is a strong hint that the base type promises the wrong thing.

The rules a subclass must follow

So far every violation crashed with an exception, which makes it easy to spot. The harmful ones are those that **quietly produce a wrong result and keep running**.

Example: `Square extends Rectangle`. Geometry says every square is a rectangle, so the subclass looks natural. To remain square, `Square` keeps both sides equal: setting the width also changes the height. No exception is thrown. Yet a method written for `Rectangle` that sets width 5 and height 4 expects an area of 20 and receives 16. In production that kind of error becomes an incorrect bill or inventory figure that nobody notices for weeks.

The rule that `Rectangle` implied without ever stating is **width and height can be changed independently**; the two separate setters invited every caller to rely on it. Mathematically a square is a rectangle, but it is **not a valid subtype of this `Rectangle` class**, because the class makes a promise a square cannot honour. **Base inheritance on the promises written in the code, not on how things are classified in the real world.**

A subclass is free to do the job *differently*. What it may not do is **require more** from its callers, **give them less**, or **break an assumption they depend on**. The rules below spell that out. Their vocabulary comes from Bertrand Meyer's **Design by Contract**: a method has **preconditions** (what the caller must provide), **postconditions** (what the method guarantees afterwards) and **invariants** (what is always true of the object).

Rule 1 — Preconditions may not be strengthened. A precondition is what must be true before the call. An overriding method may accept a *wider* range of inputs than the parent, never a narrower one. In the example, `Discount` accepts any amount of zero or more, while `SmallOrderDiscount` refuses anything from 100 upward. A caller that passes 250, which the parent allows, now fails, and would have to find out which discount it was given, the very check substitution was meant to make unnecessary.

Rule 2 — Postconditions may not be weakened. A postcondition is what the method guarantees when it returns. An override may guarantee *more*, never less. `Account.withdraw` guarantees the balance stays at zero or above. `OverdraftAccount` lets it go negative: a reasonable banking feature, but a broken guarantee. Every caller that relied on "balance ≥ 0" is now silently wrong. Nothing crashes; a payment job might, for example, keep paying suppliers from an account that is already overdrawn. An overdraft account can be a perfectly good class, just not a subtype of an account that promises a non-negative balance.

Rule 3 — Invariants must be preserved. An invariant is a condition that holds throughout the object's life. `Square` broke "width and height are independent". (The same bug can equally be described as a weakened postcondition: `Rectangle.setWidth` implicitly guarantees "the height is unchanged", and `Square.setWidth` drops that guarantee. Martin describes it that way; either description leads to the same conclusion.) Invariants are the hardest rule to follow because they are rarely written down: a subclass inherits every promise of its parent, including the ones nobody documented.

Rule 4 — No new exceptions callers cannot handle. An override may throw the exceptions the parent already declares (or subtypes of them), nothing new: a new exception type arrives at callers that have no `catch` for it. `ElectricCar.refuel()` broke this rule. Note that Java's compiler enforces this only for **checked** exceptions; `UnsupportedOperationException` is unchecked, so the violating code compiled without complaint. This is the most visible rule to break and the least harmful, because the failure is immediate and loud.

Rule 5 — The history constraint. Liskov and Wing added a rule about how state changes over time: **a subtype must not allow state changes that the parent type does not allow.** In the example, `Price` promises that its value never changes after creation. `AdjustablePrice` adds an `adjust()` method. Each call looks innocent, but a caller that captured a quote of 100 is later charged 120 on "the same" price. This is why immutable Java classes such as `String` and `Integer` are declared `final`: a mutable subclass could break the immutability callers rely on.

Here are all of them in runnable code:

```java
// File: code/lld/ch04/lsp/rules/Discount.java
package lld.ch04.lsp.rules;

import java.math.BigDecimal;
import java.math.RoundingMode;

/** Contract -- precondition: any amount >= 0. Postcondition: result = 90% of amount. */
public class Discount {
    private static final BigDecimal RATE = new BigDecimal("0.90");

    public BigDecimal apply(BigDecimal amount) {
        if (amount.signum() < 0) {
            throw new IllegalArgumentException("amount must be >= 0");
        }
        return amount.multiply(RATE).setScale(2, RoundingMode.HALF_EVEN);
    }
}
```

```java
// File: code/lld/ch04/lsp/rules/SmallOrderDiscount.java
package lld.ch04.lsp.rules;

import java.math.BigDecimal;

/** RULE 1 BROKEN: demands MORE than the parent (amount must also be under 100). */
public class SmallOrderDiscount extends Discount {
    private static final BigDecimal LIMIT = new BigDecimal("100");

    @Override
    public BigDecimal apply(BigDecimal amount) {
        if (amount.compareTo(LIMIT) >= 0) {
            throw new IllegalArgumentException("only for orders under 100");
        }
        return super.apply(amount);
    }
}
```

```java
// File: code/lld/ch04/lsp/rules/Account.java
package lld.ch04.lsp.rules;

import java.math.BigDecimal;

/** Contract -- postcondition of withdraw: the balance is never negative. */
public class Account {
    protected BigDecimal balance;

    public Account(BigDecimal balance) {
        this.balance = balance;
    }

    /** Withdraws only if funds allow; returns the balance afterwards (always >= 0). */
    public BigDecimal withdraw(BigDecimal amount) {
        if (amount.compareTo(balance) <= 0) {
            balance = balance.subtract(amount);
        }
        return balance;
    }
}
```

```java
// File: code/lld/ch04/lsp/rules/OverdraftAccount.java
package lld.ch04.lsp.rules;

import java.math.BigDecimal;

/** RULE 2 BROKEN: promises LESS -- the balance may now go negative. Nothing throws. */
public class OverdraftAccount extends Account {
    public OverdraftAccount(BigDecimal balance) {
        super(balance);
    }

    @Override
    public BigDecimal withdraw(BigDecimal amount) {
        balance = balance.subtract(amount);
        return balance;
    }
}
```

```java
// File: code/lld/ch04/lsp/rules/Rectangle.java
package lld.ch04.lsp.rules;

/** Unwritten invariant: width and height can be set independently. */
public class Rectangle {
    protected int width;
    protected int height;

    public Rectangle(int width, int height) {
        this.width = width;
        this.height = height;
    }

    public void setWidth(int width) {
        this.width = width;
    }

    public void setHeight(int height) {
        this.height = height;
    }

    public int area() {
        return width * height;
    }
}
```

```java
// File: code/lld/ch04/lsp/rules/Square.java
package lld.ch04.lsp.rules;

/** RULE 3 BROKEN: to stay square it couples the two setters -- a silent wrong answer. */
public class Square extends Rectangle {
    public Square(int side) {
        super(side, side);
    }

    @Override
    public void setWidth(int width) {
        this.width = width;
        this.height = width;
    }

    @Override
    public void setHeight(int height) {
        this.width = height;
        this.height = height;
    }
}
```

```java
// File: code/lld/ch04/lsp/rules/Price.java
package lld.ch04.lsp.rules;

import java.math.BigDecimal;

/** Contract (history): once created, a Price never changes value. */
public class Price {
    private final BigDecimal value;

    public Price(BigDecimal value) {
        this.value = value;
    }

    public BigDecimal value() {
        return value;
    }
}
```

```java
// File: code/lld/ch04/lsp/rules/AdjustablePrice.java
package lld.ch04.lsp.rules;

import java.math.BigDecimal;

/**
 * HISTORY CONSTRAINT BROKEN: adds a mutator, so an object the caller believed was
 * frozen can now change between two reads. No single method call looks wrong.
 */
public class AdjustablePrice extends Price {
    private BigDecimal current;

    public AdjustablePrice(BigDecimal value) {
        super(value);
        this.current = value;
    }

    @Override
    public BigDecimal value() {
        return current;
    }

    public void adjust(BigDecimal newValue) {
        this.current = newValue;
    }
}
```

Why it matters so much. Code written against a base type has no way to protect itself: it cannot see which subclass it received, and it should not need to. Only the subclass author can keep the contract.

The fix for Rectangle/Square. Do not share a mutable promise that one of them cannot keep. Make both **immutable** and give them a common interface that promises only what both can do (`area()`). "Resizing" returns a new object, so no setter can break an invariant. Java 21 `record`s and a `sealed` interface make this short:

```java
// File: code/lld/ch04/lsp/shapes/Shape.java
package lld.ch04.lsp.shapes;

/** The fix for Rectangle/Square: promise only what every shape can keep. */
public sealed interface Shape permits Rect, Sq {
    int area();
}
```

```java
// File: code/lld/ch04/lsp/shapes/Rect.java
package lld.ch04.lsp.shapes;

/** Immutable: "resizing" returns a new object, so no setter can break an invariant. */
public record Rect(int width, int height) implements Shape {
    public Rect withWidth(int w) {
        return new Rect(w, height);
    }

    @Override
    public int area() {
        return width * height;
    }
}
```

```java
// File: code/lld/ch04/lsp/shapes/Sq.java
package lld.ch04.lsp.shapes;

public record Sq(int side) implements Shape {
    @Override
    public int area() {
        return side * side;
    }
}
```

And the driver that runs every example, with each client method written only against the base type:

```java
// File: code/lld/ch04/lsp/Main.java
package lld.ch04.lsp;

import java.math.BigDecimal;
import java.util.List;
import lld.ch04.lsp.birds.composition.Bird;
import lld.ch04.lsp.birds.composition.Flying;
import lld.ch04.lsp.birds.composition.Running;
import lld.ch04.lsp.birds.composition.Swimming;
import lld.ch04.lsp.car.after.Vehicle;
import lld.ch04.lsp.rules.Account;
import lld.ch04.lsp.rules.AdjustablePrice;
import lld.ch04.lsp.rules.Discount;
import lld.ch04.lsp.rules.OverdraftAccount;
import lld.ch04.lsp.rules.Price;
import lld.ch04.lsp.rules.Rectangle;
import lld.ch04.lsp.rules.SmallOrderDiscount;
import lld.ch04.lsp.rules.Square;
import lld.ch04.lsp.shapes.Rect;
import lld.ch04.lsp.shapes.Shape;
import lld.ch04.lsp.shapes.Sq;

public class Main {

    // ---- Client code: every method below knows ONLY the base type ----

    static void service(lld.ch04.lsp.car.before.Car car) {
        car.start();
        car.refuel();
        car.stop();
    }

    static void takeATrip(Vehicle v) {
        v.start();
        v.replenishEnergy();
        v.stop();
    }

    static void checkout(Discount d, BigDecimal amount) {
        try {
            System.out.println("  Charged: " + d.apply(amount));
        } catch (IllegalArgumentException e) {
            System.out.println("  Broke on a valid amount: " + e.getMessage());
        }
    }

    static void paySupplier(Account account, BigDecimal amount, String label) {
        BigDecimal balance = account.withdraw(amount);
        System.out.println("  " + label + " balance after payment: " + balance
                + (balance.signum() < 0 ? "   <-- the caller never expected this" : ""));
    }

    /** A contract test written against Rectangle -- run it for every subclass. */
    static void resizeAndCheck(Rectangle r, String label) {
        r.setWidth(5);
        r.setHeight(4);
        System.out.println("  " + label + " expected area 20, got " + r.area());
    }

    static void quoteThenCharge(Price p, Runnable somethingElseHappens) {
        BigDecimal quoted = p.value();
        somethingElseHappens.run();
        System.out.println("  quoted " + quoted + ", charged " + p.value());
    }

    public static void main(String[] args) {
        System.out.println("=== 1. Car / ElectricCar (exception rule) ===");
        service(new lld.ch04.lsp.car.before.Car());
```

```
        try {
            service(new lld.ch04.lsp.car.before.ElectricCar());
        } catch (UnsupportedOperationException e) {
            System.out.println("  substitution broke: " + e.getMessage());
        }

        System.out.println("=== 2. Fixed hierarchy: Vehicle -> Car | ElectricCar ===");
        List<Vehicle> fleet = List.of(new lld.ch04.lsp.car.after.Car(),
                new lld.ch04.lsp.car.after.ElectricCar());
        fleet.forEach(Main::takeATrip);

        System.out.println("=== 3. Precondition strengthened ===");

        checkout(new SmallOrderDiscount(), new BigDecimal("250.00"));

        System.out.println("=== 4. Postcondition weakened ===");
        paySupplier(new Account(new BigDecimal("50.00")), new BigDecimal("80.00"), "Account:         ");
        paySupplier(new OverdraftAccount(new BigDecimal("50.00")), new BigDecimal("80.00"),
                "OverdraftAccount:");

        System.out.println("=== 5. Invariant broken (Rectangle / Square) ===");
        resizeAndCheck(new Rectangle(1, 1), "Rectangle:");
        resizeAndCheck(new Square(1), "Square:   ");

        System.out.println("=== 6. History constraint broken ===");
        quoteThenCharge(new Price(new BigDecimal("100.00")), () -> { });
        AdjustablePrice sneaky = new AdjustablePrice(new BigDecimal("100.00"));
        quoteThenCharge(sneaky, () -> sneaky.adjust(new BigDecimal("120.00")));

        System.out.println("=== 7. Fix for shapes: no shared mutable promise ===");
        List<Shape> shapes = List.of(new Rect(5, 4), new Sq(4), new Rect(2, 3).withWidth(5));
        for (Shape s : shapes) {
            System.out.println("  " + s + " area=" + s.area());
        }

        System.out.println("=== 8. Birds: inheritance vs composition ===");
        List<lld.ch04.lsp.birds.inheritance.Bird> old = List.of(
                new lld.ch04.lsp.birds.inheritance.Sparrow(),
                new lld.ch04.lsp.birds.inheritance.Penguin());
        for (var b : old) {
            try {
                b.fly();
            } catch (UnsupportedOperationException e) {
                System.out.println("  Substitution broke: " + e.getMessage());
            }
        }
        List<Bird> birds = List.of(
                new Bird("Sparrow", new Flying()),
                new Bird("Penguin", new Swimming()),
                new Bird("Ostrich", new Running()));
        birds.forEach(Bird::travel);
        Bird sparrow = birds.get(0);
        sparrow.changeMovement(new Running()); // behaviour swapped at run time
        sparrow.travel();
    }
}
```

Output:

```
=== 1. Car / ElectricCar (exception rule) ===
Car is starting
Car is refueling
Car is stopping
Car is starting
  substitution broke: Electric cars don't need refueling
=== 2. Fixed hierarchy: Vehicle -> Car | ElectricCar ===
Car is starting
Car is pumping gasoline
Car is stopping
ElectricCar is starting
Electric car is charging its battery
ElectricCar is stopping
=== 3. Precondition strengthened ===
  Charged: 225.00
  Broke on a valid amount: only for orders under 100
=== 4. Postcondition weakened ===
  Account:          balance after payment: 50.00
  OverdraftAccount: balance after payment: -30.00   <-- the caller never expected this
=== 5. Invariant broken (Rectangle / Square) ===
  Rectangle: expected area 20, got 20
  Square:    expected area 20, got 16
=== 6. History constraint broken ===
  quoted 100.00, charged 100.00
  quoted 100.00, charged 120.00
=== 7. Fix for shapes: no shared mutable promise ===
  Rect[width=5, height=4] area=20
  Sq[side=4] area=16
  Rect[width=5, height=3] area=15
=== 8. Birds: inheritance vs composition ===
Sparrow is flying
  Substitution broke: Penguins can't fly
Sparrow is flying through the air
Penguin is swimming through the water
Ostrich is running along the ground
Sparrow is running along the ground
```

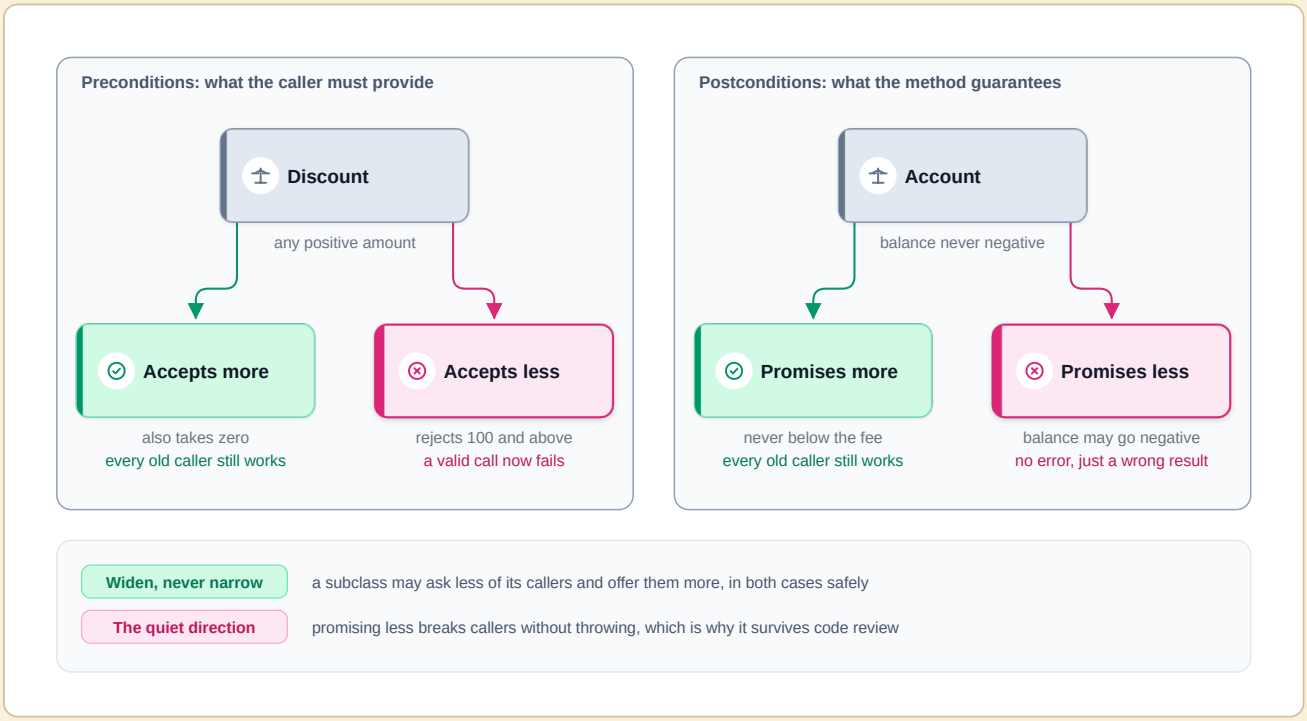

Figure — preconditions and postconditions: accepting more or promising more is safe; accepting less or promising less breaks callers (course diagram)

The figure above sums up the direction: **widen, never narrow.** A subclass may ask less of its callers and offer them more. (In the figure the parent `Discount` accepts positive amounts and the safe subclass also accepts zero;

in this chapter's code the parent already accepts zero, but the direction of the rule is the same. Likewise the figure's "promises more" account keeps the balance above a fee, a stronger guarantee than "never negative".)

The contract in one table:

Rule	The subclass may not…	How it usually shows up
Preconditions	demand more from the caller	valid input is rejected
Postconditions	guarantee less to the caller	a returned value breaks a caller's assumption
Invariants	break a rule that always held	a silently wrong result (the square)
Exceptions	throw something new	a crash in code with no matching `catch`
History	allow state changes the parent forbids	a "fixed" value changes between two reads

Signature rules (the part the compiler checks). Behavioural subtyping also has type-level rules: parameter types may be *wider* (contravariant), return types may be *narrower* (covariant), and exceptions may only be *narrower*. Java enforces a version of this for you:

- an overriding method may return a **subtype** of the parent's return type (covariant returns),
- it may **not** declare new or broader **checked** exceptions,
- it may **not** reduce visibility (a `public` method stays `public`),
- parameter types must match exactly (a different parameter type is an **overload**, not an override; use `@Override` so the compiler catches this).

Java checks none of the **behavioural** rules. Unchecked exceptions, weakened postconditions and broken invariants all compile happily. That part is on you.

How to check a subclass

1. **List the parent's promises before writing the subclass.** Promises, not method signatures: "the balance never drops below zero", "width and height change independently". Most violations slip in because the promise was never stated, so its breach went unnoticed.
2. **Write one test against the parent type and run it for every subclass.** `resizeAndCheck(Rectangle)` is such a test: it never mentions `Square`, yet `Square` fails it. Whenever a base-type test fails for some subclass, that subclass violates LSP, regardless of how reasonable its code looks. (In JUnit, the standard Java testing library, this is an *abstract contract test* that each subclass's test class extends.)

Why LSP is important

- **Prevents fragile code** — callers are not surprised by a subclass.
- **Keeps polymorphism usable** — new subclasses plug in without `instanceof` checks, which is what makes OCP work.
- **Correctness** — results stay right, not just "no crash".
- **Reuse** — base types can be extended safely.

Trade-offs

Following LSP gains	Costs
Callers trust the base type; no type checks	You must think about and document contracts
New subclasses are safe to add	Some "natural" hierarchies (Square/Rectangle) must be abandoned
Composition gives run-time flexibility	More small objects; behaviour is spread out

When not to use it

LSP is not optional where you use polymorphism. What you can skip is inheritance itself: if a subclass cannot keep the parent's promises, **do not make it a subclass**.

Common mistakes

- Modelling the real world ("a square is a rectangle", "a penguin is a bird") instead of the code's promises.
- "Fixing" a violation by making the method do nothing silently. That just changes a loud failure into a quiet wrong result.

- Thinking LSP is only about exceptions. The silent rules (postconditions, invariants, history) are more dangerous.
- Believing that siblings must substitute for each other. Substitution is only child → parent.

Refactorings and smells

- Smell: **Refused Bequest** (a subclass does not want what it inherits).
- Fixes: **Replace Subclass with Delegate**, **Replace Superclass with Delegate** (composition), **Extract Superclass** (raise a general parent), **Push Down Method** (move a method only some subclasses support out of the parent).

Real-world examples

- **`java.sql.Date extends java.util.Date`**: its time methods such as `getHours()` throw `IllegalArgumentException`, because an SQL date has no time part. Code written against `java.util.Date` can break.
- **`java.sql.Timestamp`**: its Javadoc (the official documentation generated from code comments) warns that its `equals` is not symmetric with `java.util.Date.equals`, and says the inheritance is implementation inheritance, not type inheritance. A textbook LSP warning in the JDK itself.
- **`java.util.Stack extends Vector`**: a stack inherits `insertElementAt` and `get(int)`, which let callers break stack order. The Javadoc now recommends `Deque` (a double-ended queue that adds and removes only at its ends) instead.
- **`List.of(...)` and `Collections.unmodifiableList(...)`** throw `UnsupportedOperationException` from `add`. The `List` interface marks `add` as an *optional operation*, so this is written into the contract, but it is a known design compromise: a caller holding a `List` cannot know whether `add` works.

In the interview

30-second answer: "LSP says a subclass must work anywhere its parent is expected, giving correct results, not just no crash. Concretely: it cannot demand more input, promise less output, break an invariant, throw new exceptions, or allow state changes the parent forbids. Square extending a mutable Rectangle is the classic silent break: set width 5 and height 4 and you get 16. I test it by writing one test against the base type and running it for every subclass. When a subclass must refuse a method, I either raise a better parent or move the behaviour into a composed object."

Follow-ups:

- *"Give an LSP violation you've seen."* — The Rectangle/Square case, or `java.sql.Date` throwing from `getHours()`. Then state the rule: demand no more, promise no less, keep the invariants.
- *"Composition over inheritance, always?"* — No. Inheritance is fine when the child truly honours every parent method. The signal to switch is a subclass refusing an inherited method.
- *"Is `ElectricCar` a substitute for `Car` after your fix?"* — No, and it should not be. Both substitute for `Vehicle`; siblings do not substitute for each other.

Self-check

1. **Q:** A subclass accepts **fewer** inputs than its parent. Which rule? **A:** Preconditions strengthened (rule 1).
2. **Q:** Why is the Square/Rectangle bug more dangerous than `ElectricCar.refuel()` throwing? **A:** It gives a silent wrong answer; the exception fails loudly and is found at once.
3. **Q:** What is the history constraint? **A:** A subtype must not allow state changes the parent does not allow, e.g. a mutable subclass of an immutable class.
4. **Q:** What does `@Override` protect you from? **A:** Accidentally overloading (different parameter type) instead of overriding.
5. **Q:** What is "Tell, Don't Ask"? **A:** Tell an object to do the job (`bird.travel()`), instead of inspecting its type or state and deciding for it.

TL;DR

A subclass must keep every promise of its parent: accept at least as much, deliver at least as much, keep invariants and history, throw nothing new. Inheritance follows promises, not real-world categories. When a subclass must refuse something, raise a better parent or use composition.

4.9 Interface Segregation Principle (ISP)

What it is

Clients should not be forced to depend on methods they do not use. Instead of one large, general interface, offer smaller interfaces shaped around what each kind of caller needs.

Where it comes from. Robert C. Martin describes meeting the problem while consulting for Xerox. A printer system had one big `Job` class used by every task (printing, stapling and so on), so a change for one task forced every other task's code to be rebuilt. Splitting the class's services into separate interfaces, one per kind of client, fixed it.

> **Analogy:** a restaurant that hands every guest the full 40-page menu, including the wine list, the kids' menu and the catering price list, even to someone who only wants a coffee. A coffee card is enough for them.

A **fat interface** is an interface with many methods, usually because it grew one feature at a time. A **role interface** is a small interface describing the role an object plays for one kind of caller.

The problem it solves

- Implementers are forced to write methods they cannot honour, so they throw or do nothing (which also breaks LSP).
- Callers depend on methods they never call, so a change to those methods still reaches them (recompiles, redeploys, retests).
- Test doubles become long, because a fake must implement every method.

Example: a bloated `Printer` interface

One interface for everything a printer might do: print, scan, fax, staple.

```java
// File: code/lld/ch04/isp/fat/Printer.java
package lld.ch04.isp.fat;

/** A FAT interface: one list of everything any printer might ever do. */
public interface Printer {
    void printDocument(String doc);

    void scanDocument(String doc);

    void faxDocument(String doc);

    void stapleDocument(String doc);
}
```

```java
// File: code/lld/ch04/isp/fat/BasicPrinter.java
package lld.ch04.isp.fat;

/** VIOLATION: forced to "implement" three methods it can only refuse. */
public class BasicPrinter implements Printer {
    @Override
    public void printDocument(String doc) {
        System.out.println("BasicPrinter printing " + doc);
    }

    @Override
    public void scanDocument(String doc) {
        throw new UnsupportedOperationException("BasicPrinter cannot scan");
    }

    @Override
    public void faxDocument(String doc) {
        throw new UnsupportedOperationException("BasicPrinter cannot fax");
    }

    @Override
    public void stapleDocument(String doc) {
        throw new UnsupportedOperationException("BasicPrinter cannot staple");
    }
}
```

```java
// File: code/lld/ch04/isp/fat/AdvancedPrinter.java
package lld.ch04.isp.fat;

/** The wide interface is honest for this device -- it really does all four jobs. */
public class AdvancedPrinter implements Printer {
    @Override
    public void printDocument(String doc) {
        System.out.println("AdvancedPrinter printing " + doc);
    }

    @Override
    public void scanDocument(String doc) {
        System.out.println("AdvancedPrinter scanning " + doc);
    }

    @Override
    public void faxDocument(String doc) {
        System.out.println("AdvancedPrinter faxing " + doc);
    }

    @Override
    public void stapleDocument(String doc) {
        System.out.println("AdvancedPrinter stapling " + doc);
    }
}
```

`BasicPrinter` only prints, but it must "implement" scanning, faxing and stapling, and the only honest thing it can do is throw. `AdvancedPrinter` really does all four, so for it the wide interface is fine.

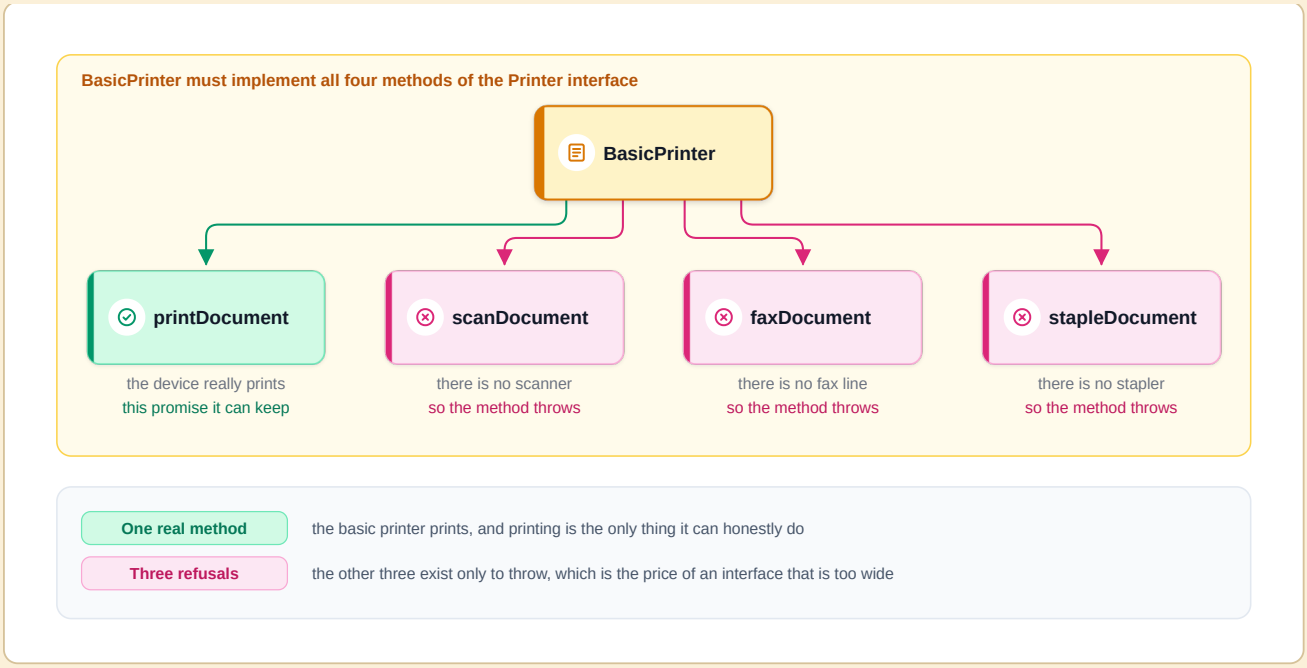

Figure — BasicPrinter keeps one real method and three that exist only to throw (course diagram)

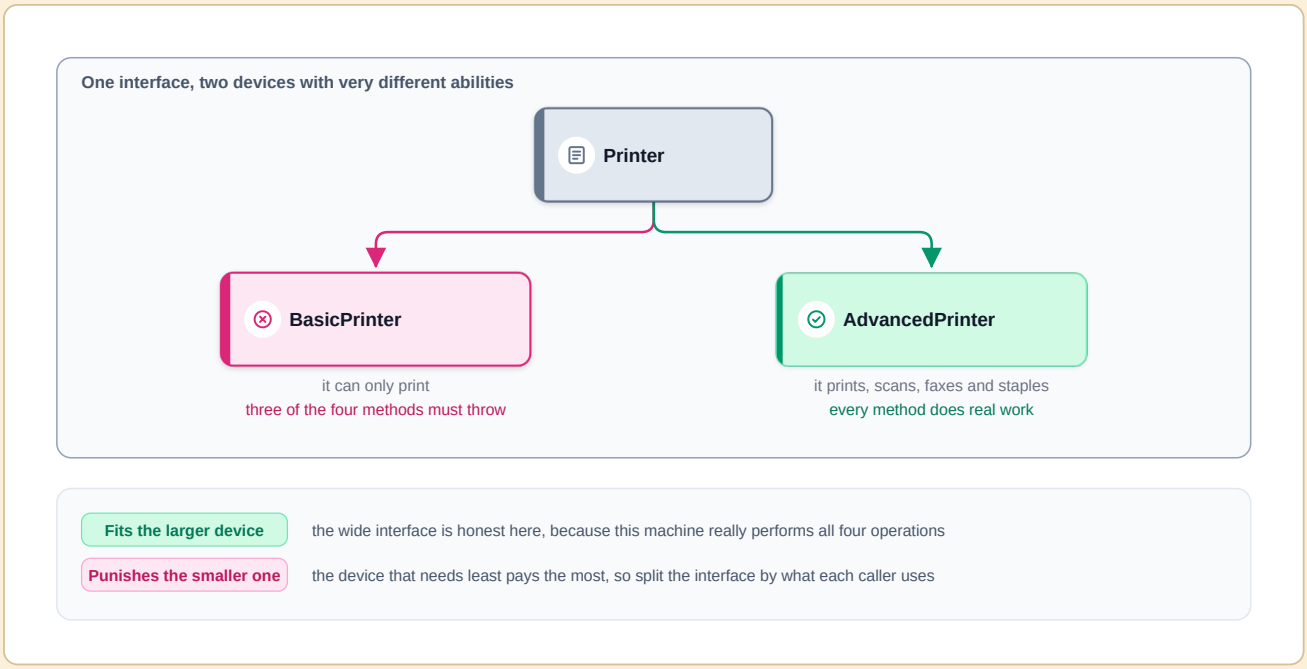

Figure — one interface, two devices: it fits the larger device and punishes the smaller one (course diagram)

The two figures above capture ISP in one picture: the simplest device carries the heaviest burden. Split the interface according to what each caller actually uses.

Restructuring: first attempt, one interface per capability

Split the big interface into `Printer`, `Scanner`, `Fax` and `Stapler`. `BasicPrinter` implements only `Printer`; `AdvancedPrinter` implements all four. No class implements anything it cannot do.

```java
// File: code/lld/ch04/isp/split/Printer.java
package lld.ch04.isp.split;

public interface Printer {
    void printDocument(String doc);
}
```

```java
// File: code/lld/ch04/isp/split/Scanner.java
package lld.ch04.isp.split;

public interface Scanner {
    void scanDocument(String doc);
}
```

```java
// File: code/lld/ch04/isp/split/Fax.java
package lld.ch04.isp.split;

public interface Fax {
    void faxDocument(String doc);
}
```

```java
// File: code/lld/ch04/isp/split/Stapler.java
package lld.ch04.isp.split;

public interface Stapler {
    void stapleDocument(String doc);
}
```

```java
// File: code/lld/ch04/isp/split/BasicPrinter.java
package lld.ch04.isp.split;

/** Implements only what it can honour. */
public class BasicPrinter implements Printer {
    @Override
    public void printDocument(String doc) {
        System.out.println("BasicPrinter printing " + doc);
    }
}
```

```java
// File: code/lld/ch04/isp/split/AdvancedPrinter.java
package lld.ch04.isp.split;

/** Opts in to every capability it really has. */
public class AdvancedPrinter implements Printer, Scanner, Fax, Stapler {
    @Override
    public void printDocument(String doc) {
        System.out.println("AdvancedPrinter printing " + doc);
    }

    @Override
    public void scanDocument(String doc) {
        System.out.println("AdvancedPrinter scanning " + doc);
    }

    @Override
    public void faxDocument(String doc) {
        System.out.println("AdvancedPrinter faxing " + doc);
    }

    @Override
    public void stapleDocument(String doc) {
        System.out.println("AdvancedPrinter stapling " + doc);
    }
}
```

This satisfies ISP and makes the mechanics easy to see. But **one interface per method is not the goal.** If every scanning device can also fax, and every caller uses both, putting them in separate interfaces adds names while removing no dependency at all.

How small should an interface be?

Group by caller, not by method: an interface should carry the methods that one kind of caller needs. The size is right when both answers below are "no":

1. **Is any implementer forced to supply a method it cannot honour?** If yes, the interface is too wide.
2. **Does any caller depend on methods it never calls?** If yes, it is too wide for that caller.

It might have one method or six. The count was never the measure.

What over-splitting costs. Now add a caller to the one-method-per-interface design. `OfficeWorkflow` scans, prints and staples, so it needs three constructor parameters, and whoever creates it hands over **one device three times:**

```java
// File: code/lld/ch04/isp/split/OfficeWorkflow.java
package lld.ch04.isp.split;

/** OVER-SPLIT: needs all three, so it takes three dependencies -- and gains nothing. */
public class OfficeWorkflow {
    private final Printer printer;
    private final Scanner scanner;
    private final Stapler stapler;

    public OfficeWorkflow(Printer printer, Scanner scanner, Stapler stapler) {
        this.printer = printer;
        this.scanner = scanner;
        this.stapler = stapler;
    }

    public void run(String doc) {
        scanner.scanDocument(doc);
        printer.printDocument(doc);
        stapler.stapleDocument(doc);
    }
}
```

The code runs and technically follows ISP, yet nothing was gained: `OfficeWorkflow` calls all three methods, so the split took away no dependency. It only added two extra type names and two extra parameters.

Grouping by role. `OfficeWorkflow` wants one device that can scan, print and staple, so that is a single role, `DocumentProcessor`. `PrintQueue` only ever prints, which is a different role, `Printer`. The reason two interfaces are justified is that a `BasicPrinter` can play the second role but not the first. In Java, `DocumentProcessor extends Printer`, so any document processor can also be placed in a print queue.

```java
// File: code/lld/ch04/isp/roles/Printer.java
package lld.ch04.isp.roles;

/** Role interface for callers that only print (e.g. PrintQueue). */
public interface Printer {
    void printDocument(String doc);
}
```

```java
// File: code/lld/ch04/isp/roles/DocumentProcessor.java
package lld.ch04.isp.roles;

/** Role interface for callers that scan, print AND staple (e.g. OfficeWorkflow). */
public interface DocumentProcessor extends Printer {
    void scanDocument(String doc);

    void stapleDocument(String doc);
}
```

```java
// File: code/lld/ch04/isp/roles/BasicPrinter.java
package lld.ch04.isp.roles;

public class BasicPrinter implements Printer {
    @Override
    public void printDocument(String doc) {
        System.out.println("Basic printer printing " + doc);
    }
}
```

```java
// File: code/lld/ch04/isp/roles/OfficeDevice.java
package lld.ch04.isp.roles;

public class OfficeDevice implements DocumentProcessor {
    @Override
    public void printDocument(String doc) {
        System.out.println("Printing " + doc);
    }

    @Override
    public void scanDocument(String doc) {
        System.out.println("Scanning " + doc);
    }

    @Override
    public void stapleDocument(String doc) {
        System.out.println("Stapling " + doc);
    }
}
```

```java
// File: code/lld/ch04/isp/roles/PrintQueue.java
package lld.ch04.isp.roles;

/** Depends on printing only, so a basic printer is enough. */
public class PrintQueue {
    private final Printer printer;

    public PrintQueue(Printer printer) {
        this.printer = printer;
    }

    public void submit(String doc) {
        printer.printDocument(doc);
    }
}
```

```java
// File: code/lld/ch04/isp/roles/OfficeWorkflow.java
package lld.ch04.isp.roles;

/** One dependency, because one role covers everything it needs. */
public class OfficeWorkflow {
    private final DocumentProcessor processor;

    public OfficeWorkflow(DocumentProcessor processor) {
        this.processor = processor;
    }

    public void run(String doc) {
        processor.scanDocument(doc);
        processor.printDocument(doc);
        processor.stapleDocument(doc);
    }
}
```

```java
// File: code/lld/ch04/isp/Main.java
package lld.ch04.isp;

import java.util.List;
import lld.ch04.isp.roles.BasicPrinter;
import lld.ch04.isp.roles.OfficeDevice;
import lld.ch04.isp.roles.OfficeWorkflow;
import lld.ch04.isp.roles.PrintQueue;

public class Main {
    public static void main(String[] args) {
        System.out.println("=== 1. Fat interface ===");
        List<lld.ch04.isp.fat.Printer> printers = List.of(
                new lld.ch04.isp.fat.AdvancedPrinter(), new lld.ch04.isp.fat.BasicPrinter());
        for (var p : printers) {
            p.printDocument("report.pdf");
            try {
                p.scanDocument("report.pdf");
            } catch (UnsupportedOperationException e) {
                System.out.println("  forced to implement: " + e.getMessage());
            }
        }

        System.out.println("=== 2. One interface per method ===");
        new lld.ch04.isp.split.BasicPrinter().printDocument("memo.pdf");
        var adv = new lld.ch04.isp.split.AdvancedPrinter();
        adv.faxDocument("memo.pdf");
        // The same object passed three times -- a sign the split went too far.
        new lld.ch04.isp.split.OfficeWorkflow(adv, adv, adv).run("contract.pdf");

        System.out.println("=== 3. Role interfaces (grouped by caller) ===");
        new PrintQueue(new BasicPrinter()).submit("receipt.pdf");
        new PrintQueue(new OfficeDevice()).submit("receipt.pdf"); // bigger device fits the small role
        new OfficeWorkflow(new OfficeDevice()).run("contract.pdf");
    }
}
```

Output:

```
=== 1. Fat interface ===
AdvancedPrinter printing report.pdf
AdvancedPrinter scanning report.pdf
BasicPrinter printing report.pdf
  forced to implement: BasicPrinter cannot scan
=== 2. One interface per method ===
BasicPrinter printing memo.pdf
AdvancedPrinter faxing memo.pdf
AdvancedPrinter scanning contract.pdf
AdvancedPrinter printing contract.pdf
AdvancedPrinter stapling contract.pdf
=== 3. Role interfaces (grouped by caller) ===
Basic printer printing receipt.pdf
Printing receipt.pdf
Scanning contract.pdf
Printing contract.pdf
Stapling contract.pdf
```

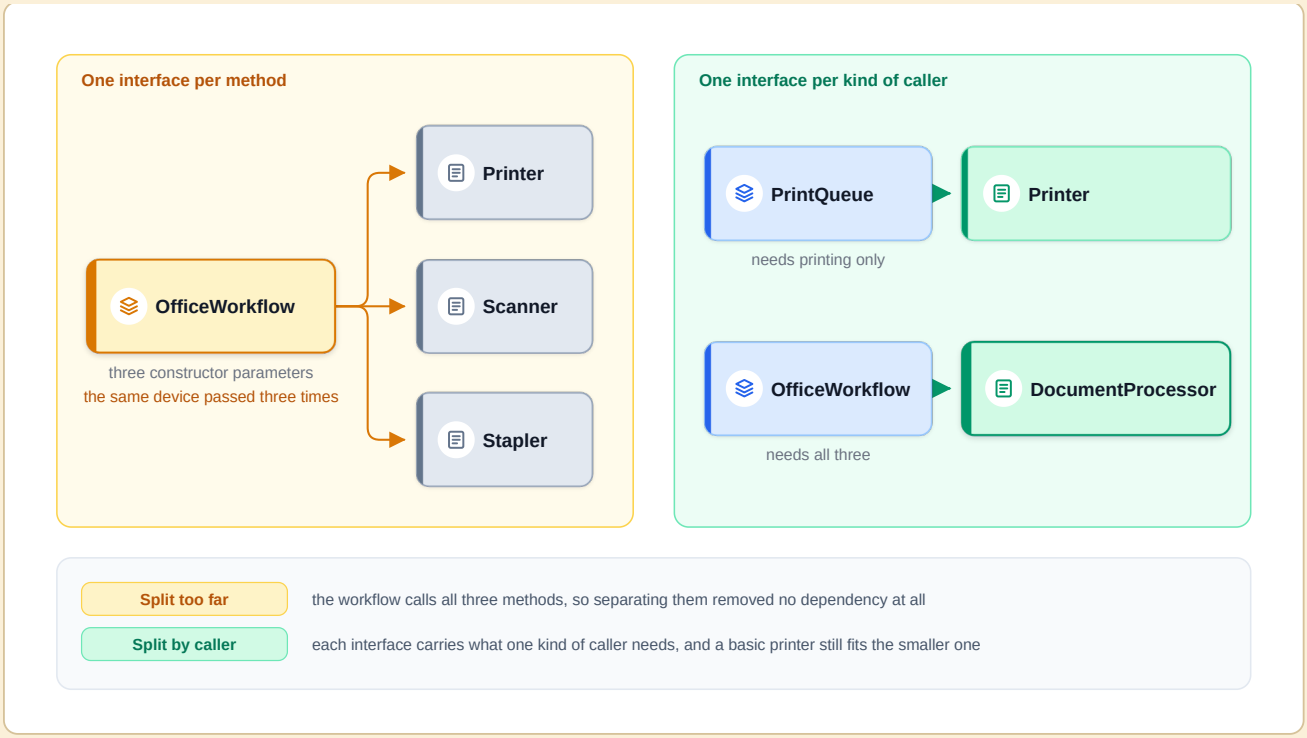

Figure — split too far (three interfaces, the same device passed three times) vs split by caller (one role per kind of caller) (course diagram)

	Four interfaces, one method each	Two role interfaces
Implementer forced to supply what it cannot do?	No	No
Caller depending on unused methods?	No	No
Dependencies for `OfficeWorkflow`	3	1
Names to learn	4	2

Both designs satisfy ISP. The role-based one is leaner because its interfaces were shaped around callers instead of around methods.

Rule of thumb: only split an interface when you can **point to the caller** that needs the smaller piece; without such a caller the split is speculation. The converse also holds: two interfaces that are always implemented by the same classes and always consumed by the same callers should probably be merged.

Languages without an `interface` keyword. Python and JavaScript have no `interface` keyword, but the interface is still there, just invisible: it is **the set of methods a caller actually calls**. Handing a 20-method object to a function that calls one of them creates exactly the same needless dependency, only no compiler points it out. Testing hides it further: in Java a wide interface forces a long stub (a fake class with every method filled in), while in Python you can pass a tiny object with one method and the test passes, which is convenient but masks the problem. So check deliberately: look at what a function calls on its argument and ask whether the argument is far bigger than that. Python's `abc` module and `typing.Protocol` (Python's two ways to declare an interface) let you write the role down when it is worth it; for a role used in only one place, a comment listing the methods the function needs is often enough.

Five signals of an ISP violation

1. Low cohesion in the interface. The methods belong to unrelated groups.

```
interface MediaDevice { void playAudio(); void playVideo(); void recordVideo(); }
// A Speaker can only playAudio(); playVideo() and recordVideo() must throw.
```

2. A fat interface. A long method list that grew one feature at a time. Method names that name a specific mechanism are a tell: some implementer will not use them.

```
interface PaymentProcessor { void processCreditCard(BigDecimal a); void processPayPal(BigDecimal a); void processBankTransfer(BigDecimal a); }
// A shop that only takes PayPal must still supply the other two.
// Better: interface PaymentMethod { void pay(BigDecimal amount); } with one class per method.
```

3. Empty or throwing methods. The clearest signal: the interface asks for something the class cannot provide.

```
interface Vehicle { void drive(); void fly(); void sail(); }
// A Car drives; fly() and sail() throw UnsupportedOperationException.
```

4. One interface serving several kinds of client. It describes a whole category ("everything an employee can do") instead of one caller's needs, so every role implements the union of all roles.

```
interface Employee { void calculateSalary(); void handleCustomerQueries(); void manageTeam(); }
// A support agent handles queries; the other two methods must throw.
```

5. Tests that need long stand-ins. This one appears while writing tests rather than reading code. A fake for a wide interface must implement every method, even if the test exercises just one; dozens of empty method bodies for a single call mean the interface is too wide **for that caller**. What this signal really measures is the distance between what a caller uses and what it is forced to depend on.

Signals 1 and 2 show up when you read the interface, 3 and 4 when you read its implementers, and 5 when you write a test.

Signal	When it shows up	Typical cause
Low cohesion	Reading the interface	Groups of unrelated methods should be split into their own interfaces
Fat interface	Reading the interface	It grew feature by feature and was never split
Empty / throwing methods	Reading an implementer	The implementer was forced to accept what it cannot do
One interface, many roles	Comparing implementers	It describes a category, not a caller's needs
Long test stand-ins	Writing a test	Callers are tied to much more than they actually call

How it works (step by step)

1. For each caller of an interface, list the methods it actually calls.
2. Group callers whose lists are the same; each group is a **role**.
3. Create one interface per role (interfaces may extend each other, like `DocumentProcessor extends Printer`).
4. Let each class implement every role it can honestly fill.
5. Change each caller's parameter type to the narrowest role it needs.

Importance of ISP

- **No bloated classes** forced to implement unneeded methods.
- **Maintainability** — a change to one role does not ripple to callers of another.
- **Flexibility** — small roles are easy to implement in new ways.
- **Simpler tests** — fakes implement one or two methods.
- **Clearer design** — each interface documents one relationship.

How ISP relates to the other principles

- **SRP**: ISP is SRP for interfaces. Each interface has one focused purpose.
- **OCP**: new capabilities arrive as new small interfaces instead of edits to a big one.
- **LSP**: implementers of small interfaces can honour every method, so substitution is safe. A fat interface **forces** LSP violations (the throwing `BasicPrinter`).
- **DIP**: high-level code depends on the smallest abstraction it needs.

Trade-offs

Small role interfaces gain	Costs
No forced, throwing methods	More interface names
Callers insulated from unrelated changes	Over-splitting adds wiring with no benefit
Tiny test doubles; lambdas for one-method roles	Harder to see "everything this device can do" in one place

When not to use it

- When every implementer supports every method and every caller uses them all (the interface is already right-sized).
- When you cannot name the caller that wants the smaller piece.

Common mistakes

- **One interface per method everywhere.** The most common mistake among people who just learned ISP. A fat interface at least makes its cost visible; hundreds of tiny ones cost you slowly, in names and wiring, and are harder to undo.
- Splitting by the implementer's features instead of the caller's needs.
- Keeping the fat interface and adding an "adapter" base class with empty methods (like AWT's `MouseAdapter`; AWT is Java's original desktop user-interface toolkit): convenient, but a symptom that the interface is too wide.

Real-world examples

- **Java's tiny role interfaces**: `Runnable`, `Comparable`, `AutoCloseable`, `Iterable`, `CharSequence`, and the whole `java.util.function` package. `try-with-resources` needs only `AutoCloseable`, not "a file".
- **AWT** `MouseListener` has five methods; most listeners need one, so the JDK added `MouseAdapter` with empty bodies. Later APIs (JavaFX event handlers) use one-method handlers.
- **Collections**: `List.of(...)` and unmodifiable views throw on `add`, because `Collection` bundles reading and writing. Kotlin (another language that runs on the JVM), by contrast, separates `List` (read) and `MutableList` (write).
- **Spring Data** (a Spring library that generates repository code for you): `CrudRepository`, `PagingAndSortingRepository`, and the bare `Repository` marker let you expose only the operations a repository needs.

In the interview

> **30-second answer:** "ISP says no caller should depend on methods it does not use. The symptom is a class implementing an interface method by throwing, or a test fake full of empty methods. I split interfaces by caller: one role interface per kind of caller, not one per method. For printers, a print queue needs `Printer`, an office workflow needs `DocumentProcessor`. I split only when I can name the caller that wants the smaller piece."

Follow-ups:

- *"Difference between SRP and ISP?"* — SRP protects the **class** (one reason to change); ISP protects the **caller** (no unused dependencies). SRP splits classes, ISP splits interfaces; you can break either without the other.
- *"How small is too small?"* — When a caller has to take several interfaces that are always the same object. Always implemented together and always used together means one interface.

Self-check

1. **Q:** What two questions decide if an interface is the right size? **A:** Is any implementer forced to supply something it cannot do? Does any caller depend on methods it never calls?
2. **Q:** Name three signals of an ISP violation. **A:** Throwing/empty methods, a fat interface with mechanism-named methods, long test stand-ins (also: low cohesion, one interface for several roles).
3. **Q:** Why did the four-interface version not help `OfficeWorkflow`? **A:** It uses all three methods, so no dependency was removed; only names and parameters were added.

TL;DR

One interface per kind of caller. Throwing methods and long fakes mean it is too wide; the same object passed three times means it is too thin.

4.10 Dependency Inversion Principle (DIP)

What it is

Robert C. Martin's two statements, paraphrased:

1. **High-level modules should not depend on low-level modules. Both should depend on abstractions.**
2. **Abstractions should not depend on details. Details should depend on abstractions.**

Terms:

- A **high-level module** holds the business policy: *what* the application does (e.g. "notify the user when an order ships").
- A **low-level module** handles a technical detail: *how* it is done (SMTP email, SMTP being the protocol for sending mail; SMS gateway; MySQL).
- An **abstraction** is the interface in between.

Why "inversion"? In traditional layered code, high-level code calls low-level code **and** its source code depends on it (`import com.mail.SmtpClient`). DIP keeps the direction of the call (policy still calls the detail at run time) but **reverses the direction of the source-code dependency**: the detail now imports and implements an interface that belongs to the policy.

> **Analogy: a wall socket.** Your lamp does not wire itself directly into the power station. It plugs into a standard socket. The building's wiring (the detail) was built to the socket standard too. Either side can be replaced without touching the other.

The problem it solves

- Business logic is tied to one vendor or technology; switching (email → SMS) means editing the business code.
- Business logic cannot be tested without the real infrastructure (the servers and services the program runs on: a mail server, a database).
- A change in a low-level library ripples up into the policy.

Example: notifications

Before. `NotificationService` (high level) creates and names `EmailService` (low level):

```java
// File: code/lld/ch04/dip/before/EmailService.java
package lld.ch04.dip.before;

/** Low-level detail. */
public class EmailService {
    public void sendEmail(String message) {
        System.out.println("Sending email: " + message);
    }
}
```

```java
// File: code/lld/ch04/dip/before/NotificationService.java
package lld.ch04.dip.before;

/** VIOLATION: high-level policy creates and names a low-level detail. */
public class NotificationService {
    private final EmailService emailService = new EmailService();

    public void notifyUser(String message) {
        emailService.sendEmail(message);
    }
}
```

It is tightly coupled, and switching to SMS or push means editing `NotificationService`.

After, in four steps.

1. **Introduce an abstraction**, `NotificationSender`.
2. **Low-level modules implement it** (`EmailSender`, `SmsSender`): details depend on the abstraction.
3. **The high-level module depends only on the abstraction**, received through its constructor.
4. **Test it** with different senders, including a recording fake.

Look at the packages. The interface lives in `app`, **next to the policy that uses it**, not in `infra` next to the implementations. That is the part of DIP most people miss: **the high-level side owns the abstraction.** It is shaped by what the policy needs, not by what email happens to offer. `app` imports nothing from `infra`; `infra` imports `app`.

```java
// File: code/lld/ch04/dip/app/NotificationSender.java
package lld.ch04.dip.app;

/**
 * The abstraction. Note the PACKAGE: it lives with the high-level policy (app),
 * not with the implementations (infra). The policy owns the contract.
 */
public interface NotificationSender {
    void send(String recipient, String message);
}
```

```java
// File: code/lld/ch04/dip/app/NotificationService.java
package lld.ch04.dip.app;

import java.util.Objects;

/** High-level policy: depends only on an abstraction it owns. Imports nothing from infra. */
public class NotificationService {
    private final NotificationSender sender;

    public NotificationService(NotificationSender sender) { // constructor injection
        this.sender = Objects.requireNonNull(sender);
    }

    public void notifyUser(String userId, String message) {
        if (message.isBlank()) {
            throw new IllegalArgumentException("empty notification");
        }
        sender.send(userId, message);
    }
}
```

```java
// File: code/lld/ch04/dip/infra/EmailSender.java
package lld.ch04.dip.infra;

import lld.ch04.dip.app.NotificationSender;

/** Detail depends on the abstraction -- the arrow now points UP into app. */
public class EmailSender implements NotificationSender {
    @Override
    public void send(String recipient, String message) {
        System.out.println("[email -> " + recipient + "] " + message);
    }
}
```

```java
// File: code/lld/ch04/dip/infra/SmsSender.java
package lld.ch04.dip.infra;

import lld.ch04.dip.app.NotificationSender;

public class SmsSender implements NotificationSender {
    @Override
    public void send(String recipient, String message) {
        System.out.println("[sms -> " + recipient + "] " + message);
    }
}
```

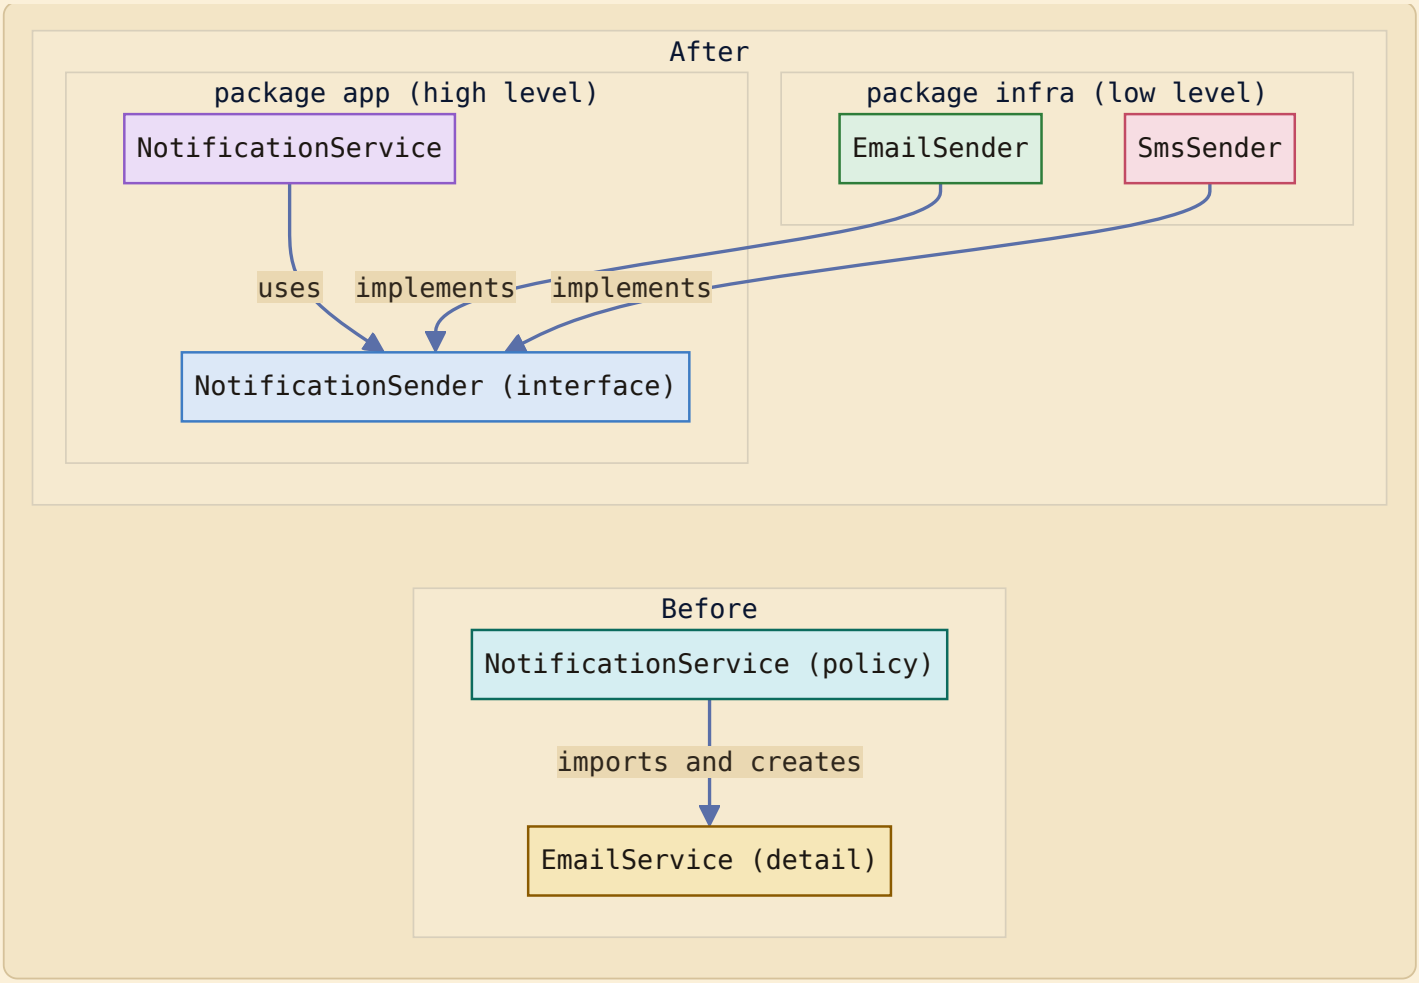
```java
// File: code/lld/ch04/dip/infra/RecordingSender.java
package lld.ch04.dip.infra;

import java.util.ArrayList;
import java.util.List;
import lld.ch04.dip.app.NotificationSender;

/** A test double: proves NotificationService can be tested with no mail server. */
public class RecordingSender implements NotificationSender {
    private final List<String> sent = new ArrayList<>();

    @Override
    public void send(String recipient, String message) {
        sent.add(recipient + ":" + message);
    }

    public List<String> sent() {
        return List.copyOf(sent);
    }
}
```



In the "After" box, every arrow between packages points **from the detail into the policy**. That is the inversion.

DIP in practice: four real-world techniques

1. Dependency Injection (DI). Give a class its dependencies from outside instead of letting it create them. Three flavours:

Kind	How	Use when
Constructor injection	Pass dependencies to the constructor	Default choice: required dependencies, immutable fields, obvious in the signature
Setter injection	Call `setX(...)` after construction	Optional dependencies with a sensible default
Method (parameter) injection	Pass the dependency to the one method that needs it	It varies per call (e.g. if the format changed on every call, `invoice.generate(generator)` instead of the constructor injection used in 4.7)

A typical web-application case: a `DataService` needs database access, so it receives a `DataRepository` interface in its constructor instead of building a MySQL repository itself; moving to another database then means passing in a different implementation, with no edit to `DataService`.

The class that does all the `new`-ing is called the **composition root**. In this chapter it is each `Main`: the one place that knows the concrete classes.

2. Service Locator. A central registry hands out services by name or type. The high-level class depends on a `Locator` abstraction and asks it for what it needs at run time.

```java
// File: code/lld/ch04/dip/locator/PaymentService.java
package lld.ch04.dip.locator;

import java.math.BigDecimal;

public interface PaymentService {
    void processPayment(BigDecimal amount);
}
```

```java
// File: code/lld/ch04/dip/locator/PayPalService.java
package lld.ch04.dip.locator;

import java.math.BigDecimal;

public class PayPalService implements PaymentService {
    @Override
    public void processPayment(BigDecimal amount) {
        System.out.println("Processing payment via PayPal: $" + amount);
    }
}
```

```java
// File: code/lld/ch04/dip/locator/Locator.java
package lld.ch04.dip.locator;

/** The high-level code depends on this abstraction, not on a concrete registry. */
public interface Locator {
    PaymentService paymentService(String name);
}
```

```java
// File: code/lld/ch04/dip/locator/ServiceLocator.java
package lld.ch04.dip.locator;

import java.util.Map;
import java.util.NoSuchElementException;
import java.util.concurrent.ConcurrentHashMap;

/** A central registry that hands out services by name. */
public class ServiceLocator implements Locator {
    private final Map<String, PaymentService> services = new ConcurrentHashMap<>();

    public void register(String name, PaymentService service) {
        services.put(name, service);
    }

    @Override
    public PaymentService paymentService(String name) {
        PaymentService s = services.get(name);
        if (s == null) {
            throw new NoSuchElementException("No payment service named " + name);
        }
        return s;
    }
}
```

```java
// File: code/lld/ch04/dip/locator/CheckoutFlow.java
package lld.ch04.dip.locator;

import java.math.BigDecimal;

/** Asks the locator at run time. Its real dependency (PaymentService) is hidden inside. */
public class CheckoutFlow {
    private final Locator locator;

    public CheckoutFlow(Locator locator) {
        this.locator = locator;
    }

    public void pay(String serviceName, BigDecimal amount) {
        locator.paymentService(serviceName).processPayment(amount);
    }
}
```

This does follow DIP: `CheckoutFlow` names no concrete payment class, and it receives the `Locator` *interface* through its constructor, so even the registry itself can be replaced (for example by a test locator) without touching `CheckoutFlow`. But be aware of the criticism (Martin Fowler compares the two approaches; Mark Seemann calls Service Locator an anti-pattern, a common solution that causes more problems than it solves): the class's **real** dependencies are hidden inside method bodies, so you cannot see from the constructor what it needs, and a missing registration fails only at run time. Prefer constructor injection; use a locator mainly at framework boundaries.

3. Inversion of Control (IoC) containers. Frameworks such as **Spring** (Java) and the built-in container in **.NET** (Microsoft's application platform) create objects and inject dependencies for you. In Spring, a class with a single constructor gets its dependencies injected automatically (the `@Autowired` annotation, an `@` tag that marks where Spring should inject, is optional for a single constructor since Spring 4.3; a **bean** is an object Spring creates and manages, and the **classpath** is the list of places Java searches for compiled classes and libraries):

```java
// Spring version -- NOT part of this chapter's compiled code (needs Spring on the classpath).
@Service
public class OrderService {
    private final PaymentService payments;          // an interface

    public OrderService(PaymentService payments) {  // Spring finds the one PaymentService bean
        this.payments = payments;
    }

    public void placeOrder(BigDecimal amount) { payments.processPayment(amount); }
}
```

Without Spring, the same wiring is one line in `main`: `new OrderService(new StripePayments())`. **The framework is a convenience for wiring, not the principle.** `OrderService` was already inverted the moment it accepted an abstraction instead of creating a concrete class.

4. Plug-in architecture. The core defines an abstraction; plug-ins implement it and are installed without changing the core. A media player defines `AudioDecoder`; MP3 and FLAC support arrive as plug-ins.

```java
// File: code/lld/ch04/dip/plugin/AudioDecoder.java
package lld.ch04.dip.plugin;

/** The plug-in contract, owned by the core media player. */
public interface AudioDecoder {
    String extension();

    void decode(String fileName);
}
```

```java
// File: code/lld/ch04/dip/plugin/Mp3Decoder.java
package lld.ch04.dip.plugin;

public class Mp3Decoder implements AudioDecoder {
    @Override
    public String extension() {
        return "mp3";
    }

    @Override
    public void decode(String fileName) {
        System.out.println("Decoding MP3 file: " + fileName);
    }
}
```

```java
// File: code/lld/ch04/dip/plugin/FlacDecoder.java
package lld.ch04.dip.plugin;

public class FlacDecoder implements AudioDecoder {
    @Override
    public String extension() {
        return "flac";
    }

    @Override
    public void decode(String fileName) {
        System.out.println("Decoding FLAC file: " + fileName);
    }
}
```

```java
// File: code/lld/ch04/dip/plugin/MediaPlayer.java
package lld.ch04.dip.plugin;

import java.util.HashMap;
import java.util.Map;

/** The core. New formats arrive as plug-ins; this class is never edited for them. */
public class MediaPlayer {
    private final Map<String, AudioDecoder> decoders = new HashMap<>();

    public void install(AudioDecoder decoder) {
        decoders.put(decoder.extension(), decoder);
    }

    public void play(String fileName) {
        String ext = fileName.substring(fileName.lastIndexOf('.') + 1);
        AudioDecoder decoder = decoders.get(ext);
        if (decoder == null) {
            System.out.println("No plug-in installed for ." + ext);
            return;
        }
        decoder.decode(fileName);
        System.out.println("Playing audio...");
    }
}
```

```java
// File: code/lld/ch04/dip/Main.java
package lld.ch04.dip;

import java.math.BigDecimal;
import lld.ch04.dip.app.NotificationService;
import lld.ch04.dip.infra.EmailSender;
import lld.ch04.dip.infra.RecordingSender;
import lld.ch04.dip.infra.SmsSender;
import lld.ch04.dip.locator.CheckoutFlow;
import lld.ch04.dip.locator.PayPalService;
import lld.ch04.dip.locator.ServiceLocator;
import lld.ch04.dip.plugin.FlacDecoder;
import lld.ch04.dip.plugin.MediaPlayer;
import lld.ch04.dip.plugin.Mp3Decoder;

/** This class is the COMPOSITION ROOT: the one place that knows the concrete classes. */
public class Main {
    public static void main(String[] args) {
        System.out.println("=== 1. Before: NotificationService builds EmailService itself ===");
        new lld.ch04.dip.before.NotificationService().notifyUser("Your order shipped");

        System.out.println("=== 2. After: inject any NotificationSender ===");
        new NotificationService(new EmailSender()).notifyUser("u-42", "Your order shipped");
        new NotificationService(new SmsSender()).notifyUser("u-42", "Your order shipped");
        var recorder = new RecordingSender();
        new NotificationService(recorder).notifyUser("u-7", "Test message");
        System.out.println("test double captured: " + recorder.sent());

        System.out.println("=== 3. Service locator ===");
        var locator = new ServiceLocator();
        locator.register("PayPal", new PayPalService());
        new CheckoutFlow(locator).pay("PayPal", new BigDecimal("100.00"));

        System.out.println("=== 4. Plug-in architecture ===");
        var player = new MediaPlayer();
        player.install(new Mp3Decoder());
        player.install(new FlacDecoder());
        player.play("song.mp3");
        player.play("concert.flac");
        player.play("voice.ogg");
    }
}
```

Output:

```
=== 1. Before: NotificationService builds EmailService itself ===
Sending email: Your order shipped
=== 2. After: inject any NotificationSender ===
[email -> u-42] Your order shipped
[sms -> u-42] Your order shipped
test double captured: [u-7:Test message]
=== 3. Service locator ===
Processing payment via PayPal: $100.00
=== 4. Plug-in architecture ===
Decoding MP3 file: song.mp3
Playing audio...
Decoding FLAC file: concert.flac
Playing audio...
No plug-in installed for .ogg
```

DI vs plug-in architecture. At first sight they are the same thing (an implementation of an interface is handed to a core), but they work at different scales. **DI** is a small-scale mechanism: how one class obtains its collaborators. **Plug-in architecture** is a system-level design for extensibility: whole modules, often built by other teams, are added independently and frequently discovered while the program runs (Java's `ServiceLoader`, OSGi, a Java module system built for plug-ins, IDE plug-in APIs).

DIP vs DI vs IoC — do not mix them up

Term	What it is	Kind	Example
Dependency Inversion (DIP)	Depend on abstractions; the policy owns the abstraction	A **principle** (what good structure looks like)	`NotificationService` depends on `NotificationSender`
Dependency Injection (DI)	Pass dependencies in from outside instead of creating them	A **technique** (one way to achieve DIP)	`new NotificationService(new SmsSender())`
Inversion of Control (IoC)	The framework calls your code, not the other way round ("don't call us, we'll call you" — the Hollywood Principle)	A broad **idea**; DI is one form of it	Spring creating beans; a servlet container (a Java web server such as Tomcat) calling `doGet`; JUnit calling your `@Test` methods
IoC container	A framework that performs DI for you	A **tool**	Spring `ApplicationContext`, Google Guice (a lightweight DI library)

Two combinations prove they are different:

- **Injection without inversion**: `new OrderService(new MySqlDatabase())` where the parameter type is the concrete `MySqlDatabase`. It is injected, but the policy still depends on a detail.
- **Inversion without a framework**: everything in this chapter. Constructor + interface + a `main` that wires it. No container needed.

Stable vs volatile dependencies

DIP targets **volatile** dependencies: things that change often or that you want to fake in tests (databases, networks, clocks, third-party APIs, i.e. services run by other companies that your code calls, business rules that vary). Depending directly on **stable** concrete classes is fine: `String`, `List`, `LocalDate`, `Math`. Nobody wraps `String` in an interface. (Head First's version of DIP gives guidelines like "no variable should hold a reference to a concrete class", and then admits they are ideals you will break; the stable/volatile distinction is how you decide when.)

Importance of DIP

- **Flexibility** — swap implementations without touching business logic.
- **Maintainability** — detail changes stay in the detail.
- **Testability** — pass fakes and mocks (fakes that also record how they were called, so a test can check it); no real database or mail server in unit tests.

How DIP relates to the other principles

- **SRP**: injected collaborators keep each class focused on its own job; creating and configuring dependencies becomes the composition root's job.
- **OCP**: high-level code depends on abstractions, so new implementations extend it without edits.
- **LSP**: all implementations of the abstraction must be proper substitutes, or injection becomes dangerous.
- **ISP**: the abstraction the high-level module owns should be the **smallest** role it needs.

How it works (step by step)

1. Find a high-level class that names or creates a volatile low-level class.
2. Write down what the high-level class **needs** from it, in its own words (`send(recipient, message)`).
3. Make that an interface **in the high-level package**.
4. Make the low-level class implement it.
5. Inject the implementation (constructor by default).
6. Move all `new` calls for concrete classes to the composition root (`main`, a factory, or a DI container).

Trade-offs

You gain	You pay
Policy independent of technology	An interface per volatile dependency
Easy unit tests with fakes	Wiring code (or a framework and its learning curve)
Swappable implementations	Indirection: "go to implementation" takes an extra hop

When not to use it

- For stable classes (`String`, collections, value objects).
- For an interface that would have exactly one implementation forever and no test double.
- In tiny scripts.

Common mistakes

- Putting the interface in the **low-level** package (e.g. `mysql.MySqlRepository` and `mysql.Repository`). The policy then still depends on the detail's package.
- Designing the interface around one vendor's API (`sendSmtpMessage(...)`) instead of the policy's need (`send(...)`). Changing vendors then changes the interface too.
- Breaking the **second** clause ("abstractions should not depend on details"): an interface whose methods return `java.sql.ResultSet` or throw `javax.mail.MessagingException` is technically an abstraction, but it drags the detail's types into the policy. Use the policy's own types (`Optional<Order>`, a box that may or may not hold an order; a domain exception, an error type named in business terms) instead.
- Believing "we use Spring, so we follow DIP". Spring can inject concrete classes just as happily.
- Calling `new ConcreteThing()` inside a class "just this once".

Real-world examples

- **JDBC**: your code depends on `java.sql.Connection` / `DataSource` interfaces; drivers from MySQL, PostgreSQL, Oracle implement them. `DriverManager` finds drivers through `ServiceLoader`.
- **SLF4J**: the application depends on the logging facade; Logback or Log4j 2 is the plugged-in detail.
- **Spring** and **Jakarta EE CDI** (the enterprise-Java standard's built-in injection): IoC containers doing constructor injection.
- **JPA** (Java's standard API for saving objects to SQL databases): code uses `EntityManager`; Hibernate or EclipseLink implements it.
- **Hexagonal architecture (ports and adapters)**: the core defines *ports* (interfaces); *adapters* for HTTP, databases and queues (message queues, see System Design Fundamentals) implement them. This is DIP applied to a whole service.

In the interview

30-second answer: "DIP says business logic should not depend on technical details; both depend on an abstraction, and the business side owns that abstraction. So `NotificationService` depends on a `NotificationSender` interface in its own package, and email and SMS senders implement it. I inject the implementation through the constructor and wire everything in `main`. That makes the service testable with a fake and lets me swap providers. DI is the technique; DIP is the principle; Spring is just a tool that does the wiring."

Follow-ups:

- *"Difference between dependency inversion and dependency injection?"* — Inversion is the principle (depend on abstractions); injection is one technique (pass dependencies in). You can inject a concrete class, which is injection without inversion.
- *"Who should own the interface?"* — The high-level module that uses it.
- *"Is Service Locator OK?"* — It satisfies DIP but hides dependencies and fails late. I prefer constructor injection.

Self-check

1. **Q:** What is "inverted" in DIP? **A:** The source-code dependency: the detail depends on (implements) an abstraction owned by the policy, instead of the policy importing the detail.
2. **Q:** Is `new OrderService(new MySqlDatabase())` with a `MySqlDatabase` parameter DIP? **A:** No. It is injection of a concrete class; the policy still depends on the detail.
3. **Q:** What is a composition root? **A:** The one place (usually `main` or the container config) where concrete classes are created and wired.
4. **Q:** Should you put `String` behind an interface? **A:** No. It is stable; DIP is for volatile dependencies.

TL;DR

Business code depends on interfaces it owns; details implement them; `main` (or a container) wires them. DI is the how, DIP is the why, IoC containers are the tool.

4.11 Refactoring one class through all five principles

In real code the principles seldom show up one at a time; they tend to appear **in a fixed sequence**, each exposing the need for the next. This section refactors a single order-checkout class five times. The class checks the order, prices it, saves it and emails the customer, the sort of class that has been growing unnoticed for a couple of years.

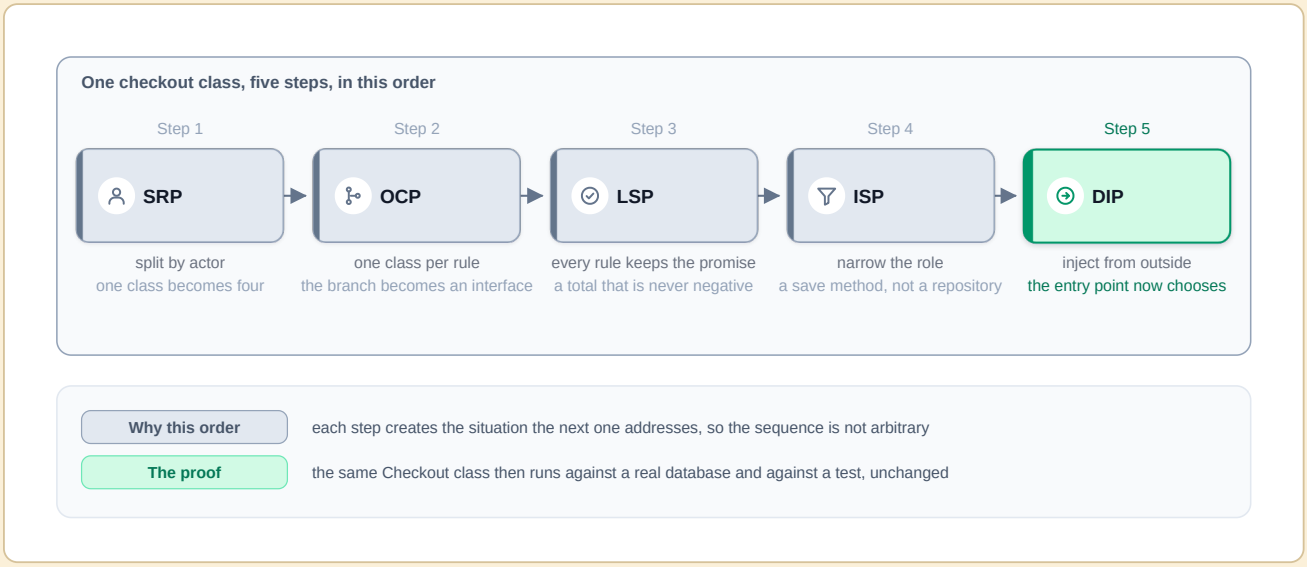


Figure — one checkout class, five steps: SRP, OCP, LSP, ISP, DIP, each creating the situation the next addresses (course diagram)

Step 0: the starting class

The code runs correctly, and yet each of the five principles finds something to object to.

```java
// File: code/lld/ch04/checkout/step0/CustomerOrder.java
package lld.ch04.checkout.step0;

import java.math.BigDecimal;

/** The original order shape: the customer type travels with the order as a string. */
public record CustomerOrder(String orderId, String customerType, BigDecimal amount, String email) { }
```

```java
// File: code/lld/ch04/checkout/step0/OrderService.java
package lld.ch04.checkout.step0;

import java.math.BigDecimal;
import java.math.RoundingMode;

/** STEP 0 -- the class that grew quietly for two years. It works. */
public class OrderService {
    public void process(CustomerOrder order) {
        // 1. Validation  (business-rules owner)
        if (order.amount().signum() <= 0) {
            System.out.println("Rejected: amount must be positive");
            return;
        }
        // 2. Pricing, one branch per customer type  (finance)
        BigDecimal total = order.amount();
        if (order.customerType().equals("member")) {
            total = total.multiply(new BigDecimal("0.90"));
        } else if (order.customerType().equals("staff")) {
            total = total.multiply(new BigDecimal("0.70"));
        }
        total = total.setScale(2, RoundingMode.HALF_EVEN); // money: always 2 decimals
        // 3. Storage  (database team)
        System.out.println("INSERT INTO orders VALUES ('" + order.orderId() + "', " + total + ")");
        // 4. Telling the customer  (marketing)
        System.out.println("Emailing " + order.email() + ": your order total is " + total);
    }
}
```

Step 1: Single Responsibility — split by actor

List everyone who might request a change to `process`:

Section of `process`	Requested by
Validation	The business-rules owner
Pricing	Finance
The `INSERT` statement	The database team
The email wording	Marketing

One method answers to four different groups, so rewording the email forces a redeploy of the pricing logic. Split it by actor into `OrderValidator`, `PriceCalculator`, `OrderRepository` and `Notifier`:

```java
// File: code/lld/ch04/checkout/step1/OrderValidator.java
package lld.ch04.checkout.step1;

import lld.ch04.checkout.step0.CustomerOrder;

/** Actor: business-rules owner. */
public class OrderValidator {
    public boolean isValid(CustomerOrder order) {
        return order.amount().signum() > 0;
    }
}
```

```java
// File: code/lld/ch04/checkout/step1/PriceCalculator.java
package lld.ch04.checkout.step1;

import java.math.BigDecimal;
import java.math.RoundingMode;
import lld.ch04.checkout.step0.CustomerOrder;

/** Actor: finance. SRP is satisfied, but the branch is still here -> OCP problem next. */
public class PriceCalculator {
    public BigDecimal total(CustomerOrder order) {
        BigDecimal total = switch (order.customerType()) {
            case "member" -> order.amount().multiply(new BigDecimal("0.90"));
            case "staff" -> order.amount().multiply(new BigDecimal("0.70"));
            default -> order.amount();
        };
        return total.setScale(2, RoundingMode.HALF_EVEN);
    }
}
```

```java
// File: code/lld/ch04/checkout/step1/OrderRepository.java
package lld.ch04.checkout.step1;

import java.math.BigDecimal;
import lld.ch04.checkout.step0.CustomerOrder;

/** Actor: database team. */
public class OrderRepository {
    public void save(CustomerOrder order, BigDecimal total) {
        System.out.println("INSERT INTO orders VALUES ('" + order.orderId() + "', " + total + ")");
    }
}
```

```java
// File: code/lld/ch04/checkout/step1/Notifier.java
package lld.ch04.checkout.step1;

import java.math.BigDecimal;
import lld.ch04.checkout.step0.CustomerOrder;

/** Actor: marketing (owns the wording). */
public class Notifier {
    public void send(CustomerOrder order, BigDecimal total) {
        System.out.println("Emailing " + order.email() + ": your order total is " + total);
    }
}
```

```java
// File: code/lld/ch04/checkout/step1/Checkout.java
package lld.ch04.checkout.step1;

import java.math.BigDecimal;
import lld.ch04.checkout.step0.CustomerOrder;

/** STEP 1 (SRP): coordinates four single-actor classes. Still news them up itself. */
public class Checkout {
    private final OrderValidator validator = new OrderValidator();
    private final PriceCalculator calculator = new PriceCalculator();
    private final OrderRepository repository = new OrderRepository();
    private final Notifier notifier = new Notifier();

    public void process(CustomerOrder order) {
        if (!validator.isValid(order)) {
            System.out.println("Rejected: amount must be positive");
            return;
        }
        BigDecimal total = calculator.total(order);
        repository.save(order, total);
        notifier.send(order, total);
    }
}
```

Step 2: Open/Closed — one class per pricing rule

Inside `PriceCalculator` the branch on customer type survived the split, so a new "student" rate would still mean editing working code. Give each rate its own class behind a `PricingRule` interface. From here on the order stops carrying a type string; whoever calls the checkout picks the rule:

```java
// File: code/lld/ch04/checkout/Order.java
package lld.ch04.checkout;

import java.math.BigDecimal;

/** From step 2 on, the order no longer carries a customer-type string: the rule is chosen outside. */
public record Order(String orderId, BigDecimal amount, String email) { }
```

```java
// File: code/lld/ch04/checkout/pricing/PricingRule.java
package lld.ch04.checkout.pricing;

import java.math.BigDecimal;

/**
 * STEP 2 (OCP): one class per rate; a new rate is a new class.
 * CONTRACT every implementation must keep (STEP 3, LSP):
 *   precondition : amount >= 0
 *   postcondition: result >= 0, rounded to 2 decimals   (a total is never negative)
 */
@FunctionalInterface
public interface PricingRule {
    BigDecimal apply(BigDecimal amount);
}
```

```java
// File: code/lld/ch04/checkout/pricing/RegularPrice.java
package lld.ch04.checkout.pricing;

import java.math.BigDecimal;
import java.math.RoundingMode;

public class RegularPrice implements PricingRule {
    @Override
    public BigDecimal apply(BigDecimal amount) {
        return amount.setScale(2, RoundingMode.HALF_EVEN);
    }
}
```

```java
// File: code/lld/ch04/checkout/pricing/MemberDiscount.java
package lld.ch04.checkout.pricing;

import java.math.BigDecimal;
import java.math.RoundingMode;

public class MemberDiscount implements PricingRule {
    private static final BigDecimal RATE = new BigDecimal("0.90");

    @Override
    public BigDecimal apply(BigDecimal amount) {
        return amount.multiply(RATE).setScale(2, RoundingMode.HALF_EVEN);
    }
}
```

```java
// File: code/lld/ch04/checkout/pricing/StaffDiscount.java
package lld.ch04.checkout.pricing;

import java.math.BigDecimal;
import java.math.RoundingMode;

public class StaffDiscount implements PricingRule {
    private static final BigDecimal RATE = new BigDecimal("0.70");

    @Override
    public BigDecimal apply(BigDecimal amount) {
        return amount.multiply(RATE).setScale(2, RoundingMode.HALF_EVEN);
    }
}
```

```java
// File: code/lld/ch04/checkout/step2/PriceCalculator.java
package lld.ch04.checkout.step2;

import java.math.BigDecimal;
import lld.ch04.checkout.Order;
import lld.ch04.checkout.pricing.PricingRule;

/** STEP 2: no branch left. The calculator never learns how many rates exist. */
public class PriceCalculator {
    public BigDecimal total(Order order, PricingRule rule) {
        return rule.apply(order.amount());
    }
}
```

A student rate is now one new class and no edits.

Step 3: Liskov Substitution — every rule keeps the promise

Once one interface has several implementations, you have to ask whether each of them can really stand in for the others. Finance now wants a **fixed** discount of 20 rather than a percentage. A naive version turns a 10 order into a total of **−10**, with no exception at all: the negative total is saved, and later the customer may be credited

money they never paid. This is the postcondition/invariant rule from 4.8: every pricing rule must guarantee **a total that is never negative**, and a rule that does not is not a valid substitute. The fix is to state the promise explicitly (it is in the `PricingRule` Javadoc), make every rule honour it, and verify that with one contract test applied to every implementation:

```java
// File: code/lld/ch04/checkout/pricing/CarelessFixedDiscount.java
package lld.ch04.checkout.pricing;

import java.math.BigDecimal;
import java.math.RoundingMode;

/** LSP VIOLATION kept for the demo: 20 off a 10 order gives -10. Nothing throws. */
public class CarelessFixedDiscount implements PricingRule {
    private final BigDecimal off;

    public CarelessFixedDiscount(BigDecimal off) {
        this.off = off;
    }

    @Override
    public BigDecimal apply(BigDecimal amount) {
        return amount.subtract(off).setScale(2, RoundingMode.HALF_EVEN);
    }
}
```

```java
// File: code/lld/ch04/checkout/pricing/FixedDiscount.java
package lld.ch04.checkout.pricing;

import java.math.BigDecimal;
import java.math.RoundingMode;

/** STEP 3 fix: keeps the promise that a total is never negative. */
public class FixedDiscount implements PricingRule {
    private final BigDecimal off;

    public FixedDiscount(BigDecimal off) {
        if (off.signum() < 0) {
            throw new IllegalArgumentException("discount must be >= 0");
        }
        this.off = off;
    }

    @Override
    public BigDecimal apply(BigDecimal amount) {
        return amount.subtract(off).max(BigDecimal.ZERO).setScale(2, RoundingMode.HALF_EVEN);
    }
}
```

```java
// File: code/lld/ch04/checkout/step3/PricingRuleContract.java
package lld.ch04.checkout.step3;

import java.math.BigDecimal;
import java.util.List;
import lld.ch04.checkout.pricing.PricingRule;

/** STEP 3: ONE test written against the interface, run for EVERY implementation. */
public final class PricingRuleContract {
    private static final List<BigDecimal> SAMPLE_AMOUNTS = List.of(
            new BigDecimal("0.00"), new BigDecimal("10.00"),
            new BigDecimal("100.00"), new BigDecimal("250.00"));

    private PricingRuleContract() { }

    public static boolean holds(PricingRule rule) {
        for (BigDecimal amount : SAMPLE_AMOUNTS) {
            BigDecimal total = rule.apply(amount);
            if (total.signum() < 0) {
                System.out.println("  " + rule.getClass().getSimpleName()
                        + " broke the contract: apply(" + amount + ") = " + total);
                return false;
            }
        }
        System.out.println("  " + rule.getClass().getSimpleName() + " keeps the contract");
        return true;
    }
}
```

Step 4: Interface Segregation — the checkout needs a save method, not a repository

Repositories tend to accumulate methods (`save`, `findById`, `delete`, `listAll`) as other parts of the system ask for them. The checkout, however, only ever **saves**. If it is typed against the full repository, each new query added for reporting becomes one more method it depends on without calling. So describe the **role** the checkout needs instead of the class it is handed: an order saver, exactly one method wide. The real repository is free to play that role and others:

```java
// File: code/lld/ch04/checkout/fin/OrderSaver.java
package lld.ch04.checkout.fin;

import java.math.BigDecimal;
import lld.ch04.checkout.Order;

/** STEP 4 (ISP): the role the checkout needs -- one method wide, owned by the checkout. */
@FunctionalInterface
public interface OrderSaver {
    void save(Order order, BigDecimal total);
}
```

```java
// File: code/lld/ch04/checkout/fin/OrderFinder.java
package lld.ch04.checkout.fin;

import java.util.List;
import java.util.Optional;
import lld.ch04.checkout.Order;

/** A different role, for reporting callers. The checkout never sees it. */
public interface OrderFinder {
    Optional<Order> findById(String orderId);

    List<Order> listAll();
}
```

```java
// File: code/lld/ch04/checkout/fin/OrderNotifier.java
package lld.ch04.checkout.fin;

import java.math.BigDecimal;
import lld.ch04.checkout.Order;

@FunctionalInterface
public interface OrderNotifier {
    void send(Order order, BigDecimal total);
}
```

```java
// File: code/lld/ch04/checkout/fin/SqlOrderRepository.java
package lld.ch04.checkout.fin;

import java.math.BigDecimal;
import java.util.ArrayList;
import java.util.List;
import java.util.Optional;
import lld.ch04.checkout.Order;

/** The full repository grows (save, find, list...) but plays two separate roles. */
public class SqlOrderRepository implements OrderSaver, OrderFinder {
    private final List<Order> table = new ArrayList<>(); // stands in for a real DB table

    @Override
    public void save(Order order, BigDecimal total) {
        table.add(order);
        System.out.println("  INSERT INTO orders VALUES ('" + order.orderId() + "', " + total + ")");
    }

    @Override
    public Optional<Order> findById(String orderId) {
        return table.stream().filter(o -> o.orderId().equals(orderId)).findFirst();
    }

    @Override
    public List<Order> listAll() {
        return List.copyOf(table);
    }
}
```

Step 5: Dependency Inversion — the entry point decides

A last problem remains: the step-1 `Checkout` constructs its collaborators itself, so it refers to concrete classes (a SQL repository, an email notifier) and cannot run in a test without a database and a mail server. Instead, have the abstractions passed in. The checkout then mentions no concrete class, and the program's entry point chooses the implementations:

```java
// File: code/lld/ch04/checkout/fin/InMemoryOrders.java
package lld.ch04.checkout.fin;

import java.math.BigDecimal;
import java.util.ArrayList;
import java.util.List;
import lld.ch04.checkout.Order;

/** Test double: one method to implement, because the role is one method wide. */
public class InMemoryOrders implements OrderSaver {
    private final List<String> saved = new ArrayList<>();

    @Override
    public void save(Order order, BigDecimal total) {
        saved.add(order.orderId() + "=" + total);
        System.out.println("  kept " + order.orderId() + " in memory");
    }

    public List<String> saved() {
        return List.copyOf(saved);
    }
}
```

```java
// File: code/lld/ch04/checkout/fin/EmailNotifier.java
package lld.ch04.checkout.fin;

import java.math.BigDecimal;
import lld.ch04.checkout.Order;

public class EmailNotifier implements OrderNotifier {
    @Override
    public void send(Order order, BigDecimal total) {
        System.out.println("  emailing " + order.email() + ": total " + total);
    }
}
```

```java
// File: code/lld/ch04/checkout/fin/SilentNotifier.java
package lld.ch04.checkout.fin;

import java.math.BigDecimal;
import lld.ch04.checkout.Order;

public class SilentNotifier implements OrderNotifier {
    @Override
    public void send(Order order, BigDecimal total) {
        System.out.println("  (test run, no email sent)");
    }
}
```

```java
// File: code/lld/ch04/checkout/fin/Checkout.java
package lld.ch04.checkout.fin;

import java.math.BigDecimal;
import java.util.Objects;
import lld.ch04.checkout.Order;
import lld.ch04.checkout.pricing.PricingRule;

/**
 * STEP 5 (DIP): every volatile collaborator arrives from outside.
 * No concrete database, mail or pricing class is named here.
 */
public class Checkout {
    private final PricingRule rule;
    private final OrderSaver orders;
    private final OrderNotifier notifier;

    public Checkout(PricingRule rule, OrderSaver orders, OrderNotifier notifier) {
        this.rule = Objects.requireNonNull(rule);
        this.orders = Objects.requireNonNull(orders);
        this.notifier = Objects.requireNonNull(notifier);
    }

    public boolean process(Order order) {
        // Validation has not varied yet, so it stays a plain check (see "What we did not do").
        if (order.amount().signum() <= 0) {
            System.out.println("  rejected: amount must be positive");
            return false;
        }
        BigDecimal total = rule.apply(order.amount());
        orders.save(order, total);
        notifier.send(order, total);
        return true;
    }
}
```

```java
// File: code/lld/ch04/checkout/Main.java
package lld.ch04.checkout;

import java.math.BigDecimal;
import java.util.List;
import lld.ch04.checkout.fin.Checkout;
import lld.ch04.checkout.fin.EmailNotifier;
import lld.ch04.checkout.fin.InMemoryOrders;
import lld.ch04.checkout.fin.SilentNotifier;
import lld.ch04.checkout.fin.SqlOrderRepository;
import lld.ch04.checkout.pricing.CarelessFixedDiscount;
import lld.ch04.checkout.pricing.FixedDiscount;
import lld.ch04.checkout.pricing.MemberDiscount;
import lld.ch04.checkout.pricing.PricingRule;
import lld.ch04.checkout.pricing.RegularPrice;
import lld.ch04.checkout.pricing.StaffDiscount;
import lld.ch04.checkout.step0.CustomerOrder;
import lld.ch04.checkout.step0.OrderService;
import lld.ch04.checkout.step2.PriceCalculator;
import lld.ch04.checkout.step3.PricingRuleContract;

public class Main {
    private static final BigDecimal TWENTY = new BigDecimal("20.00");

    public static void main(String[] args) {
        System.out.println("=== Step 0: the original class ===");
        var legacy = new OrderService();
        legacy.process(new CustomerOrder("A-1", "regular", new BigDecimal("100.00"), "ada@example.com"));
        legacy.process(new CustomerOrder("A-2", "staff", new BigDecimal("100.00"), "grace@example.com"));

        System.out.println("=== Step 1: SRP -- split by actor (same output) ===");
        new lld.ch04.checkout.step1.Checkout()
                .process(new CustomerOrder("A-2", "staff", new BigDecimal("100.00"), "grace@example.com"));

        System.out.println("=== Step 2: OCP -- one class per pricing rule ===");
        var calc = new PriceCalculator();
        var order = new Order("A-3", new BigDecimal("100.00"), "ada@example.com");
        for (PricingRule r : List.of(new RegularPrice(), new MemberDiscount(), new StaffDiscount())) {
            System.out.println("  " + r.getClass().getSimpleName() + " -> " + calc.total(order, r));
        }

        System.out.println("=== Step 3: LSP -- every rule must keep 'total >= 0' ===");
        var small = new Order("A-4", new BigDecimal("10.00"), "ada@example.com");
        System.out.println("  careless FixedDiscount(20) on 10 -> "
                + calc.total(small, new CarelessFixedDiscount(TWENTY)));
        System.out.println("  correct  FixedDiscount(20) on 10 -> "
                + calc.total(small, new FixedDiscount(TWENTY)));
        List<PricingRule> all = List.of(new RegularPrice(), new MemberDiscount(),
                new StaffDiscount(), new FixedDiscount(TWENTY), new CarelessFixedDiscount(TWENTY));
        long passing = all.stream().filter(PricingRuleContract::holds).count();
        System.out.println("  " + passing + "/" + all.size() + " rules are safe substitutes");

        System.out.println("=== Steps 4+5: ISP + DIP -- same Checkout, two wirings ===");
        var a9 = new Order("A-9", new BigDecimal("200.00"), "ada@example.com");
        System.out.println("Production wiring:");
        var db = new SqlOrderRepository();
        new Checkout(new MemberDiscount(), db, new EmailNotifier()).process(a9);
        System.out.println("  reporting side can still find it: " + db.findById("A-9").isPresent());

        System.out.println("Test wiring, same Checkout class:");
        var fake = new InMemoryOrders();
        new Checkout(new MemberDiscount(), fake, new SilentNotifier()).process(a9);
        System.out.println("  test double recorded " + fake.saved());

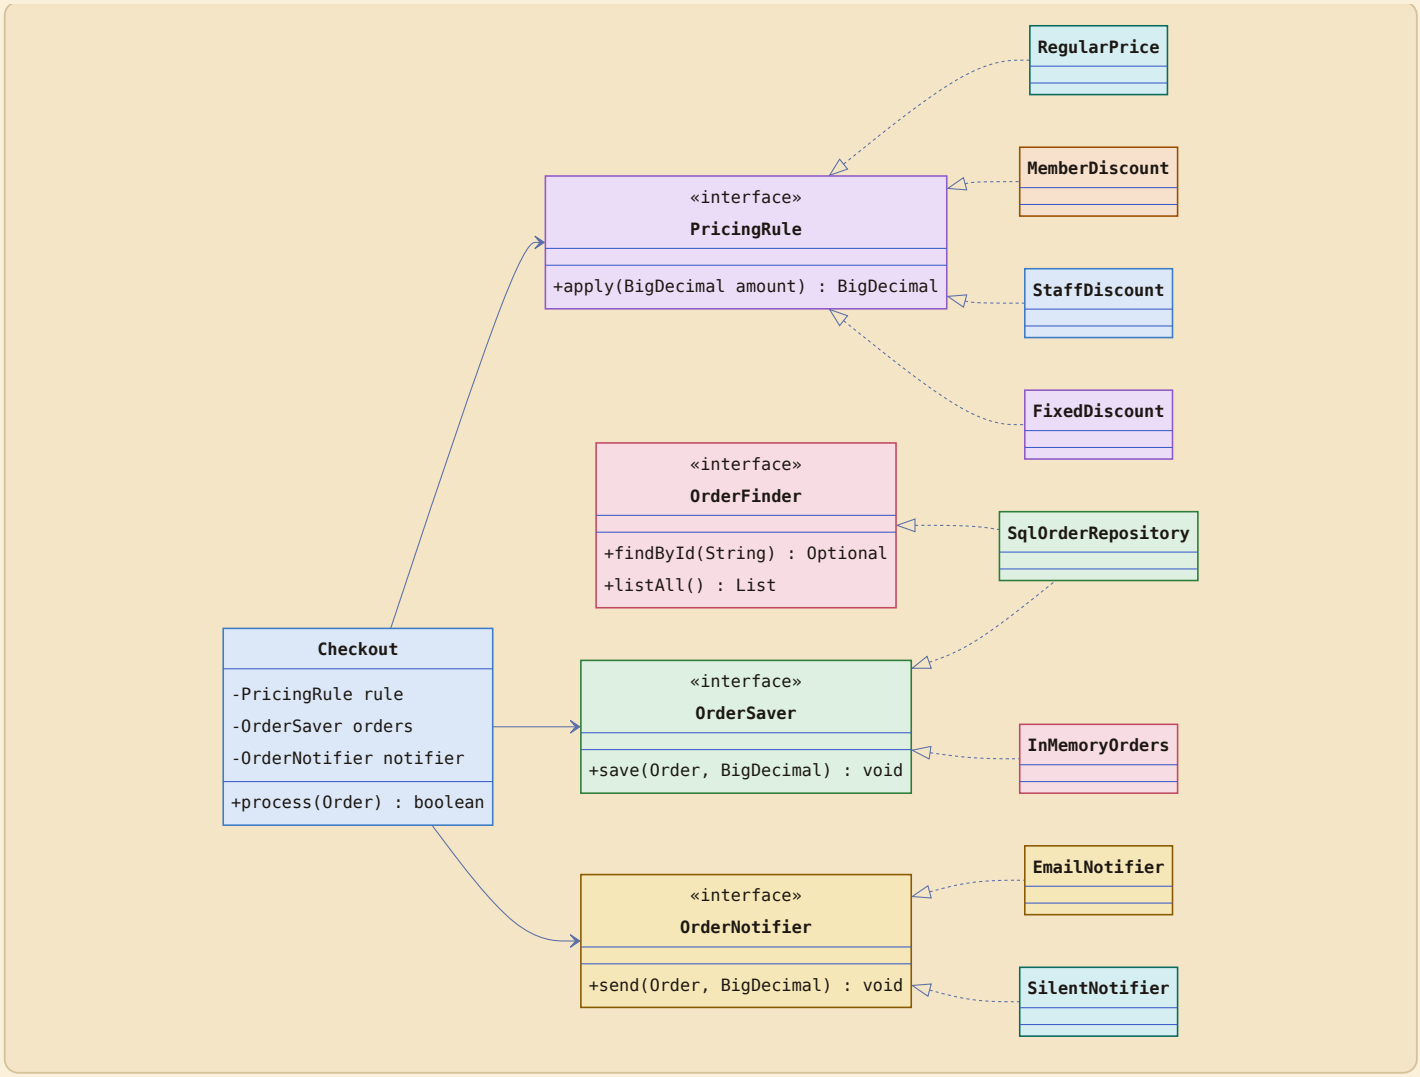
        System.out.println("Lambda wiring (roles are functional interfaces):");
        new Checkout(amount -> amount, (o, t) -> System.out.println("  saved " + o.orderId()),
                (o, t) -> System.out.println("  notified " + o.email())).process(a9);
        new Checkout(new RegularPrice(), fake, new SilentNotifier())
```

```
                .process(new Order("A-10", BigDecimal.ZERO, "x@example.com"));
    }
}
```

Output:

```
=== Step 0: the original class ===
INSERT INTO orders VALUES ('A-1', 100.00)
Emailing ada@example.com: your order total is 100.00
INSERT INTO orders VALUES ('A-2', 70.00)
Emailing grace@example.com: your order total is 70.00
=== Step 1: SRP -- split by actor (same output) ===
INSERT INTO orders VALUES ('A-2', 70.00)
Emailing grace@example.com: your order total is 70.00
=== Step 2: OCP -- one class per pricing rule ===
  RegularPrice -> 100.00
  MemberDiscount -> 90.00
  StaffDiscount -> 70.00
=== Step 3: LSP -- every rule must keep 'total >= 0' ===
  careless FixedDiscount(20) on 10 -> -10.00
  correct  FixedDiscount(20) on 10 -> 0.00
  RegularPrice keeps the contract
  MemberDiscount keeps the contract
  StaffDiscount keeps the contract
  FixedDiscount keeps the contract
  CarelessFixedDiscount broke the contract: apply(0.00) = -20.00
  4/5 rules are safe substitutes
=== Steps 4+5: ISP + DIP -- same Checkout, two wirings ===
Production wiring:
  INSERT INTO orders VALUES ('A-9', 180.00)
  emailing ada@example.com: total 180.00
  reporting side can still find it: true
Test wiring, same Checkout class:
  kept A-9 in memory
  (test run, no email sent)
  test double recorded [A-9=180.00]
Lambda wiring (roles are functional interfaces):
  saved A-9
  notified ada@example.com
  rejected: amount must be positive
```

One unmodified `Checkout` class ran against production collaborators, against test doubles and even against lambdas, **without being edited or subclassed**. That is what the five steps bought.



Reading the five steps back

Step	The question it asked	What changed
SRP	Who might request changes here?	The single class split into four, one per actor
OCP	What breaks when a new case shows up?	Each pricing branch turned into its own class
LSP	Does each rule work when called through the interface?	All rules guarantee the total never drops below zero
ISP	Is the caller tied to more than it calls?	Checkout depends on one save method rather than a whole repository
DIP	Who decides which concrete class is used?	The entry point decides, not the checkout

The sequence has a reason. SRP goes first because the point where behaviour varies stays hidden until each class has a single job. OCP then introduces an interface. LSP becomes relevant as soon as that interface has a second implementation. ISP becomes relevant when new callers (reporting) show up. DIP is last because inversion needs abstractions to point at. Every step sets up the problem the next step solves, which is why the five are normally learned as a group.

What we did not do

- **Not every principle was applied to every class.** `Order` remains a simple record without an interface, because no requirement has made it vary.
- **Not every class was closed against every change.** Adding a validation rule still means editing `Checkout`. That is fine while validation stays stable; the day a third validation rule is requested is the day validation

deserves the treatment pricing received.

- **Not everything was injected.** `Order` and the `BigDecimal` arithmetic are stable, so they are used directly.

Pre-emptively applying all five principles to every class turns a small, clear program into a confusing one. **Each step above was triggered by an actual change request, never by a checklist.**

Self-check

1. **Q:** Why does SRP come before OCP here? **A:** Until pricing lived in its own class, the varying part (the branch on customer type) was buried in a method that did four things.
2. **Q:** What contract did step 3 add? **A:** Every `PricingRule` returns a total ≥ 0 for any amount ≥ 0.
3. **Q:** Why is `OrderSaver` one method wide? **A:** The checkout only saves; depending on the full repository would tie it to reporting methods it never calls.
4. **Q:** What proves the design worked? **A:** One `Checkout` class ran with three different wirings (production, test doubles, lambdas) without being edited.

TL;DR

SRP → OCP → LSP → ISP → DIP, each triggered by a real change. Proof: one class, several wirings, zero edits.

4.12 SOLID and design patterns

Most classic design patterns (Chapters 8–11) exist because of these principles. Learning the principles first makes the patterns look inevitable rather than arbitrary: **the principles say what good structure looks like; the patterns are named, reusable ways to produce it.**

Pattern	Principle(s) it serves	How
Strategy	OCP, DIP	A varying algorithm behind an interface (`InvoiceGenerator`, `PricingRule`)
Template Method	OCP	A fixed skeleton in a base class; subclasses fill in hook steps
Decorator	OCP, SRP	Adds behaviour by wrapping, without modifying the original class
Adapter	DIP, ISP	Lets a caller keep depending on the interface it already owns while a foreign class is plugged in
Factory Method / Abstract Factory	DIP, OCP	Keeps callers away from concrete constructors; the `switch` lives in one place
Observer	OCP, DIP	New reactions are new subscribers; the subject depends only on a listener interface
Composite	LSP, OCP	Leaves and groups share one interface, so callers treat them the same
Proxy	SRP, OCP	Adds access control, caching or laziness (creating things only when first needed) in a separate class
Command	SRP, OCP	Each request is its own object; new commands are new classes
Visitor	OCP (for operations)	Easy to add operations, hard to add element types: OCP along a different axis
Null Object	LSP	A do-nothing implementation that still keeps the contract, instead of `null` checks

Head First Design Patterns states several of the same ideas as its "OO design principles": **encapsulate what varies**, **favour composition over inheritance**, **program to an interface, not an implementation**, **classes should be open for extension but closed for modification** (its Decorator chapter), **depend upon abstractions, do not depend upon concrete classes** (its Factory chapter's name for DIP), and **a class should have only one reason to change** (its Iterator/Composite chapter). *Clean Code* covers SRP and "organising for change" in its chapter on classes, and "isolating from change" is DIP by another name.

4.13 SOLID in the design interview

Keeping the design honest: five checks over your class diagram

A complete class diagram can still be a poor design. In an OOD interview, SOLID is most useful as **five quick checks over the diagram you just drew**, taking about five minutes. Run them in this order:

1. **Single responsibility.** Say each class's responsibility in one sentence. If the sentence needs an "and", the class has two jobs. A `ParkingLot` that assigns spots **and** prints receipts changes when pricing changes and again when the layout changes: two classes. *Quick check:* name the change that would force you to edit the class; if you can name two unrelated changes, split it.
2. **Open/closed.** Look for a `switch` or `if` chain over a type. In a parking lot, pricing as a switch over rate types means a weekend rate edits the class that prices everything. Put pricing behind a small interface and the weekend rate is a new class. *Quick check:* pick one likely feature; if adding it edits three existing classes, the design is closed to the wrong thing.
3. **Liskov substitution.** Read each inheritance arrow: can the child be handed to code expecting the parent? If any parent method would throw, do nothing or refuse, the arrow is wrong. Check this again at the end: inheritance arrows get added late, when time is short.
4. **Interface segregation.** Look for a big interface where implementers leave methods empty. Split until every implementer uses everything it promised. A library `Search` interface with four methods is fine if the catalog genuinely implements all four.
5. **Dependency inversion.** Find high-level classes naming low-level ones. A `ParkingLot` that constructs a `CreditCardTransaction` cannot be tested without a payment provider and cannot take cash without an edit. Make it depend on `Payment` and let something else decide which kind arrives.

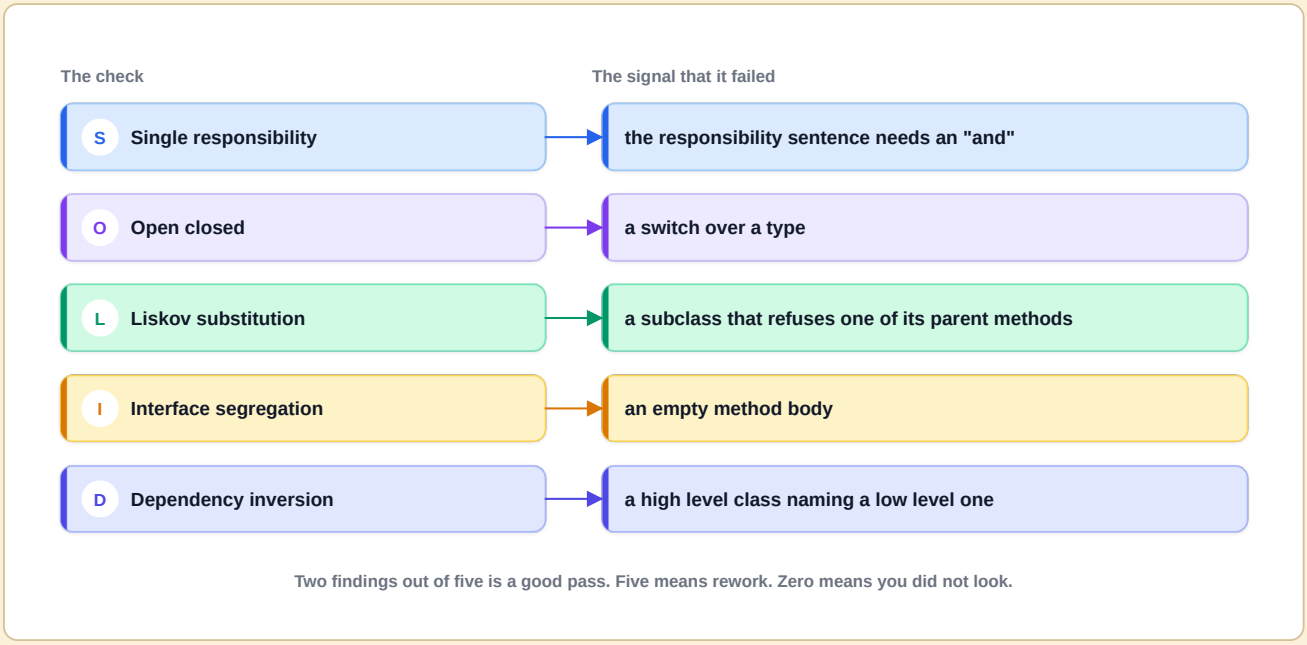


Figure — each check and the signal that it failed: an "and" in the sentence, a switch over a type, a refused parent method, an empty method body, a high-level class naming a low-level one (course diagram)

In the figure above, the right-hand column is what to scan for. The note at the bottom is the calibration: **two findings out of five is a good pass; five means rework; zero means you did not look.**

The two that earn the most credit. SRP improves your class list: twelve well-named classes beat six that each do three things. **OCP** is the one interviewers probe, usually as a late requirement ("what if trucks are charged a different rate?"). "Add a class" is a stronger answer than "add a branch in this switch".

A five-minute pass over a parking lot design:

Check	Finding
Single responsibility	`ParkingLot` issues tickets and finds spots: two reasons to change. Split if there is time; name it out loud if not.
Open/closed	Pricing sits behind `ParkingRate`, so a new rate is a new class. Passes.
Liskov substitution	Five spot subclasses add no behaviour. Collapse them into one class with a `type` field.
Interface segregation	No wide interfaces. Passes.
Dependency inversion	The lot depends on `Payment`, not on the card class. Passes.

Two real findings, each explainable in a sentence. That is what a good pass looks like.

Where SOLID is not the answer. It is a set of checks, not a scoring system. Do **not** add an interface for everything: an interface with one implementer, added because a rule "seemed to ask for it", is indirection with no benefit; add it when a second implementation exists or is clearly coming. Do **not** split classes further than a reader can follow: thirty classes with two methods each cannot be held in anyone's head. The one-sentence test is the boundary: if the responsibility fits in one sentence, the class is small enough.

Naming a design problem out loud

Interviewers seldom ask for a definition of OCP. They ask for a parking lot, a rate limiter (a component that caps how many requests are allowed per time window) or a file store, and then judge whether you can **explain the reasons behind the shape of your design**, which separates someone who memorised five acronyms from someone who uses them. Three things are weighed, most important first:

1. **Can you spot and name a problem in the code in front of you?** Shown a class with an ever-growing `if/else` on a type field, can you state the flaw in one crisp sentence?
2. **Can you defend a choice?** "SOLID says so" earns nothing. "Pricing rules change every quarter, and I don't want every change to reopen the checkout" earns a lot.
3. **Do you know when to hold back?** This is what marks a senior candidate. Adding abstractions is easy; choosing which ones to skip is the rarer skill.

A sentence pattern that works — say three things, in this order:

1. **What you see** — a specific fact about the code.
2. **What it will cost** — the future change that this makes painful.
3. **What you would do, and what that costs you** — the remedy and its price. This third part is the one most people leave out, and it is exactly what makes an answer sound like it comes from experience rather than from memory.

Example: a `ReportGenerator` that formats a report, writes it to disk and emails it.

- Weak: "It breaks SRP since it does three things; I'd make three classes." Correct, but it sounds like a definition recalled from last night's reading.
- Strong: "Three different owners can request changes here: marketing controls the wording, the platform team controls where files land, and the email owners control delivery. That means a copy edit redeploys the file-writing code. I'd pull formatting apart from delivery, likely into a formatter and a sink (the destination the output is sent to). It costs me two more classes and a little wiring, which pays off because the wording changes frequently." It names the actors, the pain, the fix and its price, and ends in a decision.

Say the observation before the principle. "`Reporting` implements nine methods but calls only two of them, which is an interface segregation problem" shows that you noticed something. Opening with "This violates ISP because…" sounds like you went looking for a place to use the acronym. Do still name the principle at the end, because it hands the interviewer a label for the write-up.

"Would you always do that?" This follow-up checks whether you understand the price of your own suggestion; it is rarely a trap, and the right answer is almost never "yes". Keep honest limits ready:

- *On splitting classes:* "No. If the two parts would always be edited together, I've just created an extra file. I split when two different people would ask for two different changes."
- *On extension points:* "No. I keep the `if/else` until a second or third case actually appears. An extension point built in advance is usually wasted effort and makes the code harder to follow in the meantime."

- *On interfaces:* "Only where behaviour varies or a test needs a substitute. An interface with a single implementation and no fake is just one more file."

Treating a principle as unconditional is the quickest way to show you have never actually applied it.

Three things that cost marks:

- **Reciting definitions** without tying them to the code on the whiteboard.
- **Applying everything at once.** Five interfaces for a forty-line problem looks inexperienced, not thorough; real systems earn their abstractions.
- **Naming the wrong principle confidently.** Mixing up cohesion and coupling reveals that the vocabulary is second-hand. When unsure, describe the issue in plain words and leave the label out: an accurate unnamed description beats a confidently wrong name.

A one-minute drill for any class you own: (1) Who can ask me to change this class, and which parts belong to whom? (2) What is the next feature likely to be, and would I have to edit this class for it? (3) Which dependencies could I not replace in a test, and does that matter? Practising this on your own code prepares you better than rereading definitions, and the interview will ask you to do it on code you have never seen.

> `In the interview:` describe before you label, and end every recommendation with its cost, for example: "I'd move delivery into its own class; that costs a file and some wiring, and in return a wording change no longer touches file handling."

4.14 Common questions about SOLID (with short answers)

Give the two-line version and stop; expand only if asked. Long unprompted answers about definitions eat the time you need for the design itself.

1. What is the difference between SRP and ISP? The difference is *whom* each one guards. **SRP guards the class** that does the work: does it have more than one reason to change? **ISP guards the caller** at a boundary: must it depend on methods it never calls? A `Printer` interface with `print`, `scan` and `fax` is an ISP issue for a basic printer, which has to supply two operations it cannot perform. A `ReportService` that both formats and emails is an SRP issue with no interface in sight. *Short answer:* SRP splits classes, ISP splits interfaces, and either can be violated without the other.

2. When would you not apply these principles? This question separates candidates, so have a concrete answer. Skip them when nothing has varied yet (an extension point for a case that never arrives adds indirection and returns nothing); in small or throwaway code (a one-off script needs no interfaces); when the split would be arbitrary (you cannot name the two groups who would each ask for changes); and when it would hurt readability (five four-line files can be harder to follow than one twenty-line file). *Framing:* each principle buys **flexibility later** with **simplicity now**; if "later" never comes, the price was paid for nothing.

3. Is SOLID still relevant, given the criticism? Yes, and being aware of the criticism counts in your favour. The objections are reasonable: the principles came from large object-oriented systems and are frequently taught as absolute rules to people building small ones, which yields layers of interfaces with a single implementation each. Some engineers argue that plainer advice (keep functions small, make dependencies explicit) captures most of the benefit. What outlasts the criticism is the **vocabulary and the diagnosis**: a compact way to explain why a piece of code will resist change, in any language or paradigm. *Short answer:* valuable as diagnostic tools, misleading as rules; treat them as names for problems, not a checklist.

4. Dependency inversion vs dependency injection? Candidates mix these up constantly, so a crisp answer stands out. Inversion is the **principle** (depend on abstractions); injection is one **technique** for reaching it (supply dependencies from outside rather than constructing them inside). Injecting a concrete class is injection without inversion, and a hand-written constructor with no framework is inversion without a container. Spring only automates the wiring; it is not the principle.

5. Give an example of an LSP violation. Prefer one from your own work; failing that, Square/Rectangle, but explain the underlying rule rather than just the story: `Rectangle` lets callers set width and height separately, `Square` cannot permit that and remain a square, so code written for `Rectangle` computes a wrong area without any error. The general rule: a subclass must not require more, guarantee less, or break an assumption callers depend on; an exception is merely the most obvious way to break it.

6. Does OCP mean I can never edit a file? No, and saying so plainly is a good answer. It means one more variation *of a kind you already support* can be added without touching existing code; the file is not frozen. Bug fixes, refactorings and changes to the extension point itself all involve edits. Closure is also relative to a kind of change: the invoice design in 4.7 was closed to new formats yet fully open to new discount rules, and that was the right trade at the time.

7. Composition over inheritance, always? No; it is a guideline, not a rule. Inherit when the child really is a kind of the parent and keeps every inherited promise. Compose when a behaviour differs between objects or a subclass would have to reject an inherited method. That rejection is the thing to watch for: an override that throws, does nothing, or is documented as "don't call this on X" belongs in a separate object.

8. How do these principles relate to design patterns? Many patterns are these principles in concrete form, which is why learning the principles first makes the patterns feel natural. **Strategy** applies OCP to an algorithm that varies; **Adapter** lets a caller go on using the interface it already knows; **Decorator** adds behaviour without editing the wrapped class; **Factory** hides concrete constructors from callers, which serves DIP. The principles describe good structure; the patterns are named, reusable recipes for producing it (see 4.12).

9. Which principle is violated most often? There is no single right answer, but two defensible ones. **SRP**, because classes grow by small accumulations: no one sets out to write a two-thousand-line service; it builds up one sensible-looking addition at a time. **ISP in reverse** (over-splitting): engineers fresh from learning it create an interface per method, meeting the wording of the rule while adding names and removing no dependency. Citing the second shows you have watched the principles being misused, not merely ignored.

> **Interview tip:** if the interviewer invites you to go deeper, the two questions worth expanding are "when would you not apply this?" and "dependency inversion vs dependency injection", since most candidates stay vague on both and a precise answer stands out. The strongest answers on SOLID always **admit a limit**: anyone can praise a principle; saying where it stops paying off is what sounds like real maintenance experience.

4.15 Over-engineering: the warnings in one place

Warning sign	Principle misapplied	What to do instead
Classes named `XHelper`, `XUtils`, `XManager2` after a split	SRP	Split by actor; each new class needs a name that stands alone
Six small classes that always change in the same commit	SRP (over-split) — *Shotgun Surgery*	Merge them back
An interface + factory + registry for a single implementation	OCP — *Speculative Generality*	Write the `if`; refactor at the second or third case (rule of three)
A subclass that "works" by silently doing nothing	LSP	Raise a better parent or use composition
One interface per method; the same object passed three times	ISP (over-split)	Group by caller into role interfaces
An interface in front of `String`-like stable classes	DIP	Invert only volatile dependencies
A DI container for a 200-line program	DIP	Wire by hand in `main`

YAGNI ("You Aren't Gonna Need It", from Extreme Programming, an agile method built on small frequent releases and heavy testing) is the counterweight to all of SOLID: do not build for requirements you do not have. SOLID tells you **what** a good seam looks like; YAGNI tells you **when** to cut it: when a real change asks for it.

Chapter self-check

1. **Q:** State each SOLID principle in one line. **A:** SRP: one reason (actor) to change. OCP: add behaviour by adding code, not editing. LSP: subtypes must be substitutable for their base types. ISP: no caller depends on

methods it does not use. DIP: policy and details both depend on abstractions owned by the policy.

2. **Q:** A class has a `switch (vehicleType)` that computes parking fees. Which principle, and what fix? **A:** OCP. Put fees behind a `ParkingRate` interface with one class per rate (Strategy), chosen at the edge.
3. **Q:** `ReadOnlyList extends ArrayList` and throws on `add`. Which principle? **A:** LSP (a new exception / refused bequest). Prefer composition or a read-only interface.
4. **Q:** A `Robot` class implements a `Worker` interface with `work()` and `eat()`. What is wrong? **A:** ISP: the robot must implement `eat()`. Split into `Workable` and `Eater` roles based on callers.
5. **Q:** `OrderService` has `private final MySqlOrderDao dao = new MySqlOrderDao();`. What two problems? **A:** Tight coupling / DIP violation (names and creates a volatile detail) and untestable without MySQL. Inject an `OrderSaver` interface owned by the service.
6. **Q:** Why is Square/Rectangle a worse bug than `Penguin.fly()` throwing? **A:** It is silent: the program continues with a wrong result.
7. **Q:** Coupling vs cohesion in one sentence each. **A:** Cohesion is how well the insides of one class belong together; coupling is how much one class depends on another.
8. **Q:** In what order do the principles usually appear during a refactor, and why? **A:** SRP → OCP → LSP → ISP → DIP; each creates the situation the next one addresses.
9. **Q:** What is the difference between DIP, DI and IoC? **A:** DIP is the principle (depend on abstractions); DI is a technique (pass dependencies in); IoC is the broader idea that a framework calls your code, and IoC containers perform DI.
10. **Q:** When should you not add an interface? **A:** When there is one implementation, no test double, and nothing has varied; or when the dependency is stable.

TL;DR

- **SOLID** = five names for the ways code becomes painful to change. Use them to diagnose, not as a checklist.
- **SRP**: one actor per class. Split by *who asks for changes*, not by method count. High cohesion inside, and check coupling after every split.
- **OCP**: put the part that *has* varied behind an interface; add variants as classes (Strategy). A class is closed against a specific kind of change.
- **LSP**: a subclass must accept at least as much, promise at least as much, keep invariants and history, and throw nothing new. Inheritance follows promises, not real-world categories. Prefer composition when a subclass would refuse a method.
- **ISP**: one role interface per kind of caller. Throwing methods mean too wide; the same object passed three times means too thin.
- **DIP**: policy owns the abstraction; details implement it; `main` wires them. DI is the technique, IoC containers are the tool.
- **Order**: SRP → OCP → LSP → ISP → DIP, each triggered by a real change.
- **In the interview**: observation → cost → fix → price of the fix. Always know when *not* to apply a principle.

Chapter 5 — More Design Principles

SOLID (Chapter 4) is only five of the rules good designers use. This chapter covers the rest of the everyday toolkit: short rules of thumb (DRY, KISS, YAGNI), rules about how objects talk to each other (Law of Demeter, Tell-Don't-Ask, loose coupling, the Hollywood Principle), the object-oriented principles that *Head First Design Patterns* and the Gang of Four book (*Design Patterns*, 1994, by Gamma, Helm, Johnson and Vlissides — "GoF" for short) build every pattern on (encapsulate what varies, favour composition, program to an interface), rules about correctness (fail fast, immutability, Design by Contract) **GRASP** — nine guidelines for deciding *which class should do what* — and, finally, the essentials of **Domain-Driven Design**, which decides *which classes exist and where their boundaries are* by starting from the business.

Key terms used throughout (defined once here):

Term	Meaning
Coupling	How much one class depends on (knows about) another. High coupling = a change in one forces changes in the other.
Cohesion	How closely the things inside one class belong together. High cohesion = the class does one focused job.
Abstraction	A simplified view (usually an interface or abstract class) that hides details that callers do not need.
Encapsulation	Keeping an object's data private and letting other code change it only through the object's methods.
Invariant	A fact about an object that must always be true (e.g. "balance is never negative").
Side effect	Anything a method changes besides returning a value: fields, files, the database, the screen.
Responsibility	Something a class *knows* (its data) or *does* (its behaviour).

Chapter map

#	Principle	One-line idea	Comes from
1	DRY	Each piece of knowledge has one authoritative home	Hunt & Thomas, *The Pragmatic Programmer* (1999)
2	KISS	Choose the simplest design that works	US Navy (1960); popularised by Kelly Johnson, Lockheed Skunk Works
3	YAGNI	Don't build features before they are needed	Extreme Programming, late 1990s (usually credited to Ron Jeffries)
4	Law of Demeter	Only talk to your immediate friends	Ian Holland / Karl Lieberherr, Demeter project, Northeastern University (1987)
5	Tell, Don't Ask	Tell objects what to do; don't pull their data out and decide for them	Andy Hunt & Dave Thomas (Pragmatic Programmers), building on Alec Sharp's *Smalltalk by Example* (1997); explained by Martin Fowler
6	Composition over inheritance	Prefer "has-a" to "is-a" for reuse	GoF book (1994), *Effective Java* (Joshua Bloch)
7	Program to an interface	Depend on supertypes, not concrete classes	GoF book
8	Encapsulate what varies	Isolate the part that changes	GoF book, *Head First Design Patterns*
9	Loose coupling	Interacting objects should know little about each other	*Head First Design Patterns*
10	Hollywood Principle / IoC	"Don't call us, we'll call you"	*Head First*; frameworks, IoC containers
11	Separation of Concerns	Each part of the program handles one concern	Edsger Dijkstra (1974)
12	Least Astonishment	Behave the way readers expect	User-interface and programming-language design folklore (no single author)
13	Fail fast	Detect problems early and loudly	Popularised by Jim Shore's "Fail Fast" article, *IEEE Software* (2004)
14	Immutability	Objects that never change after creation	*Effective Java* ("minimize mutability")
15	Design by Contract	Preconditions, postconditions, invariants	Bertrand Meyer, Eiffel language (term coined 1986)
16	GRASP (9 patterns)	Guidelines for assigning responsibilities	Craig Larman, *Applying UML and Patterns* (1st ed. 1997; today's nine from the 2nd ed. 2001)
17	Domain-Driven Design essentials	Model the business: bounded contexts, entities vs value objects, aggregates, domain events, repositories	Eric Evans, *Domain-Driven Design* (2003); Vaughn Vernon, *Implementing Domain-Driven Design* (2013)

How to read each section. Every principle follows the same path: what it is → the problem → how to apply it → a Java *before/after* program you can run → trade-offs → when not to use it → mistakes → real-world examples → interview answer → self-check → TL;DR. All code lives in `code/lld/ch05/<topic>/Main.java` and was compiled with `javac --release 21` (`javac` is the Java compiler, which turns source code into runnable bytecode; `--release 21` targets Java 21) and run; the output shown is the real output.

---

1. DRY — Don't Repeat Yourself

What it is

DRY says: every piece of *knowledge* in a system — a business rule, a formula, a validation, a constant — should have **a single, unambiguous, authoritative representation** — one place where it is defined. Everything else refers to that place. The principle comes from Andy Hunt and Dave Thomas's *The Pragmatic Programmer* (1999).

Analogy: a company keeps one master price list. Shops look prices up from it. If each shop kept its own hand-written copy, a price change would reach some shops and not others.

Important: DRY is about **knowledge**, not about lines of text that happen to look the same. Two pieces of code that look identical but represent *different* rules (which may change for different reasons) are *not* a DRY violation.

The problem it solves

When a rule is copied into several places, the copies eventually **drift**: someone updates one copy and forgets the others. The system then gives two different answers to the same question — a bug that is hard to spot because each copy looks reasonable on its own. Duplication also multiplies the effort of every change.

How it works

1. Notice a rule that appears in more than one place (a regex, a tax rate, a status check, a SQL fragment). A *regex* (regular expression) is a compact pattern that text must match, such as "something@something"; *SQL* is the standard language for querying relational databases.
2. Ask: *"If this rule changes, must all copies change together?"* If yes, it is one piece of knowledge.
3. Give it one home: a constant, a method, a value object, an enum, a config entry or a shared module.
4. Replace every copy with a reference to that home.
5. Apply the **Rule of Three** for code-level duplication (a heuristic credited to Don Roberts and popularised by Martin Fowler's *Refactoring* — refactoring means improving code's structure without changing what it does, see Chapter 7): the first time, just write it; the second time, notice the duplication but tolerate it; the third time, extract.

Java example — before/after

The *before* has two services that each carry their own copy of "what a valid email is" and "what the tax is". The copies have already drifted. The *after* puts the email rule inside an `EmailAddress` value object (a small immutable type — one whose value can never change after it is created — whose constructor validates its value) and the tax rule inside `TaxPolicy`.

```java
// File: lld/ch05/dry/Main.java
package lld.ch05.dry;

import java.math.BigDecimal;
import java.math.RoundingMode;
import java.util.regex.Pattern;

/** DRY: one piece of knowledge (what a valid email is, what the tax rate is) lives in ONE place. */
public class Main {

    // ---------------- BEFORE: the same rule is written twice and the copies have drifted ----------------
    static class Before {
        static class SignupService {
            boolean signup(String email) {
                // copy #1 of the rule (someone relaxed it later)
                return email != null && email.contains("@");
            }
            BigDecimal priceWithTax(BigDecimal price) {
                return price.multiply(new BigDecimal("1.18")).setScale(2, RoundingMode.HALF_UP); // 18% hard-coded
            }
        }
        static class ProfileService {
            boolean changeEmail(String email) {
                // copy #2 of the rule (the stricter original)
                return email != null && email.matches("[^@\\s]+@[^@\\s]+\\.[a-z]{2,}");
            }
            BigDecimal priceWithTax(BigDecimal price) {
                return price.multiply(new BigDecimal("1.18")).setScale(2, RoundingMode.HALF_UP); // 18% again
            }
        }
    }

    // ---------------- AFTER: each rule has a single, authoritative home ----------------
    static class After {
        /** The ONLY definition of "valid email" in the system. */
        record EmailAddress(String value) {
            private static final Pattern FORMAT = Pattern.compile("[^@\\s]+@[^@\\s]+\\.[a-z]{2,}");
            EmailAddress {
                if (value == null || !FORMAT.matcher(value).matches())
                    throw new IllegalArgumentException("invalid email: " + value);
            }
        }

        /** The ONLY definition of the tax rule. */
        static final class TaxPolicy {
            private static final BigDecimal RATE = new BigDecimal("0.18");
            private TaxPolicy() {}
            static BigDecimal withTax(BigDecimal price) {
                return price.add(price.multiply(RATE)).setScale(2, RoundingMode.HALF_UP);
            }
        }

        static class SignupService {
            String signup(String rawEmail) { return "signed up " + new EmailAddress(rawEmail).value(); }
        }
        static class ProfileService {
            String changeEmail(String rawEmail) { return "email changed to " + new EmailAddress(rawEmail).value();
}
        }
    }

    public static void main(String[] args) {
        System.out.println("== BEFORE ==");
        var signup = new Before.SignupService();
        var profile = new Before.ProfileService();
        String sloppy = "bob@localhost";
        System.out.println("signup accepts '" + sloppy + "'? " + signup.signup(sloppy));
        System.out.println("profile accepts '" + sloppy + "'? " + profile.changeEmail(sloppy) + "   <-- same rule,
```

```
two answers");

        System.out.println("== AFTER ==");
        var s = new After.SignupService();
        var p = new After.ProfileService();
        System.out.println(s.signup("bob@example.com"));
        System.out.println(p.changeEmail("bob@example.com"));
        for (String candidate : new String[]{sloppy}) {
            try { s.signup(candidate); } catch (IllegalArgumentException e) { System.out.println("signup rejected:
" + e.getMessage()); }
            try { p.changeEmail(candidate); } catch (IllegalArgumentException e) { System.out.println("profile
rejected: " + e.getMessage()); }
        }
        System.out.println("price 100.00 with tax = " + After.TaxPolicy.withTax(new BigDecimal("100.00")));
    }
}
```

Output:

```
== BEFORE ==
signup accepts 'bob@localhost'? true
profile accepts 'bob@localhost'? false   <-- same rule, two answers
== AFTER ==
signed up bob@example.com
email changed to bob@example.com
signup rejected: invalid email: bob@localhost
profile rejected: invalid email: bob@localhost
price 100.00 with tax = 118.00
```

What each part does:

- `Before.SignupService` and `Before.ProfileService` each re-implement the email rule; the output shows them disagreeing about `bob@localhost`.
- `After.EmailAddress` is a Java **record** (a compact, immutable data class). Its *compact constructor* (a record constructor written without a parameter list, used only to check or normalise the incoming values) runs the check, so an invalid email simply cannot exist as an `EmailAddress`.
- `After.TaxPolicy` holds the rate in one private constant; changing GST from 18% means editing one line.

Trade-offs

Benefit	Cost
One change point per rule; no drift	A shared abstraction couples its users together
Less code to read and test	A premature or wrong abstraction is worse than duplication
Rules get a name (self-documenting)	Extra indirection to find the real code

When not to use it

- When two snippets look alike **by coincidence** and will evolve separately (e.g. "max username length 30" and "max tag length 30"). Merging them creates false coupling.
- Across service boundaries in **microservices** (an architecture where one application is split into many small services, each deployed on its own and talking over the network): sharing a domain library between independently deployed services can couple their release cycles. Some duplication is the lesser evil.
- In tests, a little repetition often makes each test easier to read on its own (this is sometimes called DAMP — "descriptive and meaningful phrases").

Common mistakes

- Treating DRY as "never have two similar lines" and building one monster function with flags for every caller.
- Extracting after the first repetition, before you understand what really varies.
- Forgetting non-code duplication: the same rule in code *and* in a database constraint *and* in docs.

Real-world examples

- **Spring's `@Value` / `application.yml`** (Spring is the most widely used Java framework for server applications; `@Value` is an *annotation* — a `@`-prefixed tag on code that tools and frameworks read — and `application.yml` is its configuration file): configuration values live in one file and are injected wherever needed.
- **Database normalisation** is DRY for data: a customer's address is stored once and referenced by key (a unique ID column that other tables point to).
- **Bean Validation (`jakarta.validation`) annotations** such as `@Email` on a field define the rule once and reuse it for REST input (data arriving through a web API built on HTTP's standard verbs and URLs), forms and persistence (saving data so it outlives the program, usually in a database).
- **OpenAPI / Protobuf schemas** (machine-readable descriptions of an API's messages — OpenAPI for HTTP APIs that exchange JSON, a plain-text key–value data format; Protobuf for Google's compact binary format) generate client and server code from one contract, so the message format is not hand-copied.

In the interview

> **30-second answer:** "DRY means each piece of knowledge has one authoritative representation. It is about rules, not about identical-looking text. I extract a rule when copies must change together — for example, validation into a value object — and I use the Rule of Three so I don't abstract too early."

Follow-ups:

- *Q: Is duplicated code always a DRY violation?* A: No. If the two copies represent different rules that change for different reasons, merging them adds wrong coupling.
- *Q: DRY vs. SRP?* A: They cooperate (SRP is the Single Responsibility Principle from Chapter 4: a class should have only one reason to change). DRY gives each rule one home; SRP makes sure that home has only one reason to change.
- *Q: How do you spot duplication of knowledge?* A: Ask "if this business rule changes, how many files do I edit?" More than one is a smell.

Self-check

1. Q: What exactly must not be repeated? → A: Knowledge (rules, formulas, decisions), not merely similar-looking lines.
2. Q: What is the Rule of Three? → A: Tolerate a second copy; extract a shared abstraction when a third appears.
3. Q: What bug does duplication cause? → A: Drift — copies change independently and start disagreeing.

TL;DR

One rule, one home. Extract when copies must change together; leave coincidental look-alikes alone.

---

2. KISS — Keep It Simple, Stupid

What it is

KISS says most systems work best when they are kept simple. The phrase was used by the US Navy around 1960 and is associated with Kelly Johnson, lead engineer of Lockheed's Skunk Works, who wanted jet aircraft a mechanic could repair in the field with basic tools. Choose the plainest design that fully solves the real problem. *Simple* means easy to understand and change — not necessarily the fewest lines.

Analogy: to hang one picture you use a nail, not a motorised track system with remote control.

The problem it solves

Engineers love clever solutions: home-made frameworks, deep inheritance trees, generic engines configured by lambdas (short unnamed functions written inline, e.g. `x -> x * 2`). Every extra moving part must be read, tested, debugged and explained to new team members. Accidental complexity (complexity we add, as opposed to complexity the problem truly has) is the biggest source of bugs and slow delivery.

How it works

1. State the actual requirement in one sentence.

2. Write the most direct solution using standard language features and libraries.
3. Ask: "Could a new team member understand this in two minutes?"
4. Add structure (patterns, abstractions) only when a concrete need — a second variant, a test seam, a real performance issue — shows up.
5. Delete cleverness that no longer earns its keep.

Java example — before/after

Three fixed customer tiers get three fixed discounts. The *before* builds a priority-sorted rule engine of predicates and functions. The *after* is a `switch` expression, which the compiler also checks for completeness: a `switch` *expression* over an enum (a type with a fixed list of named constants) with no `default` must cover every constant, so adding a new tier makes it fail to compile until you handle the new case. (Old-style `switch` *statements* are not checked this way.) Money is `BigDecimal` (Java's exact decimal-number class), never `double` (binary floating point cannot represent most decimal amounts exactly).

```java
// File: lld/ch05/kiss/Main.java
package lld.ch05.kiss;

import java.math.BigDecimal;
import java.math.RoundingMode;
import java.util.ArrayList;
import java.util.Comparator;
import java.util.List;
import java.util.function.Function;
import java.util.function.Predicate;

/** KISS: the simplest design that fully solves today's problem wins. Money is BigDecimal, never double. */
public class Main {

    enum Tier { REGULAR, SILVER, GOLD }

    static final BigDecimal SILVER_FACTOR = new BigDecimal("0.90");
    static final BigDecimal GOLD_FACTOR = new BigDecimal("0.80");

    static BigDecimal times(BigDecimal amount, BigDecimal factor) {
        return amount.multiply(factor).setScale(2, RoundingMode.HALF_UP);
    }

    // ---------------- BEFORE: a home-made "rule engine" for three fixed discounts ----------------
    static class Before {
        record Rule(int priority, Predicate<Tier> when, Function<BigDecimal, BigDecimal> apply) {}

        static class DiscountRuleEngine {
            private final List<Rule> rules = new ArrayList<>();
            DiscountRuleEngine register(int priority, Predicate<Tier> when, Function<BigDecimal, BigDecimal> apply)
{
                rules.add(new Rule(priority, when, apply));
                rules.sort(Comparator.comparingInt(Rule::priority).reversed());
                return this;
            }
            BigDecimal evaluate(Tier tier, BigDecimal amount) {
                return rules.stream().filter(r -> r.when().test(tier)).findFirst()
                        .map(r -> r.apply().apply(amount)).orElse(amount);
            }
        }

        static DiscountRuleEngine build() {
            return new DiscountRuleEngine()
                    .register(10, t -> t == Tier.GOLD, a -> times(a, GOLD_FACTOR))
                    .register(5, t -> t == Tier.SILVER, a -> times(a, SILVER_FACTOR))
                    .register(0, t -> true, a -> a);
        }
    }

    // ---------------- AFTER: a plain switch expression; the compiler checks every tier is handled ---------------
-
    static class After {
        static BigDecimal discounted(Tier tier, BigDecimal amount) {
            return switch (tier) {
                case GOLD -> times(amount, GOLD_FACTOR);
                case SILVER -> times(amount, SILVER_FACTOR);
                case REGULAR -> amount;
            };
        }
    }

    public static void main(String[] args) {
        BigDecimal price = new BigDecimal("100.00");
        var engine = Before.build();
        System.out.println("== BEFORE (rule engine) ==");
        for (Tier t : Tier.values()) System.out.printf("%-7s -> %s%n", t, engine.evaluate(t, price));
        System.out.println("== AFTER (switch) ==");
        for (Tier t : Tier.values()) System.out.printf("%-7s -> %s%n", t, After.discounted(t, price));
```

```
    }
}
```

Output:

```
== BEFORE (rule engine) ==
REGULAR -> 100.00
SILVER  -> 90.00
GOLD    -> 80.00
== AFTER (switch) ==
REGULAR -> 100.00
SILVER  -> 90.00
GOLD    -> 80.00
```

Both produce identical results, but the *after* has no ordering bugs to worry about (in the engine, forgetting a priority would silently change behaviour), no mutable list, and reads like the business rule.

Trade-offs

Simple design	"Flexible" complex design
Fast to read, change, test	Handles hypothetical cases
May need refactoring when real variation arrives	Costs you every day, even if variation never arrives
Uses standard, well-known constructs	Custom mechanisms need docs and training

When not to use it

KISS is never "wrong", but it is not an excuse to ignore the real complexity of the problem. A payment system *needs* idempotency (repeating the same request — say, after a timeout — has the same effect as doing it once, so nobody is charged twice; see System Design Fundamentals), retries and auditing; leaving them out is not simplicity, it is incompleteness. Also, when a rule-engine really is the requirement (business users edit rules at runtime — while the program is running), build or buy one.

Common mistakes

- Confusing *simple* with *easy* or *short*: a one-line stream with five nested lambdas may be shorter but harder to read than a loop.
- Using KISS to justify skipping tests, error handling or validation.
- Copy-pasting instead of simplifying (that violates DRY).

Real-world examples

- **Unix philosophy** — small tools that do one thing and compose through pipes (`|`, which feeds one program's output into the next program's input).
- **Go language design** deliberately left out many features to keep the language simple.
- `java.util.Optional` was intentionally kept small (no `Serializable`, not meant as a field type) to steer people toward its one purpose: return values that might be absent.

In the interview

30-second answer: "KISS means picking the simplest design that fully meets the requirements. In an interview I start with a straightforward model and only introduce patterns when a requirement demands variation or extension — and I say why."

Follow-ups:

- *Q: Isn't a design pattern always better?* A: No. A pattern adds classes and indirection; it's worth it only if it solves a problem you actually have.
- *Q: How do KISS and YAGNI differ?* A: KISS is about *how* you build (the simplest form); YAGNI is about *what* you build (only needed features).

Self-check

1. Q: What is accidental complexity? → A: Complexity introduced by our solution rather than required by the problem.
2. Q: Why did the `switch` version win? → A: Same behaviour, fewer moving parts, compiler-checked exhaustiveness.

TL;DR

Solve the real problem in the plainest way; add machinery only when a real need appears.

---

3. YAGNI — You Aren't Gonna Need It

What it is

YAGNI says: do not build a capability until you actually need it. It comes from Extreme Programming (XP), the agile method (a way of building software in short cycles with frequent feedback) created by Kent Beck in the late 1990s; the slogan is usually credited to XP co-founder Ron Jeffries. The opposite habit — building hooks, options and layers "just in case" — is called **speculative generality**, a **code smell** (a visible sign in the code that usually points to a deeper design problem) in Martin Fowler's *Refactoring*.

Analogy: you don't buy a 7-seater car because you *might* have five children one day.

The problem it solves

Features built early cost four times: the time to build them, the time to maintain and test them, the complexity they add to everything around them, and the cost of being wrong (the real future requirement usually looks different from the guess, so the speculative code must be rewritten anyway).

How it works

1. Implement the stories/requirements you have **now** (a *user story* is a short feature request written from the user's point of view: "As a shopper I can …").
2. Keep the code clean (tested, well-factored) so that it is cheap to change later — YAGNI depends on refactoring being easy.
3. When a new requirement actually arrives, extend the design then.
4. Delete unused options, parameters and classes you discover.

Java example — before/after

The requirement: *export orders as CSV* (comma-separated values — a plain-text table with one row per line). The *before* builds a universal exporter with five formats, encodings and compression — four formats and compression throw `UnsupportedOperationException`. The *after* is one method.

```java
// File: lld/ch05/yagni/Main.java
package lld.ch05.yagni;

import java.math.BigDecimal;
import java.util.List;
import java.util.stream.Collectors;

/** YAGNI: build what the current requirement needs ("export orders as CSV"), not what might be asked one day. */
public class Main {

    record Order(String id, String customer, BigDecimal total) {}   // money as BigDecimal, never double

    // ---------------- BEFORE: speculative generality ----------------
    static class Before {
        enum Format { CSV, PDF, XML, EXCEL, YAML }

        /** Five formats, pluggable encodings, compression... only CSV was requested. */
        interface ReportExporter {
            String export(List<Order> orders, Format format, String encoding, boolean compress);
        }

        static class UniversalExporter implements ReportExporter {
            @Override
            public String export(List<Order> orders, Format format, String encoding, boolean compress) {
                if (compress) throw new UnsupportedOperationException("compression not implemented yet");
                return switch (format) {
                    case CSV -> orders.stream().map(o -> o.id() + "," + o.customer() + "," +
o.total().toPlainString())
                            .collect(Collectors.joining("\n", "id,customer,total\n", ""));
                    case PDF, XML, EXCEL, YAML -> throw new UnsupportedOperationException(format + " not
implemented yet");
                };
            }
        }
    }

    // ---------------- AFTER: exactly what is needed today ----------------
    static class After {
        static String toCsv(List<Order> orders) {
            return orders.stream()
                    .map(o -> String.join(",", o.id(), o.customer(), o.total().toPlainString()))
                    .collect(Collectors.joining("\n", "id,customer,total\n", ""));
        }
    }

    public static void main(String[] args) {
        List<Order> orders = List.of(new Order("o1", "asha", new BigDecimal("250.00")),
                                     new Order("o2", "ravi", new BigDecimal("99.50")));
        System.out.println("== BEFORE ==");
        var exporter = new Before.UniversalExporter();
        System.out.println(exporter.export(orders, Before.Format.CSV, "UTF-8", false));
        try {
            exporter.export(orders, Before.Format.PDF, "UTF-8", false);
        } catch (UnsupportedOperationException e) {
            System.out.println("dead option: " + e.getMessage());
        }
        System.out.println("== AFTER ==");
        System.out.println(After.toCsv(orders));
    }
}
```

Output:

```
== BEFORE ==
id,customer,total
o1,asha,250.00
o2,ravi,99.50
dead option: PDF not implemented yet
== AFTER ==
id,customer,total
o1,asha,250.00
o2,ravi,99.50
```

Every caller of the *before* API (Application Programming Interface — the methods and types that other code calls) must pass three meaningless arguments, and every reader wonders which formats really work.

Trade-offs

YAGNI	Build ahead
Less code, faster delivery	Might save time if the guess is right
Design fits real needs	Guesses are usually wrong in detail
Needs good tests + refactoring discipline	Leaves dead options that confuse readers

When not to use it

- **Hard-to-change decisions** — public API formats, database schemas (the structure of tables and columns) with huge data, security, data retention laws. Think ahead there because changing later is very expensive.
- Architectural qualities that are known requirements (e.g. "must scale to 10k requests/s" — a *throughput* target, i.e. how much work per second the system must handle) are not speculation; they are requirements.

Common mistakes

- Using YAGNI as an excuse for messy code ("we'll never need clean code").
- Ignoring a requirement the interviewer *did* mention because "YAGNI".
- Adding `interface` + `Impl` pairs for every class "in case we swap it" — only add the interface when there is a second implementation or a test seam need (a *test seam* is a place where a test can swap in a fake collaborator).

Real-world examples

- **Minimum Viable Product (MVP)** thinking in startups is YAGNI at the product level.
- **Feature flags** (on/off switches in configuration that enable a code path without redeploying; e.g. LaunchDarkly, Unleash) let teams ship only what is needed now and turn on more later, rather than building every variant up front.
- XP teams (and many agile teams) plan per iteration so that only near-term work is built.

In the interview

30-second answer: "YAGNI means I build what the requirements need today and keep the design easy to extend. In an LLD (low-level design — designing the classes, interfaces and their interactions) interview I'll mention an extension point — say a `PaymentStrategy` interface — only if the interviewer hinted at multiple variants; otherwise I note it verbally as a possible extension."

Follow-ups:

- *Q: Doesn't YAGNI conflict with OCP?* A: Not really. OCP (the Open/Closed Principle from Chapter 4: open for extension, closed for modification) is applied where variation is known or likely; YAGNI stops you from inventing variation that isn't there.
- *Q: What makes YAGNI safe?* A: A good test suite (the full set of automated tests for the code) and clean code, so adding the feature later is cheap.

Self-check

1. Q: Name the smell YAGNI prevents. → A: Speculative generality.

2. Q: When should you design ahead anyway? → A: For expensive-to-reverse decisions (public APIs, schemas, security).

TL;DR

Build for today's requirements with clean, changeable code; tomorrow's features get built tomorrow.

---

4. Law of Demeter (Principle of Least Knowledge)

What it is

The **Law of Demeter (LoD)**, also called the **Principle of Least Knowledge**, says a method should only talk to its **immediate friends**, not to strangers it reaches through other objects. Formally, a method `m` of object `O` should only call methods on:

1. `O` itself (`this`);
2. objects passed to `m` as parameters;
3. objects `m` creates;
4. `O`'s own fields (its direct components).

(The original formulation by Ian Holland and Karl Lieberherr at Northeastern University, 1987, also allows global objects accessible to `O`; modern summaries usually list the four above.)

The famous slogan: **"use only one dot"** — e.g. `a.getB().getC().doIt()` is a **train wreck** (a chain of calls that looks like connected railway cars).

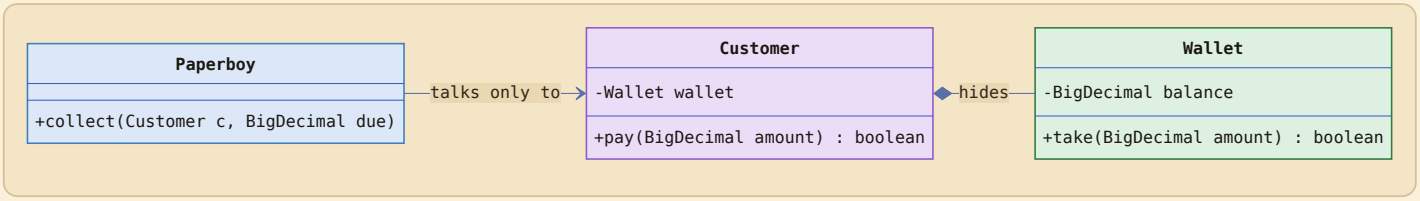
Analogy: when a paperboy collects money, he asks the customer to pay. He doesn't reach into the customer's pocket, pull out the wallet and take the cash himself.

The problem it solves

A train wreck couples the caller to the **whole chain's structure**. In `customer.getWallet().getBalance()`, the paperboy now depends on `Customer` *and* `Wallet`. If the customer starts paying by UPI (India's instant bank-to-bank mobile payment system) instead of a wallet, the paperboy breaks. Knowledge of internal structure leaks everywhere.

How it works

1. Spot a chain that navigates through other objects' internals.
2. Ask: *what does the caller really want?* ("get paid", not "get the wallet").
3. Add a method on the first object that does that job (`customer.pay(amount)`), delegating internally.
4. Keep the internal object private.



Java example — before/after

```java
// File: lld/ch05/demeter/Main.java
package lld.ch05.demeter;

import java.math.BigDecimal;
import java.util.List;

/** Law of Demeter ("only talk to your immediate friends"): the paperboy should not reach into the customer's
wallet. */
public class Main {

    // ---------------- BEFORE: a train wreck -- paperboy -> customer -> wallet -> balance ----------------
    static class Before {
        static class Wallet {
            private BigDecimal balance;
            Wallet(BigDecimal balance) { this.balance = balance; }
            BigDecimal getBalance() { return balance; }
            void setBalance(BigDecimal b) { balance = b; }
        }
        static class Customer {
            private final String name;
            private final Wallet wallet;
            Customer(String name, Wallet wallet) { this.name = name; this.wallet = wallet; }
            String getName() { return name; }
            Wallet getWallet() { return wallet; }
        }
        static class Paperboy {
            BigDecimal collected = BigDecimal.ZERO;
            void collect(Customer c, BigDecimal due) {
                // knows Customer has a Wallet, knows Wallet has a balance, changes it directly
                if (c.getWallet().getBalance().compareTo(due) >= 0) {
                    c.getWallet().setBalance(c.getWallet().getBalance().subtract(due));
                    collected = collected.add(due);
                    System.out.println("collected " + due + " from " + c.getName());
                } else {
                    System.out.println(c.getName() + " cannot pay");
                }
            }
        }
    }

    // ---------------- AFTER: the paperboy asks the customer (a direct friend) to pay ----------------
    static class After {
        static class Wallet {
            private BigDecimal balance;
            Wallet(BigDecimal balance) { this.balance = balance; }
            boolean take(BigDecimal amount) {
                if (amount.compareTo(balance) > 0) return false;
                balance = balance.subtract(amount);
                return true;
            }
        }
        static class Customer {
            private final String name;
            private final Wallet wallet;   // private detail -- could become a card or UPI tomorrow
            Customer(String name, Wallet wallet) { this.name = name; this.wallet = wallet; }
            String name() { return name; }
            /** Customer decides HOW to pay. */
            boolean pay(BigDecimal amount) { return wallet.take(amount); }
        }
        static class Paperboy {
            BigDecimal collected = BigDecimal.ZERO;
            void collect(Customer c, BigDecimal due) {
                if (c.pay(due)) {                       // talk only to a parameter: allowed
                    collected = collected.add(due);
                    System.out.println("collected " + due + " from " + c.name());
                } else {
```

```
                    System.out.println(c.name() + " cannot pay");
                }
            }
        }
    }

    public static void main(String[] args) {
        BigDecimal due = new BigDecimal("4.00");
        System.out.println("== BEFORE ==");
        var boy1 = new Before.Paperboy();
        boy1.collect(new Before.Customer("Meera", new Before.Wallet(new BigDecimal("10.00"))), due);
        boy1.collect(new Before.Customer("Kabir", new Before.Wallet(new BigDecimal("2.00"))), due);

        System.out.println("== AFTER ==");
        var boy2 = new After.Paperboy();
        boy2.collect(new After.Customer("Meera", new After.Wallet(new BigDecimal("10.00"))), due);
        boy2.collect(new After.Customer("Kabir", new After.Wallet(new BigDecimal("2.00"))), due);
        System.out.println("total collected = " + boy2.collected);

        // Chained calls on a fluent API / stream are NOT Demeter violations: each call returns the same kind of
thing.
        long longNames = List.of("Meera", "Kabir", "Jo").stream().filter(n -> n.length() > 2).count();
        System.out.println("stream chain is fine: " + longNames + " long names");
    }
}
```

Output:

```
== BEFORE ==
collected 4.00 from Meera
Kabir cannot pay
== AFTER ==
collected 4.00 from Meera
Kabir cannot pay
total collected = 4.00
stream chain is fine: 2 long names
```

What changed: in *before*, `Paperboy` knows three classes and even sets the balance directly. In *after*, `Paperboy` knows only `Customer.pay`, and `Customer` is free to change how it pays.

Trade-offs

Following LoD	Ignoring LoD
Changes to internals stay local	Structural changes ripple to callers
Easier mocking (mock = fake object used in tests) — one collaborator	Tests must build whole object graphs
May add small **wrapper/delegate methods**	No extra methods
Too many wrappers can bloat the middle class	—

When not to use it

- **Fluent interfaces and builders** (APIs whose methods return an object so calls can be chained; a builder assembles an object step by step — `StringBuilder.append(..).append(..)`, `stream().filter().map()`) return the same object or a sibling of the same abstraction — they are *not* violations.
- **Data structures / DTOs** (Data Transfer Objects — plain data with no behaviour, see Chapter 6) are meant to expose their data; `order.shippingAddress().city()` on a record is fine.
- Don't mechanically add dozens of pass-through methods — that is the **Middle Man** smell. Rethink responsibilities instead.

Common mistakes

- Counting dots instead of thinking about *knowledge*: splitting a chain into temp variables (`var w = c.getWallet(); w.getBalance()`) still violates the law.

- Adding getters (methods like `getWallet()` that just return a field) for everything, which invites train wrecks.

Real-world examples

- *Head First Design Patterns* presents it as "talk only to your immediate friends" in the Facade chapter — a **Facade** (one simple class placed in front of a group of complex classes) reduces how many classes a client talks to.
- **Spring Data** repositories (a *repository* is an object that loads and saves domain objects while hiding the database): services call `orderRepository.findByCustomerId(id)` rather than navigating `entityManager.getSession().getConnection()...`.
- `java.nio.file.Files.readString(path)` hides channels, buffers and decoders behind a single call.

In the interview

> **30-second answer:** "The Law of Demeter says a method should only call methods on itself, its parameters, objects it creates and its own fields. Long chains like `a.getB().getC()` couple the caller to internal structure. I fix them by adding a method that expresses intent — `customer.pay()` instead of reaching for the wallet."

Follow-ups:

- *Q: Is `list.stream().map(...).collect(...)` a violation?* A: No — each call returns a stream/collection abstraction meant for chaining (a Java *stream* is a pipeline that processes a sequence of elements step by step); you're not navigating an object's internals.
- *Q: What's the cost of following it strictly?* A: Wrapper methods can pile up (Middle Man). Balance by moving behaviour to where the data is (Tell-Don't-Ask).

Self-check

1. Q: List the four "friends" of a method. → A: `this`, parameters, objects it creates, its own fields.
2. Q: What is a train wreck? → A: A chain of getters navigating through several objects.
3. Q: Do records/DTOs have to obey it? → A: Not really; they are data structures meant to expose data.

TL;DR

Only talk to your friends. Replace `a.getB().getC().do()` with a method on `a` that says what you want.

---

5. Tell, Don't Ask

What it is

Tell, Don't Ask (TDA) says: instead of *asking* an object for its data and then making a decision for it, *tell* the object what you want and let it decide using its own data. Behaviour should live with the data it needs. The idea was popularised by Andy Hunt and Dave Thomas (the Pragmatic Programmers), who built on Alec Sharp's observation in *Smalltalk by Example* (1997) that procedural code (code organised as functions acting on separate data) fetches data and then decides, while object-oriented code tells objects to act.

Analogy: you tell a taxi driver "take me to the airport". You don't ask for the steering wheel angle and the speed every second and decide the turns yourself.

The problem it solves

When callers ask-then-act (`if (acc.getBalance() >= x) acc.setBalance(acc.getBalance() - x)`), the business rule is spread over every caller. Soon one caller forgets part of the rule (e.g. "frozen accounts can't withdraw") and the object's **invariant** breaks. The object becomes a passive data bag — the **Anemic Domain Model** anti-pattern.

How it works

1. Look for code that reads an object's fields, decides something, then writes back.
2. Move that decision into a method on the object (`withdraw(amount)`).
3. Make the object reject illegal requests (exceptions or result types).

4. Remove setters (methods like `setBalance(x)` that just overwrite a field) that are no longer needed.

Java example — before/after

```
// File: lld/ch05/telldontask/Main.java
package lld.ch05.telldontask;

/** Tell, Don't Ask: tell an object what you want; don't pull its data out, decide, and push data back in. */
public class Main {

    // ---------------- BEFORE: callers ask for state and make the decision themselves ----------------
    static class Before {
        static class Account {
            private long balancePaise;
            private boolean frozen;
            Account(long balance) { this.balancePaise = balance; }
            long getBalance() { return balancePaise; }
            void setBalance(long b) { balancePaise = b; }
            boolean isFrozen() { return frozen; }
            void setFrozen(boolean f) { frozen = f; }
        }
        // ATM remembered the "frozen" rule...
        static void atmWithdraw(Account a, long amt) {
            if (!a.isFrozen() && a.getBalance() >= amt) a.setBalance(a.getBalance() - amt);
        }
        // ...the mobile app forgot it. The business rule is scattered and now inconsistent.
        static void appWithdraw(Account a, long amt) {
            if (a.getBalance() >= amt) a.setBalance(a.getBalance() - amt);
        }
    }

    // ---------------- AFTER: the rule lives with the data it protects ----------------
    static class After {
        static final class Account {
            private long balancePaise;
            private boolean frozen;
            Account(long balance) { this.balancePaise = balance; }
            void freeze() { frozen = true; }
            void withdraw(long amt) {
                if (amt <= 0) throw new IllegalArgumentException("amount must be positive");
                if (frozen) throw new IllegalStateException("account is frozen");
                if (amt > balancePaise) throw new IllegalStateException("insufficient funds");
                balancePaise -= amt;
            }
            long balance() { return balancePaise; }   // queries are fine for display -- just don't decide outside
        }
    }

    public static void main(String[] args) {
        System.out.println("== BEFORE ==");
        var a = new Before.Account(1_000);
        a.setFrozen(true);
        Before.atmWithdraw(a, 300);
        System.out.println("after ATM on frozen account: " + a.getBalance());
        Before.appWithdraw(a, 300);
        System.out.println("after APP on frozen account: " + a.getBalance() + "   <-- rule bypassed");

        System.out.println("== AFTER ==");
        var b = new After.Account(1_000);
        b.withdraw(300);
        System.out.println("withdrew 300, balance " + b.balance());
        b.freeze();
        try { b.withdraw(300); } catch (IllegalStateException e) { System.out.println("rejected: " +
e.getMessage()); }
        System.out.println("balance still " + b.balance());
    }
}
```

Output:

```
== BEFORE ==
after ATM on frozen account: 1000
after APP on frozen account: 700   <-- rule bypassed
== AFTER ==
withdrew 300, balance 700
rejected: account is frozen
balance still 700
```

In *before*, the ATM and the app each reimplement the rule and the app forgets `frozen`. In *after*, `withdraw` is the only way to take money, so the rule cannot be bypassed.

Trade-offs

Tell	Ask
Invariants protected in one place	Rules duplicated across callers
Richer, more expressive objects	Simple data objects
Risk: object grows too many responsibilities	Fine for pure data (DTOs, reports)

When not to use it

- For **queries whose purpose is display or reporting** — asking for a balance to show it on screen is fine. The rule is about *deciding* outside.
- When the decision genuinely belongs to another object that combines data from several sources (then that other object is the Information Expert — see GRASP).

Common mistakes

- Adding a getter "just for this one check" — that is where the rule starts leaking.
- Pushing *every* behaviour into the entity, including emails and database calls (breaks SRP; use services for cross-cutting work).

Real-world examples

- `java.util.List.removeIf(predicate)` — you tell the list what to remove instead of iterating and removing yourself.
- `Map.computeIfAbsent`, `Map.merge` — tell the map the update you want; it handles the check-then-act.
- `AtomicInteger.incrementAndGet()` — the object performs the read-modify-write atomically (as one indivisible step that no other thread can interrupt); asking then setting would be a **race condition** (a bug where the result depends on the unlucky timing of two *threads* — independent paths of execution running at the same time — touching the same data).

In the interview

30-second answer: "Tell, Don't Ask means sending commands to the object that owns the data, e.g. `account.withdraw(100)`, rather than reading its balance and setting a new one. It keeps invariants in one place and avoids anemic models."

Follow-ups:

- *Q: How is it related to the Law of Demeter?* A: Both push behaviour to where the data is; LoD focuses on *who* you talk to, TDA on *what* you ask for.
- *Q: Concurrency angle?* A: Ask-then-act across two calls is a check-then-act race; a single `withdraw` method can be made atomic.

Self-check

1. Q: What anti-pattern does TDA fight? → A: The Anemic Domain Model (data bags with logic outside).
2. Q: Are getters forbidden? → A: No; they're fine for display. Avoid deciding outside the object.

TL;DR

Don't pull data out to make the object's decisions — tell the object what you want.

---

6. Composition over Inheritance

What it is

Favour object composition over class inheritance (from the GoF book). *Inheritance* ("is-a") reuses code by making a subclass of another class. *Composition* ("has-a") reuses code by holding a reference to another object and **delegating** (forwarding) calls to it.

Analogy: a car *has* an engine. You can swap a petrol engine for an electric one. If "car" *inherited from* "petrol engine", you could never swap it.

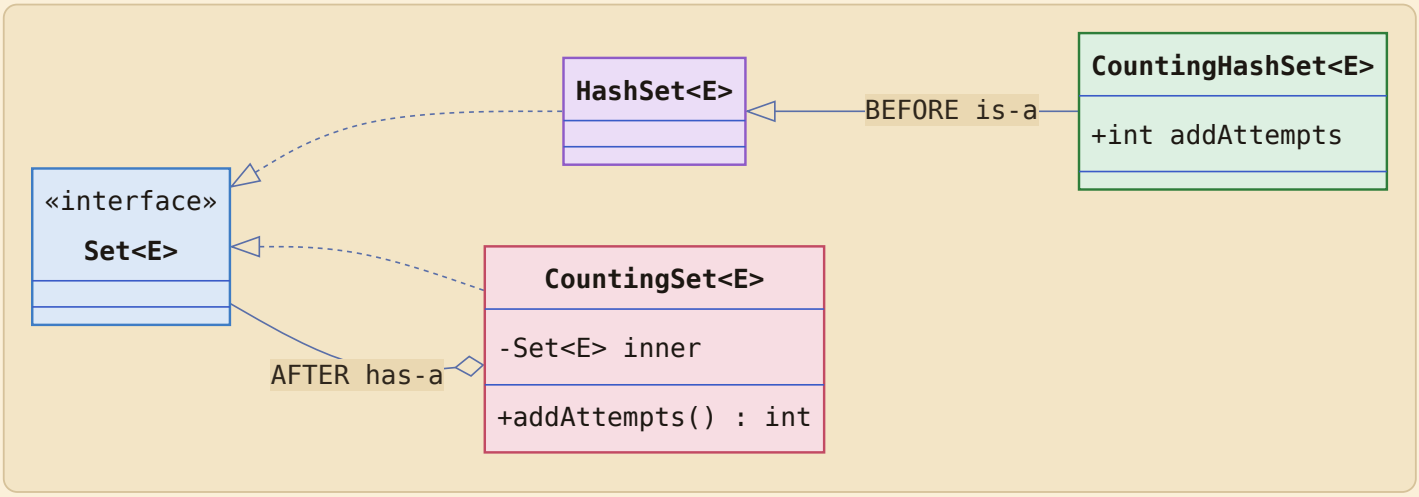
The problem it solves

Inheritance is the tightest coupling in object-oriented programming:

- **Fragile base class problem** — a subclass can break when the parent's *internal* implementation changes, even if the parent's public API is unchanged. The subclass depends on details like "does `addAll` call `add`?".
- **Fixed at compile time** (decided when the code is compiled, before it ever runs) — you cannot change the parent at runtime.
- **Class explosion** — combining features by subclassing (`LoggingCachingBufferedStream`) multiplies classes.
- It exposes all parent methods, even those that make no sense for the child.

How it works

1. Instead of `class B extends A`, give `B` a private field of type `A` (preferably an interface type).
2. Implement `B`'s methods by adding your behaviour and **forwarding** to the wrapped object.
3. Receive the wrapped object through the constructor, so any implementation can be plugged in.
4. Keep inheritance for genuine "is-a" relationships where the subclass truly is substitutable (Liskov Substitution, Chapter 4) and the parent was **designed for extension** (documented hooks, often abstract).



Java example — before/after

We want to count how many elements were ever added to a set. This is the classic trap described in *Effective Java*.

```java
// File: lld/ch05/composition/Main.java
package lld.ch05.composition;

import java.util.Collection;
import java.util.HashSet;
import java.util.Iterator;
import java.util.List;
import java.util.Set;
import java.util.AbstractSet;

/** Composition over inheritance: extending a concrete class couples you to its private implementation details. */
public class Main {

    // ---------------- BEFORE: inherit from HashSet to count insert attempts ----------------
    static class Before {
        @SuppressWarnings("serial")
        static class CountingHashSet<E> extends HashSet<E> {
            int addAttempts;
            @Override public boolean add(E e) { addAttempts++; return super.add(e); }
            @Override public boolean addAll(Collection<? extends E> c) {
                addAttempts += c.size();
                return super.addAll(c);   // HashSet's inherited addAll calls add() for each element -> counted
twice!
            }
        }
    }

    // ---------------- AFTER: wrap ANY Set and forward calls (a decorator) ----------------
    static class After {
        static final class CountingSet<E> extends AbstractSet<E> {
            private final Set<E> inner;   // "has-a", not "is-a"
            private int addAttempts;
            CountingSet(Set<E> inner) { this.inner = inner; }
            @Override public boolean add(E e) { addAttempts++; return inner.add(e); }
            @Override public boolean addAll(Collection<? extends E> c) { addAttempts += c.size(); return
inner.addAll(c); }
            @Override public boolean contains(Object o) { return inner.contains(o); }   // keep the inner set's
O(1)/O(log n) lookup
            @Override public boolean remove(Object o) { return inner.remove(o); }
            @Override public Iterator<E> iterator() { return inner.iterator(); }
            @Override public int size() { return inner.size(); }
            int addAttempts() { return addAttempts; }
        }
    }

    public static void main(String[] args) {
        List<String> words = List.of("red", "green", "blue");

        var before = new Before.CountingHashSet<String>();
        before.addAll(words);
        System.out.println("BEFORE: added 3 items, counter says " + before.addAttempts);

        var after = new After.CountingSet<String>(new HashSet<>());
        after.addAll(words);
        System.out.println("AFTER : added 3 items, counter says " + after.addAttempts());

        // Bonus: composition works with any Set implementation, chosen at runtime.
        var sorted = new After.CountingSet<String>(new java.util.TreeSet<>());
        sorted.addAll(words);
        System.out.println("AFTER over a TreeSet: " + sorted + " attempts=" + sorted.addAttempts());
    }
}
```

Output:

```
BEFORE: added 3 items, counter says 6
AFTER : added 3 items, counter says 3
AFTER over a TreeSet: [blue, green, red] attempts=3
```

Why the *before* prints 6: `HashSet` does not override `addAll`; it inherits `AbstractCollection.addAll`, which loops and calls `add` for every element. Our `addAll` adds 3, then the parent's loop calls *our overridden* `add` three more times. We depended on an implementation detail ("self-use") that `HashSet` does not promise to keep — the fragile base class problem. The *after* wraps any `Set` and forwards; the inner set's internal calls never reach our counter. It also forwards `contains` and `remove`: `AbstractSet` would otherwise implement them by scanning the iterator (an object that walks through a collection one element at a time) — O(n), i.e. time grows in step with the number of elements *n* (*Big-O notation*) — instead of using the inner set's fast lookup. It also works with a `TreeSet` chosen at runtime.

Trade-offs

Composition	Inheritance
Loose coupling to the public API only	Coupled to parent internals
Swap behaviour at runtime	Fixed at compile time
Combine behaviours freely (decorators)	Class explosion for combinations
More boilerplate (forwarding methods)	Free reuse of all parent methods
No automatic polymorphism (one variable working with many types) — need an interface	Subclass is automatically a subtype

When not to use it

- True "is-a" hierarchies with a base class **designed for extension**: e.g. extending `AbstractList` (implement `get` and `size`) or a Template Method base (see Hollywood Principle below).
- Sealed type hierarchies (a `sealed` type lists exactly which subtypes may exist) modelling a closed set of variants (`sealed interface Shape permits Circle, Square`).
- When you control both classes and they are in the same package and evolve together.

Common mistakes

- Inheriting just to reuse a few helper methods ("`OrderService extends BaseDao`").
- Composition without an interface — then you can't substitute implementations.
- Exposing the wrapped object with a getter, defeating encapsulation.

Real-world examples

- **JDK mistakes admitted by its own authors:** `java.util.Stack extends Vector` (so a stack lets you insert in the middle) and `java.util.Properties extends Hashtable` (so you can put non-String values). *Effective Java* cites both.
- **`java.io` streams** — `new BufferedInputStream(new FileInputStream(f))` composes behaviour (Decorator pattern, Chapter 9).
- **`Collections.unmodifiableList(list)` / `synchronizedList(list)`** wrap a list instead of subclassing each list type.
- **Game engines (Unity)** use an Entity–Component model: a game object *has* components (physics, renderer) instead of deep inheritance trees.

In the interview

30-second answer: "Inheritance couples a subclass to its parent's implementation, is fixed at compile time and explodes combinatorially. Composition holds a reference to an interface and delegates, so behaviour can be swapped at runtime. I use inheritance only for true is-a relationships with classes designed for extension."

Follow-ups:

- *Q: Which patterns are built on composition?* A: Strategy, Decorator, Composite, State, Bridge, Proxy, Adapter (object form) — most GoF patterns.

- *Q: Give a concrete inheritance failure.* A: The counting `HashSet` above, or `Stack extends Vector` exposing `insertElementAt`.
- *Q: When is inheritance OK?* A: When substitutable (LSP holds) and the parent documents its self-use or provides abstract hooks.

Self-check

1. Q: What is the fragile base class problem? → A: Subclasses breaking because the parent's internal implementation changed.
2. Q: What does "forwarding" mean? → A: The wrapper's method calls the same method on the wrapped object.
3. Q: Why did `CountingHashSet` count 6? → A: The inherited `addAll` calls the overridden `add`.

TL;DR

Reuse by holding and delegating ("has-a"); reserve "is-a" for real substitutable subtypes designed for extension.

---

7. Program to an Interface, Not an Implementation

What it is

Declare variables, fields, parameters and return types using the **most general supertype** (a parent type higher up the hierarchy) that offers what you need (an interface or abstract class), not a concrete class. "Interface" here means *supertype*, not only the Java `interface` keyword.

Analogy: a phone charger is designed for the USB-C *standard*, not for one specific phone model. Any USB-C phone works.

The problem it solves

Code written against a concrete class (`ArrayList`, `MySqlUserStore`) can only ever work with that class. You cannot test it without the real thing (e.g. a MySQL server), cannot swap implementations and cannot reuse it with other types. Changing the implementation means editing every caller.

How it works

1. Identify the **role** a collaborator plays ("stores users", "a collection of names").
2. Express the role as an interface with only the needed methods (`UserRepository.findById`).
3. Type fields/parameters by that interface (`List<String>`, `Collection<String>`, `UserRepository`).
4. Create concrete objects only at the edges — in `main`, a factory (an object or method whose job is creating other objects), or a DI container (a framework component, such as Spring's, that builds objects and wires their dependencies automatically) — and pass them in (**Dependency Injection**: giving an object its collaborators from outside instead of letting it `new` them).
5. For parameters, accept the widest type you can (`Collection` beats `List` beats `ArrayList`); for return types, return an interface but a specific enough one to be useful.

Java example — before/after

```
// File: lld/ch05/interfaces/Main.java
package lld.ch05.interfaces;

import java.util.ArrayList;
import java.util.Collection;
import java.util.HashMap;
import java.util.List;
import java.util.Map;
import java.util.Optional;
import java.util.TreeSet;

/** Program to an interface (a supertype), not an implementation. */
public class Main {

    record User(String id, String name) {}

    // ---------------- BEFORE: every signature names a concrete class ----------------
    static class Before {
        /** Pretend this talks to a real MySQL server -- impossible to use in a unit test. */
        static class MySqlUserStore {
            User load(String id) { throw new IllegalStateException("no MySQL server on this laptop"); }
        }
        static class GreetingService {
            private final MySqlUserStore store = new MySqlUserStore();   // hard-wired concrete dependency
            String greet(String id) { return "Hello, " + store.load(id).name(); }
        }
        static int countLongNames(ArrayList<String> names) {         // only accepts ArrayList
            int n = 0;
            for (String s : names) if (s.length() > 4) n++;
            return n;
        }
    }

    // ---------------- AFTER: depend on the supertype; pick the implementation at the edge ----------------
    static class After {
        interface UserRepository { Optional<User> findById(String id); }

        static final class InMemoryUserRepository implements UserRepository {
            private final Map<String, User> data = new HashMap<>();
            InMemoryUserRepository save(User u) { data.put(u.id(), u); return this; }
            @Override public Optional<User> findById(String id) { return Optional.ofNullable(data.get(id)); }
        }

        static final class GreetingService {
            private final UserRepository users;                  // any implementation
            GreetingService(UserRepository users) { this.users = users; }
            String greet(String id) {
                return users.findById(id).map(u -> "Hello, " + u.name()).orElse("Hello, stranger");
            }
        }

        static int countLongNames(Collection<String> names) {   // works for List, Set, Queue...
            return (int) names.stream().filter(s -> s.length() > 4).count();
        }
    }

    public static void main(String[] args) {
        System.out.println("== BEFORE ==");
        try {
            System.out.println(new Before.GreetingService().greet("u1"));
        } catch (IllegalStateException e) {
            System.out.println("cannot even run it: " + e.getMessage());
        }
        System.out.println("long names in ArrayList: " + Before.countLongNames(new ArrayList<>(List.of("Anand",
"Li", "Priya"))));
        // Before.countLongNames(new TreeSet<>(...)) would not compile.
```

```
        System.out.println("== AFTER ==");
        After.UserRepository repo = new After.InMemoryUserRepository().save(new User("u1", "Asha"));
        var service = new After.GreetingService(repo);
        System.out.println(service.greet("u1"));
        System.out.println(service.greet("u2"));
        System.out.println("long names in List:    " + After.countLongNames(List.of("Anand", "Li", "Priya")));
        System.out.println("long names in TreeSet: " + After.countLongNames(new TreeSet<>(List.of("Anand", "Li",
"Priya"))));
    }
}
```

Output:

```
== BEFORE ==
cannot even run it: no MySQL server on this laptop
long names in ArrayList: 2
== AFTER ==
Hello, Asha
Hello, stranger
long names in List:    2
long names in TreeSet: 2
```

The *before* service creates its own `MySqlUserStore`, so it cannot even run on a laptop, and `countLongNames` accepts only `ArrayList`. The *after* depends on `UserRepository` and `Collection`; an in-memory implementation makes it runnable and testable, and any collection works.

Trade-offs

Interface-typed	Concrete-typed
Swappable, testable (fakes/mocks)	Simple, one less type
Callers can't use implementation-only methods	Access to everything (e.g. `ArrayList.trimToSize`)
Extra interface to maintain	Changes ripple to callers

When not to use it

- **Value types / data classes** (`String`, `LocalDate`, records) — no need for an interface.
- A class with exactly one implementation and no testing seam need — creating `FooService` + `FooServiceImpl` for everything is ceremony (see YAGNI). Add the interface when the second implementation or test double (any stand-in object used in tests: fake, stub or mock) appears.
- When you truly need implementation-specific behaviour (e.g. `LinkedHashMap` access order for an LRU cache (a *cache* keeps recently used data close at hand for fast reuse; LRU = evict the Least Recently Used entry when full) — then declare it as such).

Common mistakes

- Interfaces that mirror a class one-to-one with 30 methods (violates Interface Segregation, Chapter 4).
- Declaring `List` but then casting to `ArrayList` inside.
- Still calling `new ConcreteThing()` inside the class that uses the interface — the dependency is typed abstractly but still hard-wired.

Real-world examples

- **Java Collections Framework**: code uses `List`, `Map`, `Set`; `Collections.sort(List)` works on any list.
- **JDBC** (Java Database Connectivity — the standard Java API for talking to SQL databases): your code uses `java.sql.Connection`, `PreparedStatement`, `ResultSet` interfaces; the driver (MySQL, PostgreSQL) supplies the implementation.
- **SLF4J** (a logging *facade*: one logging API in front of many logging libraries): code logs through the `org.slf4j.Logger` interface; Logback or Log4j2 is plugged in at deployment.
- **Spring** injects beans (objects created and managed by the Spring container) by interface type (`@Autowired PaymentGateway gateway`).

In the interview

> **30-second answer:** "I type dependencies by roles — interfaces — and inject concrete implementations from the outside. It lets me swap implementations, e.g. an in-memory repository for tests, and keeps callers stable when implementations change. It's the practical form of the Dependency Inversion Principle."

Follow-ups:

- *Q: Relationship to DIP?* A: DIP says high-level modules depend on abstractions; programming to an interface is how you do it at each variable/field.
- *Q: Should every class have an interface?* A: No — only roles with multiple implementations or a need for test doubles.

Self-check

1. Q: What does "interface" mean in this principle? → A: Any supertype (interface or abstract class).
2. Q: Where should `new ConcreteClass()` appear? → A: At the edges: `main`, factories, DI configuration.

TL;DR

Depend on roles (`List`, `UserRepository`), not on concrete classes; choose the concrete class once, at the edge.

---

8. Encapsulate What Varies

What it is

Find the parts of your application that **change** (or differ between cases) and **separate them** from the parts that stay the same. Put the varying part behind its own abstraction so it can change without touching stable code. *Head First Design Patterns* calls this the first design principle; the GoF book phrases it as "encapsulate the concept that varies".

Analogy: a camera body stays the same while you swap lenses. The lens mount is the stable interface; lenses are the varying part.

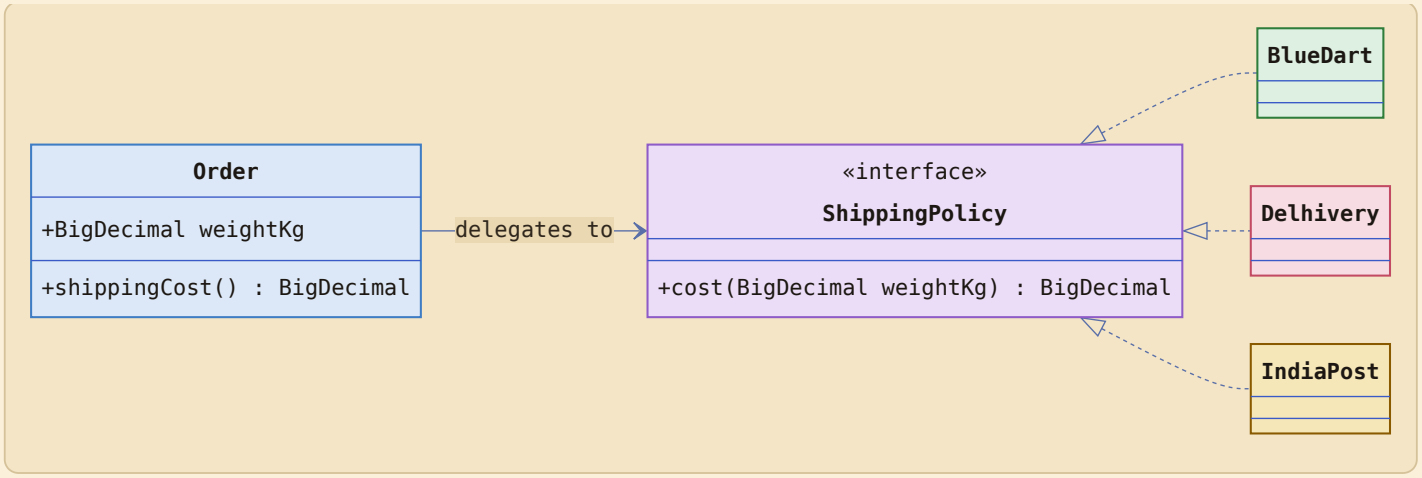
The problem it solves

When a volatile rule (shipping prices, tax, discounts, file formats) is written inline in a stable class, every change to the rule edits that class, re-tests it and risks breaking unrelated behaviour. Long `if/else` or `switch` chains on a "type" string grow forever (violating the Open/Closed Principle).

How it works

1. Ask: "Which parts of this class changed in the last few releases, or differ per customer/region/type?"
2. Extract that part behind an interface (or a functional interface — an interface with exactly one abstract method, which a lambda can implement).
3. Give the stable class a field of that interface type and delegate to it.
4. Add new variants as new implementations; the stable class does not change.

Almost every design pattern (a named, reusable solution to a recurring design problem; Chapters 8–11) is an application of this principle: Strategy (varying algorithm), State (varying state-dependent behaviour), Factory (varying creation), Observer (varying set of listeners), Template Method (varying steps).



Order
+BigDecimal weightKg
+shippingCost() : BigDecimal
delegates to
«interface»
ShippingPolicy
+cost(BigDecimal weightKg) : BigDecimal
BlueDart

IndiaPost

Java example — before/after

```
// File: lld/ch05/encapsulatevaries/Main.java
package lld.ch05.encapsulatevaries;

import java.math.BigDecimal;
import java.math.RoundingMode;
import java.util.Map;

/** Encapsulate what varies: find the part that keeps changing (shipping rules) and put it behind its own
abstraction. */
public class Main {

    /** Rupee amount = base + perKg * weight, exact decimal arithmetic (money is never a double). */
    static BigDecimal linear(String base, String perKg, BigDecimal weightKg) {
        return new BigDecimal(base).add(new BigDecimal(perKg).multiply(weightKg)).setScale(2,
RoundingMode.HALF_UP);
    }

    // ---------------- BEFORE: the changing part is tangled into a stable class ----------------
    static class Before {
        static class Order {
            final BigDecimal weightKg;
            final String carrier;
            Order(BigDecimal weightKg, String carrier) { this.weightKg = weightKg; this.carrier = carrier; }

            BigDecimal shippingCost() {
                // every new carrier or price change edits Order -- a class that should be stable
                if (carrier.equals("BLUEDART")) return linear("50", "20", weightKg);
                else if (carrier.equals("DELHIVERY")) return linear("40", "25", weightKg);
                else if (carrier.equals("INDIA_POST")) return linear("30", "10", weightKg);
                throw new IllegalArgumentException("unknown carrier " + carrier);
            }
        }
    }

    // ---------------- AFTER: the varying part is a separate, swappable object ----------------
    static class After {
        @FunctionalInterface
        interface ShippingPolicy { BigDecimal cost(BigDecimal weightKg); }

        /** Stable catalogue of today's policies. Adding one = adding one entry; Order never changes. */
        static final Map<String, ShippingPolicy> POLICIES = Map.of(
                "BLUEDART", w -> linear("50", "20", w),
                "DELHIVERY", w -> linear("40", "25", w),
                "INDIA_POST", w -> linear("30", "10", w));

        record Order(BigDecimal weightKg, ShippingPolicy shipping) {
            BigDecimal shippingCost() { return shipping.cost(weightKg); }
        }
    }

    public static void main(String[] args) {
        BigDecimal twoKg = new BigDecimal("2");
        System.out.println("== BEFORE ==");
        for (String c : new String[]{"BLUEDART", "DELHIVERY", "INDIA_POST"})
            System.out.printf("%-10s %s%n", c, new Before.Order(twoKg, c).shippingCost());

        System.out.println("== AFTER ==");
        for (String c : new String[]{"BLUEDART", "DELHIVERY", "INDIA_POST"})
            System.out.printf("%-10s %s%n", c, new After.Order(twoKg, After.POLICIES.get(c)).shippingCost());
        // A brand new flat-rate promo, with zero edits to Order:
        System.out.printf("%-10s %s%n", "PROMO", new After.Order(twoKg, w -> new
BigDecimal("0.00")).shippingCost());
    }
}
```

Output:

```
== BEFORE ==
BLUEDART   90.00
DELHIVERY  90.00
INDIA_POST 50.00
== AFTER ==
BLUEDART   90.00
DELHIVERY  90.00
INDIA_POST 50.00
PROMO      0.00
```

In *after*, `Order` never changes when a carrier is added or re-priced; a brand-new policy (the promo) was added with zero edits to `Order`. The diagram draws named classes for clarity; the code uses lambdas implementing the same interface.

Trade-offs

Encapsulated	Inline
New variants without touching stable code	Everything in one place, easy to see
Each variant testable alone	Simple for 2 variants that never change
More types / indirection	Grows into long conditionals

When not to use it

When the "varying" thing has never varied and there is no sign it will (YAGNI). Two fixed branches are fine inline; extract when the third arrives or change becomes frequent.

Common mistakes

- Guessing the wrong axis of variation (extracting something that never changes while the real volatile part stays inline).
- Leaving the `switch` on type in the client code after introducing the strategy (just moving the conditional).

Real-world examples

- `java.util.Comparator` — sorting algorithm stable, comparison varies.
- `java.util.concurrent.ThreadPoolExecutor` takes a `RejectedExecutionHandler` (what to do when full varies) and a `ThreadFactory` (how threads are made varies).
- **Payment gateways** in e-commerce apps (Razorpay, Stripe, PayPal) behind one `PaymentGateway` interface.

In the interview

> **30-second answer:** "I identify what is likely to change — say pricing or payment method — and hide it behind an interface so the core classes stay closed to modification. It's the principle behind Strategy, State and most other patterns."

Follow-ups:

- *Q: How do you know what varies?* A: From requirements ("multiple payment methods"), from history (what changed often), and from the interviewer's hints.
- *Q: Relation to OCP?* A: Encapsulating the variation is how you make a class open for extension and closed for modification.

Self-check

1. Q: Which pattern encapsulates a varying algorithm? → A: Strategy.
2. Q: What code smell signals a missing encapsulation? → A: A growing `if/else` / `switch` on a type code.

TL;DR

Separate what changes from what stays the same; put the changing part behind an interface.

---

9. Strive for Loosely Coupled Designs

What it is

Loose coupling means objects that interact know as little as possible about each other — ideally only a small interface. *Head First Design Patterns* states it as: strive for loosely coupled designs between objects that interact.

Analogy: a radio station broadcasts; it doesn't know who is listening or what brand of radio they own. Listeners tune in or out freely.

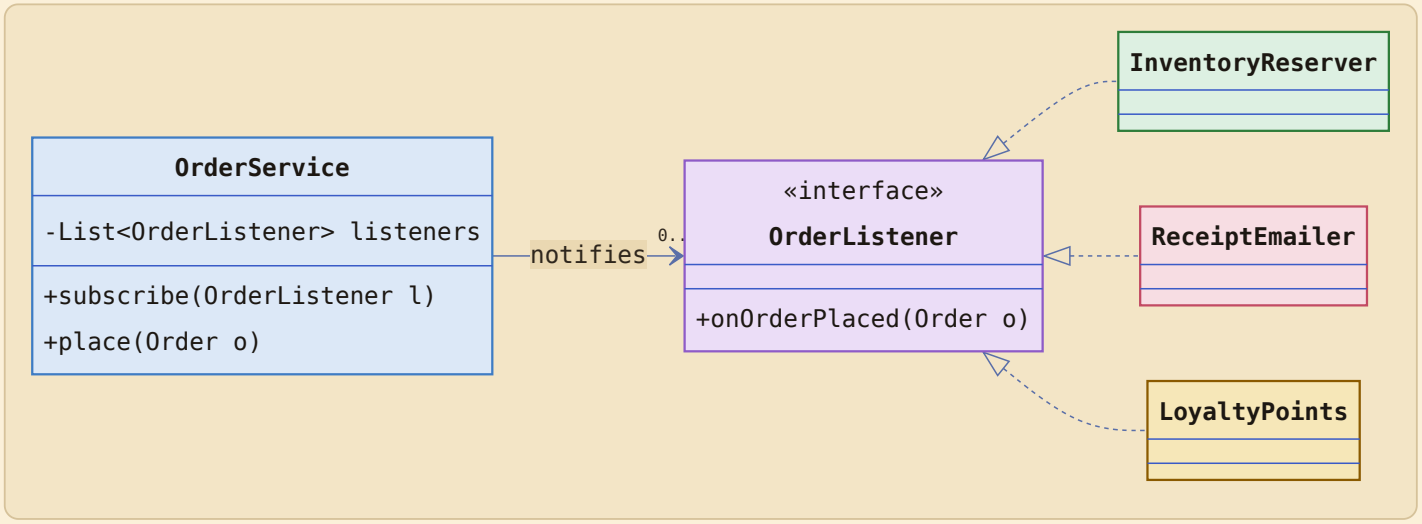
The problem it solves

In a **tightly coupled** design, a class creates and calls many concrete collaborators directly. Adding, removing or changing any collaborator edits that class. You can't reuse it without dragging all its dependencies along, and you can't test it in isolation.

How it works

1. Depend on **interfaces**, not concrete classes.
2. **Inject** dependencies instead of creating them inside.
3. Communicate through **events or messages** when the sender shouldn't know the receivers (Observer / publish-subscribe — senders publish events and any number of subscribers receive them without knowing each other).
4. Keep interfaces **narrow** (a single method is ideal for listeners).
5. Pass data as immutable values (records) rather than shared mutable objects.

Kinds of coupling from tightest to loosest (a common classification): *content* (reaching into another's internals) → *common* (shared global data) → *external* (sharing an externally imposed format, protocol or device interface) → *control* (passing flags that steer the other's logic) → *stamp* (passing a big structure when only part is needed) → *data* (passing only needed values) → *message* (communicating only through messages/events).



Java example — before/after

```
// File: lld/ch05/loosecoupling/Main.java
package lld.ch05.loosecoupling;

import java.util.List;
import java.util.concurrent.CopyOnWriteArrayList;

/** Strive for loosely coupled designs between objects that interact. */
public class Main {

    record Order(String id, String email, int items) {}

    // ---------------- BEFORE: OrderService knows every class that cares about an order ----------------
    static class Before {
        static class EmailSender { void sendReceipt(Order o) { System.out.println("  email receipt to " +
o.email()); } }
        static class Inventory { void reserve(Order o) { System.out.println("  reserve " + o.items() + " items"); }
}
        static class Analytics { void track(Order o) { System.out.println("  track order " + o.id()); } }

        static class OrderService {
            private final EmailSender email = new EmailSender();   // concrete, created inside
            private final Inventory inventory = new Inventory();
            private final Analytics analytics = new Analytics();
            void place(Order o) {
                System.out.println("placed " + o.id());
                inventory.reserve(o);
                email.sendReceipt(o);
                analytics.track(o);          // adding "loyalty points" means editing this class
            }
        }
    }

    // ---------------- AFTER: OrderService only knows a tiny listener interface ----------------
    static class After {
        @FunctionalInterface
        interface OrderListener { void onOrderPlaced(Order o); }

        static final class OrderService {
            private final List<OrderListener> listeners = new CopyOnWriteArrayList<>();
            void subscribe(OrderListener l) { listeners.add(l); }
            void place(Order o) {
                System.out.println("placed " + o.id());
                listeners.forEach(l -> l.onOrderPlaced(o));   // doesn't know who listens or what they do
            }
        }
    }

    public static void main(String[] args) {
        System.out.println("== BEFORE ==");
        new Before.OrderService().place(new Order("o-1", "asha@example.com", 2));

        System.out.println("== AFTER ==");
        var service = new After.OrderService();
        service.subscribe(o -> System.out.println("  reserve " + o.items() + " items"));
        service.subscribe(o -> System.out.println("  email receipt to " + o.email()));
        service.subscribe(o -> System.out.println("  track order " + o.id()));
        service.subscribe(o -> System.out.println("  +" + o.items() * 10 + " loyalty points"));  // new, no edits
        service.place(new Order("o-2", "ravi@example.com", 3));
    }
}
```

Output:

```
== BEFORE ==
placed o-1
  reserve 2 items
  email receipt to asha@example.com
  track order o-1
== AFTER ==
placed o-2
  reserve 3 items
  email receipt to ravi@example.com
  track order o-2
  +30 loyalty points
```

The *after* `OrderService` depends on one tiny interface. Adding "loyalty points" needed zero edits to it. A `CopyOnWriteArrayList` (a thread-safe list that copies its internal array on every write) is used so listeners can subscribe safely even while notifications run on other threads.

Trade-offs

Loose	Tight
Change and test parts independently	Easy to follow control flow
Add features by adding listeners	Direct calls are faster to trace in a debugger
Flow is less visible ("who handles this event?")	Every change edits the central class
Error handling/ordering between listeners must be designed	Order is explicit

When not to use it

- Inside a small, cohesive module where classes always change together — decoupling them adds ceremony.
- When the order and atomicity (all steps happen, or none do) of steps is critical (e.g. debit then credit in a transfer) — explicit orchestration is clearer and safer than fire-and-forget events.

Common mistakes

- "Decoupling" with a global event bus (one shared channel that every component publishes to and listens on) for everything, making the flow impossible to follow.
- Hidden coupling via shared mutable static state.
- Listeners that throw and stop the other listeners from running (decide a policy: catch and log per listener).

Real-world examples

- **Swing / JavaFX / Android** event listeners (`ActionListener`, `OnClickListener`).
- **Spring** `ApplicationEventPublisher` and `@EventListener`.
- **Apache Kafka** (a distributed *message broker*: producers append messages to named *topics*, and *consumer groups* read them at their own pace; see System Design Fundamentals) — producers write to topics without knowing which consumer groups read them; an order service at an e-commerce company publishes `OrderPlaced`, and inventory, notifications and analytics each consume independently.

In the interview

> **30-second answer:** "Loose coupling means collaborators know only small interfaces about each other. I achieve it with interfaces, dependency injection and events. In the order example, the order service just publishes 'order placed' and new features subscribe without touching it."

Follow-ups:

- *Q: Coupling vs cohesion?* A: Coupling is between modules (want low); cohesion is within a module (want high).
- *Q: Downside of event-driven decoupling?* A: Harder to trace flows, ordering and failure handling; needs good logging and clear contracts.

Self-check

1. Q: Which pattern is the classic loose-coupling tool for one-to-many notifications? → A: Observer.

2. Q: Name two techniques for loose coupling. → A: Depend on interfaces; inject dependencies (also: events, narrow interfaces).

TL;DR

Let interacting objects share only small interfaces; inject them and use events so parts change independently.

---

10. The Hollywood Principle (Inversion of Control)

What it is

"Don't call us, we'll call you." High-level components (a framework or base class) control the flow and **call** low-level components at the right moments. Low-level components **hook into** the system but never call the high-level components directly. This reversal of who-calls-whom is called **Inversion of Control (IoC)**.

Analogy: actors audition and leave their number; the studio calls them when there's a role. Actors don't phone the studio every hour.

Library vs framework: you call a library; a framework calls you. That is IoC.

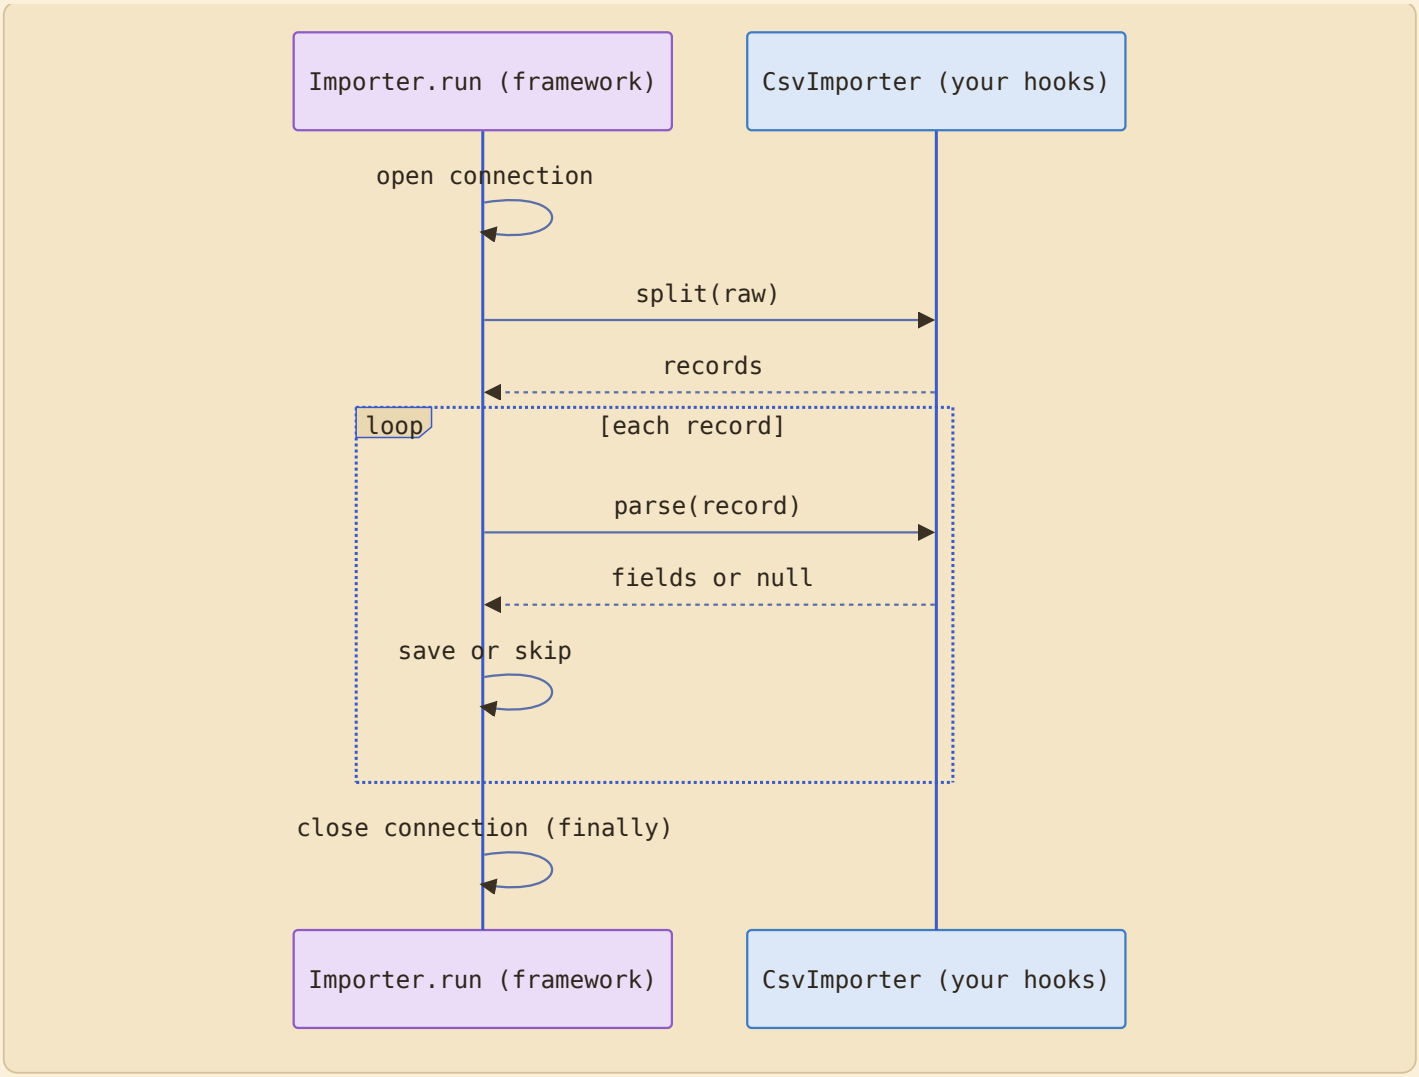
The problem it solves

Without it, every component drives the whole process itself: it re-implements the algorithm's skeleton, decides the order of steps and calls shared services directly. You get duplicated control flow, forgotten steps (like closing a database connection — the open session a program holds with a database) and **dependency rot** — high-level and low-level components depending on each other in tangled ways.

How it works

There are several ways to invert control:

1. **Template Method** — a base class defines a `final` algorithm and calls abstract "hook" methods that subclasses fill in.
2. **Callbacks / listeners** — you register a function; the system calls it on an event (Observer).
3. **Dependency Injection** — a container creates your objects and passes them their dependencies; your class never looks them up.
4. **Lifecycle management** — a container starts/stops your components (`@PostConstruct`, servlet `init`/`destroy`; a *servlet* is a Java class that handles web requests inside a server such as Tomcat).



Importer.run (framework)
CsvImporter (your hooks)
open connection
split(raw)
records
loop
[each record]
parse(record)
fields or null
save or skip
close connection (finally)
Importer.run (framework)
CsvImporter (your hooks)

Java example — before/after

```java
// File: lld/ch05/hollywood/Main.java
package lld.ch05.hollywood;

import java.util.ArrayList;
import java.util.List;

/** Hollywood Principle: "Don't call us, we'll call you." The high-level framework owns the flow and calls your
hooks. */
public class Main {

    // ---------------- BEFORE: each importer re-implements the whole flow and drives it itself ----------------
    static class Before {
        static class CsvImporter {
            void run(String raw) {
                System.out.println("  open connection");              // step order copied into every importer
                for (String row : raw.split(";")) {
                    String[] f = row.split(",");
                    if (f.length != 2) { System.out.println("  skip bad row '" + row + "'"); continue; }
                    System.out.println("  save " + f[0] + "=" + f[1]);
                }
                // forgot to close the connection -- nothing forced it
            }
        }
    }

    // ---------------- AFTER: Template Method -- the framework calls you ----------------
    static class After {
        abstract static class Importer {
            /** The fixed algorithm. final = subclasses cannot reorder or skip steps. */
            public final void run(String raw) {
                System.out.println("  open connection");
                try {
                    for (String record : split(raw)) {
                        String[] fields = parse(record);
                        if (fields == null) { System.out.println("  skip bad record '" + record + "'"); continue; }
                        System.out.println("  save " + fields[0] + "=" + fields[1]);
                    }
                } finally {
                    System.out.println("  close connection");       // guaranteed by the framework
                }
            }
            protected abstract List<String> split(String raw);       // hooks: WE call YOU
            protected abstract String[] parse(String record);
        }

        static final class CsvImporter extends Importer {
            @Override protected List<String> split(String raw) { return List.of(raw.split(";")); }
            @Override protected String[] parse(String r) { String[] f = r.split(","); return f.length == 2 ? f :
null; }
        }
        static final class KeyValueImporter extends Importer {
            @Override protected List<String> split(String raw) { return List.of(raw.split("\n")); }
            @Override protected String[] parse(String r) { String[] f = r.split("="); return f.length == 2 ? f :
null; }
        }

        /** A tiny IoC "container": components register, the container decides when to start/stop them. */
        interface Lifecycle { void start(); void stop(); }
        static final class Container {
            private final List<Lifecycle> components = new ArrayList<>();
            void register(Lifecycle c) { components.add(c); }
            void boot() { components.forEach(Lifecycle::start); }
            void shutdown() { components.reversed().forEach(Lifecycle::stop); }  // reverse order, like Spring
        }
    }
```

```
    public static void main(String[] args) {
        System.out.println("== BEFORE ==");
        new Before.CsvImporter().run("a,1;b,2;oops");
        System.out.println("== AFTER ==");
        new After.CsvImporter().run("a,1;b,2;oops");
        new After.KeyValueImporter().run("x=9\ny=8");

        var container = new After.Container();
        for (String name : List.of("database", "cache", "web")) {
            container.register(new After.Lifecycle() {
                public void start() { System.out.println("  start " + name); }
                public void stop() { System.out.println("  stop " + name); }
            });
        }
        container.boot();
        container.shutdown();
    }
}
```

Output:

```
== BEFORE ==
  open connection
  save a=1
  save b=2
  skip bad row 'oops'
== AFTER ==
  open connection
  save a=1
  save b=2
  skip bad record 'oops'
  close connection
  open connection
  save x=9
  save y=8
  close connection
  start database
  start cache
  start web
  stop web
  stop cache
  stop database
```

The *before* importer drives the flow and forgot to close the connection. In *after*, `Importer.run` is `final`: subclasses only supply `split` and `parse`, and the framework guarantees the close. The tiny `Container` shows IoC for lifecycles: components never start themselves; the container starts them in order and stops them in reverse order (the same idea Spring uses when destroying singletons — objects of which only one instance exists in the application).

Trade-offs

IoC	Direct control
Framework guarantees flow, ordering, cleanup	You see the whole flow in your code
Less duplication across components	Duplicated skeletons
"Magic": harder to debug who calls what	Explicit, simple for tiny programs
Components tied to the framework's hooks	Independent

When not to use it

For small scripts or one-off logic where there is no repeated skeleton — a framework or template adds indirection with nothing to share.

Common mistakes

- Letting low-level hooks call back up into the framework (e.g. a subclass calling `run()` recursively).
- Forgetting `final` on the template method, so subclasses override the skeleton.
- Confusing IoC (the general idea) with DI (one specific form of it).

Real-world examples

- **JUnit** (the standard Java unit-testing framework) discovers and calls your `@Test` methods; you never call them.
- **Servlets**: the container calls `doGet`/`doPost` (handlers for HTTP GET and POST requests); **Spring MVC** calls your `@GetMapping` methods.
- **Spring IoC container** creates beans, injects dependencies and calls `@PostConstruct`/`@PreDestroy`.
- **Android** calls `Activity.onCreate`, `onResume`, `onDestroy`.
- **`java.util.AbstractList`** — you implement `get` and `size`; the base class implements iteration, `indexOf`, `equals` by calling your methods.
- **Spring `JdbcTemplate`** runs the connection/statement/cleanup skeleton and calls your `RowMapper`.

In the interview

> **30-second answer:** "The Hollywood Principle — 'don't call us, we'll call you' — means the high-level component controls the flow and calls low-level hooks. It's what separates a framework from a library. Template Method, callbacks and dependency injection are all ways to apply it, and it prevents low-level parts from depending on high-level ones."

Follow-ups:

- *Q: IoC vs DI?* A: IoC is the general reversal of control; DI is IoC applied to obtaining dependencies (they're given to you rather than looked up).
- *Q: Hollywood vs Dependency Inversion?* A: DIP is about depending on abstractions; Hollywood is about who calls whom. They often appear together.

Self-check

1. Q: In Template Method, who calls whom? → A: The base class's template method calls the subclass hooks.
2. Q: Why make the template method `final`? → A: So subclasses cannot reorder or skip steps.
3. Q: Library or framework: which one calls your code? → A: Framework.

TL;DR

Let the framework own the flow and call your hooks; low-level parts plug in and never call up.

---

11. Separation of Concerns (SoC)

What it is

A **concern** is one aspect of what a program does: reading input, business rules, storage, presentation, security, logging. **Separation of Concerns** means each part of the program deals with one concern, so you can think about, change and test it without thinking about the others. Edsger Dijkstra coined the phrase in his 1974 essay "On the role of scientific thought" (EWD 447).

Analogy: in a restaurant the waiter takes orders, the chef cooks, the cashier bills. If one person did all three at once, every change (a new menu, a new payment method) would disrupt everything.

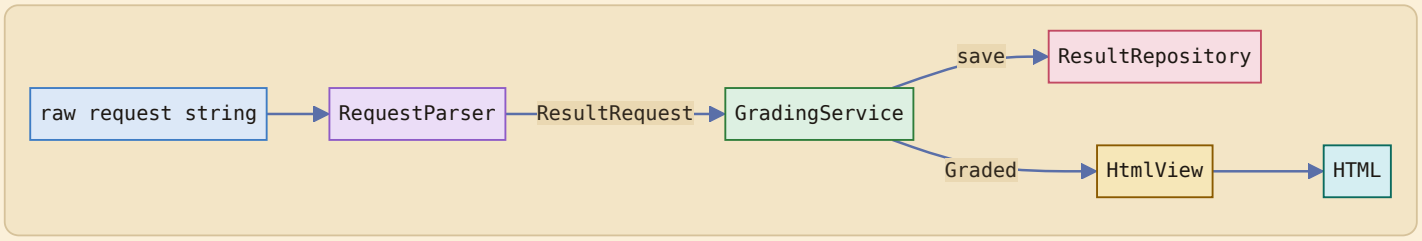
SoC is the **big-picture** version of the Single Responsibility Principle: SRP is about one class; SoC applies at every level — functions, classes, layers (MVC — Model–View–Controller, which keeps data/rules, display and input handling apart; controller/service/repository — a common backend layering where the controller receives web requests, the service holds business rules and the repository talks to the database), services and even languages (HTML for structure, CSS for style, JS for behaviour).

The problem it solves

Mixed concerns create code where you can't change the HTML without risking the grading rule, can't test the rule without parsing strings, and can't switch storage without editing presentation. Everything is tangled — *spaghetti code*.

How it works

1. List the concerns in the feature (input parsing, validation/rules, persistence, output format).
2. Give each its own unit (function → class → layer), with clear inputs and outputs (typed objects, not raw strings).
3. Let data flow in one direction: parse → apply rules → store → present.
4. Make lower layers not know about higher ones (the service doesn't know about HTML).
5. Handle **cross-cutting concerns** (logging, security, transactions — a *transaction* is a group of database changes that succeed or fail as one) with dedicated mechanisms — filters, decorators, proxies (stand-in objects that intercept calls to the real one) or aspects (AOP, aspect-oriented programming: write code such as logging once and have it applied around many methods automatically) — rather than sprinkling them everywhere (see Chapter 6, *Systems*).



Java example — before/after

```java
// File: lld/ch05/soc/Main.java
package lld.ch05.soc;

import java.util.HashMap;
import java.util.Map;

/** Separation of Concerns: parsing, business rules, storage and presentation each live in their own place. */
public class Main {

    // ---------------- BEFORE: one method does input parsing, rules, persistence AND HTML ----------------
    static class Before {
        static final Map<String, Integer> DB = new HashMap<>();
        static String handle(String request) {                    // "name=Asha&marks=87"
            String name = null; int marks = -1;
            for (String kv : request.split("&")) {
                String[] p = kv.split("=");
                if (p[0].equals("name")) name = p[1];
                if (p[0].equals("marks")) marks = Integer.parseInt(p[1]);
            }
            if (marks < 0 || marks > 100) return "<p style='color:red'>bad marks</p>";
            String grade = marks >= 90 ? "A" : marks >= 75 ? "B" : marks >= 50 ? "C" : "F";
            DB.put(name, marks);
            return "<p>" + name + " got " + grade + "</p>";
        }
    }

    // ---------------- AFTER: each concern is a separate class with one job ----------------
    static class After {
        record ResultRequest(String name, int marks) {}
        record Graded(String name, int marks, String grade) {}

        /** Concern 1: turn raw input into a typed request. */
        static final class RequestParser {
            ResultRequest parse(String raw) {
                Map<String, String> m = new HashMap<>();
                for (String kv : raw.split("&")) { String[] p = kv.split("=", 2); m.put(p[0], p[1]); }
                return new ResultRequest(m.get("name"), Integer.parseInt(m.get("marks")));
            }
        }
        /** Concern 2: business rules only. No HTML, no storage. */
        static final class GradingService {
            private final ResultRepository repo;
            GradingService(ResultRepository repo) { this.repo = repo; }
            Graded record(ResultRequest r) {
                if (r.marks() < 0 || r.marks() > 100) throw new IllegalArgumentException("marks must be 0..100");
                String grade = r.marks() >= 90 ? "A" : r.marks() >= 75 ? "B" : r.marks() >= 50 ? "C" : "F";
                repo.save(r.name(), r.marks());
                return new Graded(r.name(), r.marks(), grade);
            }
        }
        /** Concern 3: storage. */
        interface ResultRepository { void save(String name, int marks); int count(); }
        static final class InMemoryResultRepository implements ResultRepository {
            private final Map<String, Integer> rows = new HashMap<>();
            public void save(String name, int marks) { rows.put(name, marks); }
            public int count() { return rows.size(); }
        }
        /** Concern 4: presentation. Could be swapped for JSON without touching rules. */
        static final class HtmlView {
            String render(Graded g) { return "<p>" + g.name() + " got " + g.grade() + "</p>"; }
            String error(String msg) { return "<p style='color:red'>" + msg + "</p>"; }
        }
    }

    public static void main(String[] args) {
        System.out.println("== BEFORE ==");
```

```
        System.out.println(Before.handle("name=Asha&marks=87"));
        System.out.println(Before.handle("name=Ravi&marks=140"));

        System.out.println("== AFTER ==");
        var repo = new After.InMemoryResultRepository();
        var parser = new After.RequestParser();
        var service = new After.GradingService(repo);
        var view = new After.HtmlView();
        for (String raw : new String[]{"name=Asha&marks=87", "name=Ravi&marks=140"}) {
            try {
                System.out.println(view.render(service.record(parser.parse(raw))));
            } catch (IllegalArgumentException e) {
                System.out.println(view.error(e.getMessage()));
            }
        }
        System.out.println("rows stored: " + repo.count());
    }
}
```

Output:

```
== BEFORE ==
<p>Asha got B</p>
<p style='color:red'>bad marks</p>
== AFTER ==
<p>Asha got B</p>
<p style='color:red'>marks must be 0..100</p>
rows stored: 1
```

Each *after* class can now be tested alone: `GradingService` with an in-memory repository and no strings to parse; `HtmlView` could be replaced with a JSON view without touching the rules.

Trade-offs

Separated	Mixed
Change one concern safely	Quick to write for a one-off
Parallel team work (UI vs backend)	Everything visible in one place
More types and wiring	Tangled, hard to test

When not to use it

Tiny throwaway scripts. Also avoid over-layering (five layers that just pass data through — "lasagna code").

Common mistakes

- Business rules leaking into controllers or SQL.
- Separating by *technical type* only (all DTOs in one package) while one feature's logic is scattered — prefer separating by concern and cohesive feature packages.

Real-world examples

- **MVC** (Model–View–Controller) in Spring MVC, Rails, ASP.NET.
- **HTML / CSS / JavaScript** separation on the web.
- **TCP/IP network layers** (the stack of protocols the internet runs on, from physical links up through IP addressing, TCP's reliable delivery and HTTP): each layer handles one concern and talks only to its neighbours.
- **Spring AOP / servlet filters** separate cross-cutting concerns (security, transactions, logging) from business code.

In the interview

30-second answer: "Separation of Concerns means each module handles one aspect — parsing, rules, storage, presentation — so each can change and be tested independently. In LLD I show it as layers: controller,

> service, repository, with domain objects in the middle."

Follow-ups:

- *Q: SoC vs SRP?* A: SRP is SoC applied to a single class — one reason to change.
- *Q: What is a cross-cutting concern?* A: A concern that touches many modules (logging, auth, transactions); handled by AOP, proxies, decorators or filters.

Self-check

1. Q: Name four concerns in a typical web request. → A: Parsing input, business rules, persistence, presentation.
2. Q: Who coined the term? → A: Edsger Dijkstra (1974).

TL;DR

Give each concern its own home and let them communicate through clear, typed interfaces.

---

12. Principle of Least Astonishment (POLA)

What it is

Also called the **Principle of Least Surprise**: a component should behave the way most of its users *expect* from its name, signature and context. If a behaviour would surprise a reasonable reader, change the behaviour or the name.

Analogy: a light switch that also locks the front door would be "correct" according to its designer, but it surprises everybody.

The problem it solves

Surprising code causes bugs even when it "works as designed", because callers use it based on expectations. Typical surprises: methods named like queries that change state, methods that mutate and return `this` so aliases (other variables pointing to the same object) change, inconsistent naming (`size()` vs `length()` vs `count()` in one API), 0-based vs 1-based confusion, and silently swallowed errors.

How it works

1. Make names tell the truth: `find` / `get` / `is` must not modify state; if it creates, say so (`getOrCreate`).
2. Follow language and platform conventions (the `equals`/`hashCode` contract — equal objects must return the same *hash code*, the number hash-based collections like `HashMap` use to locate them — Java naming, `close()` via `AutoCloseable`).
3. Be consistent within your API — same word for same concept.
4. Prefer immutable results and no hidden side effects.
5. Signal "maybe absent" in the type (`Optional`, a box that either holds a value or is empty), not with a surprise `null` or a magic value.
6. Document any unavoidable surprise prominently.

Java example — before/after

```
// File: lld/ch05/leastastonishment/Main.java
package lld.ch05.leastastonishment;

import java.math.BigDecimal;
import java.util.Arrays;
import java.util.HashMap;
import java.util.List;
import java.util.Map;
import java.util.Optional;

/** Principle of Least Astonishment: code should behave the way its name and its readers expect. */
public class Main {

    // ---------------- BEFORE: surprising behaviour hidden behind innocent names ----------------
    static class Before {
        static class Money {
            long paise;
            Money(long paise) { this.paise = paise; }
            Money add(Money other) { this.paise += other.paise; return this; }   // looks pure, actually mutates
            @Override public String toString() { return "Rs " + BigDecimal.valueOf(paise, 2); }   // exact, no
double
        }
        static class UserDirectory {
            final Map<String, String> users = new HashMap<>();
            String findUser(String id) {                        // "find" silently CREATES a user
                return users.computeIfAbsent(id, k -> "new-user-" + k);
            }
        }
    }

    // ---------------- AFTER: names tell the truth; no hidden side effects ----------------
    static class After {
        record Money(long paise) {
            Money plus(Money other) { return new Money(paise + other.paise); }   // returns a NEW value
            @Override public String toString() { return "Rs " + BigDecimal.valueOf(paise, 2); }   // exact, no
double
        }
        static class UserDirectory {
            private final Map<String, String> users = new HashMap<>();
            Optional<String> findUser(String id) { return Optional.ofNullable(users.get(id)); }
            String getOrCreateUser(String id) { return users.computeIfAbsent(id, k -> "new-user-" + k); }
            int size() { return users.size(); }
        }
    }

    public static void main(String[] args) {
        System.out.println("== BEFORE ==");
        var price = new Before.Money(10_000);
        var withTip = price.add(new Before.Money(1_000));
        System.out.println("price=" + price + " withTip=" + withTip + "   <-- price changed too!");
        var dir = new Before.UserDirectory();
        dir.findUser("ghost");
        System.out.println("users after a *find*: " + dir.users.size());

        System.out.println("== AFTER ==");
        var p = new After.Money(10_000);
        var t = p.plus(new After.Money(1_000));
        System.out.println("price=" + p + " withTip=" + t);
        var d = new After.UserDirectory();
        System.out.println("find ghost -> " + d.findUser("ghost") + ", users=" + d.size());
        System.out.println("getOrCreate ghost -> " + d.getOrCreateUser("ghost") + ", users=" + d.size());

        System.out.println("== Real JDK surprises (good to know) ==");
        System.out.println("new BigDecimal(\"2.0\").equals(new BigDecimal(\"2.00\")) = "
                + new BigDecimal("2.0").equals(new BigDecimal("2.00")));
        System.out.println("new BigDecimal(\"2.0\").compareTo(new BigDecimal(\"2.00\")) = "
```

```
                + new BigDecimal("2.0").compareTo(new BigDecimal("2.00")));
        List<String> fixed = Arrays.asList("a", "b");
        try { fixed.add("c"); } catch (UnsupportedOperationException e) {
            System.out.println("Arrays.asList(...).add -> UnsupportedOperationException (fixed-size list)");
        }
    }
}
```

Output:

```
== BEFORE ==
price=Rs 110.00 withTip=Rs 110.00   <-- price changed too!
users after a *find*: 1
== AFTER ==
price=Rs 100.00 withTip=Rs 110.00
find ghost -> Optional.empty, users=0
getOrCreate ghost -> new-user-ghost, users=1
== Real JDK surprises (good to know) ==
new BigDecimal("2.0").equals(new BigDecimal("2.00")) = false
new BigDecimal("2.0").compareTo(new BigDecimal("2.00")) = 0
Arrays.asList(...).add -> UnsupportedOperationException (fixed-size list)
```

The last block shows *real* JDK behaviour that surprises many developers: `BigDecimal.equals` compares scale as well as value (`2.0` ≠ `2.00`), while `compareTo` says they are equal; and `Arrays.asList` returns a fixed-size list backed by the array. These are documented, but they are classic interview gotchas — use `compareTo` for numeric equality and `new ArrayList<>(Arrays.asList(...))` or `List.of(...)` depending on whether you need mutability.

Trade-offs

Following POLA sometimes means a longer name (`getOrCreateUser`) or an extra method. That's cheap compared to the bugs surprises cause. The only real tension: what's "expected" depends on the audience — follow the conventions of *your* platform and team.

When not to use it

There's no case where surprising users is good. But don't twist a design to match a *wrong* expectation; instead, fix the name so expectations become correct.

Common mistakes

- Getters with side effects (lazy creation, logging to DB, incrementing counters).
- Overloading `equals` (writing `equals(Money m)`) instead of overriding `equals(Object o)` — the collection classes silently ignore it.
- Methods whose behaviour changes based on a hidden global flag.

Real-world examples

- **`java.time`** was designed to fix the surprises of `java.util.Date`/`Calendar` (mutable dates, months numbered 0–11).
- `java.net.URL.equals` may perform DNS resolution (a network lookup that turns a host name into an IP address) (documented) — a notorious surprise; `java.net.URI` is usually preferred as a map key.
- **Unix** `rm` has no undo; tools like `trash` exist to reduce astonishment for new users.
- UI design: "Save" always in the same place; "Cancel" never saves.

In the interview

> **30-second answer:** "Least astonishment means an API should do what its name and conventions suggest. Queries don't mutate, creation is named explicitly, absence is typed with Optional, and value objects are immutable. Surprises like `BigDecimal.equals` considering scale are exactly what we try not to create."

Follow-ups:

- *Q: Example of violating it in Java?* A: A `get` method that lazily writes to the database, or `Money.add` mutating `this`.

- *Q: How does CQS help?* A: Command-Query Separation (Chapter 6) makes it obvious which methods change state.

Self-check

1. Q: What should `findUser` do if the user doesn't exist? → A: Return an empty `Optional` (or throw a documented exception), never silently create one.
2. Q: Why is `a.add(b)` returning a mutated `this` surprising? → A: Other references to `a` change unexpectedly (aliasing).

TL;DR

Do what the name promises and nothing more; follow conventions; make absence and side effects visible.

---

13. Fail Fast

What it is

A **fail-fast** system detects an invalid state or input **immediately**, at the point where it arises, and stops with a clear error — rather than carrying on and failing mysteriously later (**fail slow / fail silently**).

Analogy: a smoke alarm that beeps at the first smoke, not after the house is on fire.

The problem it solves

If a `null` endpoint (the URL of a service to call) or a negative retry count is accepted in a constructor, the crash happens hours later, deep in unrelated code, with a stack trace (the list of method calls that were active when the error happened) that points to the symptom, not the cause. Bad data may also be saved and corrupt other data before anyone notices. The longer the gap between cause and failure, the more expensive the bug.

How it works

1. **Validate at boundaries**: constructors, public method entry, API/controller input, configuration load at startup.
2. Use **guard clauses** (checks at the top of a method that throw or return immediately on bad input) — `Objects.requireNonNull`, `if (bad) throw new IllegalArgumentException(...)` at the top of the method.
3. Throw specific exceptions with a helpful message (what was wrong, what value, what was expected).
4. Make invalid objects **unconstructable** (validation in constructor/factory + immutability).
5. Fail at **startup** for misconfiguration rather than on the first request.
6. Don't swallow exceptions (`catch (Exception e) {}`).

Fail fast vs fail safe: *fail-safe* means a failure leaves the system in a safe state (e.g. a lift's brakes engage on power loss). Interview literature (not the JDK documentation, which says "snapshot" or "weakly consistent") also calls **iterators** "fail-safe" when they never throw `ConcurrentModificationException` — `CopyOnWriteArrayList` iterates over a snapshot, `ConcurrentHashMap` iterators are weakly consistent — in contrast to *fail-fast* iterators (e.g. `ArrayList`) that throw `ConcurrentModificationException` when the collection is structurally modified during iteration. Note the JDK documents fail-fast iterators as **best-effort** — you must not rely on them for correctness.

Java example — before/after

```java
// File: lld/ch05/failfast/Main.java
package lld.ch05.failfast;

import java.time.Duration;
import java.util.ArrayList;
import java.util.ConcurrentModificationException;
import java.util.List;
import java.util.Objects;

/** Fail fast: detect a bad state at the earliest point, loudly, close to its cause. */
public class Main {

    // ---------------- BEFORE: garbage is accepted and blows up far away, much later ----------------
    static class Before {
        static class RetryConfig {
            final String endpoint; final int maxAttempts; final Duration backoff;
            RetryConfig(String endpoint, int maxAttempts, Duration backoff) {
                this.endpoint = endpoint; this.maxAttempts = maxAttempts; this.backoff = backoff;  // no checks
            }
        }
        static String callWithRetry(RetryConfig c) {
            // Hours later, deep inside business code:
            return "calling " + c.endpoint.toUpperCase() + " up to " + c.maxAttempts + " times, backoff "
                    + c.backoff.toMillis() + "ms";
        }
    }

    // ---------------- AFTER: validate at the boundary -- the object can never exist in a bad state ----------
--
    static class After {
        record RetryConfig(String endpoint, int maxAttempts, Duration backoff) {
            RetryConfig {
                Objects.requireNonNull(endpoint, "endpoint");
                Objects.requireNonNull(backoff, "backoff");
                if (maxAttempts < 1) throw new IllegalArgumentException("maxAttempts must be >= 1, was " +
maxAttempts);
                if (backoff.isNegative()) throw new IllegalArgumentException("backoff must not be negative");
            }
        }
    }

    public static void main(String[] args) {
        System.out.println("== BEFORE ==");
        var bad = new Before.RetryConfig(null, 0, null);   // constructed "successfully"
        System.out.println("config created, nothing complained...");
        try { Before.callWithRetry(bad); }
        catch (NullPointerException e) { System.out.println("much later: NullPointerException far from the real
mistake"); }

        System.out.println("== AFTER ==");
        try { new After.RetryConfig(null, 3, Duration.ofMillis(100)); }
        catch (NullPointerException e) { System.out.println("rejected at construction: " + e.getMessage()); }
        try { new After.RetryConfig("https://pay", 0, Duration.ofMillis(100)); }
        catch (IllegalArgumentException e) { System.out.println("rejected at construction: " + e.getMessage()); }
        System.out.println("ok: " + new After.RetryConfig("https://pay", 3, Duration.ofMillis(100)));

        System.out.println("== JDK fail-fast iterator ==");
        List<String> list = new ArrayList<>(List.of("a", "b", "c"));
        try {
            for (String s : list) if (s.equals("a")) list.remove(s);   // structural change during iteration
        } catch (ConcurrentModificationException e) {
            System.out.println("ArrayList iterator threw ConcurrentModificationException");
        }
        list.removeIf(s -> s.equals("b"));                              // the safe way
        System.out.println("after removeIf: " + list);
```

```
    }
}
```

Output:

```
== BEFORE ==
config created, nothing complained...
much later: NullPointerException far from the real mistake
== AFTER ==
rejected at construction: endpoint
rejected at construction: maxAttempts must be >= 1, was 0
ok: RetryConfig[endpoint=https://pay, maxAttempts=3, backoff=PT0.1S]
== JDK fail-fast iterator ==
ArrayList iterator threw ConcurrentModificationException
after removeIf: [c]
```

`RetryConfig` in *after* cannot exist with bad values; the error message names exactly what's wrong. The last block shows the JDK's own fail-fast iterator and the safe alternative `removeIf`. (Note: `list.remove("a")` itself succeeded before the iterator noticed the change on its next step, which is why only `"b"` was left for `removeIf` to delete.)

Trade-offs

Fail fast	Fail slow / silently
Bugs found early, near their cause	System "keeps running"
Clear diagnostics	Data corruption, confusing symptoms
Some upfront validation code	Less code, more debugging
May stop a whole process for a minor issue	—

When not to use it

Fail fast *inside* a component, but think about **resilience at system boundaries**: a UI shouldn't crash because one widget failed to load, and a batch job (a program that processes a large set of records in one run, often on a schedule) may skip and log a bad record rather than abort millions of good ones. The rule is: detect early, then decide deliberately how to handle (reject, retry, degrade) — never ignore.

Common mistakes

- Catching and ignoring exceptions, or returning `null` / `-1` on error.
- Validating deep inside business logic instead of at entry.
- Using `assert` for argument validation in public methods — Java assertions are **disabled by default** (enabled with `-ea`), so they can't be the only guard.

Real-world examples

- `Objects.requireNonNull`, `List.of(null)` throws `NullPointerException` immediately.
- **Spring Boot** (Spring's ready-made setup for quickly building runnable applications) fails at startup if a required bean or property is missing, and `@Validated` configuration properties fail on bad values.
- **Circuit breakers** (a wrapper around remote calls that "trips" after repeated failures and rejects further calls for a while; libraries: Resilience4j; earlier Netflix Hystrix, now in maintenance mode) fail fast: when a downstream service (one your service depends on and calls) is unhealthy, calls are rejected immediately instead of waiting for timeouts.
- **Erlang/OTP "let it crash"**: processes fail fast and supervisors restart them.
- **CI pipelines** (Continuous Integration: an automated build-and-test run on every code change) stop on the first failing stage.

In the interview

30-second answer: "Fail fast means validating at the boundary and throwing a clear error immediately, so the failure is close to its cause. In LLD I put guard clauses in constructors and public methods so invalid

objects can't exist. At the system level, circuit breakers fail fast to avoid piling up on slow dependencies."

Follow-ups:

- *Q: Fail-fast vs fail-safe iterators?* A: Fail-fast (`ArrayList`, `HashMap`) throw `ConcurrentModificationException` on structural modification during iteration (best-effort); fail-safe/weakly consistent ones (`CopyOnWriteArrayList`, `ConcurrentHashMap`) iterate over a snapshot or tolerate concurrent changes and never throw it.
- *Q: Isn't crashing bad for users?* A: Fail fast inside; handle gracefully at the edge (show an error, retry, degrade).

Self-check

1. Q: Where should validation go? → A: At boundaries: constructors, public method entry, startup config, API input.
2. Q: Why not rely on `assert` for public argument checks? → A: Assertions are disabled by default at runtime.

TL;DR

Check early, throw clearly, never swallow; make invalid states impossible to construct.

---

14. Immutability

What it is

An **immutable object** cannot change its observable state after it is constructed. To "change" it, you create a new object. `String`, `Integer`, `LocalDate`, `BigDecimal` and records with immutable components are examples.

Analogy: a printed receipt. If the amount is wrong, you print a new receipt; you don't edit the old one in everyone's hands.

The problem it solves

Mutable shared objects cause:

- **Aliasing bugs** — two references to the same object; one changes it, the other is surprised.
- **Broken invariants** — someone calls a setter and leaves the object half-valid.
- **Thread-safety problems** — concurrent reads and writes need locks (a mechanism that lets only one thread at a time run a protected piece of code).
- **Hash-based collection bugs** — changing a field used by `hashCode` after putting the object in a `HashSet` makes it "disappear".

Immutable objects are **inherently thread-safe** (can be shared freely without locks), can be cached and reused, are safe as map keys, and are easy to reason about.

How it works

The five rules from *Effective Java*'s item "Minimize mutability" (Joshua Bloch):

1. Don't provide methods that modify the object's state (no setters, no mutators).
2. Ensure the class can't be extended (`final` class, or private constructors + static factories — `static` methods such as `of(...)` that create instances). Records are implicitly final.
3. Make all fields `final`.
4. Make all fields `private`.
5. Ensure exclusive access to any mutable components: **defensively copy** mutable inputs in the constructor (`List.copyOf`) and never hand out references to mutable internals (return copies or unmodifiable views).

A common extra convenience: "wither" methods that return a new instance with one thing changed (`withStart`, `plusCity`).

Unmodifiable vs immutable: `Collections.unmodifiableList(list)` is a read-only *view* — if someone still holds the original list and changes it, the view shows the change. `List.copyOf` / `List.of` create an independent unmodifiable list. Records are **shallowly** immutable: a `List` component could still be mutable unless you copy it.

Java example — before/after

```
// File: lld/ch05/immutability/Main.java
package lld.ch05.immutability;

import java.time.LocalDate;
import java.util.ArrayList;
import java.util.List;

/** Immutability: once created, an object's observable state never changes. */
public class Main {

    // ---------------- BEFORE: a mutable class that leaks its internals ----------------
    static class Before {
        static class Itinerary {
            private final List<String> cities;              // 'final' reference, but the LIST is mutable
            private LocalDate start;
            Itinerary(List<String> cities, LocalDate start) { this.cities = cities; this.start = start; }
            List<String> getCities() { return cities; }      // hands out the internal list
            void setStart(LocalDate d) { start = d; }
            @Override public String toString() { return start + " " + cities; }
        }
    }

    // ---------------- AFTER: final class, final fields, defensive copies, "wither" methods ----------------
    static class After {
        /** A record is shallowly immutable; List.copyOf makes the list part immutable too. */
        record Itinerary(List<String> cities, LocalDate start) {
            Itinerary {
                cities = List.copyOf(cities);   // copy in: caller's later edits cannot reach us
            }
            Itinerary withStart(LocalDate newStart) { return new Itinerary(cities, newStart); }
            Itinerary plusCity(String c) {
                List<String> next = new ArrayList<>(cities);
                next.add(c);
                return new Itinerary(next, start);
            }
        }
    }

    public static void main(String[] args) {
        System.out.println("== BEFORE ==");
        List<String> input = new ArrayList<>(List.of("Delhi", "Agra"));
        var trip = new Before.Itinerary(input, LocalDate.of(2026, 10, 1));
        input.add("Jaipur");                          // caller edits its own list...
        trip.getCities().clear();                     // ...another caller wipes ours
        System.out.println("shared trip is now: " + trip + "   <-- changed by outsiders");

        System.out.println("== AFTER ==");
        List<String> input2 = new ArrayList<>(List.of("Delhi", "Agra"));
        var t1 = new After.Itinerary(input2, LocalDate.of(2026, 10, 1));
        input2.add("Jaipur");
        try { t1.cities().clear(); } catch (UnsupportedOperationException e) { System.out.println("cannot clear:
unmodifiable"); }
        var t2 = t1.plusCity("Jaipur").withStart(LocalDate.of(2026, 11, 5));
        System.out.println("t1 = " + t1);
        System.out.println("t2 = " + t2);

        System.out.println("== JDK immutables ==");
        String s = "hello";
        String upper = s.toUpperCase();
        LocalDate d = LocalDate.of(2026, 1, 31);
        System.out.println(s + " / " + upper + " ; " + d + " plusMonths(1) = " + d.plusMonths(1) + " (d unchanged:
" + d + ")");
    }
}
```

Output:

```
== BEFORE ==
shared trip is now: 2026-10-01 []   <-- changed by outsiders
== AFTER ==
cannot clear: unmodifiable
t1 = Itinerary[cities=[Delhi, Agra], start=2026-10-01]
t2 = Itinerary[cities=[Delhi, Agra, Jaipur], start=2026-11-05]
== JDK immutables ==
hello / HELLO ; 2026-01-31 plusMonths(1) = 2026-02-28 (d unchanged: 2026-01-31)
```

In *before*, `final List` only stops the *reference* from changing; outsiders both added to and cleared the list. In *after*, the compact constructor copies the list, the accessor returns an unmodifiable list, and "changes" produce new `Itinerary` values while `t1` stays intact. The JDK line shows `LocalDate.plusMonths` returning a new date (and clamping Jan 31 + 1 month to Feb 28).

Trade-offs

Immutable	Mutable
Thread-safe, no locks	Needs synchronisation when shared
Safe map keys, cacheable, easy reasoning	In-place updates, no allocation
Allocation for every "change" (usually cheap on modern JVMs — Java Virtual Machines, which run Java code)	Aliasing and invariant bugs
Large objects: copying cost (use builders or persistent data structures, which share unchanged parts between versions)	—

When not to use it

- Hot loops building big results — use a mutable builder locally (`StringBuilder`, then `toString()`), and expose the immutable result.
- Entities whose identity persists while state changes (a `BankAccount` balance) — keep them mutable but encapsulated; make their *values* (Money, Address) immutable.
- ORM entities (ORM = Object-Relational Mapping, a library that maps classes to database tables; JPA is Java's standard ORM API) usually need no-arg constructors and setters.

Common mistakes

- Thinking `final` fields make an object immutable (not if the field refers to a mutable object).
- Returning the internal list from a getter.
- Using `Collections.unmodifiableList` over a list the caller still holds.
- Letting `this` escape during construction (e.g. registering a listener in the constructor) — other threads may see a half-built object.

Real-world examples

- `String`, wrapper types, `BigDecimal`, `java.time.*`, `List.of`, `Map.of`, records.
- **Git commits** (saved versions in Git, the version-control tool) are immutable snapshots identified by hash (a fingerprint-like ID computed from the content).
- **Kafka log records** are immutable once appended.
- **Redux / React state** is treated as immutable; updates produce new state objects so change detection is a cheap reference check.

In the interview

30-second answer: "Immutable objects never change after creation: final class, private final fields, no setters, defensive copies in and out. They're thread-safe without locks and safe as map keys. In designs I make value objects like Money, Address and configuration immutable, and keep mutable state encapsulated inside entities."

Follow-ups:

- *Q: Are records immutable?* A: Shallowly — fields are final, but a mutable component (like an `ArrayList`) must be defensively copied.
- *Q:* `unmodifiableList` *vs* `List.copyOf`*?* A: The first is a live read-only view; the second is an independent unmodifiable copy.
- *Q: Why must immutable classes be final?* A: A subclass could add mutable state or override methods to break the guarantees.

Self-check

1. Q: Does `private final List<String> items` make a class immutable? → A: No; the list itself can still be modified.
2. Q: What is a "wither" method? → A: A method returning a new instance with one field changed.
3. Q: Why are immutable objects thread-safe? → A: No thread can modify them, so there are no data races on their state (given safe construction).

TL;DR

No setters, final everything, copy mutable inputs and outputs; "changing" means creating a new value.

---

15. Design by Contract (DbC)

What it is

Design by Contract, from Bertrand Meyer and the Eiffel language, treats a method like a business contract between a **client** (caller) and a **supplier** (the method):

- **Precondition** — what must be true *before* the call. The caller's obligation. (e.g. `pop` requires a non-empty stack.)
- **Postcondition** — what the method guarantees *after* the call if the precondition held. The supplier's obligation. (e.g. after `push(x)`, size grew by one and the top is `x`.)
- **Class invariant** — what is always true about every object between public calls. (e.g. `0 ≤ size ≤ capacity`.)

Analogy: a courier contract: you must pack the parcel and pay (precondition); they promise delivery within 2 days (postcondition); the parcel is never opened in transit (invariant).

The problem it solves

Without explicit contracts, each side guesses: the caller doesn't know what inputs are allowed; the method either checks everything defensively (duplicated checks everywhere) or checks nothing and silently corrupts state. Errors show up as ambiguous return values (`-1`) or lost data.

How it works

1. For each public method, write down the precondition, postcondition and the class invariant (in Javadoc — the structured `/** ... */` comments that generate Java API docs — at least).
2. Check preconditions at entry and throw a clear exception when violated (`IllegalArgumentException`, `IllegalStateException`).
3. Check postconditions and invariants during development/testing (assertions or internal checks).
4. Give callers **query methods** to check preconditions themselves (`isEmpty()`, `isFull()`), so they can avoid violations.
5. With inheritance, obey the **contract rules of subtyping** (which is what the Liskov Substitution Principle formalises): a subclass may **weaken** (accept more) preconditions and **strengthen** (promise more) postconditions, never the reverse, and must preserve the invariant.

Java example — before/after

```java
// File: lld/ch05/contract/Main.java
package lld.ch05.contract;

import java.util.Arrays;

/** Design by Contract: preconditions (caller's duty), postconditions (method's promise), invariants (always true).
*/
public class Main {

    // ---------------- BEFORE: no stated contract; misuse silently corrupts state ----------------
    static class Before {
        static class BoundedStack {
            private final int[] items;
            private int size;
            BoundedStack(int capacity) { items = new int[Math.max(capacity, 0)]; }
            void push(int x) { if (size < items.length) items[size++] = x; }        // silently drops when full
            int pop() { return size > 0 ? items[--size] : -1; }                    // -1: is that data or an error?
        }
    }

    // ---------------- AFTER: every public method states and checks its contract ----------------
    static class After {
        static final class BoundedStack {
            private final int[] items;
            private int size;

            BoundedStack(int capacity) {
                require(capacity > 0, "capacity > 0");
                items = new int[capacity];
                checkInvariant();
            }
            /** pre: !isFull(). post: size() == old size + 1 and peek() == x. */
            void push(int x) {
                require(!isFull(), "push requires !isFull()");
                int oldSize = size;
                items[size++] = x;
                ensure(size == oldSize + 1 && peek() == x, "push postcondition");
                checkInvariant();
            }
            /** pre: !isEmpty(). post: size() == old size - 1. */
            int pop() {
                require(!isEmpty(), "pop requires !isEmpty()");
                int oldSize = size;
                int top = items[--size];
                ensure(size == oldSize - 1, "pop postcondition");
                checkInvariant();
                return top;
            }
            int peek() { require(!isEmpty(), "peek requires !isEmpty()"); return items[size - 1]; }
            boolean isEmpty() { return size == 0; }
            boolean isFull() { return size == items.length; }
            int size() { return size; }
            @Override public String toString() { return Arrays.toString(Arrays.copyOf(items, size)); }

            // invariant: 0 <= size <= capacity
            private void checkInvariant() { if (size < 0 || size > items.length) throw new
AssertionError("invariant broken"); }
            private static void require(boolean ok, String what) { if (!ok) throw new
IllegalStateException("precondition failed: " + what); }
            private static void ensure(boolean ok, String what) { if (!ok) throw new AssertionError("postcondition
failed: " + what); }
        }
    }

    public static void main(String[] args) {
        System.out.println("== BEFORE ==");
```

```
        var s = new Before.BoundedStack(2);
        s.push(1); s.push(2); s.push(3);                          // 3 vanishes
        System.out.println("pop=" + s.pop() + " pop=" + s.pop() + " pop=" + s.pop() + "   <-- 3 lost, -1
ambiguous");

        System.out.println("== AFTER ==");
        var t = new After.BoundedStack(2);
        t.push(1); t.push(2);
        System.out.println("stack " + t + " full=" + t.isFull());
        try { t.push(3); } catch (IllegalStateException e) { System.out.println(e.getMessage()); }
        System.out.println("pop=" + t.pop() + " pop=" + t.pop());
        try { t.pop(); } catch (IllegalStateException e) { System.out.println(e.getMessage()); }
    }
}
```

Output:

```
== BEFORE ==
pop=2 pop=1 pop=-1   <-- 3 lost, -1 ambiguous
== AFTER ==
stack [1, 2] full=true
precondition failed: push requires !isFull()
pop=2 pop=1
precondition failed: pop requires !isEmpty()
```

The *before* stack silently drops pushes when full and returns `-1` when empty (is `-1` a value or an error?). The *after* stack documents and enforces its contract: violations are reported immediately and precisely, and callers can check `isFull()`/`isEmpty()` first.

Trade-offs

Explicit contracts	Implicit
Clear responsibilities, precise errors	Less code
Documentation that can be executed	Ambiguity, defensive checks everywhere
Runtime cost of checks (can be disabled for postconditions/invariants in production)	Silent corruption

When not to use it

Full postcondition/invariant checking in performance-critical inner loops — keep precondition checks on public APIs, and move expensive postcondition checks into tests or `assert` statements.

Common mistakes

- Using `assert` for public preconditions (disabled by default).
- Subclasses strengthening preconditions (e.g. a `SavingsAccount.withdraw` that rejects amounts the base `Account.withdraw` contract allowed) — an LSP violation. (The classic `Square extends Rectangle` problem is the mirror case: `Square.setWidth` breaks the *postcondition* that the height stays unchanged.)
- Returning special values instead of stating a precondition.

Real-world examples

- **Java's own API docs** are contracts: `List.get(int)` states it throws `IndexOutOfBoundsException` if the index is out of range; `Comparable.compareTo` and `Object.equals`/`hashCode` specify contracts every implementation must honour (e.g. equal objects must have equal hash codes).
- **Guava** `Preconditions.checkArgument/checkState` and Spring's `Assert` utilities are precondition helpers.
- **Kotlin** `require()` / `check()` mirror preconditions and state checks.
- **Eiffel** has `require`, `ensure` and `invariant` built into the language; **Ada 2012** has `Pre`/`Post` aspects.

In the interview

> **30-second answer:** "Design by Contract defines preconditions the caller must satisfy, postconditions the method guarantees, and invariants always true for the object. I enforce preconditions with guard clauses, expose query methods like `isEmpty`, and remember that subclasses can only weaken preconditions and strengthen postconditions — that's LSP."

Follow-ups:

- *Q: DbC vs defensive programming?* A: Defensive programming checks everything everywhere; DbC assigns each check to one party — preconditions to the caller (verified at entry), postconditions to the supplier.
- *Q: Which exceptions fit?* A: `IllegalArgumentException` for bad arguments, `IllegalStateException` when the object's state forbids the call, `NullPointerException` for nulls (via `requireNonNull`).

Self-check

1. Q: Whose duty is a precondition? → A: The caller's.
2. Q: What can a subclass do to preconditions? → A: Weaken (accept more), never strengthen.
3. Q: State the invariant of a bounded stack. → A: `0 ≤ size ≤ capacity`.

TL;DR

State and enforce who promises what: preconditions (caller), postconditions (method), invariants (always).

---

16. GRASP — General Responsibility Assignment Software Patterns

What it is

GRASP is a set of nine patterns (Larman calls them patterns; many people say principles or guidelines) by Craig Larman, from *Applying UML and Patterns* (UML, the Unified Modeling Language, is the standard diagram notation for classes and their interactions), for the most frequent question in object design: **"Which class should be responsible for this?"** A *responsibility* is either *knowing* something (data, related objects, derived values) or *doing* something (computing, creating, coordinating). GRASP is a thinking aid — a vocabulary for justifying design decisions — rather than a set of code templates.

History note: GRASP first appeared in the book's 1st edition (1997), where the ninth item was "Don't Talk to Strangers" (the Law of Demeter). From the 2nd edition (2001) it was replaced by the more general **Protected Variations**, giving the nine listed below.

#	GRASP guideline	Question it answers	Short answer
1	Information Expert	Who does this job?	The class that has the information needed
2	Creator	Who creates an object A?	A class that contains, records, closely uses or has the data to initialise A
3	Controller	Who first handles a system event from the UI?	A non-UI object representing the use case (one user goal, e.g. checkout) or the whole system
4	Low Coupling	How do we reduce the impact of change?	Assign responsibilities to keep dependencies few
5	High Cohesion	How do we keep classes focused and understandable?	Assign responsibilities so each class does related work
6	Polymorphism	How do we handle behaviour that varies by type?	Give each type its own implementation of a shared operation
7	Pure Fabrication	What if no domain class fits without hurting cohesion/coupling?	Invent a helper class (e.g. a repository)
8	Indirection	How do we avoid direct coupling between two things?	Put an intermediate object between them
9	Protected Variations	How do we shield elements from changes in others?	Wrap points of instability behind a stable interface

Analogy: staffing a hospital. The person who has the patient's chart (Expert) writes the summary; the maternity ward registers newborns (Creator); the front desk routes every visitor to the right department (Controller); nobody needs to know everyone (Low Coupling); each department has a focused speciality (High Cohesion).

The problem it solves

Beginners often end up with one "god" class (one class that knows and does far too much — often the UI screen or a `Manager`) that knows everything, and many anemic data classes. Or they spread logic randomly so that no one knows where anything lives. GRASP gives repeatable reasons for placing each responsibility, which also makes your interview explanations concrete ("I put `total()` on `Sale` because it's the Information Expert").

How it works

1. List the system events/use cases (e.g. `scan item`, `pay`).
2. For each event, choose a **Controller** to receive it.
3. For each thing that must be *known* or *computed*, find the **Information Expert**.
4. For each object that must be *created*, find the **Creator**.
5. Check **Low Coupling** and **High Cohesion** as evaluative forces; if a choice hurts them, reconsider.
6. Where behaviour varies by type, use **Polymorphism**; where an external or unstable thing touches you, use **Protected Variations** via **Indirection** (an interface or adapter — a class that converts one interface into the one your code expects).
7. When no domain object is a good home (persistence, I/O — input/output such as files and network calls), create a **Pure Fabrication**.

Java example — before/after (all nine in one checkout)

The *before* is a UI `CheckoutScreen` that creates line items, reaches into them to total the sale, hard-codes tax rules and builds SQL. The *after* assigns each responsibility using GRASP; each class's Javadoc names the guideline it illustrates.

```java
// File: lld/ch05/grasp/Main.java
package lld.ch05.grasp;

import java.math.BigDecimal;
import java.math.RoundingMode;
import java.util.ArrayList;
import java.util.HashMap;
import java.util.List;
import java.util.Map;

/**
 * GRASP on a tiny checkout: who should do what?
 * Information Expert, Creator, Controller, Low Coupling, High Cohesion,
 * Polymorphism, Pure Fabrication, Indirection, Protected Variations.
 */
public class Main {

    record Product(String sku, String name, BigDecimal price) {}

    // ---------------- BEFORE: a "god" screen class does everything ----------------
    static class Before {
        static class LineItem { Product product; int qty; }
        static class Sale { List<LineItem> items = new ArrayList<>(); }

        /** UI class that computes totals, calls the tax vendor directly and builds SQL. */
        static class CheckoutScreen {
            final Sale sale = new Sale();
            final List<String> sqlLog = new ArrayList<>();
            void onScan(Product p, int qty) {
                LineItem li = new LineItem();               // UI creates domain parts
                li.product = p; li.qty = qty;
                sale.items.add(li);
            }
            void onPayClicked(String region) {
                BigDecimal total = BigDecimal.ZERO;         // UI reaches into Sale -> LineItem -> Product
                for (LineItem li : sale.items) total =
total.add(li.product.price().multiply(BigDecimal.valueOf(li.qty)));
                BigDecimal tax = region.equals("IN") ? total.multiply(new BigDecimal("0.18"))   // vendor rule
inline
                        : total.multiply(new BigDecimal("0.07"));
                sqlLog.add("INSERT INTO sales VALUES(" + total.add(tax) + ")");
                System.out.println("screen shows total " + total.add(tax).setScale(2, RoundingMode.HALF_UP));
            }
        }
    }

    // ---------------- AFTER: responsibilities assigned with GRASP ----------------
    static class After {

        /** INFORMATION EXPERT: a line item knows its product and quantity, so it computes its own subtotal. */
        record LineItem(Product product, int qty) {
            BigDecimal subtotal() { return product.price().multiply(BigDecimal.valueOf(qty)); }
        }

        /** EXPERT for the total + CREATOR of LineItems (a Sale contains/aggregates them). HIGH COHESION: only sale
logic. */
        static final class Sale {
            private final String id;
            private final List<LineItem> items = new ArrayList<>();
            Sale(String id) { this.id = id; }
            void addItem(Product p, int qty) { items.add(new LineItem(p, qty)); }        // Creator
            BigDecimal total() { return items.stream().map(LineItem::subtotal).reduce(BigDecimal.ZERO,
BigDecimal::add); }
            String id() { return id; }
            List<LineItem> items() { return List.copyOf(items); }
        }

        /** PROTECTED VARIATIONS: tax rules vary by region/vendor -> hide them behind a stable interface. */
```

```
        interface TaxCalculator { BigDecimal taxFor(Sale sale); }

        /** POLYMORPHISM: each variant is its own type; no if/else on region in the domain. */
        static final class IndiaGst implements TaxCalculator {
            public BigDecimal taxFor(Sale s) { return s.total().multiply(new BigDecimal("0.18")); }
        }
        static final class FlatUsSalesTax implements TaxCalculator {
            public BigDecimal taxFor(Sale s) { return s.total().multiply(new BigDecimal("0.07")); }
        }

        /** A third-party library with its own, awkward API (we don't control it): it even returns tax as a double.
*/
        static final class LegacyTaxEngine {
            double computeTaxCents(long amountCents, String countryCode) { return amountCents *
("GB".equals(countryCode) ? 0.20 : 0.0); }
        }
        /** INDIRECTION: an adapter sits between our domain and the vendor, so neither knows the other. */
        static final class LegacyTaxAdapter implements TaxCalculator {
            private final LegacyTaxEngine engine; private final String country;
            LegacyTaxAdapter(LegacyTaxEngine engine, String country) { this.engine = engine; this.country =
country; }
            public BigDecimal taxFor(Sale s) {   // converts to/from the vendor's types at the boundary only
                long cents = s.total().movePointRight(2).longValueExact();
                return BigDecimal.valueOf(Math.round(engine.computeTaxCents(cents, country))).movePointLeft(2);
// whole cents
            }
        }

        /** PURE FABRICATION: not a domain concept -- invented to keep persistence out of Sale (cohesion +
coupling). */
        interface SaleRepository { String nextId(); void save(Sale sale, BigDecimal grandTotal); int count(); }
        static final class InMemorySaleRepository implements SaleRepository {
            private final Map<String, BigDecimal> rows = new HashMap<>();
            private int seq;
            public String nextId() { return "S" + (++seq); }
            public void save(Sale s, BigDecimal g) { rows.put(s.id(), g); }
            public int count() { return rows.size(); }
        }

        /** CONTROLLER: the first non-UI object that receives system events (scan, pay) and delegates. LOW
COUPLING: depends on interfaces. */
        static final class CheckoutController {
            private final TaxCalculator tax; private final SaleRepository repo;
            private Sale current;
            CheckoutController(TaxCalculator tax, SaleRepository repo) { this.tax = tax; this.repo = repo; }
            void startSale() { current = new Sale(repo.nextId()); }
            void scan(Product p, int qty) { current.addItem(p, qty); }
            BigDecimal pay() {
                BigDecimal grand = current.total().add(tax.taxFor(current)).setScale(2, RoundingMode.HALF_UP);
                repo.save(current, grand);
                return grand;
            }
        }
    }

    public static void main(String[] args) {
        Product tea = new Product("T1", "Tea", new BigDecimal("120.00"));
        Product cup = new Product("C1", "Cup", new BigDecimal("80.00"));

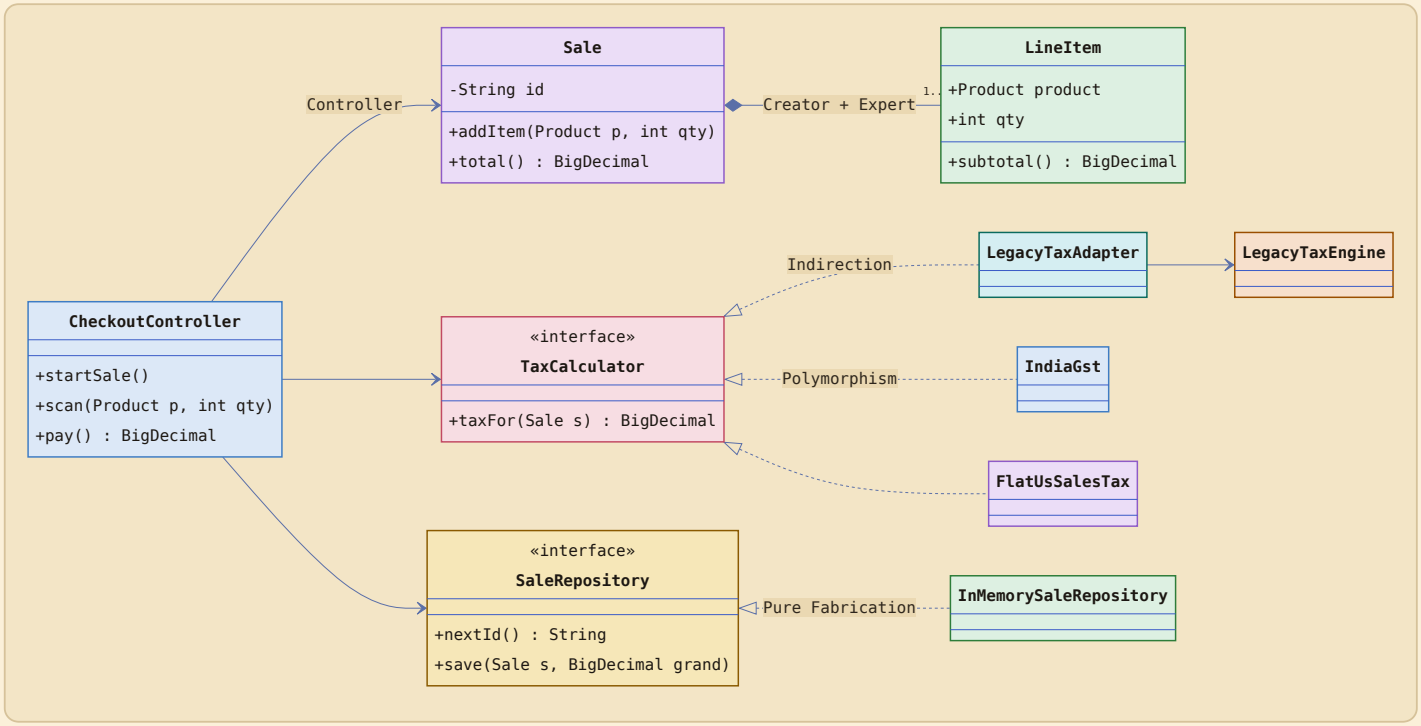
        System.out.println("== BEFORE ==");
        var screen = new Before.CheckoutScreen();
        screen.onScan(tea, 2); screen.onScan(cup, 1);
        screen.onPayClicked("IN");
        System.out.println("sql: " + screen.sqlLog);

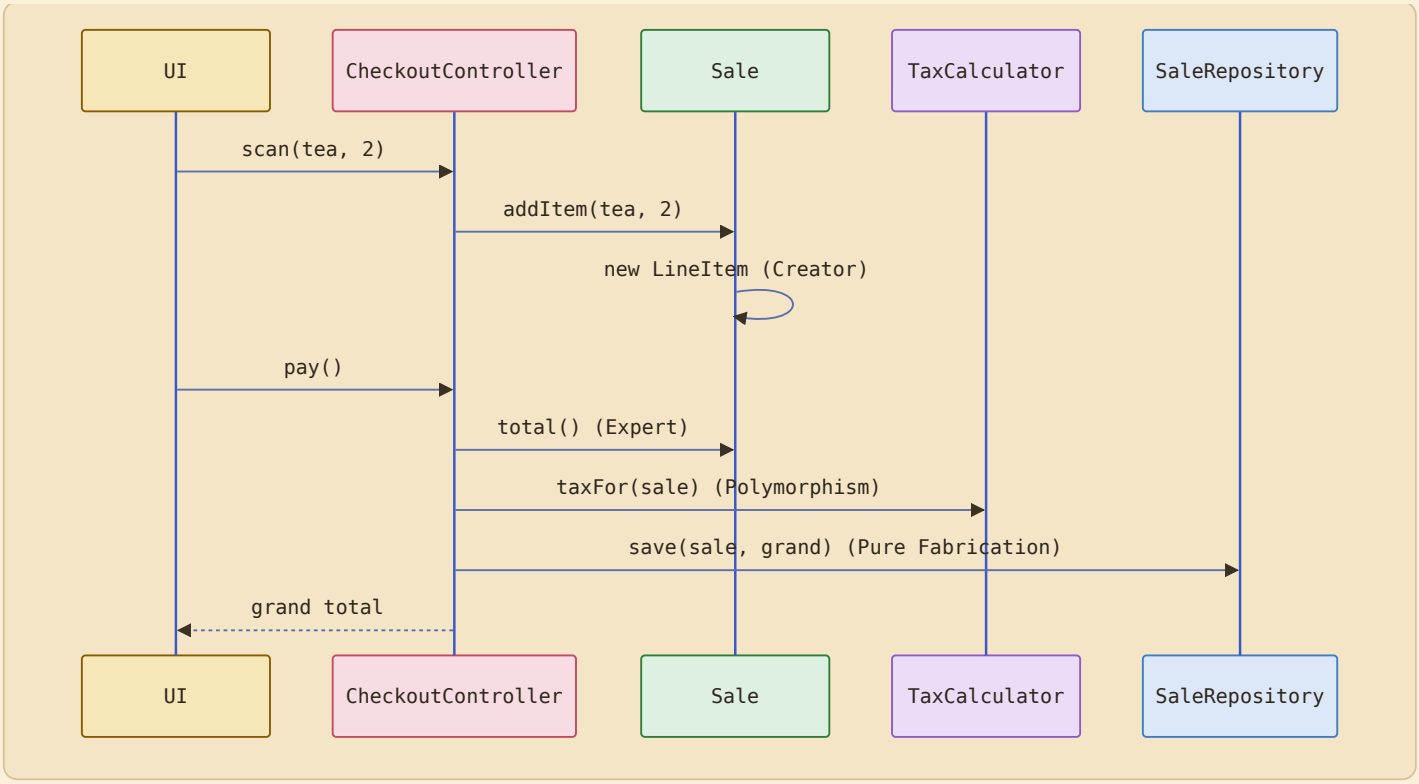
        System.out.println("== AFTER ==");
        var repo = new After.InMemorySaleRepository();
        for (After.TaxCalculator calc : List.of(new After.IndiaGst(), new After.FlatUsSalesTax(),
                new After.LegacyTaxAdapter(new After.LegacyTaxEngine(), "GB"))) {
```

```
            var controller = new After.CheckoutController(calc, repo);
            controller.startSale();
            controller.scan(tea, 2);
            controller.scan(cup, 1);
            System.out.println(calc.getClass().getSimpleName() + " -> grand total " + controller.pay());
        }
        System.out.println("sales saved: " + repo.count());
    }
}
```

Output:

```
== BEFORE ==
screen shows total 377.60
sql: [INSERT INTO sales VALUES(377.6000)]
== AFTER ==
IndiaGst -> grand total 377.60
FlatUsSalesTax -> grand total 342.40
LegacyTaxAdapter -> grand total 384.00
sales saved: 3
```





The rest of this section explains each guideline in the book's standard format.

16.1 Information Expert

What it is

Give a responsibility to the class that **has the information** needed to fulfil it. `LineItem` knows price and quantity → it computes `subtotal()`. `Sale` knows its line items → it computes `total()`.

The problem it solves

Prevents "manager" classes that pull data out of other objects to compute things (the *Feature Envy* smell), which duplicates logic and couples the manager to everyone's internals.

How it works

1. State the responsibility ("compute sale total").
2. Ask what information is needed (line item subtotals).
3. Find who holds it (Sale holds line items; each LineItem holds price × qty).
4. Split the work along those lines — partial experts cooperate.

Trade-offs

Keeps behaviour with data (Tell-Don't-Ask). But blindly applying it can hurt cohesion: `Sale` has the data to save itself, yet putting SQL into `Sale` mixes concerns — that's why Pure Fabrication exists.

When not to use it

When following it would put technical concerns (persistence, UI, network) into domain objects.

Common mistakes

Computing everything in a service with getters; or the opposite, making an entity save/print/email itself.

Real-world examples

`String.length()`, `List.size()`, `LocalDate.isLeapYear()` — the object with the data answers. In a Swiggy/Zomato-style cart, the `Cart` computes its own item total.

In the interview

"`total()` lives on `Order` because it owns the line items — Information Expert. Each `LineItem` computes its own subtotal." *Follow-up: when does Expert conflict with other principles?* When it would add persistence or UI to a domain class; then use Pure Fabrication.

Self-check

Q: Who should compute a line item's subtotal? → A: `LineItem` — it has price and quantity.

TL;DR

The one with the data does the work.

16.2 Creator

What it is

Class **B** should create instances of class **A** if one or more is true: B *contains* or aggregates A; B *records* A; B *closely uses* A; B *has the initialising data* for A. Here `Sale` creates `LineItem`s.

The problem it solves

Who calls `new`? Random placement spreads coupling to A's constructor everywhere. Choosing a class that already relates to A adds no new coupling.

How it works

1. Find the class that aggregates/contains A (strongest reason).
2. Otherwise one that records or closely uses it, or has its initial data.
3. If creation is complex or varies (families, pooling, choosing a subclass), use a **Factory** or **Builder** instead (Chapter 8).

Trade-offs

Simple and low-coupling for plain objects; not suitable when creation logic is complex or conditional.

When not to use it

Complex creation → Factory/Builder; framework-managed objects → DI container.

Common mistakes

UI or controller code doing `new LineItem(...)` and pushing it into the sale's list (the *before* code).

Real-world examples

`HashMap` creating its own internal node objects for the entries it contains; a `Document` creating its `Paragraph`s; `Thread` objects created by an `ExecutorService` through its `ThreadFactory` (a factory, because creation varies).

In the interview

"`Sale.addItem(product, qty)` creates the `LineItem` because the sale contains them — GRASP Creator. If creation got complex I'd move it to a factory." *Follow-up: Creator vs Factory?* Creator picks an existing class that already relates to A (no new coupling); a Factory is a Pure Fabrication you add when creation is complex or must choose among subclasses.

Self-check

Q: Strongest reason for B to create A? → A: B contains/aggregates A.

TL;DR

The container (or the one with the initial data) creates.

16.3 Controller

What it is

The first object **beyond the UI layer** that receives and coordinates a **system operation** (an event from an actor — a person or external system using ours — such as "scan item" or "pay"). Two kinds: a **facade controller** representing the whole system/device (e.g. `Register`, `ParkingLotSystem`) or a **use-case controller** for one scenario (e.g. `CheckoutController`, `BookTicketHandler`).

The problem it solves

Keeps business logic out of UI classes, so the same logic works from a web page, a mobile app or a test, and the UI can change freely.

How it works

1. List system events from use cases.
2. Assign each to a controller that represents the system or the use case.
3. The controller **delegates** — it coordinates, it doesn't do the domain work itself.

Trade-offs

Clean UI/domain separation; but a controller that does real work becomes **bloated** (low cohesion, many responsibilities) — split into use-case controllers and push work to experts.

When not to use it

Very small programs where the UI and logic are trivial.

Common mistakes

Fat controllers containing pricing, validation and SQL. Controllers that are UI classes (e.g. a Swing `JFrame` computing totals).

Real-world examples

Spring `@RestController` → `@Service` (the service often plays GRASP Controller for a use case); `DispatcherServlet` is a front controller (a single entry point that receives every web request and routes it); in an Uber-like app a `TripService.requestRide()` handles the rider's "request ride" event.

In the interview

"`ParkingLotController.park(vehicle)` receives the system event and delegates to `ParkingFloor` and `SpotAllocator` — GRASP Controller, kept thin." *Follow-up: facade or use-case controller?* A facade controller (one per system) is fine while there are few system events; when it grows bloated, split into use-case controllers (one per scenario).

Self-check

Q: Should a controller calculate tax? → A: No — it delegates to the expert or a tax strategy.

TL;DR

A thin non-UI coordinator receives each system event and delegates.

16.4 Low Coupling

What it is

An **evaluative** guideline: among design choices, prefer the one that keeps **dependencies between classes low**. Here the controller depends only on interfaces (`TaxCalculator`, `SaleRepository`), not on vendors or databases.

The problem it solves

High coupling means changes ripple, classes can't be reused alone, and understanding one class requires understanding many.

How it works

Compare alternatives by counting and weighing dependencies: who knows about whom? Prefer interfaces, fewer collaborators, one-directional dependencies, no cycles. Use DI.

Trade-offs

Coupling to *stable* things (JDK, `String`, `List`) is harmless. Striving for zero coupling produces bloated indirection.

When not to use it

Don't decouple from stable, standard libraries — focus on unstable or external dependencies.

Common mistakes

Circular dependencies between packages; UI knowing the database; everything depending on a god class.

Real-world examples

Microservices communicating over well-defined APIs/events; JDBC drivers decoupled from application code by interfaces.

In the interview

"My service depends on `PaymentGateway`, not on Stripe's SDK (Software Development Kit — the vendor's client library), so switching provider touches one adapter." *Follow-up: can coupling ever be zero?* No — objects must collaborate. Aim for few dependencies, pointing at stable abstractions, with no cycles.

Self-check

Q: Is depending on `java.util.List` bad coupling? → A: No — it is stable.

TL;DR

Choose the design with fewer, more stable dependencies.

16.5 High Cohesion

What it is

The other **evaluative** guideline: keep each class's responsibilities **focused and related**, so it's easy to understand and maintain. `Sale` does sale maths; persistence is in the repository; tax is in the calculator.

The problem it solves

Low-cohesion classes (e.g. `Utils`, `Manager`, a screen doing everything) are hard to understand, reuse and change; they change for many reasons (violating SRP).

How it works

When adding a responsibility, ask "is this related to what the class already does?" If not, place it elsewhere or create a new class. Larman describes four levels, from worst to best: *very low* (one class responsible for many things in very different areas) → *low* (one class alone responsible for a big, complex job in one area) → *moderate* (a few light responsibilities in different areas that relate to the class concept but not to each other) → *high* (a moderate number of related responsibilities in one area, collaborating with other objects for the rest — the goal).

Trade-offs

Many small focused classes vs a few big ones — more files, but each is simple. Coupling and cohesion usually improve together.

When not to use it

Rarely; sometimes grouping for performance (e.g. a remote API returning coarse-grained data) lowers cohesion on purpose.

Common mistakes

"Helper" and "Utils" dumping grounds; entities that also send emails.

Real-world examples

`java.time.LocalDate` (dates only), `java.util.regex.Pattern` (regex only). Spring Data repositories focus purely on persistence.

In the interview

"I split `BookingService` into seat locking, pricing and payment so each class has one focused job — high cohesion." *Follow-up: how do cohesion and coupling interact?* They usually improve together: moving unrelated work out of a class raises its cohesion and removes the dependencies that work dragged in.

Self-check

Q: Name a common low-cohesion smell. → A: A `Utils`/`Manager` class with unrelated methods.

TL;DR

Each class does one related set of things.

16.6 Polymorphism

What it is

When behaviour **varies by type**, give each type its own implementation of a shared operation (an interface method), instead of branching on the type with `if/else` or `switch`. `IndiaGst`, `FlatUsSalesTax` and `LegacyTaxAdapter` each implement `taxFor`.

The problem it solves

Type-checking conditionals repeated across the code; adding a type means finding and editing every branch (violates OCP).

How it works

1. Identify the operation that varies (`taxFor`).
2. Declare it on an interface/abstract class.
3. Implement it per variant.
4. Callers invoke it without knowing the concrete type.

Trade-offs

Easy to add new types; harder to add new operations across all types (you must touch each class — the Visitor pattern, Chapter 11, flips this trade-off).

When not to use it

For closed sets of types where you often add *operations*, a `switch` over a `sealed` hierarchy (Java 21 pattern matching — a `switch` that tests an object's type and unpacks it in one step) can be clearer.

Common mistakes

Creating polymorphic classes for variation that doesn't exist (YAGNI); `instanceof` chains after introducing the interface.

Real-world examples

`Comparator` implementations, `InputStream` subclasses, `Runnable`/`Callable`, payment methods in any checkout (card, UPI, wallet).

In the interview

"Instead of `if (vehicle instanceof Car)`, each `Vehicle` type answers `requiredSpotSize()` — GRASP Polymorphism." *Follow-up: what if I need a new operation across all types?* Adding it touches every class; if that happens often, consider a `sealed` hierarchy with pattern-matching `switch`, or the Visitor pattern.

Self-check

Q: Which kind of change does polymorphism make easy? → A: Adding a new type/variant.

TL;DR

Let each type implement the varying behaviour; don't switch on types.

16.7 Pure Fabrication

What it is

A class that **doesn't represent a real-world domain concept**, invented purely to keep high cohesion and low coupling when Information Expert would give a bad result. `SaleRepository` is a fabrication: the shop has no "repository", but putting SQL into `Sale` would ruin cohesion.

The problem it solves

Some responsibilities (persistence, logging, ID generation, messaging) don't fit any domain class without dragging technical concerns into it.

How it works

1. Notice the Expert choice would make a domain class do technical work.
2. Create a service class whose name describes the job (`SaleRepository`, `NotificationSender`, `IdGenerator`).
3. Keep it focused and reusable.

Trade-offs

Great for cohesion/reuse; overusing it produces an anemic domain where all behaviour sits in "services".

When not to use it

When a real domain object is a natural home — prefer the Expert first.

Common mistakes

Moving domain logic (pricing, rules) into fabricated "Manager" services.

Real-world examples

DAOs (Data Access Objects — classes that hide database queries)/repositories, `ObjectMapper` (Jackson, the common Java JSON library), `Clock` providers, Spring `@Service` classes for infrastructure, most GoF helper objects (Strategy, Adapter, Factory objects are fabrications).

In the interview

"`TicketRepository` isn't a domain thing — it's a pure fabrication that keeps persistence out of `Ticket`." *Follow-up: risk of too many fabrications?* An anemic domain: all rules drift into "service" classes. Keep domain rules on domain objects (Expert) and fabricate only for technical or cross-cutting work.

Self-check

Q: Is `Sale` a pure fabrication? → A: No — it's a domain concept. `SaleRepository` is.

TL;DR

Invent a helper class when no domain class is a clean home.

16.8 Indirection

What it is

Assign a responsibility to an **intermediate object** that mediates between two components so they aren't directly coupled. `LegacyTaxAdapter` sits between our `CheckoutController` and the vendor's `LegacyTaxEngine`.

The problem it solves

Direct dependencies on external or volatile components (vendor SDKs, hardware, other subsystems).

How it works

Introduce an interface plus an adapter, a facade, a mediator (a hub that objects talk through instead of to each other) or a proxy; the two sides talk through it.

Trade-offs

Decoupling vs an extra hop (small performance cost and one more class to read). A famous saying, usually attributed to David Wheeler, is that any problem in computer science can be solved by another level of indirection; the usual retort is "except the problem of too many levels of indirection".

When not to use it

Between stable, cohesive classes that always change together.

Common mistakes

Layers that add nothing (pure pass-through), making navigation painful.

Real-world examples

Adapter/Facade/Mediator/Proxy patterns; JDBC's `DriverManager`; API gateways in microservices (a single front door that routes client calls to many services); message brokers between producers and consumers.

In the interview

"I don't call the SMS vendor directly — an `SmsSender` interface with a `TwilioSmsSender` adapter provides indirection." *Follow-up: Indirection vs Protected Variations?* Indirection is the mechanism (an intermediate object); Protected Variations is the goal (shield the rest of the system from a point of change). Indirection is one common way to achieve it.

Self-check

Q: Which GoF patterns are forms of indirection? → A: Adapter, Facade, Mediator, Proxy (and Bridge).

TL;DR

Put a middleman between things that shouldn't know each other.

16.9 Protected Variations

What it is

Identify **points of predicted variation or instability** and wrap them with a **stable interface**, so variation doesn't ripple to other elements. `TaxCalculator` protects the checkout from tax-rule and vendor changes. Larman notes it is essentially David Parnas's *information hiding* (keeping design decisions that may change hidden inside one module) and Meyer's Open/Closed Principle stated as a responsibility guideline (and close to "encapsulate what varies"); the Law of Demeter — GRASP's "Don't Talk to Strangers" in the 1st edition — is one mechanism for it.

The problem it solves

Changes in one place (a vendor, a regulation, a format) forcing edits throughout the system.

How it works

1. Find variation points (external systems, rules that change, platforms).
2. Define a stable interface around each.
3. Put variants behind it (Polymorphism, Indirection, data-driven config).

Trade-offs

Protection has a cost; over-protecting things that never vary ("speculative generality") adds complexity. Protect *predicted* variation.

When not to use it

Stable, unlikely-to-change code (YAGNI).

Common mistakes

Leaky interfaces that expose vendor-specific types (e.g. returning a `StripeCharge` from `PaymentGateway`).

Real-world examples

JDBC, JPA, SLF4J, Java's `ServiceLoader` for pluggable providers; `java.nio.file.FileSystem` abstraction for different file systems.

In the interview

"Payment providers are a variation point, so `PaymentGateway` is my protected variation — the booking flow never sees provider details." *Follow-up: which variation points should you protect?* Predicted ones — external vendors, regulations, formats, platforms — not every class (that is speculative generality).

Self-check

Q: Which SOLID principle is closest to Protected Variations? → A: Open/Closed (also Dependency Inversion).

TL;DR

Wrap what's unstable behind a stable interface.

GRASP in the interview (whole set)

> **30-second answer:** "GRASP is Larman's set of nine guidelines for assigning responsibilities. I use Information Expert and Creator to place most behaviour, a thin Controller for system events, Polymorphism and Protected Variations for things that vary, Indirection and Pure Fabrication to keep technical concerns out of the domain, and I judge every choice by Low Coupling and High Cohesion."

Follow-ups:

- *Q: How does GRASP relate to GoF patterns?* A: GRASP is more fundamental: patterns like Strategy (Polymorphism + Protected Variations), Adapter (Indirection) and Repository (Pure Fabrication) are specific applications.
- *Q: Which two GRASP items are evaluative rather than assignment rules?* A: Low Coupling and High Cohesion — you use them to compare alternatives.
- *Q: Expert says `Sale` should save itself — why not?* A: It hurts cohesion and couples the domain to storage; use a Pure Fabrication (repository).

Self-check (GRASP)

1. Q: Who handles the "pay" button event after the UI? → A: A Controller (use-case or facade).
2. Q: Which guideline justifies an adapter around a vendor library? → A: Indirection (serving Protected Variations).
3. Q: Name the guideline for inventing `IdGenerator`. → A: Pure Fabrication.

TL;DR

Put work where the data is, let containers create, keep controllers thin, vary by polymorphism behind stable interfaces, invent helpers when needed — and judge it all by coupling and cohesion.

---

17. Domain-Driven Design (DDD) Essentials

What it is

Domain-Driven Design is an approach, named by Eric Evans in *Domain-Driven Design: Tackling Complexity in the Heart of Software* (2003), for building software whose code mirrors the business it serves. The **domain** is the subject area the software is about — lending, shipping, grocery retail. DDD has two halves:

- **Strategic design** — how to split a large business into parts, each with its own model: **ubiquitous language**, **bounded contexts**, **context maps** and the **anti-corruption layer**.
- **Tactical design** — the building blocks *inside* one part: **entities**, **value objects**, **aggregates**, **domain events**, **repositories**, plus domain services and factories.

The principles earlier in this chapter tell you how to shape classes; DDD tells you **which classes to have and where their boundaries are**, starting from the business rather than the database.

Analogy: a hospital. The word "patient" means one thing at the reception desk (name, insurance, appointment), another in the operating theatre (blood type, allergies, vitals) and another in billing (procedures, amounts owed). Each department keeps its own file with its own vocabulary; they exchange only what they need. Forcing one giant "Patient" form on all three would please nobody. Each department is a bounded context.

Key terms (defined once):

Term	Meaning
Ubiquitous language	The shared vocabulary that domain experts and developers both use — in conversation, in documents *and in the code*. If the business says "place an order", the method is `place()`, not `setStatus(2)`.
Bounded context	A boundary inside which one model and one language apply consistently. The same word may mean something different in another context (a Sales "order" vs a Shipping "consignment"). Often one team and one service.
Context map	A picture of the bounded contexts and how they relate (who depends on whom, who translates).
Anti-corruption layer (ACL)	A translation layer at a context's border that converts another context's (or a legacy — old, still-running — system's) model into yours, so theirs cannot leak in.
Entity	An object defined by its **identity**, which stays the same while its attributes change (an `Order` with id 1001 is the same order after items are added). Equality = same id.
Value object	An object defined only by its **attributes**, with no identity; immutable; interchangeable when equal (`Money(₹350)`, an `Address`, a `DateRange`). Equality = same values.
Aggregate	A cluster of entities and value objects treated as **one unit for changes**, with one entity as its **aggregate root** — the only object outsiders may hold or call. The root enforces the cluster's invariants.
Domain event	A record of something that happened that the business cares about, named in the past tense (`OrderPlaced`, `PaymentFailed`). Other parts react to it.
Repository	A collection-like interface for loading and saving **aggregates** (one repository per aggregate root), hiding the database (Chapter 11, §11.7.3).
Domain service	An operation that belongs to the domain but not naturally to one entity (e.g. "transfer money between two accounts"). Stateless.

The problem it solves

Big business systems fail less from bad algorithms than from **muddled models**:

- **One model for everything.** A single `Customer` or `Product` class grows fields for every department until nobody can change it safely (a "big ball of mud").

- **Translation errors.** Developers call it `status=3`, the business calls it "on hold"; requirements get lost between the two vocabularies.
- **Anemic domain model** (Martin Fowler's term): classes are data bags with getters and setters, and every rule lives in services. Rules get duplicated, and anyone can put an object into an invalid state (Tell, Don't Ask — section 5 — violated at scale).
- **No consistency boundary.** Without aggregates, code updates any object anywhere, locking and transactions sprawl, and invariants ("an order's total never exceeds the credit limit") are checked in some paths but not others.
- **Tight coupling between teams.** If Shipping reads Sales' tables directly, Sales cannot change its schema without breaking Shipping.

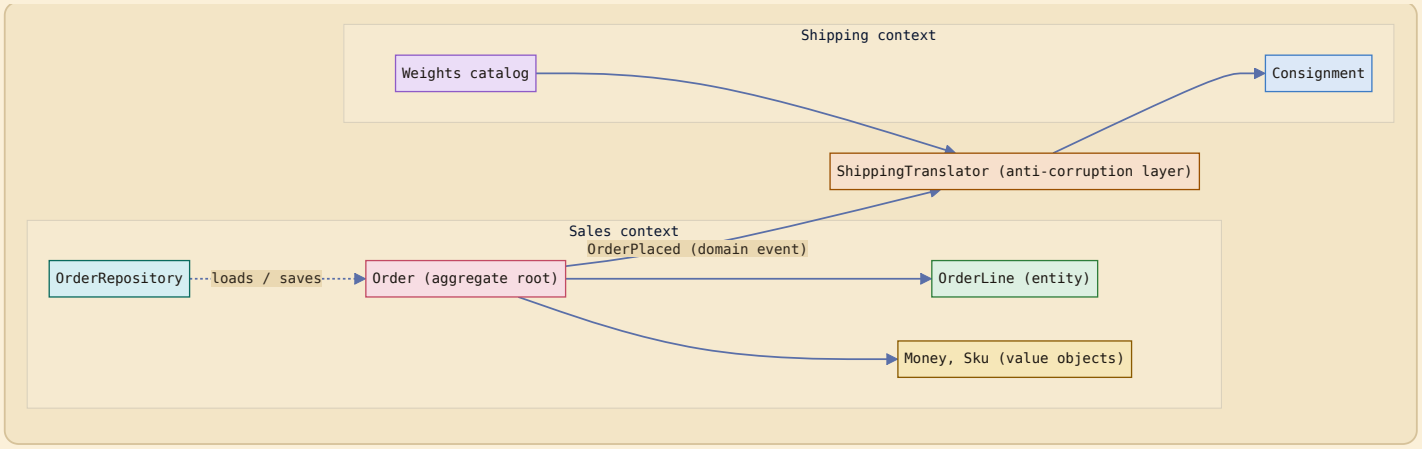
How it works

Strategic design — split by meaning, not by table

1. **Talk to domain experts and write down the language.** Nouns become candidate entities and value objects, verbs become methods, "when X happens" becomes a domain event.
2. **Draw the bounded contexts.** Where the same word starts meaning different things, you have a boundary. In an e-commerce business: *Catalog* (product descriptions, images), *Sales* (orders, prices, promotions), *Payments*, *Shipping* (parcels, weights, carriers), *Support*.
3. **Decide how contexts talk (the context map).** The common relationships: one side publishes events or an API and the other consumes it; a **shared kernel** (a small shared library both own — use sparingly); **conformist** (you simply accept the other model); and the **anti-corruption layer** (you translate the other model into yours — the safest choice against a legacy or third-party system).
4. **Map contexts to teams and services.** A bounded context is the most natural boundary for a microservice; that is why DDD is the usual starting point for splitting a monolith (an application built and deployed as one single unit) (see the Strangler Fig notes for migrating piece by piece).

Tactical design — the building blocks inside one context

- **Prefer value objects.** Wrap primitives (raw built-in types such as `double` or `String`) that carry rules: `Money` (amount + currency, no negatives), `Email`, `Quantity`, `DateRange`. They are immutable (section 14), validate themselves (Fail fast, section 13) and make method signatures honest (`transfer(Money)` instead of `transfer(double)`).
- **Entities have identity and a lifecycle.** Give them an id value object (`OrderId`), and methods named in the ubiquitous language that protect their invariants.
- **Aggregate design rules** (from Vaughn Vernon's *Implementing Domain-Driven Design*, 2013):
  1. Protect **true invariants** inside the aggregate boundary — the things that must be consistent *immediately*.
  2. Keep aggregates **small** (often the root plus a few value objects or child entities).
  3. **Reference other aggregates by id**, not by object (`CustomerId`, not `Customer`).
  4. **Change one aggregate per transaction**; keep other aggregates in step through domain events (**eventual consistency** — the other aggregates catch up shortly afterwards instead of instantly; see System Design Fundamentals).
- **Domain events** are raised inside the aggregate when a state change happens, and published **after** the change is saved. In a database-backed system the reliable way is the **transactional outbox**: write the event to an outbox table in the same transaction as the aggregate, and let a relay publish it (see the Saga notes and Event-Driven Architecture notes).
- **Repositories** exist only for aggregate roots (`OrderRepository`, never `OrderLineRepository`), because outsiders may only reach an `OrderLine` through its `Order`.
- **Application services** (a thin layer above the domain) load an aggregate from its repository, call one domain method, save it — they orchestrate, the aggregate decides (GRASP Controller, section 16.3).
- **Reads can use a different model.** When screens need data joined across aggregates, a separate read model fed by domain events is often simpler — that is **CQRS** (Command Query Responsibility Segregation — separate models for writing and reading; see the CQRS notes); storing the events themselves as the source of truth is **Event Sourcing** (Chapter 11, §11.7.6).



Shipping context
Weights catalog
Consignment
ShippingTranslator (anti-corruption layer)
Sales context
OrderPlaced (domain event)
OrderRepository
loads / saves
Order (aggregate root)
OrderLine (entity)
Money, Sku (value objects)

Java example — before/after

```java
// File: lld/ch05/ddd/Main.java
package lld.ch05.ddd;

import java.util.ArrayList;
import java.util.HashMap;
import java.util.List;
import java.util.Map;
import java.util.Objects;
import java.util.Optional;
import java.util.function.Consumer;

/** Domain-Driven Design, tactical building blocks: value objects, entities, an aggregate, domain events, a
repository, and two bounded contexts. */
public class Main {

    // ---------------- BEFORE: an anemic model — data bags with setters, rules scattered in services ------------
---
    static class Before {
        static class OrderLine { public String sku; public int qty; public double price; }
        static class Order {
            public List<OrderLine> lines = new ArrayList<>();
            public String status = "NEW";
            public double total;
        }
        static class OrderService {                       // the only place that "knows" the rules... in theory
            void addLine(Order o, String sku, int qty, double price) {
                OrderLine l = new OrderLine(); l.sku = sku; l.qty = qty; l.price = price;
                o.lines.add(l);
                o.total += qty * price;
            }
        }
    }

    // ---------------- AFTER: the rules live inside the model, in the business's own words ----------------
    static class After {
        /** Value object: no identity, immutable, equal when all fields are equal, validates itself. */
        record Money(long paise) {
            Money { if (paise < 0) throw new IllegalArgumentException("Money cannot be negative"); }
            static Money rupees(long r) { return new Money(r * 100); }
            Money plus(Money o) { return new Money(paise + o.paise); }
            Money times(int n) { return new Money(paise * n); }
            @Override public String toString() { return "Rs %d.%02d".formatted(paise / 100, paise % 100); }
        }
        record OrderId(String value) { }
        record CustomerId(String value) { }               // another aggregate is referenced by ID, not by object
        record Sku(String code) { }

        /** Domain events: facts, named in the past tense, that other parts of the system react to. */
        sealed interface DomainEvent permits OrderPlaced, OrderCancelled { }
        record OrderPlaced(OrderId orderId, CustomerId customer, Map<Sku, Integer> quantities, Money total)
implements DomainEvent { }
        record OrderCancelled(OrderId orderId, String reason) implements DomainEvent { }

        enum OrderStatus { DRAFT, PLACED, CANCELLED }

        /** Entity inside the aggregate: identity (lineNo) that is unique only within its Order. */
        static final class OrderLine {
            final int lineNo; final Sku sku; final Money unitPrice; private int quantity;
            OrderLine(int lineNo, Sku sku, Money unitPrice, int quantity) {

After.OrderId("1001")).map(After.Order::status).orElseThrow());
        order.cancel("customer request");
        repo.save(order);
    }
}
```

Output:

```
== BEFORE: anemic model ==
total=0.30000000000000004 status=SHIPPED lines=3 (a line was added after shipping, with qty -5)
== AFTER: aggregate + value objects + events ==
rejected: At most 10 units of TEA-250 per order
total Rs 709.50 (money in paise: 0.1 + 0.2 problems cannot happen)
   shipping context: created Consignment[reference=SO-1001, parcels=1, weightGrams=920]
   event published: OrderPlaced
rejected: Cannot add items: order is PLACED
== identity vs value equality ==
Money(100) equals Money(100)? true   (value object)
two Order objects with id 1001 equal? true   (entity: identity decides)
loaded from repository: PLACED
   shipping context: stop consignment SO-1001 (customer request)
   event published: OrderCancelled
```

Before, the order is a bag of public fields: `double` money prints `0.30000000000000004`, the status is a free-form string, and code outside the service added a line with quantity −5 *after* the order "shipped" — nothing could stop it. *After*, `Money` is a value object (paise — 1/100 of a rupee — in a `long`, never negative, equal by value), `Order` is the aggregate root that owns its `OrderLine` entities and refuses changes once placed or beyond 10 units per SKU (Stock Keeping Unit — a product's unique code), `place()` speaks the business language and records an `OrderPlaced` event, and the repository publishes events only after saving. The Shipping context never sees Sales' `Order`: its translator turns the event into a `Consignment` with Shipping's own concepts (weight, parcels), using Shipping's own weight catalog. Two `Order` objects with the same id are equal (entity), two `Money(100)` values are equal (value object).

Trade-offs

DDD brings	DDD costs
Code that reads like the business; rules in one place	Time with domain experts; learning the vocabulary
Clear boundaries for teams and services	More types (value objects, events, translators)
Aggregates give a clear transaction and locking unit	Eventual consistency between aggregates must be designed and explained
Models can change independently per context	Translation code at every context border
Rich model is easy to unit-test (test one class in isolation) without a database	ORMs sometimes fight rich models (private setters, value object mapping)

When not to use it

- **CRUD-shaped apps** (Create, Read, Update, Delete — apps that mostly store and show records: forms over tables, an admin panel) with few rules — a simple layered design is enough; tactical DDD would be ceremony (KISS, YAGNI).
- **Small teams with one small model** — strategic splitting pays off when there are several teams or sub-domains.
- **Technical problems** (a compiler, a video encoder) where the complexity is algorithmic, not in business rules.
- Still worth borrowing even then: **value objects** and **ubiquitous naming** cost little and help everywhere.

Common mistakes

- **Anemic aggregates** — entities with public setters and "services" holding the rules. That is the *before* code with DDD names on it.
- **Huge aggregates** ("Customer" containing all orders, addresses and payments) — every change locks everything; keep aggregates small and reference others by id.
- **One repository per table** instead of per aggregate root.
- **Publishing events before the transaction commits** — consumers react to changes that may be rolled back (undone instead of committed, i.e. made permanent); use an outbox.
- **Sharing one domain model across services** "to avoid duplication" — it couples the teams; duplicate the small bits each context needs (DRY applies *within* a context, not across).

- **Treating DDD as folders** (`entities/`, `valueobjects/`) rather than as modelling with domain experts.
- Using **primitives for domain concepts** (`String email`, `double price`) — "primitive obsession" (Chapter 7).

Real-world examples

- **Microservice boundaries** at many companies are drawn along bounded contexts (orders, payments, shipping, catalog) — the default advice in Sam Newman's *Building Microservices* and in Microsoft's .NET microservices architecture guide, which uses DDD aggregates and domain events in its reference application *eShopOnContainers*.
- **Payments**: a `Payment` aggregate with an `Amount` value object and events such as `PaymentAuthorized`, `PaymentCaptured`, `PaymentRefunded`, consumed by ledger and notification contexts.
- **Java libraries**: `java.time` types (`LocalDate`, `Duration`) and `BigDecimal` are value objects in all but name; frameworks such as Axon (used in the CQRS notes' example) are built around aggregates and events.
- In this book: the grocery POS (point-of-sale checkout system, Chapter 19) keeps `Money` and tenders as value types and a `Sale` that guards its own states; the shipping locker (Chapter 14, §14.7) separates `Compartment` (reusable door) from `Booking` (one parcel's lifecycle).

In the interview

> **30-second answer:** "DDD models the software on the business. Strategically, I split the domain into bounded contexts — each with its own model and ubiquitous language, like Sales and Shipping — and connect them through events or APIs, translating at the border with an anti-corruption layer. Tactically, inside a context I use entities for things with identity, immutable value objects for things like Money, and small aggregates whose root enforces the invariants; one aggregate changes per transaction, others follow through domain events, and each aggregate root has a repository."

Follow-ups:

- *Q: Entity or value object — how do you decide?* A: Ask whether you track it over time by identity. An `Order` is (id 1001 stays 1001); an `Address` or `Money` is not — you replace it with a new value.
- *Q: How big should an aggregate be?* A: As small as the invariants allow; reference other aggregates by id and use events for rules that can be eventually consistent.
- *Q: How do bounded contexts relate to microservices?* A: A context is a good candidate boundary for a service (often one service per context), but a context can also be a module inside a monolith.
- *Q: How do you keep two aggregates consistent?* A: Change one per transaction, publish a domain event via an outbox, let a handler (or a saga — a chain of local transactions with compensating "undo" steps — for multi-step processes) update the other.

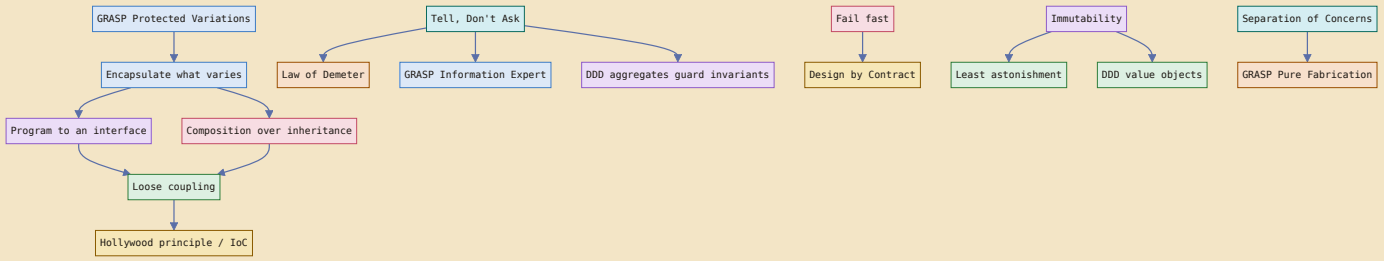
Self-check

1. Q: Two `Money(₹100)` objects — equal? Two customers named "Asha Rao" — equal? → A: Money yes (value object); customers only if they have the same id (entities).
2. Q: Why must outsiders not hold a reference to an `OrderLine`? → A: They could change it without the `Order` root checking its invariants.
3. Q: Why reference `CustomerId` instead of `Customer` inside `Order`? → A: Keeps aggregates small and independent; avoids loading or locking the customer when changing an order.
4. Q: What is an anti-corruption layer for? → A: Translating another context's or a legacy system's model into ours so its concepts don't leak in.
5. Q: When do you publish a domain event? → A: After the aggregate's change is committed — reliably via a transactional outbox.

TL;DR

Speak the business's language in code; split the domain into bounded contexts with their own models and translate at the borders; inside one context use entities (identity), immutable value objects (values), small aggregates whose root guards the invariants, domain events for everything that can happen later, and one repository per aggregate root.

Chapter summary — how the principles fit together



Principle	Main goal	Typical smell it fixes	Key Java tool
DRY	One home per rule	Duplicated rules drifting	Value objects, constants, methods
KISS	Simplicity	Over-engineering	Plain code, `switch` expressions
YAGNI	Build only what's needed	Speculative generality	Delete unused code
Law of Demeter	Hide structure	Train wrecks	Intent-revealing delegate methods
Tell, Don't Ask	Behaviour with data	Anemic model, feature envy	Command methods on the owner
Composition over inheritance	Flexible reuse	Fragile base class	Forwarding/decorators
Program to an interface	Substitutability	Hard-wired concrete deps	Interfaces + DI
Encapsulate what varies	Isolate change	Growing type-switches	Strategy, lambdas
Loose coupling	Independent change	God orchestrators	Observer, events, DI
Hollywood / IoC	Framework owns flow	Duplicated skeletons	Template Method, callbacks, DI
Separation of Concerns	One concern per unit	Spaghetti code	Layers, MVC
Least Astonishment	Predictability	Hidden side effects	Honest names, `Optional`
Fail fast	Early, clear errors	Distant NPEs (NullPointerExceptions)	Guard clauses, `requireNonNull`
Immutability	Safe sharing	Aliasing, races	Records, `List.copyOf`
Design by Contract	Clear obligations	Magic error values	Pre/postconditions, invariants
GRASP	Place responsibilities	God classes	Expert, Creator, Controller, ...
DDD	Model the business; clear boundaries	Anemic model, big ball of mud, primitive obsession	Records as value objects, aggregate roots, domain events, repositories

Tensions to remember (and mention in interviews):

- DRY vs loose coupling — sharing code couples its users; sometimes duplicate across boundaries.
- YAGNI vs Encapsulate-what-varies/OCP — only abstract variation that is real or clearly predicted.
- Law of Demeter vs cohesion — too many delegate methods create a Middle Man; move behaviour instead.
- Information Expert vs Separation of Concerns — domain objects compute, fabrications persist.
- DRY vs bounded contexts — share nothing but events and ids across contexts; a little duplication beats a shared model that couples teams.

Chapter self-check

1. Q: Which principle is violated by `order.getCustomer().getAddress().getCity()` inside a service that then decides shipping? → A: Law of Demeter (and Tell-Don't-Ask); move the decision to where the data is or ask `order.shippingZone()`.

2. Q: A `find` method that inserts a row violates? → A: Least Astonishment (and Command-Query Separation).
3. Q: A `HashSet` subclass double-counts in `addAll` — which principle? → A: Composition over inheritance (fragile base class).
4. Q: Which GRASP guideline says "put `total()` on `Order`"? → A: Information Expert.
5. Q: What makes a record *truly* immutable when it holds a list? → A: Defensively copy it with `List.copyOf` in the compact constructor.
6. Q: In DDD, why is `Money` a value object but `Order` an entity? → A: Money is defined by its amount and currency and is replaced, not changed; an order keeps its identity while its lines and status change.

TL;DR (chapter)

Keep rules in one place, keep things simple, build only what's needed, let objects own their behaviour and talk only to friends, depend on small interfaces and compose, let frameworks call you, separate concerns, don't surprise people, fail early, prefer immutable values, state your contracts, use GRASP to decide who does what — and let DDD's bounded contexts, aggregates and value objects decide which classes exist.

Chapter 6 — Clean Code

Design principles (Chapters 4–5) decide *which classes exist and how they relate*. **Clean code** is about what happens *inside* those classes: names, functions, comments, error handling, tests. In machine-coding rounds (interview rounds where you build a small, working program in about 60–120 minutes), interviewers read your code line by line — clean code is often what separates "hire" from "no hire" when two candidates reach similar designs.

This chapter covers every major topic of Robert C. Martin's *Clean Code* (2008), in the book's order (Chapters 1–17; the two long case studies, Chapters 15–16, are summarised in §13), explained in our own words with runnable Java 21 before/after programs. It finishes with three practical best-practice topics: a **code review checklist**, an **error-handling strategy** for real services and **testing strategies** (unit vs integration tests, test doubles, mocks).

Key terms (defined once here):

Term	Meaning
Clean code	Code that is easy to read, understand and change by someone other than its author. It does one thing well, has tests, and has no surprises.
Code smell	A surface symptom that *usually* signals a deeper design problem (e.g. a 200-line method). Not a bug by itself.
Refactoring	Changing the internal structure of code without changing its observable behaviour (Chapter 7).
Level of abstraction	How "high-level" a statement is. `processPayroll()` is high; `sb.append(',')` is low.
Side effect	Any change a function makes besides returning a value (fields, files, globals, output).
Test double	Any object that stands in for a real dependency during a test (dummy, stub, spy, mock, fake).
TDD	Test-Driven Development: write a failing test, make it pass, refactor — in very short cycles.

What is clean code, and why bother?

What it is

Well-known programmers describe clean code in similar ways: it reads like well-written prose, it does one thing, it is elegant and efficient, it has tests, it contains no duplication, it expresses its intent, and it looks like it was written by someone who **cares**. A simple working definition: *code whose intent is obvious to the next reader, and which is easy to change safely.*

Analogy: a well-organised kitchen. Anyone can walk in, find the knives, cook, and clean up. A messy kitchen still "works" for its owner — until someone else has to cook in it.

The problem it solves

Messy code slows teams down more and more over time. Every change takes longer because nobody understands the code, and each change adds more mess. Eventually productivity approaches zero and the team asks for a "grand redesign", which often reproduces the same mess. We read code far more than we write it (the ratio is often quoted as more than 10:1), so making code easy to read makes writing faster too. "I'll clean it up later" rarely happens — *later equals never* (a saying known as LeBlanc's law).

How it works

1. Treat readability as a first-class requirement, not decoration.
2. Follow the **Boy Scout Rule**: *always leave the code a little cleaner than you found it* — rename one variable, split one long function, delete one dead comment each time you touch a file.
3. Write tests so you can clean without fear.
4. Clean in small steps (successive refinement): first make it work, then make it right. Never ship "it works, but it's a mess".

Trade-offs

Clean code takes slightly longer *the first time* you write it; it saves time on every later read and change. For truly throwaway code (a one-off script) the balance is different.

When not to use it

There is no case where unreadable code is a goal. But avoid **gold-plating** — endlessly polishing code that is already clear and not changing.

Common mistakes

- Thinking "working" means "done".
- Blaming deadlines: going fast by making a mess is an illusion; the mess slows you down immediately.
- Big-bang rewrites instead of continuous small improvements.

Real-world examples

- **Google's code review culture** requires reviewer approval for readability, and it has a "readability" certification process per language.
- **Linters and formatters** (tools that automatically flag suspicious code or rewrite its layout) running in CI — Continuous Integration, a server that builds and tests every change automatically — (Checkstyle, SpotBugs, SonarQube, google-java-format) enforce parts of clean code automatically.

In the interview

> **30-second answer:** "Clean code is code whose intent is obvious and which is cheap to change. In a machine-coding round I use intention-revealing names, small single-purpose functions, clear exceptions instead of error codes, immutable value objects (small objects such as `Money` that never change after creation) and a few tests — and I leave time to refactor once it works."

Self-check

1. Q: What is the Boy Scout Rule? → A: Leave the code a little cleaner than you found it.
2. Q: Why does readability matter more than writing speed? → A: Code is read far more often than it is written.

TL;DR

Clean code = obvious intent + safe to change. Clean a little every time you touch code.

---

1. Meaningful Names

What it is

Names are everywhere — variables, functions, parameters, classes, packages. A good name answers three questions: **why does it exist, what does it do, how is it used**. If a name needs a comment to explain it, the name is not good enough.

Analogy: labels on moving boxes. "Kitchen — glasses — fragile" helps; "Box 7" doesn't.

The problem it solves

Bad names force readers to keep a **mental map** ("`d` is elapsed days, `i1` is status, 4 means done"). Every reader pays that cost every time, and misunderstanding causes bugs.

How it works — the rules

Rule	Bad	Good
Reveal intention	`int d;`	`int elapsedTimeInDays;`
Avoid disinformation (names that suggest something false)	`accountList` for a `Set`; `l` / `O` that look like 1/0	`accounts`
Make meaningful distinctions — no number series or noise words	`a1, a2`; `ProductInfo` vs `ProductData`; `nameString`	`source, destination`; one `Product`
Use pronounceable names	`crtdTs`	`createdAt`
Use searchable names — avoid single letters and bare numbers except tiny local scopes	`7`, `e`	`MAX_LOGIN_ATTEMPTS`, `employee`
Avoid encodings — no Hungarian notation (type codes in names), no `m_` prefixes, no `I` prefix on interfaces	`strName`, `m_desc`, `IShapeFactory`	`name`, `description`, `ShapeFactory` (+ `ShapeFactoryImpl` or better, a specific name)
Avoid mental mapping	`r` for "lower-cased URL without host"	`normalizedPath`
Class names = nouns	`Manager`, `Processor`, `Data`, `Info` (vague)	`Customer`, `Invoice`, `AddressParser`
Method names = verbs; accessors `get` / `is` / `has`	`data()`	`postPayment()`, `isPosted()`
Prefer named static factories (static creation methods like `of...`) to overloaded constructors (several constructors with different parameter lists)	`new Money(23)` (rupees? paise, 1/100 of a rupee?)	`Money.ofRupees(23)`
Don't be cute	`yeetAll()`, `nuke()`	`deleteAll()`, `terminate()`
One word per concept	`fetch` / `retrieve` / `get` in sibling classes	pick one, e.g. `get`
Don't pun (same word, different meaning)	`add` for both "sum" and "append to collection"	`append`, `insert`
Use solution-domain names for technical concepts	—	`OrderRepository`, `RetryPolicy`, `EventQueue` (programmers know these)
Use problem-domain names for business concepts	—	`Premium`, `Policy`, `Claim`
Add meaningful context	lone `state`	`shippingState` or better, an `Address` class with `state`
Don't add gratuitous context	`AcmeShopCustomerAddress` in an app called "Acme Shop"	`Address`

Length rule of thumb: the **longer the scope, the longer the name**. `i` is fine for a 3-line loop; a field used across a class deserves a full name.

Java example — before/after

```
// File: lld/ch06/names/Main.java
package lld.ch06.names;

import java.time.Duration;
import java.util.ArrayList;

/** Meaningful names: the same logic, before and after renaming. */
public class Main {

    // ---------------- BEFORE ----------------
    static class Before {
        static class DtaRcrd102 {                       // unpronounceable, encoded, meaningless
            String strNm; int i1; int i2; boolean flg;
        }
        static class Mgr {                               // vague noun
            List<DtaRcrd102> lst = new ArrayList<>();   // "lst" of what?
            // what is 4? what is 18000? why flg?
            List<DtaRcrd102> getThem() {
                List<DtaRcrd102> l1 = new ArrayList<>();
                for (DtaRcrd102 x : lst) if (x.i1 == 4 && x.i2 > 18000 && !x.flg) l1.add(x);
                return l1;
            }
            int d;                                       // elapsed time in days? seconds? since what?
        }
    }

    // ---------------- AFTER ----------------
    static class After {
        enum TaskStatus { OPEN, IN_PROGRESS, BLOCKED, DONE }

        /** Class name = noun. Field names = what they hold, with units where it matters. */
        record Task(String title, TaskStatus status, Duration timeSpent, boolean archived) {
            boolean isCompleted() { return status == TaskStatus.DONE; }          // boolean method reads as a
question
            boolean tookLongerThan(Duration limit) { return timeSpent.compareTo(limit) > 0; }
        }

        static final class TaskBoard {
            private static final Duration LONG_RUNNING = Duration.ofHours(5);  // named constant, not a magic
number
            private final List<Task> tasks = new ArrayList<>();
            void add(Task task) { tasks.add(task); }                            // method name = verb
            List<Task> findCompletedLongRunningTasks() {                        // says exactly what it returns
                List<Task> result = new ArrayList<>();
                for (Task task : tasks)
                    if (task.isCompleted() && task.tookLongerThan(LONG_RUNNING) && !task.archived())
result.add(task);
                return result;
            }
        }

        /** Static factory methods with descriptive names beat overloaded constructors. */
        record Temperature(double kelvin) {
            static Temperature ofCelsius(double c) { return new Temperature(c + 273.15); }
            static Temperature ofFahrenheit(double f) { return new Temperature((f - 32) * 5 / 9 + 273.15); }
        }
    }

    public static void main(String[] args) {
        var mgr = new Before.Mgr();
        var r = new Before.DtaRcrd102(); r.strNm = "Deploy"; r.i1 = 4; r.i2 = 20000; mgr.lst.add(r);
        System.out.println("BEFORE getThem(): " + mgr.getThem().size() + " record(s) -- but what are they?");

        var board = new After.TaskBoard();
        board.add(new After.Task("Deploy", After.TaskStatus.DONE, Duration.ofHours(6), false));
```

```
        board.add(new After.Task("Write docs", After.TaskStatus.DONE, Duration.ofHours(1), false));
        System.out.println("AFTER findCompletedLongRunningTasks(): " + board.findCompletedLongRunningTasks());
        System.out.printf("Temperature.ofCelsius(25) = %.2f K, ofFahrenheit(212) = %.2f K%n",
                After.Temperature.ofCelsius(25).kelvin(), After.Temperature.ofFahrenheit(212).kelvin());
    }
}
```

Output:

```
BEFORE getThem(): 1 record(s) -- but what are they?
AFTER findCompletedLongRunningTasks(): [Task[title=Deploy, status=DONE, timeSpent=PT6H, archived=false]]
Temperature.ofCelsius(25) = 298.15 K, ofFahrenheit(212) = 373.15 K
```

The logic is the same shape — filter a list by three conditions — but *after* you can read the rule aloud: "completed tasks that took longer than five hours and aren't archived". Magic numbers (unexplained literal values dropped into code) became a named constant, a status code became an enum (a type with a fixed set of named values), and `Temperature.ofCelsius(25)` is unambiguous where `new Temperature(25)` would not be.

Trade-offs

Longer names cost a few keystrokes (IDEs — Integrated Development Environments such as IntelliJ IDEA — autocomplete them). Very long names can hint the function does too much — split it rather than abbreviate.

When not to use it

Conventional short names are fine where universally understood: `i`/`j` loop indexes in tiny loops, `e` for a caught exception, `x`/`y` for coordinates, `T`/`K`/`V` for generics (type parameters, as in `List<T>`, that let one class work with many types).

Common mistakes

- Renaming is cheap — not doing it because "everyone knows what `tmp2` means".
- Abbreviations only the author understands (`calcAmtPrc`).
- Inconsistent vocabulary across a codebase (`customer`, `client`, `user` for the same concept).

Real-world examples

- The JDK's naming: `isEmpty()`, `getOrDefault()`, `computeIfAbsent()`, `List.of()`, `Path.of()`, `Duration.ofMinutes()` — verbs for methods, named static factories.
- **Google Java Style Guide** and Oracle's code conventions standardise casing (`UpperCamelCase` classes, `lowerCamelCase` methods, `UPPER_SNAKE_CASE` constants).

In the interview

> **30-second answer:** "I name things so the code reads like the requirement: nouns for classes, verbs for methods, booleans as questions, named constants instead of magic numbers, enums instead of status codes, and one consistent word per concept."

Follow-ups:

- *Q: Should interfaces start with `I`?* A: Not in Java convention; name the role (`PaymentGateway`) and give implementations specific names (`RazorpayGateway`).
- *Q: When is a short name okay?* A: When the scope is tiny and the meaning conventional (`i` in a short loop).

Self-check

1. Q: What's wrong with `ProductInfo` and `ProductData` in one codebase? → A: Noise words; no meaningful distinction.
2. Q: Why prefer `Temperature.ofCelsius(x)` over a constructor? → A: The name says what the argument means.
3. Q: What's a pun in naming? → A: Using one word for two different meanings.

TL;DR

Names should reveal intent, be pronounceable and searchable, use one word per concept, and let the code read like the requirement.

2. Functions

What it is

Functions (methods) are the first line of organisation in any program. Clean functions are **small**, **do one thing**, stay at **one level of abstraction**, take **few arguments**, have **no hidden side effects**, and either **do something or answer something** — never both.

Analogy: a recipe with numbered steps ("make the sauce", "boil pasta", "combine") where each step has its own sub-recipe. You'd never write one 400-line paragraph.

The problem it solves

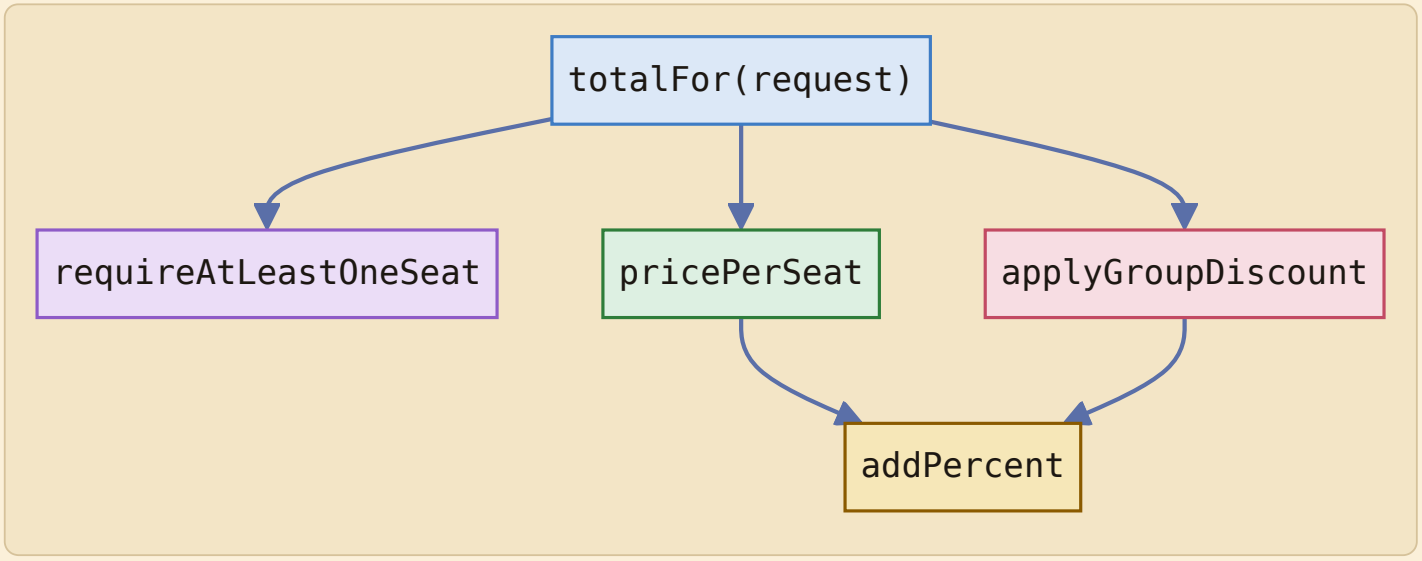
Long functions mix levels of detail, hide bugs, can't be reused, can't be named well, and can't be tested in pieces. Flag arguments and output arguments confuse callers; hidden side effects create surprising bugs; error codes clutter every caller with `if` checks.

How it works — the rules

1. **Small, then smaller.** The book says functions should hardly ever reach 20 lines, and praises functions of just two to four lines. Blocks inside `if`/`else`/`while` should ideally be one line — usually a call to a well-named function. Indentation should rarely exceed one or two levels.
2. **Do one thing.** A function does one thing if you can't extract another function from it with a name that isn't just a restatement of its body. If a function has "sections" (declarations, initialisation, processing), it's doing several things.
3. **One level of abstraction per function.** Don't mix `getHtml()` (high) with `.append("\n")` (low) in the same body.
4. **The Stepdown Rule.** Code should read top-down like a narrative: each function is followed by the functions it calls, one level of abstraction lower. "To do X, we do A, then B. To do A, we …".
5. **Switch statements.** A `switch` on a type code tends to be repeated in many places and to grow. Tolerate one only if it appears **once**, is buried in a low-level class (e.g. inside a factory — a class or method whose job is creating objects — that creates polymorphic objects, i.e. objects of different classes used through one shared interface), and is never repeated. Otherwise replace it with polymorphism (or enum data/behaviour).
6. **Use descriptive names.** A long descriptive name beats a short enigmatic one and a long comment. Small functions are easier to name.
7. **Arguments: fewer is better.** Zero (niladic) is ideal, then one (monadic), then two (dyadic); three (triadic) should be avoided where possible; more than three (polyadic) requires very special justification — and then shouldn't be used anyway. Arguments are hard to read and each one multiplies test cases.
   - Common one-argument forms: asking a question (`isValid(email)`), transforming (`Path resolve(name)`), or an event (`onLoginFailed(attempts)`) — make the kind obvious.
   - **Flag arguments** (`render(true)`) are ugly: they announce the function does two things. Split into two functions or pass an enum.
   - **Argument objects**: when several arguments travel together, wrap them (`book(BookingRequest request)` instead of `book(show, seatType, count, day)`).
   - **Argument lists** (varargs — a parameter like `Object... args` that accepts any number of values) count as one argument (`String.format(fmt, args...)`).
   - **Verbs and keywords**: encode argument roles in the name (`copyFromTo(source, target)`, `renameFileTo(newName)`).
8. **Have no side effects.** A function named `checkPassword` must not also initialise the session (the server-side record of a logged-in user). Hidden side effects create **temporal coupling** (it only works if called at the right time). If a side effect is necessary, put it in the name — or better, separate it.
9. **Avoid output arguments.** `addSignature(letter)` — does it add a signature *to* the letter, or the letter *to* something? Prefer `letter.addSignature()` (change the state of the owning object).
10. **Command-Query Separation (CQS).** A function should either *change state* (command, returns `void`) or *return information* (query, no state change), not both. `if (enable("darkMode"))` is confusing: is it asking whether it's enabled, or enabling it?
11. **Prefer exceptions to returning error codes.** Error codes force immediate `if` checks at every call site (each place in the code that calls the function) and deeply nested code; exceptions separate the happy path (the

normal, no-error flow) from error handling.

12. **Extract try/catch blocks.** Put the body of a `try` into its own function, so the function that handles errors does *only* error handling ("error handling is one thing": if `try` appears, it should be the first word in the function and nothing should follow the `catch`/`finally` blocks).
13. **Avoid an "error code magnet".** A central `enum Error` that everything imports forces recompiles and discourages new codes; exception subclasses can be added without touching existing code.
14. **Don't Repeat Yourself** — duplication is the root of much evil in software (see Chapter 5).
15. **Structured programming** (Dijkstra's one-entry, one-exit rule: one `return`, no `break`/`continue` in loops, never `goto`) matters mostly for large functions; small functions can use an occasional early `return`, `break` or `continue` when that makes them clearer (but still never `goto`).
16. **How to get there:** nobody writes clean functions the first time. Write a working rough draft with tests, then refine — split, rename, remove duplication — keeping the tests green (green = all tests passing).



Java example — before/after

```java
// File: lld/ch06/functions/Main.java
package lld.ch06.functions;

import java.util.ArrayList;
import java.util.HashMap;
import java.util.List;
import java.util.Map;

/** Clean functions: small, one thing, one level of abstraction, few args, no flags, no hidden side effects, CQS, exceptions. */
@SuppressWarnings("serial") // the nested exception classes are never serialized
public class Main {

    // ---------------- BEFORE ----------------
    static class Before {
        static final Map<String, Object> SESSION = new HashMap<>();

        /**
         * Returns total in rupees, or -1 for bad input.
         * Does validation, pricing, surcharges, discounts, logging and session updates -- all in one place.
         */
        static int book(String seatType, int count, boolean weekend, List<String> log) {   // flag arg + output arg
            if (count <= 0) return -1;                                                      // error code
            int price;
            switch (seatType) {                                                             // switch on a type code
                case "SILVER": price = 150; break;
                case "GOLD": price = 250; break;
                case "RECLINER": price = 450; break;
                default: return -1;
            }
            if (weekend) price = price + price * 20 / 100;
            int total = price * count;
            if (count >= 4) total = total - total * 10 / 100;
            log.add("booked " + count + " " + seatType);                                    // mutates the caller's list
            SESSION.put("lastTotal", total);                                                // hidden side effect
            return total;
        }
    }

    // ---------------- AFTER ----------------
    static class After {
        /** The type-code switch is replaced by data on the enum; parsing happens once, at the boundary. */
        enum SeatType {

            private static final int GROUP_DISCOUNT_PERCENT = 10;

            int totalFor(BookingRequest request) {                      // level 1: the story
                requireAtLeastOneSeat(request);
                int total = pricePerSeat(request) * request.seats();
                return applyGroupDiscount(total, request.seats());
            }

            private void requireAtLeastOneSeat(BookingRequest r) {      // level 2: the details
                if (r.seats() <= 0) throw new InvalidBookingException("seats must be positive, was " + r.seats());
            }
            private int pricePerSeat(BookingRequest r) {
                return addPercent(r.seat().basePrice, r.day().surchargePercent);
            }
            private int applyGroupDiscount(int total, int seats) {
                return seats >= GROUP_SIZE ? addPercent(total, -GROUP_DISCOUNT_PERCENT) : total;
            }
            private static int addPercent(int amount, int percent) {    // level 3: arithmetic
                return amount + amount * percent / 100;
            }
        }

        /** Command-Query Separation: book() changes state and returns nothing; history() answers and changes
    nothing. */
        static final class BookingService {
            private final TicketPricer pricer = new TicketPricer();
            private final List<String> history = new ArrayList<>();

            void book(BookingRequest request) {
                int total = pricer.totalFor(request);
                history.add(request.seats() + " x " + request.seat() + " on " + request.day() + " = Rs " + total);
            }
            List<String> history() { return List.copyOf(history); }
        }

        /** Error handling is "one thing": this function only translates failures for the UI. */
        static String bookFromForm(BookingService service, String seat, int seats, DayType day) {
            try {
                service.book(new BookingRequest(SeatType.parse(seat), seats, day));
                return "OK";
            } catch (InvalidBookingException e) {
                return "Sorry: " + e.getMessage();
            }
        }
    }

    public static void main(String[] args) {
        System.out.println("== BEFORE ==");
        List<String> log = new ArrayList<>();
        int result = Before.book("GOLD", 4, true, log);           // what does 'true' mean here?
        System.out.println("total=" + result + " log=" + log + " session=" + Before.SESSION);
        int bad = Before.book("PLATINUM", 2, false, log);
        System.out.println("bad seat returns " + bad + " -- caller must remember to check for -1");

        System.out.println("== AFTER ==");
        var service = new After.BookingService();
        System.out.println(After.bookFromForm(service, "GOLD", 4, After.DayType.WEEKEND));
        System.out.println(After.bookFromForm(service, "SILVER", 2, After.DayType.WEEKDAY));
        System.out.println(After.bookFromForm(service, "PLATINUM", 2, After.DayType.WEEKDAY));
        System.out.println(After.bookFromForm(service, "GOLD", 0, After.DayType.WEEKDAY));
        service.history().forEach(h -> System.out.println("  history: " + h));
    }
}
```

Output:

```
== BEFORE ==
total=1080 log=[booked 4 GOLD] session={lastTotal=1080}
bad seat returns -1 -- caller must remember to check for -1
== AFTER ==
OK
OK
Sorry: unknown seat type 'PLATINUM'
Sorry: seats must be positive, was 0
  history: 4 x GOLD on WEEKEND = Rs 1080
  history: 2 x SILVER on WEEKDAY = Rs 300
```

What changed and why:

- The **boolean flag** `weekend` became `DayType`, so call sites read `DayType.WEEKEND`, not a mysterious `true`.
- The **type-code switch** disappeared: each `SeatType` carries its base price; string parsing happens once at the boundary (`SeatType.parse`).
- The **error codes** (`-1`) became `InvalidBookingException` with a message saying exactly what was wrong.
- The **output argument** (`log`) and the **hidden side effect** (`SESSION`) became explicit state owned by `BookingService`.
- **CQS**: `book` is a command (returns `void`); `history` is a query (returns a copy, changes nothing). (Many real APIs pragmatically let a command return the created ID — that's a widely accepted exception.)
- **Stepdown**: `totalFor` reads as the story; the helpers below it are one level more detailed.
- **Error handling is one thing**: `bookFromForm` only translates failures into a UI message.

Trade-offs

Many small functions	Few large functions
Each is nameable, testable, reusable	Everything visible in one place
Need good names to navigate	Hard to understand, test, change
Too-tiny splitting can scatter logic	Mixed abstraction levels

When not to use it

Don't split a genuinely simple 8-line function into 8 one-liners just to hit a number; the goal is clarity, not a line count. Performance-critical inner loops rarely need manual inlining (copying a small method's body into its caller) in Java — the JIT (the Just-In-Time compiler inside the JVM, the Java Virtual Machine that runs Java programs, which turns frequently run bytecode into machine code while the program runs) inlines small methods — so size is almost never a real performance excuse.

Common mistakes

- Boolean parameters in public APIs (the methods and classes other code is meant to call).
- Getters that change state (breaking CQS and least astonishment).
- Catching exceptions deep inside and returning `null`.
- Functions whose name says one thing and body does three.

Real-world examples

- `java.util.Collections.sort(list)` vs `list.sort(comparator)` — command methods return `void`.
- `Iterator.next()` (an `Iterator` walks through a collection one element at a time) is a well-known pragmatic CQS exception (it both advances and returns); `Queue.poll()` likewise. Know them, but don't design new APIs that way without reason.
- `Files.readString`, `Files.writeString` — tiny, single-purpose APIs.

In the interview

30-second answer: "I keep functions small and single-purpose, at one level of abstraction, top-down by the stepdown rule. I avoid flag arguments with enums or separate methods, keep argument counts low with parameter objects, separate commands from queries, and throw descriptive exceptions instead of returning error codes."

Follow-ups:

- *Q: How small is small?* A: Small enough to have one clear name and one level of abstraction — often under ~20 lines, frequently 3–10.
- *Q: What's wrong with `boolean` parameters?* A: The call site is unreadable and the function does two things.
- *Q: What's CQS?* A: Commands change state and return nothing; queries return data and change nothing.

Self-check

1. Q: How do you know a function does "one thing"? → A: You can't extract another meaningful function from it that isn't a mere restatement.
2. Q: When is a `switch` acceptable? → A: Once, buried in a factory/low level, never repeated.
3. Q: What replaces 4+ related arguments? → A: An argument (parameter) object.

TL;DR

Small, one thing, one level, top-down, ≤2–3 args, no flags, no hidden side effects, commands or queries, exceptions not codes.

---

3. Comments

What it is

Comments are, at best, a necessary evil: we write them to make up for our failure to express ourselves in code. Code changes; comments often don't, so they drift and **lie**. The only truly accurate description of behaviour is the code itself. So: **explain yourself in code first**, and keep only comments that code *cannot* express.

Analogy: a road sign that says "Bridge closed" long after the bridge was reopened is worse than no sign.

The problem it solves

Comments used as a crutch for unclear code, redundant comments that repeat code, and outdated comments that mislead.

How it works

Replace a comment with a well-named function or variable whenever possible:

```
// free shipping if the order is big enough and domestic
if (order.total() >= 499 && !order.isInternational())
```

becomes `if (order.qualifiesForFreeShipping())` — the comment is no longer needed.

Good comments (keep these):

Kind	Example
Legal	Copyright/licence header
Informative	What a regex (text-matching pattern) matches, the format of a returned string
Explanation of intent	*Why* a decision was made ("we copy because callers may pass an unmodifiable list")
Clarification	Translating an obscure argument or return value from a library you can't change
Warning of consequences	"Not thread-safe" (unsafe to use from several threads at once), "takes 10 minutes to run", "billed per call"
TODO	Work that should be done but can't be now — with an owner; review them regularly
Amplification	Stressing the importance of something that looks trivial ("the trim is critical: …")
Javadoc in public APIs	Contracts callers depend on: params, return, exceptions

Bad comments (remove or replace):

Kind	What it looks like
Mumbling	A vague comment only the author understands
Redundant	`i++; // increment i`
Misleading	Subtly inaccurate description
Mandated	Javadoc on every function "because the rule says so" (`@param a the a`)
Journal	Change logs at the top of the file — version control (a tool such as Git that records every change) does this
Noise	`/** Default constructor. */`
Scary noise	Copy-pasted Javadoc noise with errors
Comment instead of a function/variable	Explaining an expression that could be named
Position markers	`// ********** Actions **********` banners
Closing-brace comments	`} // end while` — make the function shorter instead
Attributions and bylines	`/* Added by Rick */` — version control knows
Commented-out code	Others are afraid to delete it; it rots. Delete it — git remembers
HTML comments	Markup inside comments, unreadable in the editor
Nonlocal information	Commenting a system-wide default next to an unrelated function
Too much information	Historical discussions, RFC (internet standards document) excerpts
Inobvious connection	A comment that itself needs explaining
Function headers	Short, well-named functions don't need them
Javadoc in non-public code	Formal docs for internal code is usually noise

Java example — before/after

```java
// File: lld/ch06/comments/Main.java
/*
 * Copyright (c) 2026 Example Corp. Licensed under the Apache License, Version 2.0.   <-- GOOD: legal comment
 */
package lld.ch06.comments;

import java.util.List;
import java.util.regex.Pattern;

/** Comments: explain yourself in code first; keep only comments that code cannot express. */
public class Main {

    record Applicant(String name, int age, int creditScore, long monthlyIncomePaise, boolean hasDefaulted) {}

    // ---------------- BEFORE: comments used to excuse unclear code ----------------
    static class Before {
        // Changes:
        //   2019-03-01 RK: created
        //   2021-07-12 AB: fixed bug                                    <-- BAD: journal comment (git does this)
        /**
         * The eligible method.
         * @param a the a                                                <-- BAD: noise / mandated Javadoc
         * @return the boolean
         */
        static boolean eligible(Applicant a) {
            // check if applicant is eligible for a premium loan         <-- BAD: comment instead of a good name
            if (a.age() >= 21 && a.age() <= 60 && a.creditScore() > 750 && !a.hasDefaulted()
                    && a.monthlyIncomePaise() >= 5_000_000) {
                return true;   // return true                           <-- BAD: redundant
            }
            // if (a.age() > 65) return false;                          <-- BAD: commented-out code
            return false;
        } // end eligible                                               <-- BAD: closing-brace comment
    }

    // ---------------- AFTER: the code explains itself; comments add what code can't ----------------
    static class After {
        private static final int MIN_AGE = 21, MAX_AGE = 60;
        private static final int GOOD_CREDIT_SCORE = 750;
        private static final long MIN_MONTHLY_INCOME_PAISE = 5_000_000;   // Rs 50,000

        static boolean isEligibleForPremiumLoan(Applicant a) {
            return isWorkingAge(a) && hasGoodCredit(a) && earnsEnough(a);
        }
        private static boolean isWorkingAge(Applicant a) { return a.age() >= MIN_AGE && a.age() <= MAX_AGE; }
        private static boolean hasGoodCredit(Applicant a) { return a.creditScore() > GOOD_CREDIT_SCORE &&
!a.hasDefaulted(); }
        private static boolean earnsEnough(Applicant a) { return a.monthlyIncomePaise() >=
MIN_MONTHLY_INCOME_PAISE; }

        // GOOD: informative comment -- clarifies what a regex matches (format: 10-character PAN, e.g. ABCDE1234F)
        private static final Pattern PAN_FORMAT = Pattern.compile("[A-Z]{5}[0-9]{4}[A-Z]");

        static boolean looksLikePan(String s) { return PAN_FORMAT.matcher(s).matches(); }

        /**
         * GOOD: Javadoc on a public API -- states the contract callers rely on.
         * @param scores credit scores in the range 300..900
         * @return the median score; for an even count, the lower of the two middle values
         * @throws IllegalArgumentException if {@code scores} is empty
         */
        static int medianScore(List<Integer> scores) {
            if (scores.isEmpty()) throw new IllegalArgumentException("no scores");
            // GOOD: explanation of intent -- we copy because callers may pass an unmodifiable list, and sorting in
place would fail
            List<Integer> sorted = scores.stream().sorted().toList();
```

```
            return sorted.get((sorted.size() - 1) / 2);
        }

        // GOOD: warning of consequences -- this call hits the credit bureau and is billed per request.
        // TODO(loans-team): cache bureau responses for 24h once the bureau contract allows it.   <-- GOOD: TODO
        static int fetchBureauScore(String pan) { return 780; }
    }

    public static void main(String[] args) {
        var asha = new Applicant("Asha", 30, 790, 6_000_000, false);
        var ravi = new Applicant("Ravi", 30, 790, 6_000_000, true);
        System.out.println("BEFORE eligible(asha)=" + Before.eligible(asha) + ", eligible(ravi)=" +
Before.eligible(ravi));
        System.out.println("AFTER  isEligibleForPremiumLoan(asha)=" + After.isEligibleForPremiumLoan(asha)
                + ", (ravi)=" + After.isEligibleForPremiumLoan(ravi));
        System.out.println("looksLikePan(ABCDE1234F)=" + After.looksLikePan("ABCDE1234F"));
        System.out.println("medianScore([700, 820, 650, 900])=" + After.medianScore(List.of(700, 820, 650, 900)));
        System.out.println("bureau score=" + After.fetchBureauScore("ABCDE1234F"));
    }
}
```

Output:

```
BEFORE eligible(asha)=true, eligible(ravi)=false
AFTER  isEligibleForPremiumLoan(asha)=true, (ravi)=false
looksLikePan(ABCDE1234F)=true
medianScore([700, 820, 650, 900])=700
bureau score=780
```

In *before*, every comment is a smell: journal, mandated noise, a comment used instead of a name, redundant, commented-out code and a closing-brace marker. In *after*, the long condition became three named predicates and named constants; the remaining comments are the good kinds — legal header, informative (regex format), intent, public-API Javadoc, warning and a TODO with an owner.

Trade-offs

Comments are cheap to write and expensive to maintain. A few precise "why" comments are valuable; many "what" comments are a liability.

When not to use it

"No comments" is not the goal. Public libraries need Javadoc; complex algorithms (a published paper's method, a tricky concurrency protocol) deserve a comment explaining the approach and why.

Common mistakes

- Updating code but not the comment next to it.
- Keeping commented-out code "just in case".
- Using comments as a to-do list that no one ever reviews.

Real-world examples

- The **JDK's Javadoc** is a model of contract documentation (e.g. `HashMap` explains iteration order is not guaranteed; `ConcurrentHashMap` explains weakly consistent iterators).
- **SonarQube** (a server that scans code for problems) flags commented-out code; many teams' linters reject `TODO` without a ticket reference (an ID in the team's issue tracker).

In the interview

30-second answer: "I prefer expressive code over comments: named functions and constants replace most 'what' comments. I keep comments for why, warnings, legal headers, TODOs with owners and public API contracts, and I delete commented-out code because version control remembers it."

Self-check

1. Q: Name three good kinds of comment. → A: Legal, explanation of intent, warning of consequences (also informative, TODO, amplification, public Javadoc).
2. Q: What should you do with commented-out code? → A: Delete it.
3. Q: Why do comments lie? → A: Code changes and comments aren't updated.

TL;DR

Say it in code; comment only the *why*, warnings, legal text and public contracts; delete dead comments and commented-out code.

---

4. Formatting

What it is

Formatting is about **communication**: the layout of code tells the reader what belongs together and what matters most. A team should agree on one set of formatting rules and apply them automatically everywhere.

Analogy: a newspaper. The headline tells you the story, the first paragraph gives the summary, details come further down. You can stop reading at any depth and still understand the gist.

The problem it solves

Inconsistent, cramped or random layout makes readers work to understand structure before they can understand logic. It also produces noisy diffs (the line-by-line view of what changed) in code review (a teammate reading your change before it is accepted; §15).

How it works

Vertical formatting (top-to-bottom):

1. **File size** — small files are easier to understand. Many well-known Java projects keep most files around 200 lines, with very few over 500.
2. **Newspaper metaphor** — the class name and the top of the file give the high-level picture; details increase as you move down.
3. **Vertical openness** — separate distinct concepts (package, imports, each method) with blank lines.
4. **Vertical density** — lines that are tightly related appear together, without blank lines or useless comments between them.
5. **Vertical distance** — keep related concepts close:
   - declare local variables close to their first use;
   - instance variables in one well-known place (Java convention: top of the class);
   - **dependent functions**: the caller sits *above* the callee, close by;
   - **conceptual affinity**: functions that do similar things (overloads, related operations) sit near each other.
6. **Vertical ordering** — high-level functions first, details later (the stepdown rule again).

Horizontal formatting (left-to-right):

1. **Line width** — keep lines short enough to read without scrolling. Martin sets his own limit at 120 characters; Google's Java style uses 100.
2. **Horizontal openness and density** — spaces around assignment operators and between arguments; no space between a function name and its `(`; use spacing to show precedence where it helps.
3. **No horizontal alignment** of declarations in columns — it draws the eye to the wrong thing (types vs names) and breaks with every rename.
4. **Indentation** — shows scope hierarchy; never collapse a short `if` or loop body onto one line if it hides structure.
5. **Dummy scopes** — if a `while` or `for` has an empty body, make it visible (put the semicolon on its own line or use `{}`), because a trailing `;` is easy to miss.

Team rules — a codebase should look like one person wrote it. Encode the rules in an automatic formatter (IDE settings, `google-java-format`, Spotless, Checkstyle) and let CI enforce them.

Java example — before/after

```java
// File: lld/ch06/formatting/Main.java
package lld.ch06.formatting;

import java.util.ArrayList;
import java.util.List;

/** Formatting: same code, formatted two ways. The compiler doesn't care; readers do. */
public class Main {

    // ---------------- BEFORE: cramped, random order, aligned columns, no vertical openness ----------------
    static class Before {
        static class Playlist{private int cursor;
            private String helper(int i){return songs.get(i).toUpperCase();}
            public String next(){if(songs.isEmpty())return null;String s=helper(cursor);cursor=
(cursor+1)%songs.size();return s;}
            private final List<String>   songs   =   new ArrayList<>();
            private final String         name;
            public void add(String s){songs.add(s);}Playlist(String n){name=n;}
            public String name(){return name;}}
    }

    // ---------------- AFTER: newspaper order -- headline first, details below ----------------
    static class After {
        /** A looping playlist. (Headline: the class name and this one line tell you what it is.) */
        static final class Playlist {
            // 1. Fields at the top, together (vertical density for closely related lines).
            private final String name;
            private final List<String> songs = new ArrayList<>();
            private int cursor;

            // 2. Constructor next.
            Playlist(String name) {
                this.name = name;
            }

            // 3. Public API -- each concept separated by a blank line (vertical openness).
            public String name() {
                return name;
            }

            public void add(String song) {
                songs.add(song);
            }

            public String next() {
                if (songs.isEmpty()) {
                    return null;
                }
                String song = displayTitle(cursor);    // caller ABOVE callee (dependent functions close together)
                cursor = (cursor + 1) % songs.size();
                return song;
            }

            // 4. Private helpers just below the functions that use them.
            private String displayTitle(int index) {
                return songs.get(index).toUpperCase();
            }
        }
    }

    public static void main(String[] args) {
        var before = new Before.Playlist("Road trip");
        var after = new After.Playlist("Road trip");
        for (String s : List.of("Kesariya", "Yellow", "Tum Hi Ho")) { before.add(s); after.add(s); }
        StringBuilder b = new StringBuilder(), a = new StringBuilder();
        for (int i = 0; i < 4; i++) { b.append(before.next()).append(' '); a.append(after.next()).append(' '); }
```

```
        System.out.println("BEFORE " + before.name() + ": " + b.toString().trim());
        System.out.println("AFTER  " + after.name() + ": " + a.toString().trim());
        System.out.println("Same behaviour -- formatting only changes how fast a human understands it.");
    }
}
```

Output:

```
BEFORE Road trip: KESARIYA YELLOW TUM HI HO KESARIYA
AFTER  Road trip: KESARIYA YELLOW TUM HI HO KESARIYA
Same behaviour -- formatting only changes how fast a human understands it.
```

Both classes behave identically. The *after* uses the newspaper order (fields → constructor → public API → private helpers, with each helper right under its caller), blank lines between concepts, no column alignment and consistent indentation.

Trade-offs

Almost none — formatting is cheap when automated. The only cost is agreeing on the rules once.

When not to use it

Generated code (e.g. from Protobuf, Google's schema-based message format, whose compiler writes classes for you) doesn't need hand formatting; exclude it from formatters.

Common mistakes

- Mixing formatting changes with logic changes in the same commit (one saved, described change in version control) — it makes the diffs unreadable.
- Personal styles inside a team codebase.
- Aligning declarations in columns.

Real-world examples

- **google-java-format**, **Spotless** (Gradle/Maven — Java build tools), **Prettier** (JS), **gofmt** (Go formats all Go code identically — style debates disappear), **Black** (Python).
- **EditorConfig** files share indentation settings across editors.

In the interview

30-second answer: "Formatting communicates structure. I keep related lines together, separate concepts with blank lines, put callers above callees, fields at the top, and let an automatic formatter enforce one team style."

Self-check

1. Q: What is the newspaper metaphor? → A: High-level summary at the top, increasing detail below.
2. Q: Where should a private helper go? → A: Just below the function that calls it.

TL;DR

Format for the reader: headline first, related things close, concepts separated, one automated team style.

---

5. Objects and Data Structures

What it is

There are two fundamentally different kinds of types:

- An **object** *hides* its data behind abstractions and *exposes behaviour* (functions that operate on that data). Example: an `Order` with `isMetroDelivery()`.
- A **data structure** *exposes* its data and has *no meaningful behaviour*. Example: a record `Address(city, pincode)`, a DTO (Data Transfer Object — a plain data carrier).

Data abstraction: hiding implementation is not just putting getters and setters on private fields. It means exposing abstract interfaces that let users manipulate the *essence* of the data without knowing its representation (e.g. `fuelPercentRemaining()` rather than `getFuelTankCapacityInLitres()` and `getLitresOfFuel()`).

Analogy: a vending machine (object) — you press buttons and get results; you can't touch its coin box. A spreadsheet (data structure) — all values are visible; formulas live elsewhere.

The problem it solves

Confusion between the two creates **hybrids** — half object, half data structure — with public fields *and* significant behaviour. Hybrids get the worst of both worlds: hard to add new functions *and* hard to add new types. Knowing the difference also tells you which design makes your likely changes easy.

How it works — the data/object anti-symmetry

	Procedural code (data structures + functions)	**OO code (objects)**
Add a new **function** (e.g. `perimeter`)	**Easy**: add one function; data types untouched	**Hard**: add a method to every class
Add a new **type** (e.g. `Triangle`)	**Hard**: edit every function	**Easy**: add one class; existing code untouched

So: *everything is an object* is a myth. When you expect **new types**, choose objects and polymorphism. When you expect **new operations** over a stable set of types, data structures with functions (or the Visitor pattern, Chapter 11, which adds operations to a set of classes without editing them) may be better. Java 21's `sealed` interfaces (which list exactly which classes may implement them) with records and pattern-matching `switch` (a `switch` that branches on an object's type) make the procedural style safe: the compiler tells you if a `switch` misses a type.

The Law of Demeter (Chapter 5, §4) applies to objects: a method should not navigate an object's internals (`order.getCustomer().getAddress().city()`), because that exposes their structure — a **train wreck**. It does *not* strictly apply to data structures, whose whole job is to expose data. The fix for objects is to **hide structure**: ask the object to do the job (`order.isMetroDelivery()`).

Data Transfer Objects (DTOs): the purest data structure — public (or record) fields, no behaviour. Used to move data across boundaries: database rows, JSON (a plain-text key–value data format) request/response bodies, messages. *Bean* form (private fields + getters/setters) gives no real encapsulation benefit but is required by some frameworks.

Active Record: a special DTO that also has navigation methods like `save()` and `find()` and maps to one database row (Rails' ActiveRecord, some Java ORMs — Object-Relational Mappers, libraries that map classes to database tables). Common mistake: putting business rules into active records, making them hybrids. Keep business rules in separate objects that *use* the active record.

Java example — before/after

```java
// File: lld/ch06/objects/Main.java
package lld.ch06.objects;

import java.util.List;

/**
 * Objects vs data structures.
 * Objects hide data and expose behaviour; data structures expose data and have no behaviour.
 * Data/object anti-symmetry: each makes a different kind of change easy.
 */
public class Main {

    // ---------------- STYLE 1: data structures + procedures (procedural) ----------------
    static class Procedural {
        sealed interface Shape permits Square, Circle {}
        record Square(double side) implements Shape {}
        record Circle(double radius) implements Shape {}

        /** All behaviour lives here. Adding perimeter() = one new method, shapes untouched. Adding Triangle = edit
every method. */
        static final class Geometry {
            static double area(Shape s) {
                return switch (s) {
                    case Square sq -> sq.side() * sq.side();
                    case Circle c -> Math.PI * c.radius() * c.radius();
                };
            }
            static double perimeter(Shape s) {                // NEW FUNCTION: easy -- no shape class changes
                return switch (s) {
                    case Square sq -> 4 * sq.side();
                    case Circle c -> 2 * Math.PI * c.radius();
                };
            }
        }
    }

    // ---------------- STYLE 2: objects (polymorphic) ----------------
    static class ObjectOriented {
        interface Shape { double area(); }
        record Square(double side) implements Shape { public double area() { return side * side; } }
        record Circle(double radius) implements Shape { public double area() { return Math.PI * radius * radius; }
}
        record Triangle(double base, double height) implements Shape {   // NEW TYPE: easy -- nothing else changes
            public double area() { return 0.5 * base * height; }
        }
        // ...but adding perimeter() would mean editing Shape and EVERY implementation.
    }

    // ---------------- Hiding structure (Law of Demeter) ----------------
    static class Before {
        record Address(String city, String pincode) {}
        static class Customer { Address address = new Address("Pune", "411001"); Address getAddress() { return
address; } }
        static class Order { Customer customer = new Customer(); Customer getCustomer() { return customer; } }
        static boolean isMetroDelivery(Order o) {
            return List.of("Mumbai", "Delhi", "Pune").contains(o.getCustomer().getAddress().city());  // train
wreck
        }
    }
    static class After {
        record Address(String city, String pincode) {                    // a data structure: exposing data is its
job
            boolean isMetro() { return List.of("Mumbai", "Delhi", "Pune").contains(city); }
        }
        static final class Order {                                        // an object: hides its structure
            private final Address shipTo;
```

```
            Order(Address shipTo) { this.shipTo = shipTo; }
            boolean isMetroDelivery() { return shipTo.isMetro(); }        // tell the order what you need
        }
    }

    // ---------------- DTO: pure data for crossing a boundary ----------------
    /** A Data Transfer Object: public data, no behaviour; e.g. JSON returned by a REST endpoint. */
    record OrderDto(String orderId, String city, long totalPaise) {}

    public static void main(String[] args) {
        var shapes = List.<Procedural.Shape>of(new Procedural.Square(2), new Procedural.Circle(1));
        for (var s : shapes)
            System.out.printf("procedural %-22s area=%.2f perimeter=%.2f%n", s, Procedural.Geometry.area(s),
Procedural.Geometry.perimeter(s));

        var objects = List.<ObjectOriented.Shape>of(new ObjectOriented.Square(2), new ObjectOriented.Circle(1),
                new ObjectOriented.Triangle(3, 4));
        for (var s : objects) System.out.printf("object     %-22s area=%.2f%n", s, s.area());

        System.out.println("BEFORE train wreck says metro? " + Before.isMetroDelivery(new Before.Order()));
        System.out.println("AFTER  order.isMetroDelivery()? " + new After.Order(new After.Address("Pune",
"411001")).isMetroDelivery());
        System.out.println("DTO: " + new OrderDto("o-9", "Pune", 45_000));
    }
}
```

Output:

```
procedural Square[side=2.0]       area=4.00 perimeter=8.00
procedural Circle[radius=1.0]     area=3.14 perimeter=6.28
object     Square[side=2.0]       area=4.00
object     Circle[radius=1.0]     area=3.14
object     Triangle[base=3.0, height=4.0] area=6.00
BEFORE train wreck says metro? true
AFTER  order.isMetroDelivery()? true
DTO: OrderDto[orderId=o-9, city=Pune, totalPaise=45000]
```

The procedural `Geometry` gained `perimeter()` without touching the shapes; the OO version gained `Triangle` without touching anything. The train wreck `o.getCustomer().getAddress().city()` became `order.isMetroDelivery()`, while the `Address` record (a data structure) freely exposes `city`. `OrderDto` is a pure data carrier.

Trade-offs

Summarised in the anti-symmetry table above. Choose based on which change you expect more.

When not to use it

Don't force behaviour into DTOs that cross process boundaries (travel between separately running programs, e.g. over the network) — keep them dumb and version them carefully.

Common mistakes

- Adding getters and setters for every private field by reflex (that's not encapsulation).
- Hybrids: public mutable fields plus business methods.
- Business logic inside JPA (Java's standard ORM API) entities that also serve as API response bodies.

Real-world examples

- Records are Java's official data carriers; `java.awt.Point` has public fields (a data structure).
- `java.time.LocalDate` is an object: you call `plusDays`, `isLeapYear`; you never see its internal fields.
- DTOs in Spring (the main Java server framework) REST controllers (classes that handle HTTP API requests) (`@RequestBody CreateOrderRequest`); Rails ActiveRecord / Spring Data JPA entities.

In the interview

> **30-second answer:** "Objects hide data and expose behaviour; data structures expose data with no behaviour. OO makes adding types easy and functions hard; procedural does the opposite. I use records for DTOs and value data, rich objects for domain logic, and avoid hybrids and train wrecks."

Follow-ups:

- *Q: Is `a.getB().getC()` always wrong?* A: For objects, yes (Demeter). For pure data structures like records it's acceptable.
- *Q: Which pattern lets OO code add operations easily?* A: Visitor (Chapter 11), at the cost of making new types harder.

Self-check

1. Q: Which style makes adding a new shape type easy? → A: OO (polymorphic objects).
2. Q: What is a hybrid? → A: A type with both exposed data and significant behaviour — to be avoided.
3. Q: What's an Active Record? → A: A DTO with persistence/navigation methods mapped to a DB row.

TL;DR

Objects hide data and expose behaviour; data structures expose data. Pick based on whether you'll add types or operations. No hybrids, no train wrecks through objects.

---

6. Error Handling

What it is

Error handling is important, but if it **obscures the logic** it's wrong. Clean error handling keeps the happy path readable and makes failures explicit, informative and hard to ignore.

Analogy: a fire exit plan — clearly marked, separate from normal corridors, and never blocking daily traffic.

The problem it solves

Error codes clutter every caller with `if` checks and are easy to forget; `null` returns cause `NullPointerException`s far away; checked exceptions (ones the Java compiler forces every caller to catch or declare) from low-level libraries leak into every signature; vague messages make debugging slow.

How it works — the rules

1. **Use exceptions rather than return codes.** The caller's logic stays clean; errors can't be silently ignored.
2. **Write your `try-catch-finally` statement first** when writing code that can throw. The `try` block is like a transaction (a unit of work that either fully happens or is fully undone): whatever happens inside, the `catch` must leave the program consistent. In Java, prefer **try-with-resources** for anything `AutoCloseable` (any class with a `close()` method, such as a file or connection) — the resource is closed even if an exception is thrown.
3. **Use unchecked exceptions.** Checked exceptions violate the Open/Closed Principle: if a low-level method starts throwing a new checked exception, every method between it and the handler must change its signature. Modern languages (C#, Kotlin, Python, Scala) have no checked exceptions. Use checked exceptions only when a caller can and must realistically recover (a rare, deliberate choice).
4. **Provide context with exceptions.** Message should say what failed, with which values, and why (`account 'B' has 100 but 900 was requested`). Keep the original exception as the **cause** when wrapping.
5. **Define exception classes in terms of the caller's needs.** How will the caller *catch* it? Often one exception type (per area) is enough. **Wrap third-party APIs** so their exceptions are translated into yours; this minimises dependency on the vendor and makes swapping libraries easy.
6. **Define the normal flow — the Special Case pattern** (Martin Fowler): instead of throwing or returning `null` for an expected "absence" case, return an object that handles that case (`NoMembership` with 0 points, `GuestCustomer`, an empty list). Callers need no special handling.
7. **Don't return `null`.** Return an empty collection, `Optional` (a container that holds a value or is empty), a special-case object, or throw. Every `null` return is a future `NullPointerException`.

8. **Don't pass `null`.** Unless an API expects it, reject `null` arguments immediately (`Objects.requireNonNull`) — fail fast (Chapter 5).

Java example — before/after

```java
// File: lld/ch06/errors/Main.java
package lld.ch06.errors;

import java.io.IOException;
import java.util.HashMap;
import java.util.List;
import java.util.Map;
import java.util.Objects;
import java.util.Optional;

/** Error handling: exceptions not codes, unchecked with context, wrap third-party errors, special case, no null.
*/
@SuppressWarnings("serial") // the nested exception classes are never serialized
public class Main {

    // ---------------- BEFORE ----------------
    static class Before {
        static final int OK = 0, E_NO_ACCOUNT = 1, E_NO_MONEY = 2;

            int pts = Before.loyaltyPoints("B");            // auto-unboxing a null Integer
            System.out.println(pts);
        } catch (NullPointerException e) { System.out.println("loyaltyPoints(B): NullPointerException on
unboxing"); }

        System.out.println("== AFTER ==");
        var bank = new After.Bank();
        for (String[] t : new String[][]{{"A", "Z", "50"}, {"B", "A", "900"}, {"A", "B", "200"}}) {
            try {
                bank.transfer(t[0], t[1], Long.parseLong(t[2]));
                System.out.println("transfer " + t[0] + "->" + t[1] + " of " + t[2] + " ok; A=" +
bank.balanceOf("A") + " B=" + bank.balanceOf("B"));
            } catch (After.BankingException e) {
                System.out.println("transfer failed: " + e.getMessage());
            }
        }
        System.out.println("history(A) size = " + bank.history("A").size());
        System.out.println("findBalance(Z) = " + bank.findBalance("Z"));
        for (String id : List.of("A", "B")) {
            var l = bank.loyaltyOf(id);                     // no null check needed
            System.out.println("loyalty " + id + ": " + l.points() + " pts, tier " + l.tier());
```

```
        }
        try {
            new After.SmsNotifier().send("000123", "hi");
        } catch (After.BankingException e) {
            System.out.println(e.getMessage() + " (cause: " + e.getCause().getMessage() + ")");
        }
        try (var audit = new After.AuditFile()) {
            audit.write("transfer A->B 200");
            throw new IllegalStateException("simulated crash");
        } catch (IllegalStateException e) {
            System.out.println("  caught: " + e.getMessage() + " -- file was still closed first");
        }
    }
}
```

Output:

```
== BEFORE ==
transfer returned 1 (which account? caller has to decode)
history(): NullPointerException -- someone forgot the null check
loyaltyPoints(B): NullPointerException on unboxing
== AFTER ==
transfer failed: account 'Z' does not exist
transfer failed: account 'B' has 100 but 900 was requested
transfer A->B of 200 ok; A=300 B=300
history(A) size = 0
findBalance(Z) = Optional.empty
loyalty A: 40 pts, tier SILVER
loyalty B: 0 pts, tier NONE
could not send SMS to 000123 (cause: socket timeout to sms-gw-3)
  audit file opened
  audit: transfer A->B 200
  audit file closed
  caught: simulated crash -- file was still closed first
```

What each part shows:

- *Before*: `transfer` returns `1` without saying which account; `history` returns `null`; `loyaltyPoints` returns `null` that crashes on auto-unboxing (Java's automatic conversion from `Integer` to `int`, which throws on `null`).
- *After*: an unchecked hierarchy under `BankingException`, messages with context; `history` returns an empty list; `findBalance` returns `Optional`; `loyaltyOf` returns a **special case** (`NoMembership.INSTANCE`) so callers never check for `null`; the vendor's checked `IOException` is **wrapped** with the original as its cause; `try-with-resources` closes the audit file even when an exception is thrown.

Trade-offs

Choice	Pro	Con
Unchecked exceptions	Clean signatures, OCP-friendly	Compiler doesn't remind callers; document them
Checked exceptions	Compiler-enforced handling	Signature ripple; often caught and swallowed
`Optional` return	Absence visible in the type	Not for fields/parameters; small allocation
Special Case object	No checks at all in callers	Can hide a real problem if absence *should* be noticed
Result/Either type (holds either a success value or an error)	Expected failures as values, composable	More verbose in Java (see Error-handling strategy)

When not to use it

Exceptions are for exceptional or error situations, not normal control flow — e.g. don't throw to exit a loop. For *expected, frequent* outcomes (validation of user input rows), returning a result value can be cleaner (see §16).

Common mistakes

- `catch (Exception e) {}` — swallowing.
- Logging and rethrowing at every layer (the same error logged 5 times).
- Losing the cause when wrapping (`new MyException(e.getMessage())` instead of `new MyException(msg, e)`).
- Returning `null` from collections-returning methods.

Real-world examples

- **Spring's** `DataAccessException` hierarchy translates vendor-specific `SQLException`s into unchecked, meaningful exceptions (e.g. `DuplicateKeyException`) — exactly "wrap third-party APIs, define exceptions by caller's needs".
- `Collections.emptyList()`, `Optional.empty()` — JDK support for "don't return null".
- `java.util.Objects.requireNonNull` — "don't pass null".
- `UncheckedIOException` (Java 8) wraps `IOException` for use in lambdas/streams (inline functions and Java's element-processing pipelines, whose standard interfaces cannot throw checked exceptions).

In the interview

> **30-second answer:** "I throw unchecked, domain-specific exceptions with context instead of returning codes or null. I wrap third-party exceptions at the boundary, return empty collections or Optional for absence, use a special-case object when absence is normal, validate nulls at entry, and use try-with-resources for cleanup."

Follow-ups:

- *Q: Checked vs unchecked?* A: Checked forces handling but ripples through signatures and breaks OCP; I default to unchecked and reserve checked for recoverable conditions callers must handle.
- *Q: What is the Special Case pattern?* A: A subclass/object representing a special situation (e.g. no membership) that behaves sensibly, so callers need no null checks.

Self-check

1. Q: Why are error codes bad? → A: They clutter callers, are easy to ignore, and lack context.
2. Q: What should a collection-returning method return when there's nothing? → A: An empty collection.
3. Q: Why keep the cause when wrapping? → A: So the original stack trace and message aren't lost.

TL;DR

Exceptions not codes; unchecked with context; wrap vendors; special cases, empty collections or Optional instead of null; never pass null; always clean up.

---

7. Boundaries

What it is

A **boundary** is where your code meets code you don't control: third-party libraries, frameworks, other teams' services, even very general JDK types like `Map`. Clean boundaries keep that foreign code at the edge, behind interfaces shaped for *your* needs.

Analogy: a power adapter when travelling. Your laptop doesn't care about each country's socket; the adapter handles it.

The problem it solves

Providers of libraries want broad applicability; users want interfaces focused on their needs. That tension leaks: a raw `Map<String, Session>` passed around lets any code `clear()` it, put wrong values in, and forces

everyone to know the key format. When the library's API changes, every usage site breaks.

How it works

1. **Wrap boundary types.** Don't pass `Map`, vendor clients or framework types around your application. Hide them inside a class that exposes only what your app needs (`SessionRegistry.open/activeSession/close`). Keep the boundary type **`private`** or at least out of public APIs.
2. **Write learning tests.** When adopting a library, write small tests that call its API the way you intend to use it. They document your understanding, cost nothing extra (you had to learn the API anyway), and — re-run on each upgrade — tell you immediately if the library's behaviour changed.
3. **Use code that does not exist yet.** When another team's API isn't ready, define the interface *you wish you had* (`FraudCheck`), code and test against it with a fake, and later write an **`Adapter`** (Chapter 9) that bridges it to the real API. This also gives you a clean seam (a place where a test can plug in a substitute) for testing.
4. **Keep boundary knowledge in very few places** so a vendor change touches one adapter.

Java example — before/after

```java
// File: lld/ch06/boundaries/Main.java
package lld.ch06.boundaries;

import java.time.Instant;
import java.util.HashMap;
import java.util.Map;
import java.util.Optional;
import java.util.concurrent.ConcurrentHashMap;

import lld.ch06.testing.MiniTest;

/** Boundaries: wrap third-party / general-purpose APIs, learn them with tests, and define interfaces for code that doesn't exist yet. */
public class Main {

    record Session(String userId, Instant expiresAt) {}

    // ---------------- BEFORE: a raw Map passed all over the codebase ----------------
    static class Before {
        // Every caller can clear(), put(null, ...), put wrong types... and every caller must know the key format.
        static void loginHandler(Map<String, Session> sessions, String token, String user) {
            sessions.put(token, new Session(user, Instant.parse("2026-09-28T12:00:00Z")));
        }
        static void buggyAdminTool(Map<String, Session> sessions) { sessions.clear(); }   // oops: everyone logged out
    }

    // ---------------- AFTER: the Map is hidden behind an interface shaped for OUR needs ----------------
    static class After {
        static final class SessionRegistry {
            private final Map<String, Session> byToken = new ConcurrentHashMap<>();   // boundary type stays private

            void open(String token, Session session) { byToken.put(token, session); }
            Optional<Session> activeSession(String token, Instant now) {
                return Optional.ofNullable(byToken.get(token)).filter(s -> now.isBefore(s.expiresAt()));
            }
            void close(String token) { byToken.remove(token); }
            int size() { return byToken.size(); }
        }

        /** The fraud team's API isn't written yet: we define the interface WE want and code against it. */
        interface FraudCheck { boolean isSuspicious(String userId, long amountPaise); }

        /** Fake used until the real client exists; later an Adapter will wrap the real API behind the same interface. */
        static final class FakeFraudCheck implements FraudCheck {
            public boolean isSuspicious(String userId, long amountPaise) { return amountPaise > 10_000_000; }
        }
    }

    /** LEARNING TESTS: executable notes about how third-party (here: JDK) APIs really behave. Re-run them on every upgrade. */
    public static class JdkLearningTest {
        @lld.ch06.testing.Test void hashmap_allows_one_null_key() {
            Map<String, Integer> m = new HashMap<>();
            m.put(null, 1);
            MiniTest.assertEquals(1, m.get(null));
        }
        @lld.ch06.testing.Test void concurrenthashmap_rejects_null_keys() {
            MiniTest.assertThrows(NullPointerException.class, () -> new ConcurrentHashMap<String, Integer>().put(null, 1));
        }
        @lld.ch06.testing.Test void map_of_rejects_duplicate_keys() {
            MiniTest.assertThrows(IllegalArgumentException.class, () -> Map.of("k", 1, "k", 2));
        }
```

```
        @lld.ch06.testing.Test void string_split_drops_trailing_empty_strings() {
            MiniTest.assertEquals(2, "a,b,,".split(",").length);
            MiniTest.assertEquals(4, "a,b,,".split(",", -1).length);
        }
    }

    public static void main(String[] args) {
        System.out.println("== BEFORE ==");
        Map<String, Session> raw = new HashMap<>();
        Before.loginHandler(raw, "t1", "asha");
        Before.buggyAdminTool(raw);
        System.out.println("sessions after admin tool: " + raw.size() + "  <-- nothing stopped the clear()");

        System.out.println("== AFTER ==");
        var registry = new After.SessionRegistry();
        registry.open("t1", new Session("asha", Instant.parse("2026-09-28T12:00:00Z")));
        System.out.println("active at 11:00? " + registry.activeSession("t1", Instant.parse("2026-09-
28T11:00:00Z")).isPresent());
        System.out.println("active at 13:00? " + registry.activeSession("t1", Instant.parse("2026-09-
28T13:00:00Z")).isPresent());
        After.FraudCheck fraud = new After.FakeFraudCheck();
        System.out.println("fraud(asha, Rs 2,00,000)? " + fraud.isSuspicious("asha", 20_000_000));

        System.out.println("== Learning tests ==");
        var summary = MiniTest.run(JdkLearningTest.class);
        System.out.println(summary.passed() + " passed, " + summary.failed() + " failed");
    }
}
```

Output:

```
== BEFORE ==
sessions after admin tool: 0  <-- nothing stopped the clear()
== AFTER ==
active at 11:00? true
active at 13:00? false
fraud(asha, Rs 2,00,000)? true
== Learning tests ==
JdkLearningTest
  PASS  concurrenthashmap rejects null keys
  PASS  hashmap allows one null key
  PASS  map of rejects duplicate keys
  PASS  string split drops trailing empty strings
4 passed, 0 failed
```

- The raw `Map` let an admin tool wipe every session. `SessionRegistry` exposes only open/lookup/close and adds the "not expired" rule in one place.
- `FraudCheck` is the interface we want; `FakeFraudCheck` unblocks us until the real client exists.
- `JdkLearningTest` captures surprising but real API facts (`HashMap` allows one `null` key, `ConcurrentHashMap` rejects it, `Map.of` rejects duplicate keys, `String.split` drops trailing empty strings unless you pass a negative limit).

Trade-offs

Wrapping costs a class and some delegation. It pays off whenever the boundary type is used in more than one place or might change.

When not to use it

Don't wrap stable, universal types used locally (a `Map` used inside one method is fine). The rule is about *passing* boundary types around your system.

Common mistakes

- Returning vendor types from your interfaces (`PaymentGateway.charge()` returning a `StripeCharge`) — leaks the vendor.

- Skipping learning tests and discovering library behaviour in production (the live system that real users use).

Real-world examples

- **Anti-Corruption Layer** in Domain-Driven Design: a translation layer between your model and a legacy (old, still-in-use)/external system's model.
- **SLF4J** (Simple Logging Facade for Java) wraps the actual logging library; **Spring's** `RestClient` / `WebClient` abstractions let you swap the HTTP engine.
- Contract tests (e.g. Pact) between microservices (small, independently deployed services) are a team-level version of learning tests.

In the interview

> **30-second answer:** "I keep third-party code at the edges: wrap it behind an interface shaped for my domain, don't pass raw library types around, write learning tests when adopting a library, and if a dependency doesn't exist yet I define the interface I need and use a fake until an adapter can bridge to the real API."

Self-check

1. Q: What is a learning test? → A: A test that exercises a third-party API to learn and pin down its behaviour.
2. Q: How do you handle an API that isn't built yet? → A: Define your own interface, use a fake, adapt later.

TL;DR

Keep foreign code at the edge behind your own interfaces; learn it with tests; adapt, don't leak.

---

8. Unit Tests

What it is

Unit tests are small, automated tests that check one unit of behaviour (usually a class or a few collaborating objects) in isolation. *Clean Code* argues test code is **as important as production code**: it must be clean, because it's what lets you change production code without fear.

Analogy: the safety net under a trapeze artist. Without it, every new move is dangerous; with it, you can try, fall and adjust.

The problem it solves

Without tests, every change risks breaking something, so people stop cleaning code and the design rots. With *dirty* tests, the tests themselves become a burden: they break with every change, take forever to update, and are eventually abandoned — and then production code rots too.

How it works

The three laws of TDD (the book says they lock you into a cycle perhaps thirty seconds long, with the tests just a few seconds ahead of the production code):

1. You may not write production code until you have written a failing unit test.
2. You may not write more of a unit test than is sufficient to fail (and not compiling counts as failing).
3. You may not write more production code than is sufficient to pass the currently failing test.

A related, coarser description (from Kent Beck's TDD, not from these three laws) is **Red → Green → Refactor**: write a failing test (red), make it pass in the simplest way (green), then clean up both code and tests (refactor).

Keep tests clean — they enable the "-ilities": tests make code flexible, maintainable and reusable, because you can change anything as long as the tests pass.

Clean tests are readable tests:

- Use the **Build–Operate–Check** pattern (also called **Arrange–Act–Assert** or **Given–When–Then**): build the test data, operate on it, check the results.

- Build a small **domain-specific testing language**: helper functions like `cart("TEA", 3)` and `checkoutWith(coupons, audit)` hide setup noise.
- **Dual standard:** test code must be clean and readable, but it need not be as efficient as production code (e.g. building strings for assertions is fine).

One assert per test? The book suggests minimising the number of asserts, and — more importantly — **one concept per test**. Several asserts are fine if they all check the same concept.

F.I.R.S.T. — clean tests are:

Letter	Meaning	How our code does it
Fast	Run in milliseconds so you run them constantly	In-memory doubles, no network/DB
Independent	No test depends on another or on order	`MiniTest` creates a fresh instance per test
Repeatable	Same result in any environment, any time	Fixed `Clock` instead of `now()`
Self-validating	Pass/fail automatically, no reading logs	Assertions, not `println`
Timely	Written just before (or with) the production code	TDD cycle

Java example — a JUnit-free runner, clean tests and a dirty one

Instead of JUnit (the standard Java testing framework), our tiny test framework (`@Test` + `MiniTest`) uses reflection (Java's ability to inspect classes and call methods by name at runtime) to find annotated methods (methods tagged with `@Test`), runs each on a new instance and reports PASS/FAIL. The production class `Checkout` has four collaborators behind interfaces, so tests can replace them with doubles.

```
// File: lld/ch06/testing/BeforeStyleTest.java
package lld.ch06.testing;

import java.time.Clock;
import java.util.List;
import java.util.Optional;

/**
 * BEFORE: how NOT to write tests. It "passes", but:
 *  - tests several concepts at once, so a failure doesn't say what broke
 *  - uses the real system clock (not Repeatable)
 *  - prints instead of asserting (not Self-validating: a human must read the output)
 *  - cryptic name and magic numbers
 */
public class BeforeStyleTest {
    @Test void test1() {
        var c = new Checkout(sku -> 12_000L, code -> Optional.empty(), r -> {}, e -> {},
Clock.systemDefaultZone());
        long a = c.quote(List.of(new Checkout.Line("X", 3)), null);
        long b = c.quote(List.of(new Checkout.Line("X", 3)), "NOPE");
        var r = c.checkout(List.of(new Checkout.Line("X", 1)), null, "z");
        System.out.println("        a=" + a + " b=" + b + " r=" + r + "  (is this right? someone must check by
eye)");
    }
}
```

            String name = m.getName().replace('_', ' ');
            try {
                Object instance = testClass.getDeclaredConstructor().newInstance();
                m.setAccessible(true);
                m.invoke(instance);
                passed++;
                System.out.println("  PASS  " + name);
            } catch (InvocationTargetException e) {
                failed++;
                Throwable cause = e.getCause();
                String kind = cause instanceof AssertionError ? "FAIL " : "ERROR";
                System.out.println("  " + kind + " " + name + " -> " + cause);
            } catch (ReflectiveOperationException e) {
                failed++;
                System.out.println("  ERROR " + name + " -> cannot run: " + e);
            }
        }
        return new Summary(passed, failed);
    }

    // ---------- assertions ----------
    public static void assertEquals(Object expected, Object actual) {
        if (!Objects.equals(expected, actual))
            throw new AssertionError("expected <" + expected + "> but was <" + actual + ">");
    }
    public static void assertTrue(boolean condition, String message) {
        if (!condition) throw new AssertionError(message);
    }
    public static <T extends Throwable> T assertThrows(Class<T> type, Runnable action) {
        try {
            action.run();
        } catch (Throwable t) {
            if (type.isInstance(t)) return type.cast(t);
            throw new AssertionError("expected " + type.getSimpleName() + " but got " + t);
        }
        throw new AssertionError("expected " + type.getSimpleName() + " but nothing was thrown");
```

```
    }
}
```

```java
// File: lld/ch06/testing/Test.java
package lld.ch06.testing;

import java.lang.annotation.ElementType;
import java.lang.annotation.Retention;
import java.lang.annotation.RetentionPolicy;
import java.lang.annotation.Target;

/** Marks a method as a test for {@link MiniTest} -- our tiny stand-in for JUnit's @Test. */
@Retention(RetentionPolicy.RUNTIME)
@Target(ElementType.METHOD)
public @interface Test {}
```

Output:

```
BeforeStyleTest
        a=36000 b=36000 r=Receipt[email=z, totalPaise=12000]  (is this right? someone must check by eye)
  PASS  test1
CheckoutTest
  PASS  checkout sends exactly one receipt
  PASS  empty cart is rejected
  PASS  expired coupon is ignored
  PASS  high value order is audited
  PASS  quote sums price times quantity
  PASS  valid coupon takes percentage off
CheckoutIntegrationTest
  PASS  full checkout flow with real components
TOTAL: 8 passed, 0 failed
```

Reading the output: `BeforeStyleTest.test1` "passes" but proves nothing — it checks three concepts, uses the real clock, prints values for a human to judge and has a meaningless name. The `CheckoutTest` methods each check **one concept**, are named as behaviour specifications (`expired_coupon_is_ignored`), use Given/When/Then, a fixed clock and self-validating assertions. `CheckoutIntegrationTest` wires the real in-memory components together (see §17 for unit vs integration testing and the five kinds of test double used here).

Trade-offs

Well-tested code	Untested code
Fearless refactoring	Fear of change → rot
Tests are executable documentation	Knowledge in people's heads
Test code must be maintained too	Faster to write the first time

When not to use it

TDD is less useful for exploratory spikes (quick experiments to learn something — throw them away afterwards) and for pure UI layout. Don't unit-test trivial getters or framework code you don't own (use learning tests for that instead).

Common mistakes

- Testing implementation details (private methods, exact call order) so tests break on every refactor.
- Shared mutable fixtures (the data and objects set up before tests) that make tests order-dependent.
- Using `Thread.sleep` or the real clock/network in unit tests.
- Test names like `test1`, `testCheckout`.

Real-world examples

- **JUnit 5** (`@Test`, `@BeforeEach`, `assertThrows`, `@DisplayName`), **AssertJ** for fluent assertions, **Mockito** for doubles.

- JUnit 5's default lifecycle creates a **new test-class instance per test method** — the same independence choice `MiniTest` makes.
- **`java.time.Clock`** exists partly so time-dependent code can be tested with `Clock.fixed(...)`.

In the interview

> **30-second answer:** "I write small, fast, independent tests — one concept each, named as behaviour, arranged Given/When/Then. I inject collaborators behind interfaces so I can use stubs, fakes or mocks, and inject a `Clock` for time. In a machine-coding round I at least write a `main` that exercises key flows, and a few unit tests for the core logic if time allows."

Follow-ups:

- *Q: What are the three laws of TDD?* A: No production code without a failing test; write only enough test to fail; write only enough code to pass.
- *Q: What does F.I.R.S.T. stand for?* A: Fast, Independent, Repeatable, Self-validating, Timely.
- *Q: One assert per test?* A: The real rule is one concept per test; several asserts on one concept are fine.

Self-check

1. Q: What's wrong with printing results in a test? → A: Not self-validating — a human has to check.
2. Q: How do you make a time-based test repeatable? → A: Inject a `Clock` and use `Clock.fixed` in tests.
3. Q: What is Build–Operate–Check? → A: Arrange data, act on it, assert results (Given/When/Then).

TL;DR

Tests are first-class code: TDD cycle, one concept per test, readable Given/When/Then, and F.I.R.S.T.

---

9. Classes

What it is

Rules for clean classes: follow the standard **organisation**, keep classes **small** (measured in responsibilities, not lines), give each **one reason to change** (SRP), keep them **cohesive**, and **organise them for change** so new features mean new classes rather than edits to old ones.

Analogy: a well-run office has departments with clear jobs. When a new service is added, you open a new desk; you don't make accounting also handle legal.

The problem it solves

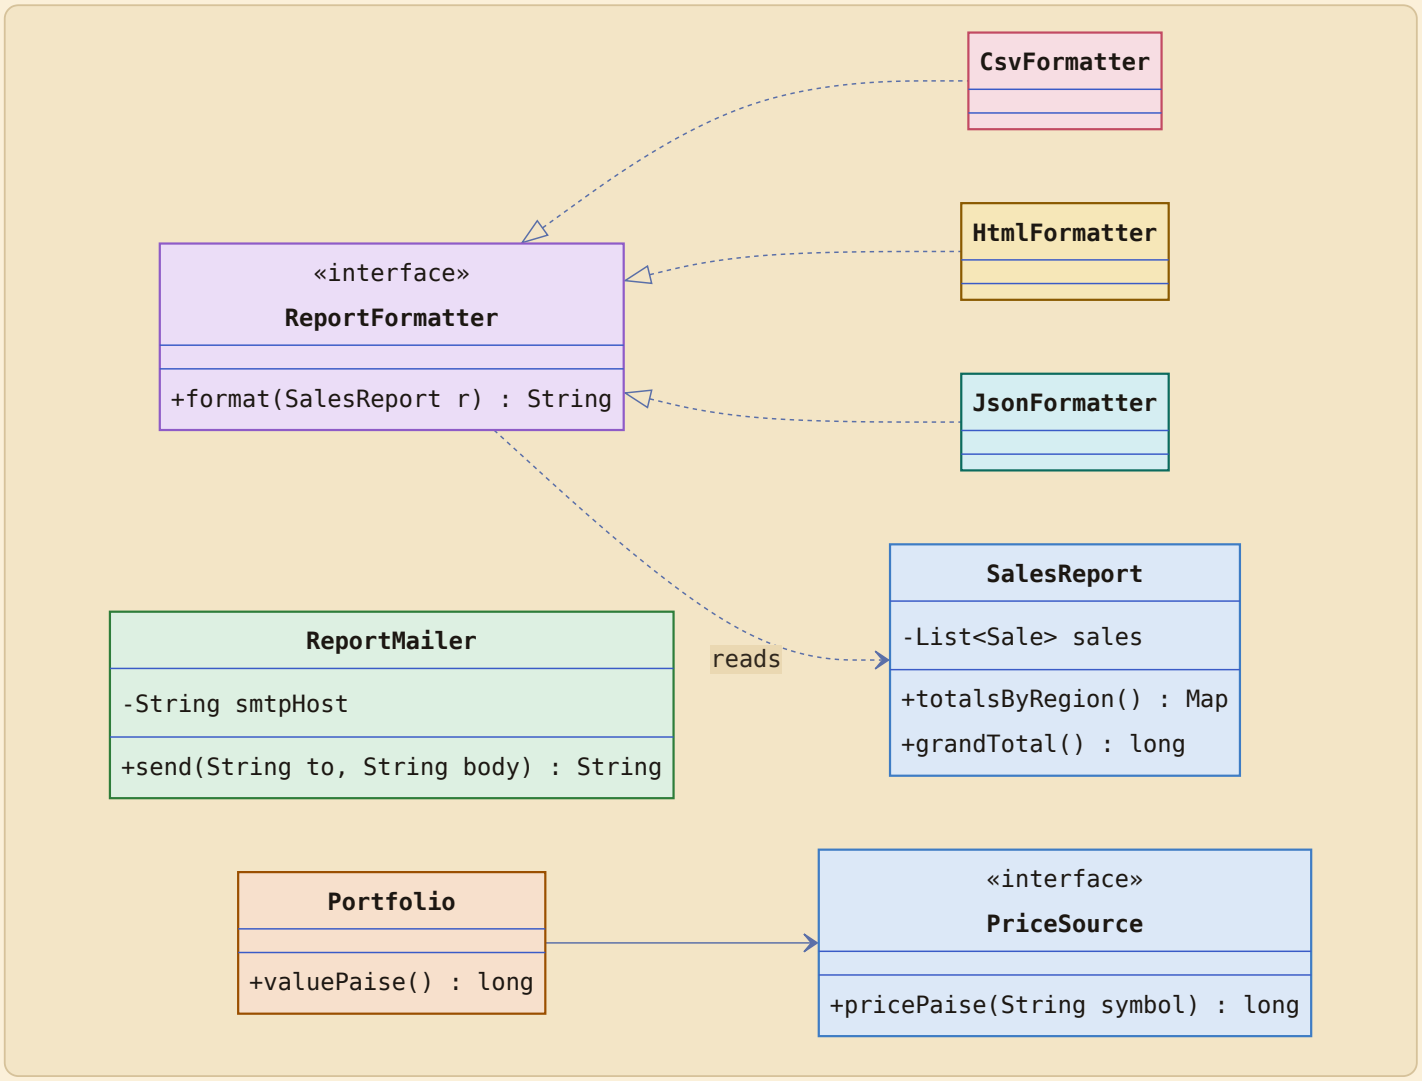
Big "god" classes with many responsibilities are hard to understand, change for many reasons, and every change risks breaking unrelated features. A long list of `if/else` branches for formats or types means reopening the same class repeatedly.

How it works

1. **Class organisation** (Java convention): public static constants → private static variables → private instance variables → public functions → private helpers right after the public function that uses them (stepdown rule). Public instance variables are rarely justified.
2. **Encapsulation**: keep fields and helpers private. Loosening to package-private/protected (visible only within the same package, or also to subclasses) *for tests* is acceptable as a last resort, but look for another way first.
3. **Classes should be small** — measured by *responsibilities*. The class name should describe them; if you can't name it concisely, or the name needs words like *Manager*, *Processor*, *Super*, or you describe it with "and"/"or"/"but", it does too much. You should be able to describe the class in about 25 words.
4. **Single Responsibility Principle**: a class should have **one reason to change** (Chapter 4). Many small classes are better than a few large ones — the total amount of code is the same; small classes are just better organised, like tools in labelled drawers instead of one big box.
5. **Cohesion**: a class is maximally cohesive if every method uses every instance variable. Aim for high cohesion. When a subset of methods uses a subset of fields, that subset wants to be its own class — **maintaining**

cohesion results in many small classes.

6. **Organise for change**: when adding a feature means *opening* a class to edit it (e.g. adding a branch to `render()`), consider splitting so that new features are new classes (Open/Closed Principle). Each report format became its own `ReportFormatter`.
7. **Isolate from change**: depend on abstractions (interfaces) rather than volatile concrete details. `Portfolio` depends on `PriceSource`, not a live stock-exchange client, so it can be tested with fixed prices (Dependency Inversion Principle).



Java example — before/after

```java
// File: lld/ch06/classes/Main.java
package lld.ch06.classes;

import java.util.List;
import java.util.Map;
import java.util.stream.Collectors;

/** Classes: small (few responsibilities), cohesive, organised for change, isolated from change. */
public class Main {

    record Sale(String region, long amountPaise) {}

    // ---------------- BEFORE: one class, many reasons to change ----------------
    static class Before {
        static class ReportManager {
            private final List<Sale> sales;

        static final class CsvFormatter implements ReportFormatter {
            public String format(SalesReport r) {
                StringBuilder sb = new StringBuilder("region,total\n");
                r.totalsByRegion().forEach((region, total) ->
sb.append(region).append(',').append(total).append('\n'));
                return sb.toString().trim();
            }
        }
```

```
        static final class HtmlFormatter implements ReportFormatter {
            public String format(SalesReport r) {
                StringBuilder sb = new StringBuilder("<table>");
                r.totalsByRegion().forEach((region, total) ->
                        sb.append("<tr><td>").append(region).append("</td><td>").append(total).append("</td>
</tr>"));
                return sb.append("</table>").toString();
            }
        }
        static final class JsonFormatter implements ReportFormatter {   // added later, nothing else edited
            public String format(SalesReport r) {
                return r.totalsByRegion().entrySet().stream()
                        .map(e -> "\"" + e.getKey() + "\":" + e.getValue())
                        .collect(Collectors.joining(",", "{", "}"));
            }
        }

        /** Separate reason to change: delivery. */
        static final class ReportMailer {
            private final String smtpHost;
            ReportMailer(String smtpHost) { this.smtpHost = smtpHost; }
            String send(String to, String body) { return "SMTP " + smtpHost + " -> " + to + ": " + body; }
        }

        /** Isolating from change: Portfolio depends on an abstraction, not on a live stock-exchange client. */
        interface PriceSource { long pricePaise(String symbol); }
        static final class Portfolio {
            private final PriceSource prices;
            private final Map<String, Integer> holdings;
            Portfolio(PriceSource prices, Map<String, Integer> holdings) { this.prices = prices; this.holdings =
Map.copyOf(holdings); }
            long valuePaise() {
                return holdings.entrySet().stream().mapToLong(h -> prices.pricePaise(h.getKey()) *
h.getValue()).sum();
            }
        }
    }

    public static void main(String[] args) {
        List<Sale> sales = List.of(new Sale("North", 5_000), new Sale("South", 7_000), new Sale("North", 1_000));

        System.out.println("== BEFORE ==");
        var manager = new Before.ReportManager(sales);
        System.out.println(manager.render().replace('\n', ' '));
        manager.setOutputFormat("HTML");
        System.out.println(manager.email("boss@example.com"));

        System.out.println("== AFTER ==");
        var report = new After.SalesReport(sales);
        for (After.ReportFormatter f : List.of(new After.CsvFormatter(), new After.HtmlFormatter(), new
After.JsonFormatter()))
            System.out.println(f.getClass().getSimpleName() + ": " + f.format(report).replace('\n', ' '));
        System.out.println(new After.ReportMailer("smtp.example.com").send("boss@example.com", new
After.JsonFormatter().format(report)));

        After.PriceSource fixedPrices = symbol -> Map.of("INFY", 150_000L, "TCS", 400_000L).get(symbol);  // test-
friendly stub
        var portfolio = new After.Portfolio(fixedPrices, Map.of("INFY", 10, "TCS", 2));
        System.out.println("portfolio value (paise) = " + portfolio.valuePaise());
    }
}
```

Output:

```
== BEFORE ==
region,total North,6000 South,7000
SMTP smtp.example.com -> boss@example.com: <table><tr><td>North</td><td>6000</td></tr><tr><td>South</td>
<td>7000</td></tr></table>
== AFTER ==
CsvFormatter: region,total North,6000 South,7000
HtmlFormatter: <table><tr><td>North</td><td>6000</td></tr><tr><td>South</td><td>7000</td></tr></table>
JsonFormatter: {"North":6000,"South":7000}
SMTP smtp.example.com -> boss@example.com: {"North":6000,"South":7000}
portfolio value (paise) = 2300000
```

`ReportManager` had three reasons to change (business totals, output format, email delivery) and an `if/else` that grows with every format. After the split, `JsonFormatter` was added without editing any existing class, and `Portfolio` is testable because it depends on the `PriceSource` abstraction.

Trade-offs

Many small classes	Few big classes
Each is easy to understand and test	Fewer files to navigate
Changes are localised	Every change touches the same class
Need good names and packages to navigate	Merge conflicts (clashing edits to the same lines), fear of change

When not to use it

Don't split a small cohesive class into many micro-classes that always change together — that's fragmentation, not SRP.

Common mistakes

- Classes named `*Manager`, `*Helper`, `*Utils` collecting unrelated methods.
- Splitting by *technical layer* only, leaving a god service.
- Making everything `public` "for tests".

Real-world examples

- JDK's `java.time` splits responsibilities across `LocalDate`, `LocalTime`, `ZonedDateTime`, `Duration`, `Period`, `DateTimeFormatter` — versus the old `java.util.Date` / `Calendar`, which mixed many concerns.
- Spring's `JdbcTemplate` delegates row mapping to `RowMapper` and parameter setting to `PreparedStatementSetter`.

In the interview

30-second answer: "I keep classes small by responsibility — one reason to change — and highly cohesive, so methods use most of the fields. When a feature would mean adding another branch to an existing class, I split so the new feature is a new class, and I depend on interfaces to isolate volatile details."

Self-check

1. Q: How do you measure a class's size? → A: By its responsibilities, not lines.
2. Q: What is maximal cohesion? → A: Every method uses every instance variable.
3. Q: What does "organise for change" mean? → A: Structure classes so new features are added as new classes, not edits.

TL;DR

Small (one responsibility), cohesive, open for extension, dependent on abstractions.

---

10. Systems

What it is

At the system level, clean code means **separating the startup process (constructing and wiring objects) from the runtime logic that uses them**, using **Dependency Injection**, handling **cross-cutting concerns** in one place, and letting the architecture **grow incrementally**.

Analogy: building a city. Nobody designs every street up front, and no single person manages everything. Cities work because of abstraction and modularity — water, power, traffic are separate systems with clear interfaces, and they grow over time.

The problem it solves

When objects create their own dependencies (`if (service == null) service = new MyServiceImpl(...)` — lazy initialisation, i.e. creating something only the first time it is needed, inside business code), the business code is hard-wired to concrete classes, can't be tested in isolation, mixes construction with use, and violates SRP. When logging, security and transactions are copied into every method, every business method becomes noisy and inconsistent.

How it works

1. **Separate construction from use.**
   - **Separation of `main`**: build all objects in `main` (or a module called at startup — the **composition root**) and pass them to the application. The application knows nothing about how its objects were built; dependencies point from `main` toward the application, never back.
   - **Factories**: when the *application* must decide *when* to create something (e.g. a `LineItem` for each scan), give it an **Abstract Factory** interface (an interface whose methods create objects, so the caller never names the concrete classes); the concrete factory still lives on the `main` side.
   - **Dependency Injection (DI)**: an object receives its dependencies (constructor, setter or method parameter) instead of creating or looking them up. DI is the application of Inversion of Control (outside code, often a framework, takes charge of creating objects and driving the flow instead of your class) to dependency management. Constructor injection is preferred: dependencies are explicit, final, and the object is complete after construction.
2. **Scale up incrementally.** Build today's system well-modularised; well-separated concerns let the architecture grow (e.g. from a monolith — one application deployed as a single unit — module to a separate service) without a rewrite.
3. **Cross-cutting concerns** (persistence, transactions, security, logging, caching — keeping recent results in fast storage for reuse; see System Design Fundamentals) cut across many objects. Handle them modularly:
   - **Java dynamic proxies** (`java.lang.reflect.Proxy`) wrap an interface and intercept every call — shown in our code.
   - **Pure-Java AOP frameworks** (AOP = aspect-oriented programming: write a concern such as logging once, as an *aspect*, and apply it to many methods; e.g. Spring AOP) generate proxies for you from annotations (`@`-tags on code)/config (`@Transactional`, `@Cacheable`, `@PreAuthorize`).
   - **AspectJ** — a full aspect-oriented language extension that weaves advice (the aspect's code) into bytecode (the compiled form of Java classes that the JVM runs).
   - Also: **decorators** and **servlet filters / interceptors** (code that runs before/after every web request) for simpler cases.
4. **Test-drive the architecture**: with business logic in plain objects (POJOs — Plain Old Java Objects, with no framework dependencies) and concerns decoupled, you can start simple and evolve the architecture as needs become clear.
5. **Optimise decision making**: postpone decisions until the last responsible moment, when you have the most information; modularity makes postponement possible.
6. **Use standards wisely** — only when they add demonstrable value (heavyweight standards can bury simple logic).
7. **Systems need domain-specific languages**: a good DSL (domain-specific language — a mini-language tailored to one problem) (or fluent API — methods designed to chain into readable sentences) lets code read like the domain (e.g. a test-fixture builder or a routing DSL).

Java example — before/after

```
// File: lld/ch06/systems/Main.java
package lld.ch06.systems;

import java.lang.reflect.InvocationHandler;
import java.lang.reflect.InvocationTargetException;
import java.lang.reflect.Proxy;
import java.util.HashMap;
import java.util.Map;

/** Systems: separate construction from use, inject dependencies, handle cross-cutting concerns in one place. */
public class Main {

    interface AccountRepository { long balance(String id); void update(String id, long balance); }
    interface AccountService { long balance(String id); void deposit(String id, long amount); }

    static final class InMemoryAccountRepository implements AccountRepository {
        private final Map<String, Long> rows = new HashMap<>(Map.of("acc-1", 100L));
        public long balance(String id) { return rows.getOrDefault(id, 0L); }
        public void update(String id, long b) { rows.put(id, b); }
    }

    // ---------------- BEFORE: the service builds its own dependency (lazy init) and mixes in logging/timing -----------
    static class Before {
        static final class AccountServiceImpl implements AccountService {
            private AccountRepository repo;
            private AccountRepository repo() {
                if (repo == null) repo = new InMemoryAccountRepository();   // construction mixed with use; hard-coded impl
                return repo;
            }
            public long balance(String id) {
                System.out.println("  LOG enter balance " + id);          // cross-cutting code copy #1
                long b = repo().balance(id);
                System.out.println("  LOG exit balance = " + b);
                return b;
            }
            public void deposit(String id, long amount) {
                System.out.println("  LOG enter deposit " + id);          // cross-cutting code copy #2
                if (amount <= 0) throw new IllegalArgumentException("amount must be positive");
                repo().update(id, repo().balance(id) + amount);
                System.out.println("  LOG exit deposit");
            }
        }
    }

    // ---------------- AFTER ----------------
    static class After {
        /** Pure business logic. Gets its dependency from outside (constructor injection). No logging code. */
        static final class AccountServiceImpl implements AccountService {
            private final AccountRepository repo;
            AccountServiceImpl(AccountRepository repo) { this.repo = repo; }
            public long balance(String id) { return repo.balance(id); }
            public void deposit(String id, long amount) {
                if (amount <= 0) throw new IllegalArgumentException("amount must be positive");
                repo.update(id, repo.balance(id) + amount);
            }
        }

        /** Cross-cutting concern written ONCE and applied to any interface via a JDK dynamic proxy (how Spring AOP works for interfaces). */
        @SuppressWarnings("unchecked")
        static <T> T withLogging(Class<T> type, T target) {
            InvocationHandler handler = (proxy, method, args) -> {
                String argText = args == null ? "" : String.join(", ",
java.util.Arrays.stream(args).map(String::valueOf).toList());
```

```
                System.out.println("  LOG -> " + method.getName() + "(" + argText + ")");
                try {
                    Object result = method.invoke(target, args);
                    System.out.println("  LOG <- " + method.getName() + (result == null ? "" : " = " + result));
                    return result;
                } catch (InvocationTargetException e) {
                    System.out.println("  LOG !! " + method.getName() + " threw " + e.getCause().getMessage());
                    throw e.getCause();                         // rethrow the real exception, not the reflection
wrapper
                }
            };
            return (T) Proxy.newProxyInstance(type.getClassLoader(), new Class<?>[]{type}, handler);
        }

        /** Composition root: the ONLY place that knows concrete classes and wires them together (the "main" side).
*/
        static AccountService buildApplication() {
            AccountRepository repo = new InMemoryAccountRepository();
            AccountService core = new AccountServiceImpl(repo);
            return withLogging(AccountService.class, core);
        }
    }

    public static void main(String[] args) {
        System.out.println("== BEFORE ==");
        var before = new Before.AccountServiceImpl();
        before.deposit("acc-1", 50);
        System.out.println("balance = " + before.balance("acc-1"));

        System.out.println("== AFTER ==");
        AccountService service = After.buildApplication();      // construction happens here, once
        service.deposit("acc-1", 50);                            // use happens everywhere else
        service.balance("acc-1");
        try { service.deposit("acc-1", -5); } catch (IllegalArgumentException e) { System.out.println("caller sees:
" + e.getMessage()); }

        // In a unit test, construct the core with a different repository -- no logging, no real storage.
        var testService = new After.AccountServiceImpl(new InMemoryAccountRepository());
        testService.deposit("acc-1", 1);
        System.out.println("test double wiring works: " + testService.balance("acc-1"));
    }
}
```

Output:

```
== BEFORE ==
  LOG enter deposit acc-1
  LOG exit deposit
  LOG enter balance acc-1
  LOG exit balance = 150
balance = 150
== AFTER ==
  LOG -> deposit(acc-1, 50)
  LOG <- deposit
  LOG -> balance(acc-1)
  LOG <- balance = 150
  LOG -> deposit(acc-1, -5)
  LOG !! deposit threw amount must be positive
caller sees: amount must be positive
test double wiring works: 101
```

In *before*, the service builds its own repository and repeats logging in every method. In *after*, `buildApplication()` (the composition root) is the only place that knows concrete classes; `AccountServiceImpl` receives its repository via its constructor; logging is written **once** in an `InvocationHandler` and applied through a JDK dynamic proxy. The last lines show that tests can wire the core differently. The proxy rethrows the *original* exception (`e.getCause()`), not the reflection wrapper.

Trade-offs

DI + composition root + proxies	Self-constructing objects
Testable, swappable, one place for wiring	Simple for tiny programs
Cross-cutting code in one place	Duplicated, inconsistent concerns
"Magic" with frameworks; proxies only intercept calls *through* the proxy	Explicit and visible

A real Spring gotcha that follows from the proxy mechanism: calling a `@Transactional` method *from another method of the same bean* (an object managed by Spring) (self-invocation) bypasses the proxy, so no transaction starts.

When not to use it

Small scripts and tiny interview programs don't need a DI framework — manual constructor injection in `main` is enough (and is what interviewers expect).

Common mistakes

- Service Locator (a global registry that code asks for its dependencies) calls (`Registry.get(Foo.class)`) scattered in business code — hides dependencies.
- Field injection with `@Autowired` on private fields — hides dependencies and blocks immutability; prefer constructor injection.
- Business logic depending on framework annotations everywhere.

Real-world examples

- **Spring IoC container / Spring Boot**, **Google Guice**, **Dagger** (compile-time DI, common on Android), **Jakarta CDI**.
- **Spring AOP** implements `@Transactional`, `@Cacheable`, `@Async` via JDK dynamic proxies (for interfaces) or CGLIB subclass proxies (generated subclasses that wrap the real class).
- Servlet filters and Spring `HandlerInterceptor`s for authentication and request logging.

In the interview

> **30-second answer:** "I separate construction from use: a composition root in `main` builds and wires everything, and classes receive dependencies through constructors. Cross-cutting concerns like logging or transactions go in one place — a decorator, proxy or aspect — not in every method. That keeps the domain in plain, testable objects."

Follow-ups:

- *Q: DI vs Service Locator?* A: DI pushes dependencies in (explicit in the constructor); a locator pulls them (hidden, harder to test).
- *Q: How does Spring implement `@Transactional`?* A: With a proxy around the bean that begins/commits/rolls back around the method call.

Self-check

1. Q: What is the composition root? → A: The one place (near `main`) where objects are constructed and wired.
2. Q: Name three ways to handle cross-cutting concerns in Java. → A: Dynamic proxies, AOP frameworks/AspectJ, decorators (also filters/interceptors).

TL;DR

Build objects in one place and inject them; put cross-cutting concerns in proxies/aspects; grow the architecture incrementally.

---

11. Emergence — Kent Beck's Four Rules of Simple Design

What it is

Good design can **emerge** from following four simple rules. In priority order, a design is simple if it:

1. **Runs all the tests** (passes them).
2. **Contains no duplication.**
3. **Expresses the intent of the programmer.**
4. **Minimises the number of classes and methods.**

(*Clean Code*'s Chapter 12, written by Jeff Langr, lists them in this order. **Kent Beck's own usual wording and order** — as summarised in Martin Fowler's "BeckDesignRules" article — is: **1. Passes the tests, 2. Reveals intention, 3. No duplication, 4. Fewest elements.** Fowler notes that the middle two are the ones people swap, and that it rarely matters because they reinforce each other. Rules 1 and 4 are always first and last. In an interview, quote Beck's order and mention that *Clean Code* swaps 2 and 3.)

Analogy: sculpting — first make sure the statue stands (tests), then remove what's repeated, then refine the expression, then trim anything unnecessary.

The problem it solves

Design decisions can feel overwhelming. These four rules give a simple, ordered checklist that consistently pushes code toward SRP, DIP and good structure.

How it works

1. **Runs all the tests** — a system you can't verify shouldn't be deployed. Making code testable pushes you toward small, single-purpose, loosely coupled classes (you need DI and interfaces to test in isolation). So rule 1 alone drives much good design.
2. **Refactor, guided by rules 2–4.** With tests in place, clean up without fear after every few lines:
   - **No duplication** — duplicate lines, and duplicate *implementation* (e.g. `isEmpty()` could be implemented as `size() == 0`). Extract methods, and use patterns like **Template Method** to remove higher-level duplication (the shared algorithm with varying steps).
   - **Expressive** — good names, small functions and classes, standard pattern names in class names (`...Command`, `...Visitor`), well-written tests as documentation. Most importantly: *care*.
   - **Minimal classes and methods** — don't create an interface for every class or split fields from behaviour dogmatically. This rule has the lowest priority: SRP and no-duplication win when they conflict.

Java example — before/after

```java
// File: lld/ch06/emergence/Main.java
package lld.ch06.emergence;

import lld.ch06.testing.MiniTest;
import lld.ch06.testing.Test;

/**
 * Kent Beck's four rules of simple design, in the priority order Clean Code gives:
 *  1. runs all the tests   2. no duplication   3. expresses intent   4. fewest classes and methods
 */
public class Main {

    record Employee(String name, int monthsWorked, boolean onProbation) {}

    // ---------------- BEFORE: duplicated algorithm, magic numbers, needless layers ----------------
    static class Before {
        interface LeaveCalcStrategyProvider { LeaveCalc get(); }            // extra element with no purpose
        static class LeaveCalc {
            int calcIN(Employee e) {                                         // unclear name
                if (e.onProbation()) return 0;
                int d = e.monthsWorked() * 18 / 12;                          // 18 per year? magic
                if (d > 45) d = 45;                                          // 45 cap? magic
                return d;
            }
            int calcUS(Employee e) {                                         // the same algorithm, copied
                if (e.onProbation()) return 0;
                int d = e.monthsWorked() * 15 / 12;
                if (d > 30) d = 30;
                return d;
            }
        }
    }

    // ---------------- AFTER: one algorithm (Template Method), named rules, only needed elements ----------------
    static class After {
        abstract static class LeavePolicy {
            /** The shared algorithm, written once (rule 2: no duplication). */
            final int earnedLeaveDays(Employee e) {
                if (e.onProbation()) return 0;
                return Math.min(daysPerYear() * e.monthsWorked() / 12, maxCarryForwardDays());
            }
            protected abstract int daysPerYear();              // what varies, with intention-revealing names (rule 3)
            protected abstract int maxCarryForwardDays();
        }
        static final class IndiaLeavePolicy extends LeavePolicy {
            protected int daysPerYear() { return 18; }
            protected int maxCarryForwardDays() { return 45; }
        }
        static final class UsLeavePolicy extends LeavePolicy {
            protected int daysPerYear() { return 15; }
            protected int maxCarryForwardDays() { return 30; }
        }
    }

    /** Rule 1 first: the refactoring is only safe because these tests pass before AND after. */
    public static class LeavePolicyTest {
        private final Employee veteran = new Employee("Asha", 48, false);
        private final Employee newHire = new Employee("Ravi", 8, false);
        private final Employee probationer = new Employee("Kabir", 3, true);

        @Test void india_policy_matches_old_behaviour() {
            var old = new Before.LeaveCalc();
            var policy = new After.IndiaLeavePolicy();
            for (Employee e : new Employee[]{veteran, newHire, probationer})
                MiniTest.assertEquals(old.calcIN(e), policy.earnedLeaveDays(e));
```

```
        }
        @Test void us_policy_matches_old_behaviour() {
            var old = new Before.LeaveCalc();
            var policy = new After.UsLeavePolicy();
            for (Employee e : new Employee[]{veteran, newHire, probationer})
                MiniTest.assertEquals(old.calcUS(e), policy.earnedLeaveDays(e));
        }
        @Test void carry_forward_is_capped() {
            MiniTest.assertEquals(45, new After.IndiaLeavePolicy().earnedLeaveDays(veteran));
        }
        @Test void probationers_earn_nothing() {
            MiniTest.assertEquals(0, new After.UsLeavePolicy().earnedLeaveDays(probationer));
        }
    }

    public static void main(String[] args) {
        var summary = MiniTest.run(LeavePolicyTest.class);
        System.out.println(summary.passed() + " passed, " + summary.failed() + " failed");
        var in = new After.IndiaLeavePolicy();
        var us = new After.UsLeavePolicy();
        for (Employee e : new Employee[]{new Employee("Asha", 48, false), new Employee("Ravi", 8, false)})
            System.out.println(e.name() + ": India " + in.earnedLeaveDays(e) + " days, US " + us.earnedLeaveDays(e)
+ " days");
    }
}
```

Output:

```
LeavePolicyTest
  PASS  carry forward is capped
  PASS  india policy matches old behaviour
  PASS  probationers earn nothing
  PASS  us policy matches old behaviour
4 passed, 0 failed
Asha: India 45 days, US 30 days
Ravi: India 12 days, US 10 days
```

The tests (rule 1) prove the refactoring kept behaviour identical. Duplicate algorithms became one Template Method (rule 2). Magic numbers became `daysPerYear()` / `maxCarryForwardDays()` (rule 3). The purposeless `LeaveCalcStrategyProvider` interface was dropped (rule 4).

Trade-offs

Rules 2–4 can pull against each other (removing duplication can add a class; expressiveness can add a method). Resolve by priority, and by looking for a better design that satisfies both.

When not to use it

Always applicable; it's a lightweight mindset, not a process.

Common mistakes

- Refactoring without tests (breaking rule 1 to satisfy the others).
- Dogmatically minimising classes at the expense of SRP.

Real-world examples

Extreme Programming teams apply these rules continuously. The Template Method refactoring in our example mirrors how `java.util.AbstractList` removes duplication across list implementations.

In the interview

30-second answer: "Kent Beck's rules of simple design, in priority order: passes the tests, reveals intention, no duplication, fewest elements. (*Clean Code* lists no-duplication before intention; the middle two reinforce each other.) I get the core working with a quick test or demo, then refactor out duplication and improve names, and I don't add classes that don't earn their place."

Self-check

1. Q: Which rule comes first and why? → A: Runs all the tests — without them you can't refactor safely, and testability itself improves design.
2. Q: Which rule has the lowest priority? → A: Minimal classes and methods.

TL;DR

Tests pass → no duplication → clear intent → nothing extra.

---

12. Concurrency

What it is

Concurrency — having several tasks in progress at once, usually on separate *threads* (independent paths of execution inside one program) — is a **decoupling strategy**: it separates *what* gets done from *when* it gets done. It can improve throughput (work completed per second; see System Design Fundamentals) and structure, but concurrent code is hard to get right. Clean concurrency means keeping concurrency code small, separate and built on well-tested library tools.

Analogy: a restaurant kitchen. Several cooks work at once. It works because each cook has their own station and ingredients; trouble starts when two cooks grab the same pan.

The problem it solves

Myths lead to bugs: *concurrency always improves performance* (only when there's waiting or multiple cores — CPU units that can each run a thread at the same moment — to exploit), *design doesn't change* (it changes a lot), *understanding concurrency doesn't matter with a container like a web server* (you still share state between requests). In reality, concurrency adds overhead, bugs are often not repeatable, and it requires a different design strategy.

How it works — defence principles

1. **Single Responsibility**: keep concurrency-related code separate from other code. Our `countWords` is pure single-threaded logic; the executor code (an executor runs tasks on a pool of reusable threads) is separate.
2. **Limit the scope of shared data**: encapsulate it and minimise the places that touch it; guard critical sections (code that touches shared data and must be run by one thread at a time, usually enforced with a *lock*).
3. **Use copies of data**: share immutable objects or give each thread its own copy and merge results at the end.
4. **Threads should be as independent as possible**: each thread processes its own data with no sharing (like each request having its own local variables).
5. **Know your library**: use thread-safe collections (`ConcurrentHashMap`), the executor framework (`ExecutorService`), non-blocking atomics (`AtomicInteger`, `LongAdder` — classes that update a value in one indivisible step without locks), and synchronisers (`CountDownLatch`, `Semaphore`, `CyclicBarrier`) instead of hand-made `wait/notify` code.
6. **Know your execution models** (Chapter 13 covers them in depth): **producer–consumer** (bounded queue between producers and consumers), **readers–writers** (many readers, exclusive writers; balance throughput vs starvation), **dining philosophers** (competing for multiple resources → deadlock, livelock, starvation). *Deadlock*: threads wait for each other forever; *starvation*: a thread never gets its turn.
7. **Beware dependencies between synchronised methods** (`synchronized` methods, which only one thread at a time can run on a given object) on the same shared object: if you must call several, use client-based locking, server-based locking (one method that does it all under its lock) or an adapted server.
8. **Keep synchronised sections small** — locks create contention (threads queuing for the same lock); lock as little code as possible, but correctness first.
9. **Writing correct shutdown code is hard** — plan graceful shutdown (letting running tasks finish before the program stops) from the start (`shutdown()` + `awaitTermination()`, then `shutdownNow()`), beware deadlocks where threads wait for signals that never come.
10. **Testing threaded code:**
    - Treat spurious, one-off failures as potential threading issues — don't dismiss them as "cosmic rays".
    - Get non-threaded code working first.

- Make threaded code **pluggable** (run with 1, 2, many threads) and **tunable** (thread counts configurable).
- Run with **more threads than processors** to force more task switching.
- Run on different platforms.
- **Instrument** code to try to force failures (hand-coded or automated "jiggling" — inserting yields/sleeps to change interleavings — the order in which different threads' steps happen to mix; tools like jcstress exist for this).

Key vocabulary: **bound resources** (fixed-size resources like connection pools — a reusable set of open database connections), **mutual exclusion** (only one thread at a time may use a resource), **starvation**, **deadlock**, **livelock** (threads keep reacting to each other and make no progress). These are covered in Chapters 12–13. (*Clean Code*'s **Appendix A, "Concurrency II"**, goes deeper into the same ideas: client- vs server-based locking, deadlock's four conditions and how to break them, and testing multithreaded code.)

Java example — before/after

```
// File: lld/ch06/concurrency/Main.java
package lld.ch06.concurrency;

import java.util.HashMap;
import java.util.List;
import java.util.Map;
import java.util.concurrent.Callable;
import java.util.concurrent.ExecutorService;
import java.util.concurrent.Executors;
import java.util.concurrent.Future;
import java.util.concurrent.TimeUnit;

/** Clean concurrency: separate concurrency from logic, limit shared data, prefer copies and independence, use the
library. */
public class Main {

    static final List<String> PAGES = List.of(
            "the cat sat on the mat", "the dog sat", "a cat and a dog", "the end");

    /** Pure, single-threaded logic -- testable without any threads (SRP: concurrency kept separate). */
    static Map<String, Integer> countWords(String page) {
        Map<String, Integer> counts = new HashMap<>();
        for (String w : page.split(" ")) counts.merge(w, 1, Integer::sum);
        return counts;
    }

    // ---------------- BEFORE: threads share an unsynchronised counter ----------------
    static class Before {
        static int theCount = 0;                                        // shared mutable state, no synchronisation
        static int run(int repeats) throws InterruptedException {
            Thread[] threads = new Thread[4];
            for (int t = 0; t < threads.length; t++) {
                threads[t] = new Thread(() -> {
                    for (int r = 0; r < repeats; r++)
                        for (String page : PAGES)
                            for (String w : page.split(" "))
                                if (w.equals("the")) theCount++;      // read-modify-write race: updates get lost
                });
                threads[t].start();
            }
            for (Thread t : threads) t.join();
            return theCount;
        }
        // (Sharing a plain HashMap this way is even worse: concurrent resizes can corrupt it.)
    }

    // ---------------- AFTER ----------------
    static class After {
        /** Each task works on its OWN data and returns a result; results are combined once, at the end. */
        static Map<String, Integer> run(int repeats, int threads) throws Exception {
            ExecutorService pool = Executors.newFixedThreadPool(threads);   // know your library
            try {
                List<Callable<Map<String, Integer>>> tasks = new java.util.ArrayList<>();
                for (int t = 0; t < threads; t++) {
                    tasks.add(() -> {
                        Map<String, Integer> local = new HashMap<>();       // thread-confined: no sharing, no
locks
                        for (int r = 0; r < repeats; r++)
                            for (String page : PAGES) countWords(page).forEach((w, c) -> local.merge(w, c,
Integer::sum));
                        return local;
                    });
                }
                Map<String, Integer> total = new HashMap<>();               // combined by ONE thread: no sharing
                for (Future<Map<String, Integer>> f : pool.invokeAll(tasks))
                    f.get().forEach((w, c) -> total.merge(w, c, Integer::sum));   // Future.get() safely hands over
```

```
each result
                return Map.copyOf(total);                                   // publish an immutable copy
            } finally {
                pool.shutdown();                                            // clean shutdown is part of
the design
                if (!pool.awaitTermination(5, TimeUnit.SECONDS)) pool.shutdownNow();
            }
        }
    }

    public static void main(String[] args) throws Exception {
        int repeats = 20_000;
        int expectedThe = 4 * repeats * 4;   // "the" appears 4 times per pass over PAGES, 4 threads
        System.out.println("pure logic: " + new java.util.TreeMap<>(countWords("the cat sat on the mat")));

        System.out.println("== BEFORE (racy; the number varies from run to run) ==");
        int racy = Before.run(repeats);
        System.out.println("count(the) = " + racy + " expected " + expectedThe + " -> lost " + (expectedThe - racy)
+ " updates");

        System.out.println("== AFTER (deterministic) ==");
        for (int threads : new int[]{1, 4, 16}) {                   // more threads than cores is a good stress
test
            Map<String, Integer> safe = After.run(repeats, threads);
            System.out.println(threads + " thread(s): count(the) = " + safe.get("the") + " expected " + (4 *
repeats * threads));
        }
    }
}
```

Output:

```
pure logic: {cat=1, mat=1, on=1, sat=1, the=2}
== BEFORE (racy; the number varies from run to run) ==
count(the) = 182526 expected 320000 -> lost 137474 updates
== AFTER (deterministic) ==
1 thread(s): count(the) = 80000 expected 80000
4 thread(s): count(the) = 320000 expected 320000
16 thread(s): count(the) = 1280000 expected 1280000
```

The *before* shares one `int` among four threads; `theCount++` is a read-modify-write, so concurrent increments overwrite each other and updates are **lost** (the exact number varies from run to run — and on rare runs it may even be correct, which is exactly why such bugs escape testing). The *after* follows the principles: pure logic separate from threading; each task owns its data; results are handed back through `Future.get()` (a `Future` is a handle to a result that a task will produce later) (which guarantees the result is safely visible to the caller) and merged by one thread; the final map is an immutable copy; the pool is shut down properly; and it is tested with 1, 4 and 16 threads (more threads than cores).

Trade-offs

Confinement + merge (after)	Shared state + locks
No locks, no races, scales well	Simple mental model for small cases
Extra memory for per-thread copies	Contention, deadlock risk
Needs a merge step	Every access must be correctly synchronised

When not to use it

Don't add concurrency without a measured need; a single thread is simpler and often fast enough. Prefer higher-level tools (parallel streams for pure CPU work, virtual threads in Java 21 — lightweight threads managed by the JVM, cheap enough to create one per task — for many blocking I/O tasks, i.e. input/output where the thread just waits, such as a network call) over manual thread management.

Common mistakes

- Sharing a `HashMap`/`ArrayList` between threads without synchronisation.
- Check-then-act races (`if (!map.containsKey(k)) map.put(k, v)`) — use `putIfAbsent`/`computeIfAbsent`.
- Forgetting to shut down executors (the JVM may not exit).
- Holding locks while calling unknown code (callbacks — functions passed in to be called later) → deadlock risk.

Real-world examples

- **`java.util.concurrent`** (Doug Lea): `ExecutorService`, `ConcurrentHashMap`, `CompletableFuture`, `ForkJoinPool` (work-stealing — idle threads take queued tasks from busy ones; used by parallel streams).
- **Map-reduce / Hadoop / Spark** (frameworks that split big-data jobs across many machines): independent workers on partitions + a merge step — the same confinement idea at cluster scale.
- **Node.js and Redis** (a JavaScript server runtime and an in-memory data store) use single-threaded event loops (one thread that handles ready events one after another) for their main processing, avoiding shared-memory races by design.

In the interview

> **30-second answer:** "I keep concurrency separate from business logic, minimise shared mutable state — preferring thread confinement (each piece of data is used by only one thread), immutable data and merging results — and use `java.util.concurrent` rather than raw threads. I plan shutdown and test with more threads than cores."

Follow-ups:

- *Q: Why is `count++` not thread-safe?* A: It's read, add, write — two threads can read the same value and one update is lost. Use `AtomicInteger`/`LongAdder` or a lock.
- *Q: Name three concurrency execution models.* A: Producer–consumer, readers–writers, dining philosophers.

Self-check

1. Q: What does concurrency decouple? → A: What gets done from when it gets done.
2. Q: How do you avoid sharing data between threads? → A: Give each task its own data (confinement) and merge results, or share only immutable data.
3. Q: How should you treat a one-off test failure in concurrent code? → A: As a likely real threading bug.

TL;DR

Separate concurrency code, share as little as possible (copies, immutability, confinement), use the library, keep locks small, plan shutdown, test hard.

---

13. Successive Refinement and the Case Studies (Chapters 14–16: how clean code is actually written)

Chapters 14–16 of *Clean Code* are long case studies rather than new rules: the author takes real code and cleans it step by step. They matter because they show the *process*.

Chapter 14 — Successive Refinement refines a command-line argument parser (`Args`) — code that reads the options typed after a program's name, like `-l -p 8080`. The lessons, in brief:

1. **Write it dirty first, then clean it.** Nobody writes clean code in one pass; a working first draft is normal. What's not acceptable is *stopping* there.
2. **Stop when it starts to rot.** When adding each new feature (a new argument type) makes the code noticeably messier, stop adding features and restructure.
3. **Refactor in tiny steps with tests** — after every small change, run the tests; never leave the system broken for long. Large "big-bang" restructurings tend to fail.
4. **Use design to absorb variation**: in the case study, each argument type became its own class behind a common interface (a polymorphic "marshaler"), so new types didn't touch the parser — the same Open/Closed move as our report formatters.

5. **Clean the error handling too** — collect error codes and messages into one exception class instead of scattering them.

Chapter 15 — JUnit Internals critiques a small class from JUnit (`ComparisonCompactor`, by Kent Beck and Erich Gamma), which was already good and well tested, and still improves it. Lessons (codes such as N6 and G28 refer to the smells-and-heuristics catalogue in §14):

- Remove encoding prefixes on fields (`fExpected` → `expected`) — N6.
- Encapsulate conditionals and prefer positive ones (`if (shouldNotCompact())` → `if (canBeCompacted())`) — G28, G29.
- Rename a function whose name hides a side effect or a second job (a `compact` method that also formats → `formatCompactedComparison`) — N7, G30.
- Make hidden temporal coupling explicit (finding the common suffix depends on first finding the common prefix, so make the order visible) — G31.
- Tidy `+1`/`-1` boundary arithmetic into well-named variables — G33.
- The point: even good code can be left a little cleaner — the Boy Scout Rule in action.

Chapter 16 — Refactoring SerialDate cleans up a date class from the open-source (published for anyone to use and modify) JCommon library. The process is the lesson:

1. **First, make it work** — write more tests: coverage (the share of code lines the tests actually execute) rose from about 50% to about 92%, and the new tests exposed real bugs, which were fixed.
2. **Then make it right** — rename (`SerialDate` → `DayDate`), replace integer constants with enums (a `Month` enum; J3), move methods to the classes that own the data (G14/G17), introduce an **Abstract Factory** so the base class no longer knows its concrete subclass (G7), and delete dead code, duplication and noise comments (G9, G5, C3).
3. Every step keeps the tests green.

TL;DR: make it work, then make it right, in small tested steps — and don't let a mess grow.

---

14. Smells and Heuristics (the checklist)

What it is

Clean Code ends with a catalogue of **smells and heuristics** — short rules, each with a code (C1, G5, N1, …), grouped by area. It extends the smells from Fowler's *Refactoring* (Chapter 7). Use it as a review checklist: each item is a *hint* that something could be cleaner, not an absolute law.

The problem it solves

Knowing principles is not enough; you need to *recognise* problems quickly while reading code. A named catalogue gives you and your reviewers a shared vocabulary ("this is G28 — encapsulate that conditional").

How it works — the catalogue, grouped (names listed; meaning in our words)

Comments (C)

Code	Heuristic	Meaning
C1	Inappropriate information	Change history, authors, ticket metadata belong in version control / issue tracker
C2	Obsolete comment	Old, irrelevant or wrong comments — update or delete
C3	Redundant comment	Says what the code already says clearly
C4	Poorly written comment	If worth writing, write it well: brief, correct grammar, precise
C5	Commented-out code	Delete it; version control remembers

Environment (E)

Code	Heuristic	Meaning
E1	Build requires more than one step	Check out, run one command, get a build (compiled, packaged program)
E2	Tests require more than one step	One command (or one click) runs all tests

Functions (F)

Code	Heuristic	Meaning
F1	Too many arguments	Zero best, then one, two, three; more needs strong justification
F2	Output arguments	Surprising; change the owning object's state instead
F3	Flag arguments	A boolean argument means the function does two things
F4	Dead function	Never called? Delete it

General (G) — the largest group, clustered by theme:

Correctness and safety

Code	Heuristic	Meaning
G2	Obvious behaviour is unimplemented	Honour the principle of least surprise; implement what users would expect from the name
G3	Incorrect behaviour at the boundaries	Test edge and corner cases (inputs at the limits: empty, zero, maximum); don't rely on intuition
G4	Overridden safeties	Don't turn off compiler warnings, skip failing tests, or ignore errors
G21	Understand the algorithm	Don't fiddle with ifs until tests pass; know *why* it works
G26	Be precise	e.g. don't use floating point (`double`, inexact for decimals) for currency; handle concurrency, nulls and ties deliberately
G31	Hidden temporal couplings	If calls must happen in order, make the order explicit (each step returns what the next needs)
G33	Encapsulate boundary conditions	Put `+1`/`-1` edge logic in one named place (`int lastIndex = size - 1;`)

Duplication and dead weight

Code	Heuristic	Meaning
G5	Duplication	"One of the most important rules" in the book: every duplication is a missed opportunity for abstraction (methods, polymorphism, Template Method, Strategy)
G9	Dead code	Unreachable/unused code — delete
G12	Clutter	Unused variables, empty default constructors, meaningless comments

Structure and placement

Code	Heuristic	Meaning
G1	Multiple languages in one source file	Minimise mixing (e.g. Java + SQL + HTML + JS in one file)
G6	Code at wrong level of abstraction	Keep high-level concepts in base classes/interfaces and details in implementations
G7	Base classes depending on their derivatives	A base class shouldn't know its subclasses
G8	Too much information	Small, focused interfaces; hide data, utilities, constants
G10	Vertical separation	Define variables and private functions close to where they're used
G13	Artificial coupling	Don't put things together that don't depend on each other (e.g. a general enum inside a specific class)
G14	Feature envy	A method more interested in another class's data than its own should move there
G17	Misplaced responsibility	Put code where a reader would expect to find it
G18	Inappropriate static	Make a method static only if it will never need polymorphic behaviour
G22	Make logical dependencies physical	If a module depends on another's assumption, ask it explicitly instead of assuming
G35	Keep configurable data at high levels	Defaults/constants that are configuration belong near the top (e.g. in `main`/config), passed down
G36	Avoid transitive navigation	Law of Demeter — don't write `a.getB().getC()`

Readability and intent

Code	Heuristic	Meaning
G11	Inconsistency	Do similar things the same way throughout
G15	Selector arguments	Arguments (booleans, enums, ints) that select behaviour → split into functions
G16	Obscured intent	Dense, clever expressions and magic hex numbers hide meaning
G19	Use explanatory variables	Break calculations into named intermediate values
G20	Function names should say what they do	`invoice.adjust(5)` — five what? up or down? Name it `applyDiscountPercent(5)`
G23	Prefer polymorphism to if/else or switch/case	"One switch" rule: at most one switch per type selection, used to create polymorphic objects
G24	Follow standard conventions	Team/industry coding standard, applied consistently
G25	Replace magic numbers with named constants	Also applies to magic strings and tokens
G27	Structure over convention	Enforce design decisions with structure (e.g. abstract methods) rather than naming conventions
G28	Encapsulate conditionals	`if (isRefundable(order))` beats `if (order.isDelivered() && order.daysSinceDelivery() <= 7)`
G29	Avoid negative conditionals	`if (user.isActive())` beats `if (!user.isNotActive())`
G30	Functions should do one thing	Split multi-step functions
G32	Don't be arbitrary	Structure code for a reason and let the reason show
G34	Functions should descend only one level of abstraction	Statements in a function sit one level below the function's name

Java (J)

Code	Heuristic	Meaning
J1	Avoid long import lists by using wildcards (`import java.util.*;`)	The book's advice; note many modern style guides (e.g. Google Java Style) forbid wildcard imports — follow your team's standard
J2	Don't inherit constants	Don't implement an interface just to get its constants; use static imports
J3	Constants versus enums	Prefer `enum` (type-safe, can carry data and behaviour) over `public static final int` codes

Names (N)

Code	Heuristic	Meaning
N1	Choose descriptive names	Names make up most of readability
N2	Choose names at the appropriate level of abstraction	Name for the concept, not the implementation (`notify(recipient)`, not `sendSms(phone)` if it may later be email or push)
N3	Use standard nomenclature where possible	Pattern names, domain terms (`...Decorator`, `...Factory`)
N4	Unambiguous names	Name should make the function's work clear
N5	Use long names for long scopes	Short names only in tiny scopes
N6	Avoid encodings	No type/scope prefixes
N7	Names should describe side effects	`getOrCreateUser`, not `getUser`, if it creates

Tests (T)

Code	Heuristic	Meaning
T1	Insufficient tests	Test everything that could break
T2	Use a coverage tool	Find untested lines and branches (e.g. JaCoCo)
T3	Don't skip trivial tests	They're cheap and document behaviour
T4	An ignored test is a question about an ambiguity	`@Disabled` tests mark unclear requirements — resolve them
T5	Test boundary conditions	Off-by-one errors (one too many or too few) live at the edges
T6	Exhaustively test near bugs	Bugs cluster; where you find one, look for more
T7	Patterns of failure are revealing	Which tests fail together often points to the cause
T8	Test coverage patterns can be revealing	Code not executed by passing tests hints at why failures happen
T9	Tests should be fast	Slow tests don't get run

Java example — several heuristics on one function

```java
// File: lld/ch06/smells/Main.java
package lld.ch06.smells;

import java.math.BigDecimal;
import java.math.RoundingMode;
import java.util.List;

/**
 * A handful of Clean Code heuristics applied to one function:
 * G25 magic numbers, G19 explanatory variables, G16 obscured intent, G28 encapsulate conditionals,
 * G29 avoid negative conditionals, F3 flag arguments, G26 be precise (no floating point for money),
 * N1/G20 descriptive names that say what the function does.
 */
public class Main {

    enum Membership { NONE, PRIME }
    record Parcel(double weightKg, int distanceKm, Membership membership, boolean fragile) {}

    // ---------------- BEFORE ----------------
    static class Before {
        static double calc(Parcel p, boolean express) {                                  // double for money (G26)
            double c;
            if (!(p.membership() != Membership.PRIME)) c = 0; else c = 40;           // double negative
            if (p.weightKg() > 20 || p.distanceKm() > 1500 && !p.fragile() == false) c += 250;   // what does this
mean?
            c += p.weightKg() * 12.5;
            if (express) c = c * 1.5;                                                    // flag argument
            if (express && p.membership() == Membership.PRIME) c = c * 0.9;
            return Math.round(c * 100) / 100.0;
        }
    }

    // ---------------- AFTER ----------------
    static class After {
        enum Speed {                                            // replaces the flag; each speed knows its
multiplier
            STANDARD("1.0"), EXPRESS("1.5");
            final BigDecimal multiplier;
            Speed(String m) { multiplier = new BigDecimal(m); }
        }

        private static final BigDecimal BASE_FEE = new BigDecimal("40");          // rupees, exact decimal (G26)
        private static final BigDecimal RATE_PER_KG = new BigDecimal("12.5");
        private static final double HEAVY_KG = 20;
        private static final int LONG_HAUL_KM = 1500;
        private static final BigDecimal SPECIAL_HANDLING_FEE = new BigDecimal("250");
        private static final BigDecimal PRIME_EXPRESS_DISCOUNT = new BigDecimal("0.9");

        static BigDecimal shippingCost(Parcel p, Speed speed) {
            BigDecimal baseFee = isPrime(p) ? BigDecimal.ZERO : BASE_FEE;
            BigDecimal handlingFee = needsSpecialHandling(p) ? SPECIAL_HANDLING_FEE : BigDecimal.ZERO;
            BigDecimal weightCharge = BigDecimal.valueOf(p.weightKg()).multiply(RATE_PER_KG);   // explanatory
variables
            BigDecimal cost = baseFee.add(handlingFee).add(weightCharge).multiply(speed.multiplier);
            if (isPrime(p) && speed == Speed.EXPRESS) cost = cost.multiply(PRIME_EXPRESS_DISCOUNT);
            return cost.setScale(2, RoundingMode.HALF_UP);                           // round once, explicitly, to
paise
        }

        private static boolean isPrime(Parcel p) { return p.membership() == Membership.PRIME; }   // positive
conditional
        private static boolean needsSpecialHandling(Parcel p) {                                  // encapsulated
conditional
            boolean heavy = p.weightKg() > HEAVY_KG;
            boolean fragileLongHaul = p.distanceKm() > LONG_HAUL_KM && p.fragile();
            return heavy || fragileLongHaul;
```

```
        }
    }

    public static void main(String[] args) {
        List<Parcel> parcels = List.of(
                new Parcel(2, 300, Membership.NONE, false),
                new Parcel(25, 100, Membership.PRIME, false),
                new Parcel(3, 2000, Membership.NONE, true),
                new Parcel(3, 2000, Membership.PRIME, false));
        for (Parcel p : parcels) {
            for (boolean express : new boolean[]{false, true}) {
                double before = Before.calc(p, express);
                BigDecimal after = After.shippingCost(p, express ? After.Speed.EXPRESS : After.Speed.STANDARD);
                boolean same = BigDecimal.valueOf(before).compareTo(after) == 0;
                System.out.printf("%-55s express=%-5s before=%7.2f after=%7s %s%n",
                        p, express, before, after, same ? "same" : "DIFFERENT");
            }
        }
    }
}
```

Output:

```
Parcel[weightKg=2.0, distanceKm=300, membership=NONE, fragile=false] express=false before=  65.00 after=  65.00
same
Parcel[weightKg=2.0, distanceKm=300, membership=NONE, fragile=false] express=true  before=  97.50 after=  97.50
same
Parcel[weightKg=25.0, distanceKm=100, membership=PRIME, fragile=false] express=false before= 562.50 after= 562.50
same
Parcel[weightKg=25.0, distanceKm=100, membership=PRIME, fragile=false] express=true  before= 759.38 after= 759.38
same
Parcel[weightKg=3.0, distanceKm=2000, membership=NONE, fragile=true] express=false before= 327.50 after= 327.50
same
Parcel[weightKg=3.0, distanceKm=2000, membership=NONE, fragile=true] express=true  before= 491.25 after= 491.25
same
Parcel[weightKg=3.0, distanceKm=2000, membership=PRIME, fragile=false] express=false before=  37.50 after=  37.50
same
Parcel[weightKg=3.0, distanceKm=2000, membership=PRIME, fragile=false] express=true  before=  50.63 after=  50.63
same
```

The "same" column proves behaviour didn't change. Fixed smells: double negative (G29), unreadable mixed `&&` / `||` / `== false` condition (G16, G28 → `needsSpecialHandling`), magic numbers (G25), flag argument (F3 → `Speed` enum), unnamed intermediate values (G19), a cryptic name `calc` (N1/G20 → `shippingCost`), and floating-point money (G26 → `BigDecimal` with one explicit `HALF_UP` rounding to paise). The *before* deliberately keeps `double` so you can see the smell; never do that in real money code.

Trade-offs

A checklist can be applied dogmatically. Each item is a heuristic: when two conflict, favour readability and correctness.

When not to use it

Don't block a critical fix on style nits; log them as follow-ups.

Common mistakes

- Treating smell counts as a metric to game.
- Ignoring the **Java** notes that are dated (J1): follow your team's style guide.

Real-world examples

Static analysers (tools that inspect code without running it) encode many of these: **SonarQube** (cognitive complexity — a score for how hard code is to follow, duplicated blocks, commented-out code), **PMD** (unused code, god class), **Checkstyle** (naming, magic numbers), **SpotBugs** (bug patterns), **Error Prone** (Google).

In the interview

> **30-second answer:** "When reviewing I look for duplication, long functions, flag and output arguments, magic numbers, negative or complex conditionals, feature envy, train wrecks, misplaced responsibilities, dead code, and weak tests. Most fixes are small refactorings: extract method, introduce constant, replace conditional with polymorphism."

Self-check

1. Q: Which heuristic does the book call one of its most important rules? → A: G5, Duplication.
2. Q: What does G28 ask you to do? → A: Encapsulate conditionals in a well-named function.
3. Q: What does T4 say about a disabled test? → A: It signals an unresolved ambiguity in requirements.

TL;DR

Use the C/E/F/G/J/N/T catalogue as a shared review vocabulary; fix with small, tested refactorings.

---

15. Code Review Checklist (best practices)

What it is

A **code review** is a peer reading a change before it's merged (combined into the team's main branch), to catch defects, share knowledge and keep the codebase consistent. A checklist makes reviews thorough and fair — and in interviews, it's what you mentally run over your own code before saying "done".

Analogy: a pilot's pre-flight checklist — experienced pilots still use it because it catches what memory misses.

The problem it solves

Unreviewed changes introduce bugs, security holes and inconsistent styles; unfocused reviews waste time on nits while missing real issues.

How it works — the checklist (from most to least important)

1. **Correctness**
   - Does it do what the requirement/ticket says? Are edge cases handled (empty, null, zero, max, duplicates, time zones, rounding)?
   - Are errors handled — no swallowed exceptions, meaningful messages, resources closed?
   - Concurrency: shared mutable state guarded? check-then-act races? thread-safe collections?
2. **Design**
   - Does it fit the existing architecture? Right class/layer for each responsibility (SRP, GRASP)?
   - Dependencies on abstractions (DIP)? Easy to extend without modification (OCP)?
   - Any over-engineering (YAGNI) or duplication (DRY)?
3. **Readability**
   - Intention-revealing names; small functions; no magic numbers; no flag arguments.
   - Comments explain *why*, not *what*; no commented-out code.
4. **Tests**
   - New behaviour covered by tests? Bug fixes include a regression test (one that makes sure the fixed bug can't return)?
   - Tests are F.I.R.S.T., one concept each, readable names?
5. **Security**
   - Input validation; no SQL/command injection (an attack where user input gets run as part of a database query or shell command; prevented by parameterised queries, which send input separately as plain data); output encoding (escaping data before putting it into HTML so it can't run as script).
   - No secrets or credentials in code or logs; sensitive data (PII — personally identifiable information such as names, phone numbers, emails) masked in logs.
   - Authorisation checks (is *this* user allowed to do *this* action?) on every sensitive operation.

6. **Performance and resources**
    - Obvious inefficiencies: N+1 queries (one query to load a list, then one more query per item), repeated work in loops, unbounded collections/caches, missing pagination (returning results page by page instead of all at once).
    - Timeouts (a maximum wait, after which the call gives up) on remote calls; connection/stream closing.
7. **Operability**
    - Useful logs at the right level (and not too many); metrics (counters and timings collected for dashboards and alerts) for important events; feature flags (switches that turn a feature on or off without redeploying) for risky changes.
    - Backwards compatibility (old clients keep working after the change) of APIs, messages and database migrations (scripted changes to the database's table structure).
8. **Style and consistency** — ideally automated by formatter/linter so humans focus on the above.

How to review well (and be reviewed well):

- Keep changes **small** (a few hundred lines at most); large diffs get rubber-stamped (approved without real reading).
- Author: write a clear description (what, why, how tested), self-review first.
- Reviewer: be specific and kind; explain *why*; separate must-fix from optional suggestions ("nit:"); ask questions rather than accuse.
- Automate the mechanical (formatting, static analysis, tests in CI) so humans review design and logic.

Java example

No separate program: every before/after in this chapter is a review finding. For example, reviewing `Before.book` in §2 you would flag: flag argument (F3), error codes, output argument (F2), hidden side effect (SESSION), switch on type code (G23), magic numbers (G25) — exactly the fixes shown in its *after* version.

Trade-offs

Reviews slow merging slightly but catch defects early, spread knowledge and keep style consistent. Too many reviewers or nit-heavy reviews slow teams without adding quality.

When not to use it

Emergency hotfixes (urgent fixes deployed straight to production) may be reviewed after merge (with a follow-up), but should still be reviewed.

Common mistakes

- Reviewing only style while missing logic and security bugs.
- Huge pull requests (a pull request is a proposed change submitted for review and merging).
- Personal preferences presented as rules.

Real-world examples

- **GitHub pull requests / GitLab merge requests / Gerrit** (used by Android and Chromium) implement review workflows.
- Google's engineering practices publish guidance for reviewers and authors (focus on design, functionality, complexity, tests, naming, comments, style).
- **CODEOWNERS** files route reviews to responsible teams.

In the interview

> **30-second answer:** "I review for correctness first — requirements, edge cases, errors, concurrency — then design, readability, tests, security and performance, and leave formatting to tools. I keep feedback specific, explain why, and mark nits as optional."

Self-check

1. Q: What should a reviewer check first? → A: Correctness (including edge cases and error handling).
2. Q: Why keep pull requests small? → A: Large diffs get shallow reviews.

TL;DR

Correctness → design → readability → tests → security → performance → operability; automate style; keep PRs small and feedback kind.

---

16. Error-Handling Strategy (best practices for real services)

What it is

Section 6 covered error-handling *rules* inside code. An **error-handling strategy** is the *system-wide policy*: which exception types exist, where errors are translated, which are retried, how they're logged, and what callers (users/other services) see.

Analogy: a hospital triage system — every problem is classified (critical, urgent, minor), routed to the right place, and recorded once in the patient chart.

The problem it solves

Without a strategy, each developer invents their own: some return `null`, some throw checked exceptions, some log and rethrow at every layer (same error logged five times), some expose stack traces to users, and some retry everything — including permanent failures, which overloads already-struggling services.

How it works

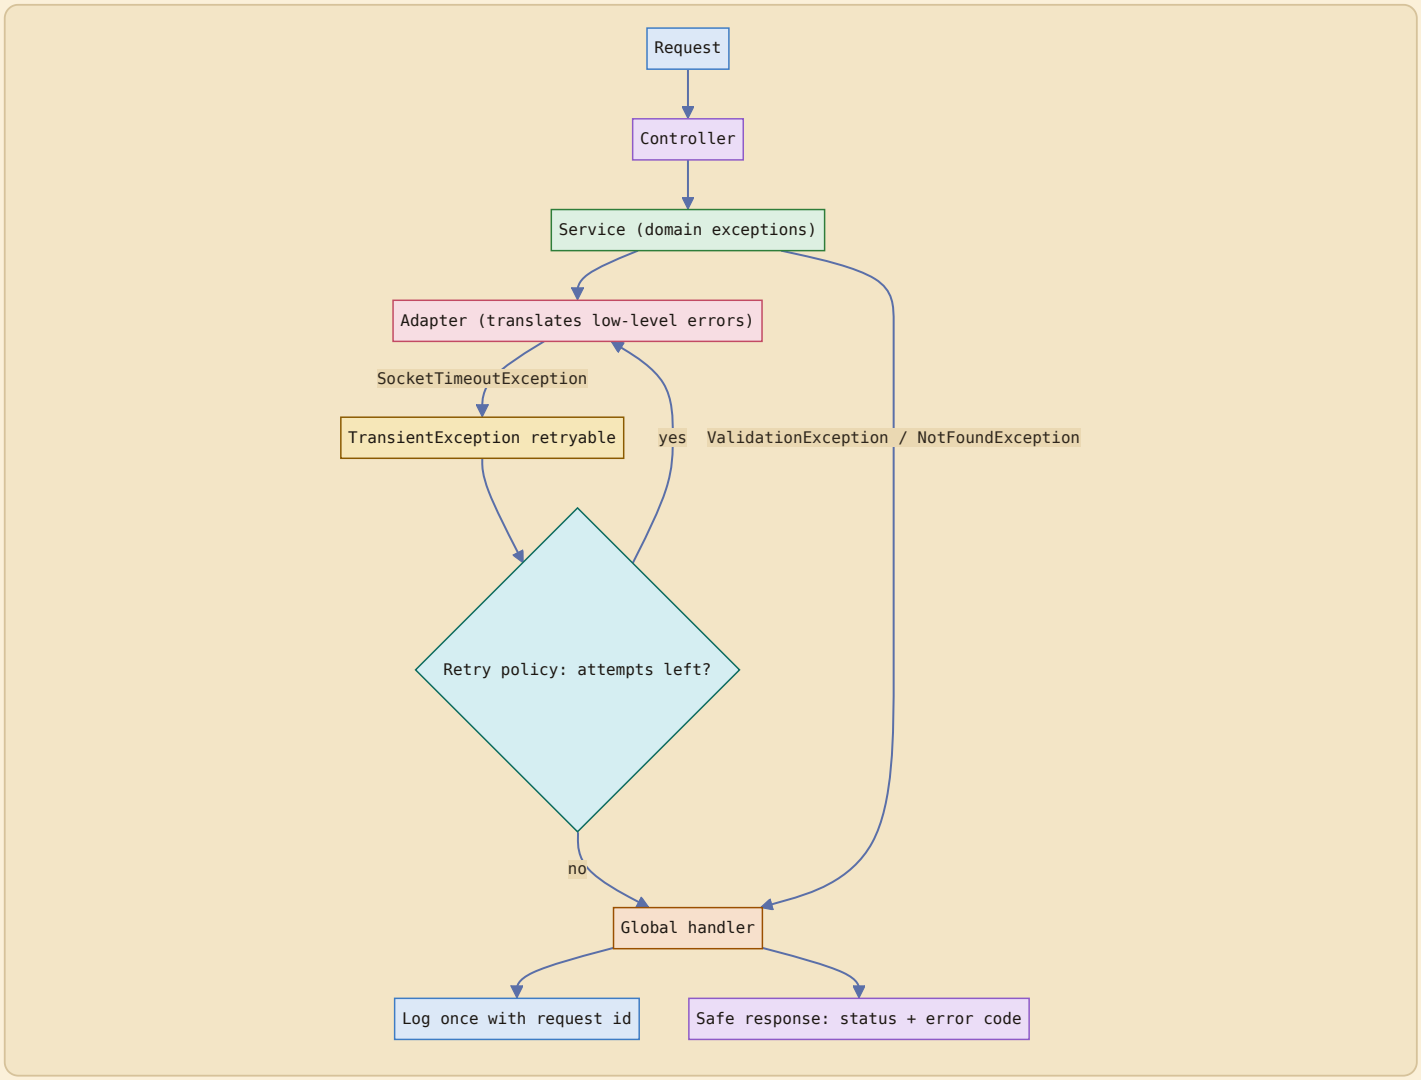
> **Key term — HTTP status codes:** every reply from a web API carries a three-digit status code. **2xx** means success (200 OK); **4xx** means the *client* sent something wrong (400 bad request, 404 not found, 409 conflict with the current state); **5xx** means the *server* failed (500 internal error, 503 service unavailable — often temporary). Retrying usually only makes sense for some 5xx errors and timeouts. See System Design Fundamentals.

1. **Classify errors:**

Class	Examples	Handling
Validation / client errors	bad input, missing field	Reject immediately, 4xx, clear message, no retry
Business rule violations	insufficient funds, seat already booked	Domain exception or result value, 4xx (e.g. 409 conflict)
Not found	unknown id	404 / empty `Optional`
Transient infrastructure	timeouts, 503, connection reset, deadlock victim	Retry with backoff — waiting longer between attempts (only if the operation is **idempotent** — safe to repeat)
Permanent infrastructure	auth failure to DB, misconfiguration	Fail fast, alert
Programming bugs	NPE, index out of bounds	Don't catch locally; generic 500 at the edge, log with details, fix the bug

2. **One exception hierarchy** with an error code and a *retryable* flag, so handlers don't need `instanceof` chains on vendor exceptions.
3. **Translate at boundaries**: adapters convert low-level exceptions (`SocketTimeoutException`, `SQLException`) into domain/infrastructure exceptions, keeping the cause.
4. **Retry only transient errors**, with a maximum number of attempts, **exponential backoff** (each wait doubles: 10 ms, 20 ms, 40 ms…) and **jitter** (randomness to avoid many clients retrying in sync). Combine with **timeouts** and **circuit breakers** (a guard that stops calling a failing dependency for a while after repeated errors) for dependencies.
5. **Use result values for expected, per-item failures** (e.g. validating 10,000 imported rows — collect all errors instead of stopping at the first).

6. **Handle globally at the edge**: one handler maps exceptions to responses (status code, stable error code, safe message) and **logs once** with a correlation/request id (a unique ID attached to one request and stamped on all its log lines, so they can be found together). Never leak stack traces or internals to clients.
7. **Keep the system consistent**: use transactions or compensating actions (follow-up steps that undo an earlier one, e.g. a refund) so partial failures don't leave corrupt state; make handlers idempotent.



Java example

```java
// File: lld/ch06/errorstrategy/Main.java
package lld.ch06.errorstrategy;

import java.net.SocketTimeoutException;
import java.util.ArrayList;
import java.util.List;
import java.util.function.Function;
import java.util.function.Supplier;

/**
 * An end-to-end error-handling STRATEGY for a service:
 *  1. one exception hierarchy with error codes (+ "retryable" flag)
 *  2. translate low-level errors at the infrastructure boundary
 *  3. retry only transient errors, with backoff and a limit
 *  4. use a Result type for EXPECTED failures (e.g. validating many rows)
 *  5. one global handler maps exceptions to responses and logs ONCE, hiding internals
 */
@SuppressWarnings("serial") // the nested exception classes are never serialized
public class Main {

    // ---------- 1. exception hierarchy ----------
    enum ErrorCode {
        VALIDATION_FAILED(400), NOT_FOUND(404), CONFLICT(409), DEPENDENCY_UNAVAILABLE(503);
        final int httpStatus;
        ErrorCode(int s) { httpStatus = s; }
    }
    static class AppException extends RuntimeException {
        final ErrorCode code;
        final boolean retryable;
        AppException(ErrorCode code, String message, boolean retryable, Throwable cause) {
            super(message, cause); this.code = code; this.retryable = retryable;
        }
    }
    static final class ValidationException extends AppException {
        ValidationException(String m) { super(ErrorCode.VALIDATION_FAILED, m, false, null); }
    }
    static final class NotFoundException extends AppException {

        System.out.println("Do NOT retry a permanent failure:");
        var healthy = new InventoryClient(0);
        System.out.println("  " + handle("req-2", () -> withRetry(() -> healthy.stockOf("X-404"), 3, 10), n -> "
{\"stock\":" + n + "}"));

        System.out.println("Give up after max attempts:");
        var down = new InventoryClient(99);
        System.out.println("  " + handle("req-3", () -> withRetry(() -> down.stockOf("TEA"), 3, 10), n -> "
{\"stock\":" + n + "}"));

        System.out.println("Unexpected bug -> generic 500, no internals leaked:");
        System.out.println("  " + handle("req-4", () -> List.<String>of().get(0), s -> s));

        System.out.println("Bulk import: collect ALL row errors instead of stopping at the first:");
        List<String> csv = List.of("TEA,2", "CUP", "PEN,abc", "INK,-1", "MUG,1");
```

```
        List<Row> ok = new ArrayList<>();
        List<String> errors = new ArrayList<>();
        for (int i = 0; i < csv.size(); i++) {
            switch (parseRow(i + 1, csv.get(i))) {
                case Result.Ok<Row> r -> ok.add(r.value());
                case Result.Err<Row> e -> errors.add(e.error());
            }
        }
        System.out.println("  imported " + ok);
        errors.forEach(e -> System.out.println("  rejected " + e));
        if (!errors.isEmpty())
            System.out.println("  " + handle("req-5", () -> { throw new ValidationException(errors.size() + "
invalid rows"); }, x -> "" + x));
    }
}
```

Output:

```
Retry a transient failure, then succeed:
    attempt 1 failed (inventory service timed out), retrying in 10ms
    attempt 2 failed (inventory service timed out), retrying in 20ms
  Response[status=200, body={"stock":7}]
Do NOT retry a permanent failure:
    [log once] req-2 NOT_FOUND: sku X-404 not found
  Response[status=404, body={"error":"NOT_FOUND","message":"sku X-404 not found"}]
Give up after max attempts:
    attempt 1 failed (inventory service timed out), retrying in 10ms
    attempt 2 failed (inventory service timed out), retrying in 20ms
    [log once] req-3 DEPENDENCY_UNAVAILABLE: inventory service timed out
  Response[status=503, body={"error":"DEPENDENCY_UNAVAILABLE","message":"inventory service timed out"}]
Unexpected bug -> generic 500, no internals leaked:
    [log once] req-4 UNEXPECTED java.lang.ArrayIndexOutOfBoundsException: Index 0 out of bounds for length 0
  Response[status=500, body={"error":"INTERNAL","requestId":"req-4"}]
Bulk import: collect ALL row errors instead of stopping at the first:
  imported [Row[line=1, sku=TEA, qty=2], Row[line=5, sku=MUG, qty=1]]
  rejected line 2: expected 2 fields
  rejected line 3: qty 'abc' is not a number
  rejected line 4: qty must be positive
    [log once] req-5 VALIDATION_FAILED: 3 invalid rows
  Response[status=400, body={"error":"VALIDATION_FAILED","message":"3 invalid rows"}]
```

- **req-1**: a transient timeout is retried with exponential backoff (10 ms, 20 ms) and then succeeds.
- **req-2**: `NotFoundException` is *not* retryable, so it fails immediately with 404.
- **req-3**: the dependency stays down; after 3 attempts we give up with 503.
- **req-4**: a programming bug becomes a generic 500 with only a request id; details go to the log.
- **Bulk import**: a sealed `Result` type (`Ok`/`Err`) with pattern-matching `switch` collects all row errors; the caller then decides to reject with 400.

Trade-offs

Choice	Benefit	Cost
Retries	Survive blips	Duplicate side effects unless idempotent; can amplify load
Global handler	Consistent responses, log once	Must avoid swallowing context
Result types	Explicit expected failures	Verbose in Java; mixing with exceptions needs a clear rule

When not to use it

Don't retry non-idempotent operations (e.g. "charge card") unless you use an **idempotency key** (a unique ID the client sends with a request so the server can recognise and ignore repeats), and never retry validation or authorisation failures.

Common mistakes

- Log-and-rethrow at every layer.

- Catching `Exception` in business code.
- Retrying immediately in a tight loop without backoff.
- Returning 200 with an error body.

Real-world examples

- **Spring** `@ControllerAdvice` + `@ExceptionHandler` — a global exception-to-response mapper; **RFC 9457 "Problem Details"** (successor of RFC 7807) standardises JSON error bodies, supported by Spring's `ProblemDetail`.
- **Resilience4j** (successor to Netflix Hystrix, which is in maintenance mode): retry, circuit breaker, rate limiter (caps calls per second), bulkhead (isolates resources so one failing part can't exhaust them all).
- **AWS SDKs** (Amazon Web Services' client libraries) retry throttling ("slow down" responses)/transient errors with exponential backoff and jitter by default.
- **Stripe's API** supports idempotency keys so clients can safely retry payment requests.

In the interview

> **30-second answer:** "I classify errors into validation, business, not-found, transient and bugs; use one exception hierarchy with codes and a retryable flag; translate low-level errors in adapters; retry only transient, idempotent operations with backoff and jitter; and map everything to safe responses in one global handler that logs once with a request id."

Follow-ups:

- *Q: Why jitter?* A: Without it, many clients retry at the same moments and overload the recovering service (thundering herd).
- *Q: How do you make payment retries safe?* A: Idempotency keys — the server stores the result per key and returns it for repeats.

Self-check

1. Q: Which errors should be retried? → A: Transient ones, and only for idempotent operations.
2. Q: Where should errors be logged? → A: Once, at the boundary/global handler (with a correlation id).

TL;DR

Classify, translate at boundaries, retry only transient + idempotent with backoff, result values for expected failures, one global handler that logs once and hides internals.

---

17. Testing Strategies (unit vs integration, test doubles, mocks)

What it is

A **testing strategy** decides *what kinds* of tests to write, *how many* of each, and *how to isolate* code under test. It builds on §8 (clean unit tests).

Analogy: car manufacturing — each part is tested alone (unit), assembled systems are tested together (integration), and finally the whole car is test-driven (end-to-end).

The problem it solves

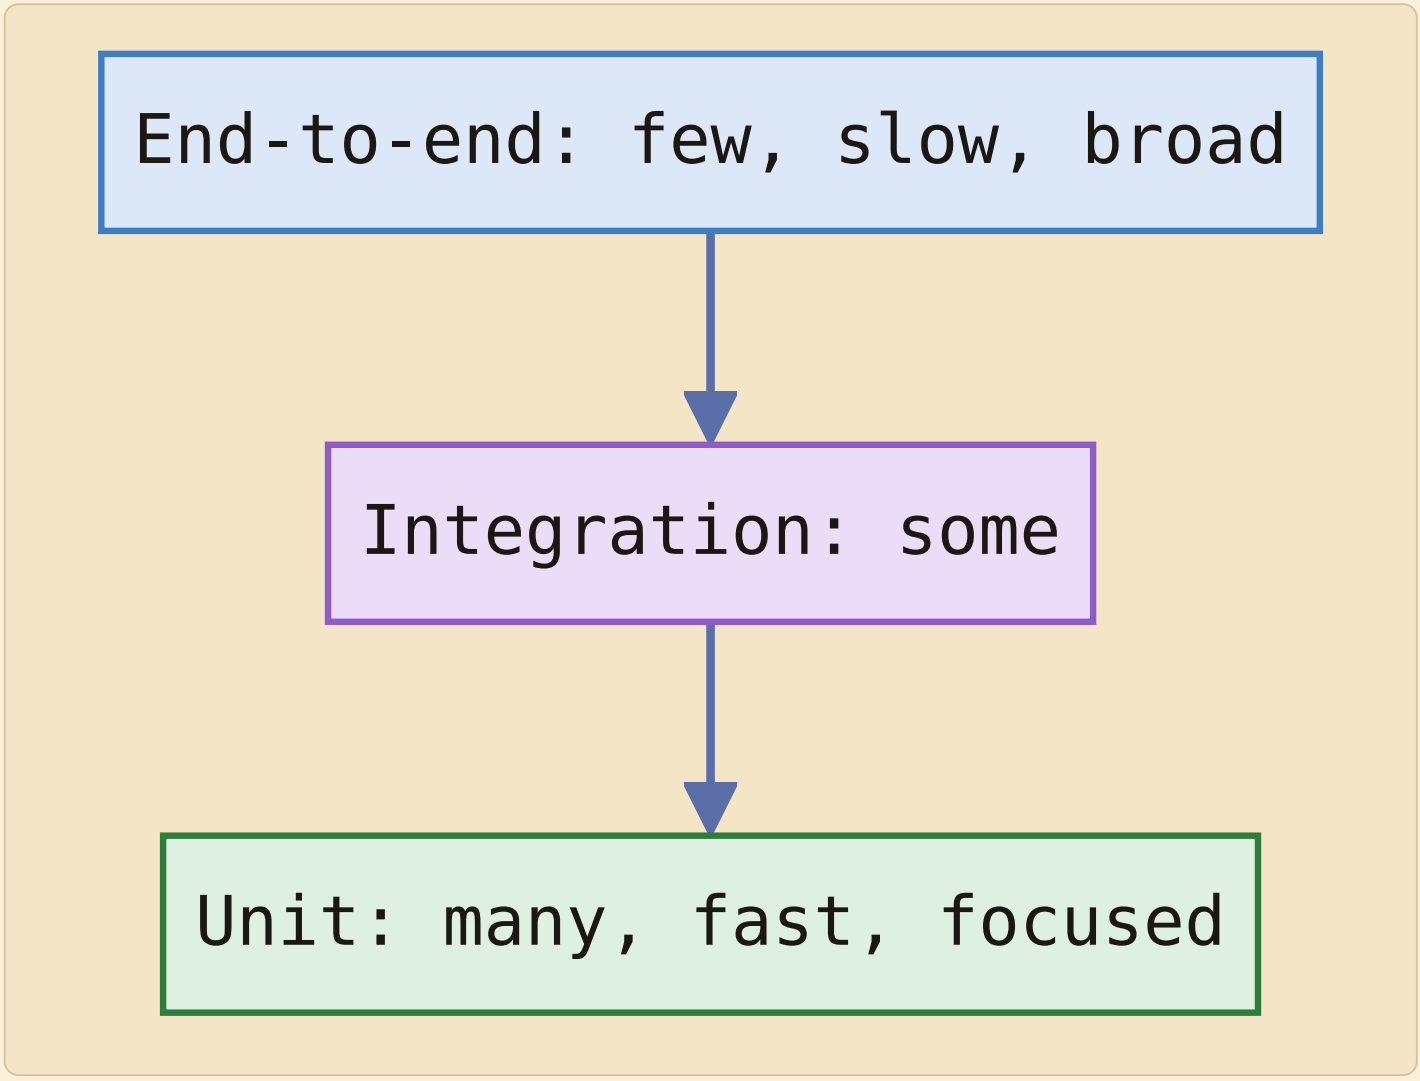
Too few tests → bugs reach production. The wrong mix (mostly slow end-to-end UI tests) → slow, flaky (sometimes passing, sometimes failing with no code change) pipelines (the automated build-and-test runs in CI) that people stop trusting. Over-mocking → tests that pass while the real system is broken, and break on every refactor.

How it works

Kinds of tests:

Kind	Scope	Speed	Catches
Unit	One class/function, collaborators replaced by doubles	Milliseconds	Logic errors
Integration	Several real components together (DB, message broker — a server that passes messages between services, your modules)	Seconds	Wiring, queries, serialisation (turning objects into bytes/text and back), config
Contract	Agreement between a consumer and a provider service	Fast	API mismatches between services
End-to-end (E2E)	The whole system through its UI/API	Slow	User-journey breakage
Others	Performance/load, security, exploratory, property-based, mutation	Varies	Non-functional issues, weak tests

The Test Pyramid (popularised by Mike Cohn): many fast unit tests at the base, fewer integration tests in the middle, very few E2E tests at the top. Avoid the "ice-cream cone" (mostly manual/E2E tests).



Test doubles (Gerard Meszaros' vocabulary, popularised by Martin Fowler):

Double	What it does	In our code
Dummy	Passed to fill a parameter; never used	`DummyAuditLog` (throws if called)
Stub	Returns canned answers to calls	`StubCatalog`
Spy	A stub that records calls for later assertions	`SpySender.sent`
Mock	Pre-programmed with expectations; verifies the interaction itself	`MockAuditLog.expect(...).verify()`
Fake	A working, simplified implementation	`FakeCoupons`, in-memory repositories

State vs behaviour verification: stubs/fakes support *state verification* (check the result or the resulting state); mocks support *behaviour verification* (check that the right calls happened). Prefer state verification; use mocks for outgoing side effects you can't observe otherwise (emails sent, audit events).

What to test: public behaviour, business rules, edge cases (empty, null, boundaries, duplicates), error paths, and every bug fix (regression tests). Don't test private methods directly, trivial accessors, or the framework itself.

Mocking rules of thumb: don't mock types you don't own (wrap them first and mock your wrapper — see Boundaries); don't mock value objects; one or two mocks per test at most; if a test needs many mocks, the class has too many dependencies.

Coverage: a coverage tool (e.g. JaCoCo) shows untested code; high coverage is *necessary but not sufficient* — mutation testing (e.g. PIT) checks whether tests actually detect changes.

Java example

The code is in §8 (`lld.ch06.testing`): `CheckoutTest` uses all five double types for fast unit tests; `CheckoutIntegrationTest` wires real in-memory implementations together; `BeforeStyleTest` shows what to avoid. The output there shows all eight tests passing.

Trade-offs

More unit tests	More integration/E2E tests
Fast, precise failure location	Higher confidence the pieces fit
May miss wiring/config bugs	Slow, flakier, harder to debug
Over-mocking couples tests to implementation	Need environments (DB, containers — isolated runtime packages such as Docker)

When not to use it

Don't insist on unit tests for thin glue code that only wires frameworks — an integration test covers it better. Don't write E2E tests for every edge case — push those down to unit tests.

Common mistakes

- Mocking everything, including value objects and the class under test.
- Flaky tests (time, randomness, order dependence, shared DB state) left unfixed — they destroy trust.
- Testing implementation details (exact internal calls) instead of outcomes.
- No tests for error paths.

Real-world examples

- **JUnit 5**, **Mockito** (mocks/spies/stubs), **AssertJ**, **Testcontainers** (real PostgreSQL/Kafka in Docker for integration tests), **WireMock** (fake HTTP services), **Pact** (consumer-driven contract tests), **PIT** (mutation testing), **JaCoCo** (coverage).
- Spring Boot test slices (`@WebMvcTest`, `@DataJpaTest`) for focused integration tests.

In the interview

> **30-second answer:** "I follow the test pyramid: many fast unit tests with test doubles, fewer integration tests with real components like the database via Testcontainers, and a handful of end-to-end tests. I prefer state verification with stubs and fakes, use mocks only for outgoing side effects, and never mock types I don't own."

Follow-ups:

- *Q: Mock vs stub?* A: A stub supplies canned answers so the test can check state; a mock is set up with expectations and verifies the calls themselves.
- *Q: Spy vs mock?* A: A spy records calls for the test to assert afterwards; a mock checks expectations itself.
- *Q: What's a fake?* A: A lightweight working implementation, e.g. an in-memory repository.

Self-check

1. Q: Name the five test doubles. → A: Dummy, stub, spy, mock, fake.
2. Q: Why a pyramid shape? → A: Lower-level tests are faster, cheaper and more precise; top-level tests are slow and brittle, so keep few.
3. Q: Is 100% coverage proof of good tests? → A: No — it shows code ran, not that assertions would catch bugs (mutation testing checks that).

TL;DR

Many unit tests, some integration, few E2E; pick the right double (dummy/stub/spy/mock/fake); verify state over interactions; don't mock what you don't own.

Chapter summary

Topic	Remember this
Names	Reveal intent, pronounceable, searchable, one word per concept
Functions	Small, one thing, one level, stepdown, ≤2–3 args, no flags, CQS, exceptions
Comments	Explain in code; comment only why/warnings/legal/public API
Formatting	Newspaper order, related things close, automated team style
Objects vs data	Objects hide data; data structures expose it; anti-symmetry decides
Error handling	Unchecked exceptions with context, wrap vendors, no null in or out
Boundaries	Wrap third-party code; learning tests; define interfaces you need
Unit tests	TDD laws, one concept per test, F.I.R.S.T.
Classes	Small by responsibility, cohesive, organised for change
Systems	Composition root + DI; cross-cutting via proxies/aspects
Emergence	Beck: tests pass → reveals intent → no duplication → fewest elements (*Clean Code* swaps the middle two)
Concurrency	Separate it, share little, use the library, test hard
Smells	C/E/F/G/J/N/T checklist
Code review	Correctness → design → readability → tests → security → performance
Error strategy	Classify, translate, retry transient, handle globally, log once
Testing strategy	Pyramid; right test double; state over behaviour verification

Chapter self-check

1. Q: A method `boolean saveAndValidate(Order o, boolean sendEmail)` breaks which rules? → A: Does two things, flag argument (F3), likely violates CQS (returns a boolean while changing state), name reveals multiple responsibilities.
2. Q: What should `findOrders(customerId)` return when there are none? → A: An empty list, never `null`.
3. Q: How do you test code that calls `LocalDate.now()`? → A: Inject a `Clock`; use `Clock.fixed` in tests.
4. Q: What does a dynamic proxy let you do cleanly? → A: Apply a cross-cutting concern (logging, transactions) to every method of an interface in one place.
5. Q: Which of Beck's rules has the highest priority? → A: Passes all the tests.

TL;DR (chapter)

Write code for the next reader: honest names, tiny single-purpose functions, few comments that explain why, consistent layout, clear exceptions instead of codes or nulls, foreign code behind your own interfaces, clean fast tests, small cohesive classes wired from one place, simple design that emerges through refactoring, careful concurrency — and review everything against a shared checklist.

Chapter 7 — Refactoring

> **What you will learn.** What refactoring is (and is not), when to do it, how tests make it safe, the full catalogue of **code smells** (the signals that tell you *where* to refactor), the full catalogue of **refactorings** from Martin Fowler's *Refactoring* (2nd edition, 2018), a smell → refactoring lookup table, a complete worked example in Java that goes from messy to clean in six compiling steps, and how refactoring leads you toward design patterns (named, reusable solutions to recurring design problems; Chapters 8–11).
>
> **Why it matters for LLD interviews.** Machine-coding rounds (interview rounds where you build a small working program in about 60–120 minutes; a core part of LLD — low-level design — interviews) often end with "now add feature X" or "what would you clean up?". Interviewers want to hear you name a smell ("this switch is repeated in three places — a Repeated Switches smell") and name the fix ("Replace Conditional with Polymorphism, which gives us a Strategy" — the Strategy pattern puts each interchangeable algorithm in its own class). This chapter gives you that vocabulary.

Chapter map

Part	Content
7.1	Refactoring fundamentals — definition, two hats, why, when, when not, tests, performance, rewrite vs refactor, IDE (Integrated Development Environment, e.g. IntelliJ IDEA) automation, legacy code
7.2	Code smells — the 24 smells of the 2nd edition, grouped the refactoring.guru way
7.3	The refactoring catalogue — all 61 named refactorings of the 2nd edition, by book chapter, plus the extra ones on refactoring.com
7.4	Smell → refactorings lookup table
7.5	Worked example — a messy invoice class refactored in six compiling steps
7.6	Refactoring toward patterns — Strategy, State, Special Case, Template Method, Factory
7.7	Trade-offs, mistakes, real-world examples, interview answers, self-check, TL;DR
7.8	Full source code and program output

7.1 Refactoring fundamentals

What it is

Refactoring (noun) is a change made to the internal structure of software to make it easier to understand and cheaper to modify, *without changing its observable behaviour*.

Refactoring (verb) is restructuring software by applying a *series* of such small, behaviour-preserving changes.

Two words in that definition do all the work:

- **Behaviour-preserving.** After the change, the program does the same thing from the outside. Same outputs for the same inputs, same side effects (changes made besides returning a value, such as writing a file), same errors. The only things that may change are *internal* — names, where code lives, how it is split up. (Performance may change a little; see 7.1.9.)
- **Small steps.** Each step is so small that it is almost impossible to get wrong, and the code compiles and the tests pass after *every* step. You chain many tiny steps to get a big change. If you ever sit with broken code for an hour, you were not refactoring — you were rewriting.

Everyday analogy. Think of reorganising a kitchen while the restaurant stays open. You move one shelf at a time. After each move, the cooks can still make every dish. You never tear the whole kitchen down on a Friday night.

> **Term — observable behaviour.** What a user (or calling code) can see: return values, printed output, data written, exceptions thrown. The *call stack* (the chain of method calls currently in progress), the *class structure*, and the *names of private methods* are not observable behaviour.

What refactoring is NOT.

Activity	Is it refactoring?	Why
Renaming a method with the IDE	Yes	Behaviour unchanged, tiny step
Fixing a bug	No	Behaviour changes (on purpose)
Adding a feature	No	Behaviour changes
Performance tuning	No	Goal is speed, not clarity (though behaviour is preserved)
"I spent two days restructuring and nothing worked until the end"	No	That is restructuring/rewriting, not refactoring
Reformatting code	Borderline	Behaviour-preserving, but it does not improve design

> **Term — restructuring.** The general word for reorganising code. Refactoring is a *specific kind* of restructuring: small, behaviour-preserving steps.

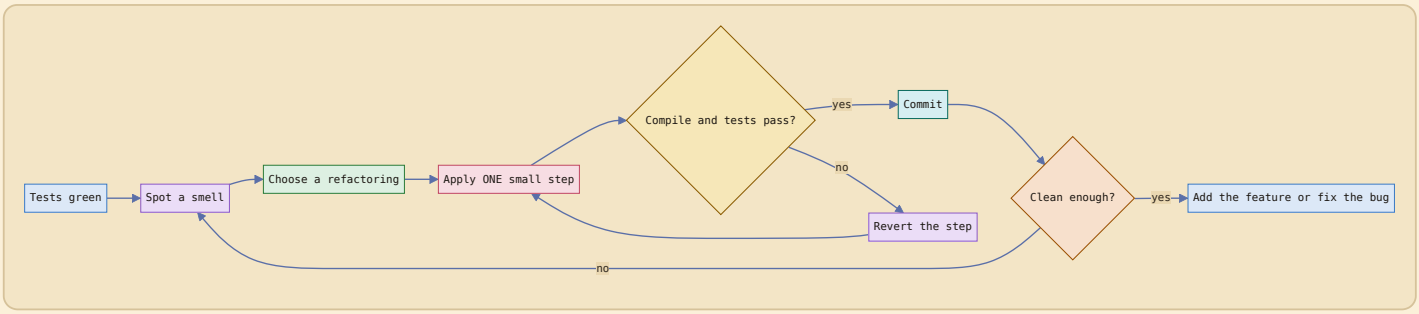
The problem it solves

Code decays. Every quick fix, every "just add another `if`", every copy-paste makes the next change a little harder. This is called **design decay** or **technical debt** — the extra cost you pay on every future change because the code is harder to work with than it needs to be.

Refactoring pays down that debt. It keeps the design good *continuously*, instead of hoping to get the design right up front (which never fully works, because requirements change).

How it works

1. **Make sure you have tests** that pin down current behaviour (7.1.7). Run them — they must be green (all passing).
2. **Spot a smell** — a surface sign that the design could be better (7.2).
3. **Pick a named refactoring** that cures the smell (7.3, 7.4).
4. **Apply one small step** of it (ideally with the IDE's automated refactoring).
5. **Compile and run the tests.** Green? Commit (locally) — i.e. save a snapshot of the code in version control such as Git. Red? Undo the step (don't debug) and take a smaller step.
6. **Repeat** until the code is clean enough for the job at hand.



7.1.1 The two hats

Kent Beck's metaphor: when you program you wear **one of two hats** at any moment.

Hat	You are allowed to	You are NOT allowed to
Adding function	Add new behaviour, add new tests	Restructure existing code
Refactoring	Restructure code	Add behaviour or tests for new behaviour (you may add tests for *existing* behaviour you forgot to cover)

You swap hats often — maybe every few minutes — but you always know which one you are wearing. Mixing them ("I'll just fix this bug while I extract this method") is how refactoring becomes risky: when a test fails you cannot tell which change caused it.

7.1.2 Why refactor

- **It improves the design.** Without it, the internal design (architecture) of a program decays as people change code to meet short-term goals. Regular refactoring keeps the code in shape. A big part of this is **removing duplication** — making sure each fact lives in exactly one place.
- **It makes software easier to understand.** Code is read far more often than it is written. Refactoring lets you move your understanding *out of your head and into the code*, so the next reader (including you in six months) does not need to rediscover it.
- **It helps you find bugs.** When you clarify the structure, assumptions become visible and bugs have fewer places to hide.
- **It helps you program faster.** This is the surprising one. Fowler calls it the **Design Stamina Hypothesis**: a team that keeps its internal quality high will, after a short while, add features *faster* than a team that does not, because each feature builds on clean code instead of fighting a mess. Speed is the economic argument for refactoring — not "clean code for its own sake".

7.1.3 When to refactor

Trigger	What it means	Example
Rule of Three (Don Roberts)	First time, just do it. Second time you do something similar, wince but duplicate. Third time, refactor.	Third copy of the same validation code → extract a validator
Preparatory refactoring	Refactor *just before* adding a feature, to make the feature easy to add. "Make the change easy, then make the easy change."	Before adding HTML output, split calculation from text formatting (see 7.5, step 3)
Comprehension refactoring	Refactor to understand code you are reading. Rename a variable once you understand it; extract a block once you know what it does. The understanding moves into the code.	Rename `d` to `daysOverdue` after working out what it holds
Litter-pickup refactoring	You notice mess while working on something else. Fix it if it is quick; if not, note it and come back. The **Boy Scout Rule** — leave the campground cleaner than you found it.	Remove an unused parameter while passing by
Planned vs opportunistic	Most refactoring should be *opportunistic* — woven into feature work and bug fixes, not scheduled separately. Planned refactoring episodes are sometimes needed when a team has neglected the code, but they should be rare.	Good: every feature PR (pull request — a change submitted for review) contains a few small refactoring commits. Warning sign: a "refactoring sprint" (a fixed 1–4-week work period) every quarter
Long-term refactoring	Big changes (replacing a library, splitting a module) done gradually over weeks, keeping the system working the whole time — e.g. with **Branch by Abstraction** (introduce an abstraction layer, switch callers to it, swap the implementation behind it, delete the old one).	Moving from one ORM (library mapping objects to database tables) to another behind a repository interface
During code review	Reviewing is a natural moment to suggest (or pair on) refactorings. Fowler prefers doing it *with the author*, trying the refactoring ideas as you go, rather than only leaving comments.	"This method has four flag parameters — can we Remove Flag Argument?"

> **Term — Rule of Three.** A heuristic: do not abstract on the first or second occurrence of a pattern (you do not yet know what varies); abstract on the third, when the shape is clear.

Should you tell your manager? Fowler's position: for a manager who does not understand technical work, do not ask permission for refactoring any more than you ask permission to write tests. It is part of how professionals deliver features quickly. (For large, planned efforts, of course, discuss them.)

7.1.4 When NOT to refactor

- **Code you never need to touch or understand.** Messy code hidden behind a clean API (the set of methods other code calls), that works and never changes, can stay messy. Refactor only what gets in your way.
- **When rewriting is cheaper** than refactoring (see 7.1.10). This is a judgement call and usually needs experience.
- **Without a safety net** — if you cannot test it and cannot use safe automated refactorings, first add tests (7.1.11 shows how for legacy code).
- **On a deadline that truly cannot move**, a big refactoring may wait — but note that the Design Stamina Hypothesis says skipping it usually makes you *slower*, even in the short term. Deadlines are rarely a good excuse for small refactorings.
- **Published interfaces** that you do not control the callers of (a public library API, a REST endpoint — a URL of a web API, see System Design Fundamentals — used by other teams). You can still refactor them, but you must keep the old version working for a while and deprecate it (mark it as outdated and due for removal) (see *Change Function Declaration*, migration mechanics).

7.1.5 Problems and costs of refactoring

Problem	What goes wrong	Mitigation
Slowing down new features	Refactoring "takes time away" from features	Refactor *because* it speeds features up; focus on code you are about to change
Code ownership	You cannot rename a method whose callers are in another team's repo (repository — a project's version-controlled code store)	Keep the old name as a delegating, `@Deprecated` method; migrate callers later; prefer weak (team-wide) code ownership
Long-lived feature branches (lines of work kept apart from the main code for a long time)	Refactoring renames and moves code, which makes merges painful	**Continuous Integration** (merge into the shared main line often, with automatic builds and tests) / trunk-based development (everyone works on one main branch): integrate at least daily, so refactorings conflict less
Missing tests	Refactoring without tests is risky	Add tests first; use only IDE-automated, provably-safe refactorings until tests exist
Legacy code	Big, untested, tangled	Feathers' techniques (7.1.11)
Databases	Schema (table structure) changes are hard to reverse	**Evolutionary database design**: small migration scripts (scripts that change the database structure), versioned with the code; use **parallel change** (add new column, copy, switch readers, remove old)

> **Term — parallel change (expand / contract).** Make a breaking change in three phases: *expand* (add the new thing alongside the old), *migrate* (move all users to the new thing), *contract* (remove the old thing). At no point is anything broken.

7.1.6 Refactoring, architecture and YAGNI

In the past people tried to get the architecture "right" before writing code. Refactoring changes that: because you can reshape code safely later, you can build **only what today's requirements need** and evolve the design when new needs appear. This is **YAGNI** ("You Aren't Gonna Need It") — do not add flexibility for imagined future requirements. YAGNI does not mean "never think about architecture"; it means you trust refactoring to add the flexibility when the need becomes real (and you think harder up front only about things that are *truly* hard to change later, like a public API or a database schema).

7.1.7 Tests as the safety net

Refactoring is safe only if you can detect a behaviour change immediately. That is what **self-testing code** gives you: a suite of automated tests that checks itself (pass/fail, no human reading output) and runs in seconds.

- Run tests after **every** small step. With fast tests, a failure points at the few lines you just changed.
- If a test fails, **revert** — do not start debugging a refactoring. Then redo it in smaller steps.

- Tests should focus on **behaviour** (public API, outputs), not on private structure. Tests that check private methods break on every refactoring and become a cost instead of a safety net.
- **Characterisation tests** (a term from Michael Feathers): for code without tests, write tests that record what the code *currently does* — even if that looks wrong — so you notice if a refactoring changes it. The worked example in 7.5 uses exactly this: a checker that compares every step's output with the original, byte for byte.
- Consider **mutation testing** (e.g. PIT for Java) to check your tests actually catch changes — it deliberately introduces small bugs and reports any your tests fail to detect.

> **Term — safety net.** Anything that tells you quickly and reliably that you broke something: unit tests (one class tested in isolation), integration tests (several real parts tested together), the compiler's type checks, and the IDE's automated refactorings (which are proven safe by the tool).

7.1.8 IDE automation

Modern IDEs perform many refactorings *automatically and safely*, using the compiler's knowledge of the code (the **syntax tree** and **symbol resolution** — the parsed structure of the code, and knowing exactly which declaration each name refers to), not text search. A text search-and-replace of `name` would also hit comments, strings and unrelated fields; the IDE's Rename only changes that one symbol and all its real references.

History in one line: Bill Opdyke's 1992 PhD thesis formalised refactorings; John Brant and Don Roberts built the Smalltalk (an early object-oriented language) *Refactoring Browser*, the first automated tool; Java IDEs (IntelliJ IDEA, Eclipse) popularised it.

Refactoring	IntelliJ IDEA (Windows/Linux · macOS)	Eclipse (Windows/Linux)
Rename	Shift+F6 · Shift+F6	Alt+Shift+R
Extract Method (Extract Function)	Ctrl+Alt+M · Cmd+Opt+M	Alt+Shift+M
Extract Variable	Ctrl+Alt+V · Cmd+Opt+V	Alt+Shift+L
Extract Field / Constant / Parameter	Ctrl+Alt+F / C / P · Cmd+Opt+F / C / P	(Refactor menu)
Inline	Ctrl+Alt+N · Cmd+Opt+N	Alt+Shift+I
Change Signature	Ctrl+F6 · Cmd+F6	Alt+Shift+C
Move	F6 · F6	Alt+Shift+V
"Refactor This" menu	Ctrl+Alt+Shift+T · Ctrl+T	Alt+Shift+T

(Shortcuts are the default keymaps; check your IDE if you use a custom keymap.)

Beyond the IDE there are **large-scale automated refactoring tools**, such as OpenRewrite (recipes that, for example, migrate a whole codebase between framework versions) and Google's Refaster templates in Error Prone (Google's bug-finding plugin for the Java compiler). These let a company apply the same refactoring across thousands of files.

> **Caution.** Automated refactorings are safe for statically known calls. They can miss **reflection** (`Class.forName("…")` — code that looks up classes or methods by name at runtime), names used in **configuration files**, **serialised field names** (serialising = turning objects into text or bytes, e.g. JSON, a plain-text data format; JSON/Jackson, JPA — Java's standard ORM API — column names inferred from field names), and code in other repositories. After an IDE rename of a field that is serialised, the JSON your API returns changes — that *is* an observable behaviour change.

7.1.9 Performance and refactoring

A common worry: "refactoring adds method calls and small objects, so the program gets slower." Fowler's answer has three parts:

1. **Most refactorings have negligible performance effect.** The JIT (Just-In-Time) compiler — the part of the JVM, Java's runtime, that compiles frequently run code to machine code while the program runs — inlines small methods (copies their body into the caller); extra method calls are nearly free in modern Java.

2. **Programs spend most of their time in a small fraction of the code.** Optimising everywhere wastes effort on code that is rarely run. (The book retells a story from Ron Jeffries about Chrysler's slow payroll system: nobody's guesses about the cause were right; profiling (measuring where a program actually spends its time) found the time going to one unexpected spot, and a small fix there made it fast.)
3. **Well-factored code is easier to tune.** When you do need speed, you profile, find the hot spot (the small piece of code where most time goes), and — because the code is well-structured — the hot spot is small and isolated, so it is easy to optimise.

So the recommended order is: **make it work → make it clean (refactor) → make it fast (profile, then optimise only the hot spots)**. Sometimes a refactoring makes code slightly slower; that is fine if it makes the later, targeted optimisation easier.

Example from this chapter. In 7.5 step 2 we replace a summing loop with a stream (Java's pipeline for processing a sequence of elements). `DoubleStream.sum()` is allowed to use *compensated summation* (a technique that tracks rounding errors to make floating-point sums more accurate; OpenJDK, the reference Java implementation, does), so it can give a result that differs in the last bit from a plain loop — a tiny *behaviour change*. To stay a true refactoring we used `reduce(0.0, Double::sum)`, which adds left to right exactly like the loop. Refactoring demands this kind of care.

7.1.10 Refactoring vs rewriting

	Refactoring	Rewriting
Unit of change	Many tiny, safe steps	One big replacement
System works during the change?	Always	Usually not until the end
Risk	Low	High — known bugs fixed years ago get reintroduced; the old system keeps evolving while you rewrite
Delivers value	Continuously	Only at the end
Good when	Code mostly works, needs reshaping	Code is so broken it does not work at all, or the technology must change completely

Even when you must replace a system, you rarely do it in one go. The **Strangler Fig** approach (named by Fowler after a vine that slowly grows around a tree) builds the new system *around* the old one, routing one feature at a time to the new code until the old code can be switched off. It is the rewrite equivalent of "small steps".

7.1.11 Legacy code

Michael Feathers (*Working Effectively with Legacy Code*, 2004) defines **legacy code as code without tests**. Such code is hard to refactor because you have no safety net, and hard to test because it was not designed for it. The way out is a loop:

1. **Identify change points** — where you need to change code.
2. **Find test points** — where you can observe behaviour.
3. **Break dependencies** — using a **seam**: a place where you can change behaviour without editing the code there, e.g. by passing in an interface instead of calling `new Database()` inside a method (constructor injection), or overriding a method in a test subclass.
4. **Write characterisation tests** that pin down current behaviour.
5. **Make the change and refactor** under that safety net.

Other useful techniques from that book:

- **Sprout Method / Sprout Class** — write the new feature as a *new*, fully tested method or class, and call it from the old code with a one-line change.
- **Wrap Method / Wrap Class** — rename the old method and create a new method with the old name that calls the old one plus the new behaviour (a Decorator-like move — a Decorator wraps an object to add behaviour).
- Use **safe automated refactorings only** (Rename, Extract Method with the IDE) until tests exist.
- Do not try to clean everything. Refactor the areas you touch; over time the most-changed code becomes the cleanest.

7.2 Code smells

What it is

A **code smell** (a term coined by Kent Beck) is a *surface sign* in the code that usually points to a deeper design problem. A smell is not a bug — the code works. It is a hint that the code will be hard to understand or change. Like a smell in a fridge, it tells you *where to look*, not exactly what is wrong.

Smells are **heuristics, not rules**. A long method is not always bad; a switch statement is not always bad. The smell tells you to look closer and use judgement.

The problem it solves

Knowing *how* to refactor is not enough; you must also know *when* and *where*. Fowler and Beck deliberately give no precise metrics ("no method longer than 10 lines"). Instead they give a catalogue of named smells, each with the refactorings that usually cure it. Names matter: in a code review, "Feature Envy" communicates in two words what would otherwise take a paragraph.

How it works

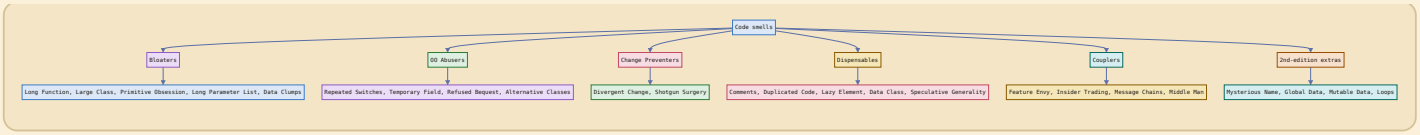
1. Read the code and notice discomfort: "I had to scroll", "I changed five files for one feature", "I can't tell what `x2` is".
2. Match the discomfort to a named smell (the table below).
3. Look up the refactorings that cure it (each smell below, and 7.4).
4. Apply them in small steps under tests.

Smell groups (refactoring.guru classification)

refactoring.guru (a popular website on refactoring and design patterns) groups smells into five families. It uses mostly the 1st-edition names, so the table maps them to the 2nd-edition names used in this chapter.

Group	Idea	Smells (2nd-ed name; refactoring.guru name in brackets if different)
Bloaters	Code, methods and classes that have grown so big they are hard to work with. They usually grow slowly.	Long Function *(Long Method)*, Large Class, Primitive Obsession, Long Parameter List, Data Clumps
Object-Orientation Abusers	Incomplete or wrong use of OO (object-oriented) principles.	Repeated Switches *(Switch Statements)*, Temporary Field, Refused Bequest, Alternative Classes with Different Interfaces
Change Preventers	One change forces many other changes.	Divergent Change, Shotgun Surgery *(also: Parallel Inheritance Hierarchies — a 1st-ed smell)*
Dispensables	Something pointless whose removal makes the code cleaner.	Comments, Duplicated Code *(Duplicate Code)*, Lazy Element *(Lazy Class)*, Data Class, Speculative Generality *(also: Dead Code — in the 2nd ed. this is the refactoring Remove Dead Code)*
Couplers	Too much coupling between classes, or too much delegation (handing work off to another object).	Feature Envy, Insider Trading *(Inappropriate Intimacy)*, Message Chains, Middle Man *(also: Incomplete Library Class — a 1st-ed smell)*
New in the 2nd edition (not in refactoring.guru's five groups)		Mysterious Name (a comprehension smell), Global Data and Mutable Data (both about uncontrolled shared state — closest to Couplers/Change Preventers), Loops (closest to Bloaters)

> **Term — coupling.** How much one piece of code depends on another. High coupling means a change in one place forces changes in others. **Cohesion** is the opposite idea inside one unit: how strongly the things inside a class or module belong together. Good design: low coupling, high cohesion.



Below are all 24 smells from the 2nd edition, in the book's order. Each has: **what it is**, **why it hurts**, a small **Java example** (smelly → cured), and **refactorings that fix it** (the ones Fowler names for that smell; anything extra is marked). The names match the catalogue in 7.3.

> **Note on the snippets.** Several short snippets use `double` for prices or balances to stay tiny. Real money should use `BigDecimal` (Java's exact decimal type) or a `Money` value object (a small immutable object compared by its value) — see 7.2.11 and `code/smells/Money.java`.

7.2.1 Mysterious Name

What it is. A function, variable, field, class or module whose name does not tell you what it does or holds: `data`, `tmp`, `proc()`, `x2`, `Manager`, `handle()`.

Why it hurts. Names are the main tool for making code understandable. A bad name forces every reader to decode the implementation. And if you *cannot* think of a good name, that is often a sign of a deeper design problem — the thing does too much or has no clear purpose.

```
// Smelly
double calc(List<Double> l, int d) { ... }

// Cured
double averageDailyRevenue(List<Double> dailyRevenues, int daysInPeriod) { ... }
```

Refactorings. Change Function Declaration (rename), Rename Variable, Rename Field.

7.2.2 Duplicated Code

What it is. The same (or nearly the same) code structure in more than one place.

Why it hurts. Every change must be made in every copy, and you must *find* every copy and check whether the small differences matter. Sooner or later one copy is missed and a bug appears.

```
// Smelly: two methods repeat the same tax rule
double invoiceTotal(double net)  { return net + net * 0.18; }
double quoteTotal(double net)    { return net + net * 0.18; }

// Cured: one place owns the rule
private static final double GST_RATE = 0.18;
double withTax(double net)       { return net + net * GST_RATE; }
double invoiceTotal(double net)  { return withTax(net); }
double quoteTotal(double net)    { return withTax(net); }
```

Refactorings. Fowler lists: Extract Function; Slide Statements (to bring similar code together so it can be extracted); Pull Up Method (if the copies are in sibling subclasses). Also useful (not in Fowler's list for this smell): Replace Inline Code with Function Call (if a library already does it); Substitute Algorithm (if two different algorithms do the same thing).

7.2.3 Long Function

What it is. A function that does too much and is too long to understand at a glance. Fowler's heuristic: whenever you feel you need a **comment** to explain a block, extract that block into a function named after the *intent* of the block.

Why it hurts. Long functions are hard to understand, hard to reuse partially, and hard to test. Short, well-named functions are self-documenting: you read the name and skip the body.

```java
// Smelly
void printOwing(Invoice inv) {
    System.out.println("*** Customer Owes ***");
    double outstanding = 0;
    for (Order o : inv.orders()) outstanding += o.amount();      // calculate outstanding
    inv.setDueDate(LocalDate.now().plusDays(30));               // record due date
    System.out.println("name: " + inv.customer());               // print details
    System.out.println("amount: " + outstanding);
}

// Cured: each block became a named function
void printOwing(Invoice inv) {
    printBanner();
    double outstanding = outstandingOf(inv);
    recordDueDate(inv);
    printDetails(inv, outstanding);
}
```

Refactorings. Extract Function (the main one, ~99% of the time), Replace Temp with Query, Introduce Parameter Object, Preserve Whole Object, Replace Function with Command, Decompose Conditional, Replace Conditional with Polymorphism, Split Loop.

7.2.4 Long Parameter List

What it is. A function that takes many parameters (often more than three or four), especially several of the same type, or boolean flags.

Why it hurts. Callers mix up the order (`move(10, 20, 5, 3)` — which is which?), every new parameter changes every caller, and long lists often hide a missing concept.

```java
// Smelly
Booking book(String hotelId, LocalDate from, LocalDate to, int adults, int children, boolean breakfast) { ... }

// Cured: parameter objects for the clumps, and an explicit enum instead of an unreadable boolean flag
record Stay(LocalDate from, LocalDate to) { }
record Guests(int adults, int children) { }
Booking book(Hotel hotel, Stay stay, Guests guests, MealPlan mealPlan) { ... }
```

Refactorings. Replace Parameter with Query, Preserve Whole Object, Introduce Parameter Object, Remove Flag Argument, Combine Functions into Class (several functions share the same parameters → make them fields of a class).

7.2.5 Global Data

What it is. Data that can be read and modified from anywhere: global variables, public static mutable fields (`static` fields belong to the class and are shared by the whole program), and mutable singletons (classes with exactly one shared instance).

Why it hurts. Any code anywhere can change it, and there is no way to find *who* changed it. Bugs appear far away from their cause. Fowler calls it one of the most pungent smells; the problems grow with the size of the program. (Class variables and singletons count too.)

```java
// Smelly
public class Config { public static double discountRate = 0.1; }      // anyone can write it

// Cured: Encapsulate Variable - one controlled access point, easy to find every writer.
// (The range check is a NEW rule added afterwards, wearing the "adding function" hat - it is a behaviour change,
not part of the refactoring.)
public final class Config {
    private static volatile double discountRate = 0.1;
    public static double discountRate() { return discountRate; }
    public static void setDiscountRate(double rate) {
        if (rate < 0 || rate > 0.5) throw new IllegalArgumentException("rate out of range");
        discountRate = rate;
    }
}
// Even better: pass the value in (dependency injection) instead of reading a static at all.
```

Refactorings. Encapsulate Variable (first step, always), then narrow its scope — ideally move it into a class or module so only a few functions can see it.

7.2.6 Mutable Data

What it is. Data that is changed after creation, especially when it is shared, or when the same variable is updated for different purposes.

Why it hurts. A change in one place can break code in another place that assumed the value stayed the same. These bugs are hard to find, especially with threads (several paths of execution running at the same time). Functional programming is built on the idea that data should never change; you do not need to go that far, but you should limit where mutation can happen.

```java
// Smelly: callers can change the list inside the object, and total is a stored copy that can go stale
class Cart {
    public List<Item> items = new ArrayList<>();
    public double total;                          // must be updated by hand after every change
}

// Cured
final class Cart {
    private final List<Item> items = new ArrayList<>();
    void add(Item item) { items.add(item); }
    List<Item> items() { return List.copyOf(items); }                    // Encapsulate Collection
    double total() { return items.stream().mapToDouble(Item::price).sum(); } // Replace Derived Variable with Query
}
```

Refactorings. Encapsulate Variable, Split Variable, Slide Statements, Extract Function, Separate Query from Modifier, Remove Setting Method, Replace Derived Variable with Query, Combine Functions into Class, Combine Functions into Transform, Change Reference to Value (use immutable value objects such as Java records — compact, immutable data classes).

7.2.7 Divergent Change

What it is. **One class is changed for many different reasons.** "I have to edit this class when we add a database, *and* when we add a financial instrument, *and* when we change the report format."

Why it hurts. The class mixes several responsibilities (it breaks the **Single Responsibility Principle**, Chapter 4). Each kind of change risks breaking the others, and different people edit the same file for unrelated reasons.

```java
// Smelly: storage, pricing and formatting in one class
class ProductService {
    void saveToMySql(Product p) { ... }         // changes when the database changes
    double priceWithTax(Product p) { ... }      // changes when tax rules change
    String toCsv(Product p) { ... }             // changes when the export format changes
}

// Cured: one reason to change per class
class ProductRepository { void save(Product p) { ... } }
class PricingService    { double priceWithTax(Product p) { ... } }
class ProductCsvWriter  { String toCsv(Product p) { ... } }
```

Refactorings. Split Phase (when the changes fall into sequential phases, e.g. parse then compute), Move Function, Extract Function, Extract Class.

7.2.8 Shotgun Surgery

What it is. The opposite of Divergent Change: **one change forces many small edits in many classes.**

Why it hurts. You have to find all the places, and it is easy to miss one. The logic for one concept is scattered.

```java
// Smelly: the "free-shipping threshold" rule appears in 4 classes
class CartView      { boolean showBanner(double t)  { return t >= 500; } }
class CheckoutCtrl  { double shipping(double t)     { return t >= 500 ? 0 : 40; } }
class EmailBuilder  { String line(double t)         { return t >= 500 ? "Free shipping!" : ""; } }
class ReportJob     { long freeOrders(List<Double> ts) { return ts.stream().filter(t -> t >= 500).count(); } }

// Cured: the concept lives in one class, and the four callers use it
final class ShippingPolicy {
    static final double FREE_SHIPPING_THRESHOLD = 500;
    static boolean isFree(double total)   { return total >= FREE_SHIPPING_THRESHOLD; }
    static double charge(double total)    { return isFree(total) ? 0 : 40; }
}
```

Refactorings. Move Function and Move Field (gather everything into one module), Combine Functions into Class, Combine Functions into Transform, Split Phase; sometimes Inline Function / Inline Class first to pull the scattered bits together, then extract a better-shaped unit.

	Divergent Change	Shotgun Surgery
Shape	One class, many reasons to change	One reason to change, many classes
Fix	Split the class	Gather the scattered code

7.2.9 Feature Envy

What it is. A method that is more interested in *another* class's data than in its own — it calls many getters (methods that just return a field) on another object to compute something.

Why it hurts. The behaviour lives away from the data it uses, so a change to that data needs changes elsewhere. The basic OO rule: **put behaviour next to the data it uses**. (Exception: patterns like Strategy and Visitor — an object that carries one operation across a group of classes — deliberately separate them, to allow swapping behaviour.)

```java
// Smelly: Order computes a line total using only Line's data
class Order {
    double lineTotal(Line line) {
        return line.getUnitPrice() * line.getQuantity() * (1 - line.getDiscount());
    }
}

// Cured: Move Function - Line computes its own total
record Line(double unitPrice, int quantity, double discount) {
    double total() { return unitPrice * quantity * (1 - discount); }
}
```

Refactorings. Move Function; Extract Function first if only *part* of the method is envious, then move that part.

7.2.10 Data Clumps

What it is. The same group of data items always appear together — as fields in several classes, or as parameters in many signatures: `(street, city, zip)`, `(startDate, endDate)`, `(x, y)`, `(amount, currency)`.

Why it hurts. The group is really a concept that has not been named. Without a class, behaviour about it (e.g. "does this range contain a date?") gets duplicated everywhere. **Test:** delete one item of the clump — if the others no longer make sense alone, they belong in an object.

```java
// Smelly
boolean isAvailable(LocalDate start, LocalDate end) { ... }
double price(LocalDate start, LocalDate end, double nightly) { ... }

// Cured (see code/smells/DateRange.java)
record DateRange(LocalDate start, LocalDate end) {
    boolean contains(LocalDate day) { return !day.isBefore(start) && !day.isAfter(end); }
}
boolean isAvailable(DateRange stay) { ... }
```

Refactorings. Extract Class (for clumps of fields), Introduce Parameter Object and Preserve Whole Object (for clumps of parameters). Then look for Feature Envy — behaviour will want to move onto the new class.

7.2.11 Primitive Obsession

What it is. Using primitive types (`int`, `double`, `String`, `boolean`) for domain concepts that deserve their own type: money as `double`, phone numbers as `String`, a status as `"ACTIVE"`, a temperature as a bare `int` without a unit.

Why it hurts. No validation (`"banana"` is a valid `String` phone number), no behaviour (formatting and comparing logic is duplicated), easy mix-ups (`transfer(double amount, double fee)` — swap them and nothing complains). Money as `double` also suffers from floating-point error (binary `double` numbers cannot store most decimal fractions exactly): `0.1 + 0.2` prints `0.30000000000000004` (see the output in 7.8).

```java
// Smelly
void charge(double amount, String currency) { ... }

// Cured (see code/smells/Money.java): validation and arithmetic live in one type
record Money(BigDecimal amount, Currency currency) {
    Money plus(Money other) { /* checks same currency, then adds */ }
}
void charge(Money amount) { ... }
```

Refactorings. Replace Primitive with Object, Replace Type Code with Subclasses, Replace Conditional with Polymorphism (for type codes that drive behaviour), Extract Class, Introduce Parameter Object.

7.2.12 Repeated Switches

What it is. The *same* `switch` (or `if/else if` chain) on the same type code (a field, such as a string or int, that says which kind of thing an object is) appears in several places. (In the 1st edition this smell was "Switch Statements" — *any* switch. In the 2nd edition Fowler narrowed it: a single switch is fine; the problem is the *repetition*.)

Why it hurts. Adding a new case means finding and updating every switch — Shotgun Surgery. Miss one and you have a bug.

```
// Smelly: three switches on the same type
double speed(Bird b)    { switch (b.type) { case "EUROPEAN": ...; case "AFRICAN": ...; case "PARROT": ...; } }
String plumage(Bird b)  { switch (b.type) { case "EUROPEAN": ...; case "AFRICAN": ...; case "PARROT": ...; } }
int    lifespan(Bird b) { switch (b.type) { ... } }

// Cured: Replace Conditional with Polymorphism
sealed interface Bird permits EuropeanSwallow, AfricanSwallow, NorwegianBlueParrot {
    double speed();
    String plumage();
}
```

Refactorings. Replace Conditional with Polymorphism. (Java note: with a `sealed` type (one that lists all its permitted subtypes) or an `enum` (a fixed set of named constants), a *switch expression* is checked for exhaustiveness — covering every case — by the compiler, which removes much of the risk. A few such switches may be acceptable; polymorphism is still better when the behaviour per case is large.)

7.2.13 Loops

What it is. A classic `for`/`while` loop that filters, maps or aggregates a collection, where a pipeline would state the intent more clearly. (New in the 2nd edition — languages now have good first-class functions (functions that can be stored in variables and passed around); in Java, the Stream API since Java 8.)

Why it hurts. A loop makes the reader simulate the steps to see what it does. A pipeline names each step: *filter*, *map*, *collect*.

```
// Smelly
List<String> names = new ArrayList<>();
for (Employee e : employees) {
    if (e.department().equals("IT")) {
        names.add(e.name());
    }
}

// Cured: Replace Loop with Pipeline
List<String> names = employees.stream()
        .filter(e -> e.department().equals("IT"))
        .map(Employee::name)
        .toList();                      // Java 16+: returns an unmodifiable list
```

Refactorings. Replace Loop with Pipeline. (Note: `Stream.toList()` returns an *unmodifiable* list, while the loop built a mutable `ArrayList`. If a caller later adds to the list, that is a behaviour change — use `collect(Collectors.toCollection(ArrayList::new))` in that case.)

7.2.14 Lazy Element

What it is. A class, function or other structure that does not pull its weight — for example a class with one trivial method, a function whose body is as clear as its name, or a subclass that adds nothing. (1st edition: "Lazy Class".)

Why it hurts. Every element costs something: a name to learn, a file to open, an indirection to follow. If it adds nothing, it is pure cost. Lazy elements are often left behind after other refactorings, or created for growth that never happened.

```
// Smelly: a wrapper that adds nothing
class NameFormatter { String format(String s) { return s.trim(); } }

// Cured: Inline Class / Inline Function
String cleanName = rawName.trim();
```

Refactorings. Inline Function, Inline Class, Collapse Hierarchy.

7.2.15 Speculative Generality

What it is. Hooks, abstract classes, parameters and special cases added "because we might need them someday" — but nobody uses them. Typical signs: an abstract class with only one subclass, unused parameters, methods only called by tests, a plug-in system with one plug-in.

Why it hurts. It makes the code harder to understand and maintain for no benefit. It violates **YAGNI**. If the need does come, refactoring can add the flexibility then — usually in a better shape, because you then know the real requirement.

```
// Smelly
interface PaymentProcessorFactoryProvider { PaymentProcessorFactory get(); }   // one implementation, ever
void pay(Money m, Map<String, Object> futureOptions) { ... }                  // futureOptions never used

// Cured
void pay(Money m) { processor.process(m); }
```

Refactorings. Collapse Hierarchy (useless abstract class), Inline Function and Inline Class (useless delegation), Change Function Declaration (remove unused parameters), Remove Dead Code (for code used only by its own tests — delete the tests too).

7.2.16 Temporary Field

What it is. A field that is set and used only in some situations (e.g. only during one complex calculation) and is empty/null the rest of the time.

Why it hurts. Readers expect an object to need all its fields. A field that is usually `null` is confusing — "why is this null? is that a bug?"

```
// Smelly: these fields are only meaningful while computeRoute() runs
class Planner {
    private Graph graph;
    private Map<Node, Integer> tmpDistances;   // null except inside computeRoute
    private Node tmpTarget;                    // null except inside computeRoute
}

// Cured: Extract Class - the temporary state gets its own short-lived object
class Planner {
    private Graph graph;
    Route computeRoute(Node from, Node to) { return new RouteSearch(graph, from, to).run(); }
}
final class RouteSearch {                      // lives only for one search
    private final Map<Node, Integer> distances = new HashMap<>();
    ...
}
```

Refactorings. Extract Class (put the fields and the code that uses them in their own class), Move Function, Introduce Special Case (for the conditional code that checks whether the field is set).

7.2.17 Message Chains

What it is. A client asks one object for another object, then asks that for another, and so on: `order.getCustomer().getAddress().getCity().getName()`. Also a long chain of temporary variables doing the same thing.

Why it hurts. The client is coupled to the *whole structure* of the navigation. Any change in an intermediate relationship breaks the client. It violates the **Law of Demeter** ("talk only to your immediate friends", Chapter 5).

```
// Smelly
String city = order.getCustomer().getAddress().getCity();

// Cured: Hide Delegate (see code/smells/Order.java)
String city = order.shippingCity();
```

Caution: do not blindly hide every delegate — that creates Middle Men. Often better: look at what the final object is *used for*, and Extract Function + Move Function that usage down the chain.

Refactorings. Hide Delegate, Extract Function, Move Function.

7.2.18 Middle Man

What it is. A class whose methods mostly just forward calls to another class, adding nothing. (Some delegation is good — that is encapsulation. The smell is when *most* of the class is pass-through.)

Why it hurts. An extra layer to read and maintain, with no value. Every new feature of the delegate requires a new forwarding method.

```
// Smelly
class Person {
    private Department dept;
    Person getManager()           { return dept.getManager(); }
    String getDepartmentCode()    { return dept.getCode(); }
    Budget getDepartmentBudget()  { return dept.getBudget(); }
    // ... ten more forwarding methods
}

// Cured: Remove Middle Man - let clients talk to the Department directly
Department department() { return dept; }
```

Refactorings. Remove Middle Man, Inline Function (for a few forwarders), Replace Superclass with Delegate or Replace Subclass with Delegate (if the middle man is tied up in inheritance).

Message Chains and Middle Man pull in opposite directions — Hide Delegate cures one and can cause the other. Use judgement to find the balance.

7.2.19 Insider Trading

What it is. Two modules (classes, packages) that exchange too much private information — they poke at each other's internals. Subclasses that know too much about their parents' internals are a common case. (1st edition: "Inappropriate Intimacy".)

Why it hurts. The modules are tightly coupled: you cannot change one without changing the other. Some trading is necessary; the goal is to keep it small and visible.

```
// Smelly: Invoice reaches into Customer's internal map
double discount = customer.internalLoyaltyTable.get(customer.tierCode) * 0.01;

// Cured: Customer owns its own rule, Invoice asks
double discount = customer.loyaltyDiscount();
```

Refactorings. Move Function and Move Field (reduce the need to talk), Hide Delegate (make a third module the go-between), Replace Subclass with Delegate or Replace Superclass with Delegate (when inheritance creates the

intimacy).

7.2.20 Large Class

What it is. A class trying to do too much — too many fields, too many methods, too much code. Often called a **God Class**.

Why it hurts. It becomes a magnet for duplication and a bottleneck for changes (everyone edits it). It usually violates the Single Responsibility Principle.

```
// Smelly
class Employee {
    String name; String email;                    // identity
    String street, city, zip;                     // address clump
    double baseSalary, bonus, taxRate;            // payroll
    List<Review> reviews; int rating;             // performance
    ...
}

// Cured: Extract Class for each cohesive subset (look for fields with common prefixes/suffixes,
// or fields used together by the same methods)
class Employee {
    String name; String email;
    Address address;
    Compensation compensation;
    PerformanceRecord performance;
}
```

Refactorings. Extract Class, Extract Superclass, Replace Type Code with Subclasses (Extract Subclass). Tip: look at how *clients* use the class — distinct groups of clients using distinct subsets of methods suggest how to split it.

7.2.21 Alternative Classes with Different Interfaces

What it is. Two classes that do the same kind of job but have different method names or signatures, so you cannot substitute one for the other: `EmailSender.sendMail(to, body)` and `SmsGateway.dispatch(msg, phone)`.

Why it hurts. You cannot treat them polymorphically (through one shared interface, without caring which class you have), so callers write `if email ... else if sms ...`. It also often hides duplicated code.

```
// Smelly
class EmailSender { void sendMail(String to, String body) { ... } }
class SmsGateway  { void dispatch(String body, String phone) { ... } }

// Cured: rename and align signatures, then extract a common interface
interface Notifier { void send(String recipient, String message); }
class EmailNotifier implements Notifier { ... }
class SmsNotifier   implements Notifier { ... }
```

Refactorings. Change Function Declaration (make signatures match), Move Function (until the protocols match), Extract Superclass (if the implementations then share code). If you cannot edit one of the classes (third-party), wrap it in an **Adapter** (Chapter 9) — a class that converts one interface into the one you expect.

7.2.22 Data Class

What it is. A class with only fields and getters/setters (setters are methods that just overwrite a field), and no behaviour. Other classes manipulate its data in detail.

Why it hurts. The behaviour that belongs with the data lives elsewhere (usually as Feature Envy in its clients), often duplicated across several clients. Public setters also allow anyone to break the object's invariants (rules that must always hold, e.g. "balance is never negative").

Important exceptions. Immutable data carriers are fine and often good: a Java **record** that is the *result* of a computation (e.g. the output of Split Phase), a DTO (Data Transfer Object) crossing a network boundary, or a value object. The smell is about *mutable* data classes whose logic is scattered around them.

```
// Smelly
class Account { private double balance; public double getBalance() {...} public void setBalance(double b) {...} }
// ...and in a service:
if (acc.getBalance() >= amt) acc.setBalance(acc.getBalance() - amt); else throw ...;

// Cured: Remove Setting Method + Move Function - the rule lives with the data
class Account {
    private double balance;
    void withdraw(double amount) {
        if (amount > balance) throw new IllegalStateException("insufficient funds");
        balance -= amount;
    }
}
```

Refactorings. Encapsulate Record, Remove Setting Method (for fields that should not change), Move Function and Extract Function (bring behaviour in from the clients), Split Phase (when the data class is the result of a phase — then it is fine as an immutable record). Also useful (not in Fowler's list for this smell): Encapsulate Collection for public collection fields.

7.2.23 Refused Bequest

What it is. A subclass inherits methods and data from its parent but does not want or need them — or worse, refuses the parent's *interface* (overrides methods to throw `UnsupportedOperationException`).

Why it hurts. The inheritance relationship is wrong. Refusing *implementation* is a mild smell (Fowler says it is often not worth fixing). Refusing the *interface* is serious: it breaks the **Liskov Substitution Principle** (Chapter 4: a subclass must work anywhere its parent is expected) — code that uses the parent type will fail with this subclass.

```
// Smelly: Stack extends a list type, and so inherits add(index, e), remove(index) ... which break stack rules
class Stack<T> extends ArrayList<T> {
    void push(T t) { add(t); }
    T pop() { return remove(size() - 1); }
}
// (java.util.Stack extends Vector - the JDK's own famous example of this smell.)

// Cured: Replace Superclass with Delegate - use a list, don't be one
final class Stack<T> {
    private final Deque<T> items = new ArrayDeque<>();
    void push(T t) { items.push(t); }
    T pop()        { return items.pop(); }
}
// Behaviour check: pop() on an empty stack now throws NoSuchElementException instead of
// IndexOutOfBoundsException, and ArrayDeque rejects null elements. If callers rely on either,
// keep the old behaviour (e.g. an ArrayList delegate) - a refactoring must not change it.
```

Refactorings. Push Down Method and Push Down Field (move unused parent members into a sibling that does use them, leaving the parent with only what is shared), Replace Subclass with Delegate, Replace Superclass with Delegate.

7.2.24 Comments

What it is. Comments are not bad in themselves — Fowler calls them a *sweet* smell. The smell is comments used as **deodorant**: a long comment explaining *what* a confusing block does, when the block should have been made clear instead.

Why it hurts. Comments go stale — the code changes and the comment does not. A comment that explains *what* code does is a sign the code does not explain itself.

Good comments (keep them): *why* something is done a particular way, a warning, a reference to an algorithm or bug ticket, a note about something you are unsure of, public API documentation (Javadoc).

```
// Smelly
// check if the customer is eligible for the senior discount
if (customer.getAge() >= 60 && customer.getMembershipYears() > 2 && !customer.isBlocked()) { ... }

// Cured: Extract Function - the name replaces the comment
if (isEligibleForSeniorDiscount(customer)) { ... }

// Smelly: comment states an assumption
// rate must never be negative here
// Cured: Introduce Assertion
assert rate >= 0 : "rate must not be negative";
```

Refactorings. Extract Function (comment explains a block), Change Function Declaration (comment explains what a function does — rename it), Introduce Assertion (comment states a required condition).

1st-edition smell names (renamed or dropped in the 2nd edition)

refactoring.guru still uses the 1st-edition (1999) names. You may hear them in interviews:

1st-edition smell	Meaning	Where it went / fix
Long Method	Method too long to understand	Renamed **Long Function**
Switch Statements	Any complex switch	Narrowed to **Repeated Switches**
Lazy Class	Class that does too little	Generalised to **Lazy Element**
Inappropriate Intimacy	Classes too involved in each other's privates	Renamed **Insider Trading**
Parallel Inheritance Hierarchies	Every time you add a subclass in one hierarchy you must add one in another	A special case of Shotgun Surgery; fix with Move Function / Move Field so one hierarchy disappears
Incomplete Library Class	A library lacks a method you need and you cannot change it	Add a wrapper or utility (Introduce Foreign Method / Introduce Local Extension in the 1st ed.), or an Adapter
Dead Code	Unused variables, parameters, methods, classes	The 2nd ed. treats it as the refactoring **Remove Dead Code**

7.3 The refactoring catalogue

What it is

A **named refactoring** is a small, well-defined transformation with a name, a *motivation* (when and why to use it), *mechanics* (the safe steps), and examples. Fowler's 2nd edition catalogues 61 of them in seven chapters (Chapters 6–12 of the book). The same catalogue, with a few extra entries, is online at refactoring.com/catalog. Many 1st-edition names (1999) were changed to be language-neutral ("function" instead of "method") — the old names are shown as *aliases*.

Many refactorings come in **inverse pairs** (Extract Function ↔ Inline Function). There is no "right direction" — you move whichever way makes the code clearer *for the change you are about to make*.

How to read each entry

- **Motivation** — when and why.
- **Before → After** — a short Java sketch. `// ...` marks irrelevant code. Sketches are illustrative fragments; the fully compiling examples are in `code/` (7.5, 7.6, 7.8).
- **Inverse** — the opposite refactoring, if one exists.

Catalogue at a glance

Book chapter	Refactorings
6 — A First Set	Extract Function, Inline Function, Extract Variable, Inline Variable, Change Function Declaration, Encapsulate Variable, Rename Variable, Introduce Parameter Object, Combine Functions into Class, Combine Functions into Transform, Split Phase
7 — Encapsulation	Encapsulate Record, Encapsulate Collection, Replace Primitive with Object, Replace Temp with Query, Extract Class, Inline Class, Hide Delegate, Remove Middle Man, Substitute Algorithm
8 — Moving Features	Move Function, Move Field, Move Statements into Function, Move Statements to Callers, Replace Inline Code with Function Call, Slide Statements, Split Loop, Replace Loop with Pipeline, Remove Dead Code
9 — Organizing Data	Split Variable, Rename Field, Replace Derived Variable with Query, Change Reference to Value, Change Value to Reference
10 — Simplifying Conditional Logic	Decompose Conditional, Consolidate Conditional Expression, Replace Nested Conditional with Guard Clauses, Replace Conditional with Polymorphism, Introduce Special Case, Introduce Assertion
11 — Refactoring APIs	Separate Query from Modifier, Parameterize Function, Remove Flag Argument, Preserve Whole Object, Replace Parameter with Query, Replace Query with Parameter, Remove Setting Method, Replace Constructor with Factory Function, Replace Function with Command, Replace Command with Function
12 — Dealing with Inheritance	Pull Up Method, Pull Up Field, Pull Up Constructor Body, Push Down Method, Push Down Field, Replace Type Code with Subclasses, Remove Subclass, Extract Superclass, Collapse Hierarchy, Replace Subclass with Delegate, Replace Superclass with Delegate
refactoring.com extras (web edition)	Replace Control Flag with Break, Replace Error Code with Exception, Replace Exception with Precheck, Replace Magic Literal, Return Modified Value

11 + 9 + 9 + 5 + 6 + 10 + 11 = **61** book refactorings.

7.3.1 A First Set of Refactorings (book chapter 6)

These are the refactorings you will use most — every day.

Extract Function *(alias: Extract Method)* · inverse: Inline Function

Motivation. Separate *intention* from *implementation*. If you have to spend effort looking at a fragment of code to work out *what* it does, extract it into a function named after that "what". Even a one-line function is worth it if the name says more than the code. Short functions are cheap in Java (the JIT inlines them).

```
// Before
void printOwing(Invoice invoice) {
    double outstanding = invoice.outstanding();
    System.out.println("name: " + invoice.customer());
    System.out.println("amount: " + outstanding);
}
// After
void printOwing(Invoice invoice) {
    printDetails(invoice, invoice.outstanding());
}
private void printDetails(Invoice invoice, double outstanding) {
    System.out.println("name: " + invoice.customer());
    System.out.println("amount: " + outstanding);
}
```

Inline Function *(alias: Inline Method)* · inverse: Extract Function

Motivation. When a function's body is as clear as its name, or when you have a tangle of badly factored small functions, put them back together — then extract again in better places. Also useful to remove needless indirection (a function that only delegates).

```
// Before
int rating(Driver d) { return moreThanFiveLateDeliveries(d) ? 2 : 1; }
boolean moreThanFiveLateDeliveries(Driver d) { return d.lateDeliveries() > 5; }
// After
int rating(Driver d) { return d.lateDeliveries() > 5 ? 2 : 1; }
```

Extract Variable ***(alias: Introduce Explaining Variable)*** **· inverse: Inline Variable**

Motivation. Complex expressions are hard to read. Name the parts with local variables. If the name makes sense beyond this function, prefer Extract Function (or Replace Temp with Query) instead so others can reuse it.

```
// Before
return order.quantity() * order.itemPrice()
     - Math.max(0, order.quantity() - 500) * order.itemPrice() * 0.05
     + Math.min(order.quantity() * order.itemPrice() * 0.1, 100);
// After
double basePrice = order.quantity() * order.itemPrice();
double quantityDiscount = Math.max(0, order.quantity() - 500) * order.itemPrice() * 0.05;
double shipping = Math.min(basePrice * 0.1, 100);
return basePrice - quantityDiscount + shipping;
```

Inline Variable ***(alias: Inline Temp)*** **· inverse: Extract Variable**

Motivation. A variable whose name says no more than the expression, or which gets in the way of another refactoring (e.g. Extract Function), should be removed.

```
// Before
double basePrice = order.basePrice();
return basePrice > 1000;
// After
return order.basePrice() > 1000;
```

Change Function Declaration ***(aliases: Rename Function, Rename Method, Add Parameter, Remove Parameter, Change Signature)***

Motivation. Function names and parameters are the joints of the system; bad ones make everything harder. Rename a function the moment you understand it better; add or remove parameters to change what the function depends on. Two ways: the **simple mechanics** (change the declaration and all callers at once — fine when you can see all callers, e.g. with the IDE) and the **migration mechanics** (create the new function, make the old one delegate to it and mark it `@Deprecated`, migrate callers gradually, then delete the old one — needed for published APIs).

```
// Before
double circum(double radius) { return 2 * Math.PI * radius; }
// After (migration mechanics)
double circumference(double radius) { return 2 * Math.PI * radius; }
@Deprecated(forRemoval = true)
double circum(double radius) { return circumference(radius); }   // delete when no callers remain
```

Encapsulate Variable ***(aliases: Encapsulate Field, Self-Encapsulate Field)***

Motivation. Data is harder to refactor than functions, because every reference must change at once. Wrapping widely accessed data in accessor functions (getter/setter methods) turns "reorganise data" into "reorganise functions" and gives you one place to add validation, logging or change notifications. Always the first step for Global Data.

```
// Before
public static Owner defaultOwner = new Owner("Martin", "Fowler");
// After
private static Owner defaultOwner = new Owner("Martin", "Fowler");
public static Owner defaultOwner() { return defaultOwner; }
public static void setDefaultOwner(Owner owner) { defaultOwner = owner; }   // add checks later, as a separate
change
```

Rename Variable

Motivation. Good names are the heart of clear code. The wider the scope of a variable, the more its name matters. A short name is fine in a three-line lambda; a field needs a descriptive name.

```
// Before
double a = height * width;
// After
double area = height * width;
```

Introduce Parameter Object

Motivation. A group of parameters that always travel together (a Data Clump) becomes one object. Signatures shrink, the relationship between the values is made explicit, and behaviour about them now has a home — often the start of a useful domain class.

```
// Before
List<Reading> readingsOutsideRange(Station s, int min, int max) { ... }
// After
record NumberRange(int min, int max) {
    boolean contains(int v) { return v >= min && v <= max; }
}
List<Reading> readingsOutsideRange(Station s, NumberRange range) { ... }
```

Combine Functions into Class

Motivation. When several functions work on the same data (often passed as the same argument to all of them), create a class that holds the data as fields and turns the functions into methods. The shared data and the common environment become explicit, and clients no longer pass the data around.

```
// Before
double base(Reading r) { ... }
double taxableCharge(Reading r) { ... }
double calculateBaseCharge(Reading r) { ... }
// After
final class ReadingCalculator {
    private final Reading reading;
    ReadingCalculator(Reading reading) { this.reading = reading; }
    double base() { ... }
    double taxableCharge() { ... }
}
```

Combine Functions into Transform

Motivation. An alternative to Combine Functions into Class when the source data is read-only: a *transform* function takes the raw data and returns an enriched copy with all derived values computed. All derivation logic lives in one place. (Use a class instead if the source data can change, since a transform's copy would go stale.)

```
// Before (derived values computed in several places)
double base = baseRate(r.month(), r.year()) * r.quantity();
double taxable = Math.max(0, base - taxThreshold(r.year()));
// After
record EnrichedReading(Reading raw, double baseCharge, double taxableCharge) { }
static EnrichedReading enrichReading(Reading r) {
    double base = baseRate(r.month(), r.year()) * r.quantity();
    return new EnrichedReading(r, base, Math.max(0, base - taxThreshold(r.year())));
}
```

Split Phase

Motivation. When code deals with two different things in sequence (e.g. parse input, then compute; or compute, then format), split it into two phases connected by an intermediate data structure. Each phase can then be understood and changed separately — a classic cure for Divergent Change. Compilers are the textbook example

(tokenise — split text into words and symbols → parse — build a tree of its structure → generate code). See the worked example, step 3.

```
// Before
String priceOrder(String orderLine) {
    String[] parts = orderLine.split("\\s+");
    Product p = catalog.get(parts[0].split("-")[1]);
    int qty = Integer.parseInt(parts[1]);
    return "Total: " + qty * p.price();
}
// After
record OrderRequest(String productId, int quantity) { }           // the intermediate data structure
OrderRequest parse(String line) {                                  // phase 1
    String[] parts = line.split("\\s+");
    return new OrderRequest(parts[0].split("-")[1], Integer.parseInt(parts[1]));
}
String price(OrderRequest req) {                                   // phase 2
    return "Total: " + req.quantity() * catalog.get(req.productId()).price();
}
String priceOrder(String orderLine) { return price(parse(orderLine)); }
```

7.3.2 Encapsulation (book chapter 7)

The key to modular design is deciding what each module *hides*. These refactorings hide data structures, temporary variables, and relationships between classes.

Encapsulate Record ***(alias: Replace Record with Data Class)***

Motivation. A raw record-like structure (a `Map<String,Object>`, an array, a struct with public fields) forces clients to know its layout and lets anyone change it. Replace it with a class (or a Java `record`) whose accessors hide the storage and can compute derived values.

```
// Before
Map<String, Object> organization = Map.of("name", "Acme", "country", "GB");
String name = (String) organization.get("name");
// After
record Organization(String name, String country) { }
Organization organization = new Organization("Acme", "GB");
String name = organization.name();
```

Encapsulate Collection

Motivation. If a getter returns the internal collection, clients can modify it without the owner knowing. Offer `add`/`remove` methods on the owner, and have the getter return a read-only view or a copy.

```
// Before
class Person {
    private List<Course> courses = new ArrayList<>();
    List<Course> getCourses() { return courses; }                  // caller can add/clear!
    void setCourses(List<Course> c) { courses = c; }
}
// After
class Person {
    private final List<Course> courses = new ArrayList<>();
    List<Course> courses()        { return Collections.unmodifiableList(courses); }
    void addCourse(Course c)      { courses.add(c); }
    void removeCourse(Course c)   { courses.remove(c); }
}
```

Replace Primitive with Object ***(aliases: Replace Data Value with Object, Replace Type Code with Class)***

Motivation. A simple value (a phone number string, a priority `"high"`) soon needs behaviour: validation, formatting, comparison. Wrap it in its own type as soon as you see that. A cure for Primitive Obsession.

```
// Before
List<Order> urgent = orders.stream().filter(o -> o.priority().equals("high") ||
o.priority().equals("rush")).toList();
// After
enum Priority { LOW, NORMAL, HIGH, RUSH;
    boolean higherThan(Priority other) { return compareTo(other) > 0; } }
List<Order> urgent = orders.stream().filter(o -> o.priority().higherThan(Priority.NORMAL)).toList();
```

Replace Temp with Query

Motivation. A temporary variable holding a computed value can only be used inside its function. Turn the computation into a method, and every other method of the class can use it too; it also makes Extract Function easier (fewer locals to pass). Works best when the temp is assigned once and its computation has no side effects.

```
// Before
double price() {
    double basePrice = quantity * itemPrice;
    return basePrice > 1000 ? basePrice * 0.95 : basePrice * 0.98;
}
// After
double price()     { return basePrice() > 1000 ? basePrice() * 0.95 : basePrice() * 0.98; }
double basePrice() { return quantity * itemPrice; }
```

Extract Class · inverse: Inline Class

Motivation. Classes grow. When a subset of fields and methods clearly go together (and change together), move them to a new class. A cure for Large Class and Divergent Change.

```
// Before
class Person {
    String name; String officeAreaCode; String officeNumber;
    String telephoneNumber() { return "(" + officeAreaCode + ") " + officeNumber; }
}
// After
class Person {
    String name; TelephoneNumber officeTelephone;
    String telephoneNumber() { return officeTelephone.toString(); }
}
record TelephoneNumber(String areaCode, String number) {
    @Override public String toString() { return "(" + areaCode + ") " + number; }
}
```

Inline Class · inverse: Extract Class

Motivation. A class that no longer does enough (often after its responsibilities moved away) should be folded into its main user. Also a useful first step when re-splitting two classes differently: merge them, then extract again.

```
// Before
class Shipment { TrackingInformation trackingInfo; }
class TrackingInformation { String shippingCompany; String trackingNumber; }
// After
class Shipment { String shippingCompany; String trackingNumber; }
```

Hide Delegate · inverse: Remove Middle Man

Motivation. If a client calls `a.getB().doSomething()`, it depends on `B`. Adding a delegating method `a.doSomething()` hides `B`; if `B` changes, only `A` changes. A cure for Message Chains and the Law of Demeter.

```
// Before
Person manager = person.getDepartment().getManager();
// After
class Person { Person manager() { return department.getManager(); } }
Person manager = person.manager();
```

Remove Middle Man · inverse: Hide Delegate

Motivation. When a class has so many delegating methods that it is just a pass-through, let clients call the delegate directly. The right amount of hiding changes as the system changes.

```
// Before
Person manager = person.manager();              // manager() only forwards
// After
Person manager = person.department().getManager();
```

Substitute Algorithm

Motivation. If you find a clearer way to do something, replace the whole body with the clearer algorithm (after decomposing the old one as far as possible, and with tests proving they agree). Also used to replace hand-written code with a library call.

```
// Before
String foundPerson(List<String> people) {
    for (String p : people) {
        if (p.equals("Don")) return "Don";
        if (p.equals("John")) return "John";
        if (p.equals("Kent")) return "Kent";
    }
    return "";
}
// After
String foundPerson(List<String> people) {
    Set<String> candidates = Set.of("Don", "John", "Kent");
    return people.stream().filter(candidates::contains).findFirst().orElse("");
}
```

7.3.3 Moving Features (book chapter 8)

These refactorings move code between contexts — between classes, between functions, and around inside a function.

Move Function *(alias: Move Method)*

Motivation. Put a function in the context (class/module) whose data and functions it references most. A cure for Feature Envy and Shotgun Surgery. Good modules keep related things together.

```
// Before
class Account {
    double overdraftCharge() {
        if (type.isPremium()) { double base = 10; return daysOverdrawn > 7 ? base + (daysOverdrawn - 7) * 0.85 :
base; }
        return daysOverdrawn * 1.75;
    }
}
// After - the rule depends mostly on AccountType, so it moves there
class AccountType {
    double overdraftCharge(int daysOverdrawn) { /* same logic, using isPremium() */ }
}
class Account { double overdraftCharge() { return type.overdraftCharge(daysOverdrawn); } }
```

Move Field

Motivation. Data structures are the backbone of a program. If you always pass a field of A alongside B, or a change in B forces a change to A's field, the field probably belongs in B. Encapsulate it first (Encapsulate Variable) to make the move easy.

```
// Before
class Customer { Plan plan; double discountRate; }
class Plan { }
// After - the discount rate is a property of the plan, not of each customer
class Customer { Plan plan; double discountRate() { return plan.discountRate(); } }
class Plan { double discountRate; double discountRate() { return discountRate; } }
```

Move Statements into Function · inverse: Move Statements to Callers

Motivation. If the same statements run every time a function is called, move them into the function, removing duplication at every call site.

```
// Before
result.add("<p>title: " + photo.title() + "</p>");
result.addAll(photoData(photo));
List<String> photoData(Photo p) { return List.of("<p>location: " + p.location() + "</p>"); }
// After
result.addAll(photoData(photo));
List<String> photoData(Photo p) {
    return List.of("<p>title: " + p.title() + "</p>", "<p>location: " + p.location() + "</p>");
}
```

Move Statements to Callers · inverse: Move Statements into Function

Motivation. When a function that was shared starts needing *different* behaviour for different callers, move the varying statements out to the callers.

```
// Before
void emitPhotoData(Writer out, Photo p) { out.write(p.title()); out.write(p.location()); }
// After - the location line moves out to every caller; behaviour is still identical
void emitPhotoData(Writer out, Photo p) { out.write(p.title()); }
// caller A:
emitPhotoData(out, p); out.write(p.location());
// caller B:
emitPhotoData(out, p); out.write(p.location());
// Now caller B can change its own line later (e.g. hide the location) - as a separate, deliberate behaviour
change.
```

Replace Inline Code with Function Call

Motivation. If code does what an existing function (yours or a library's) already does, call the function. You gain a name and one place to fix bugs.

```
// Before
boolean appliesToMass = false;
for (String s : states) { if (s.equals("MA")) appliesToMass = true; }
// After
boolean appliesToMass = states.contains("MA");
```

Slide Statements *(alias: Consolidate Duplicate Conditional Fragments)*

Motivation. Code is easier to understand when related statements are next to each other — e.g. declare a variable right before its first use. Sliding is often a preparation for Extract Function. The 1st-edition alias covers one case: a statement repeated in every branch of a conditional can slide out of the conditional. Be careful: you cannot slide past code that the statement interferes with (shared variables, side effects).

```
// Before
String pricingPlan = retrievePricingPlan();
Order order = retrieveOrder();
double baseCharge = pricingPlan.base();
// After - declare each value next to its use
Order order = retrieveOrder();
String pricingPlan = retrievePricingPlan();
double baseCharge = pricingPlan.base();
```

Split Loop

Motivation. A loop that does two things forces you to understand both whenever you change either. Split it into two loops, each doing one thing; then each can be extracted or turned into a pipeline. Worried about performance? Iterating twice is rarely a bottleneck — refactor first, optimise later if the profiler says so.

```
// Before
int youngest = Integer.MAX_VALUE; double totalSalary = 0;
for (Person p : people) {
    if (p.age() < youngest) youngest = p.age();
    totalSalary += p.salary();
}
// After
double totalSalary = 0;
for (Person p : people) totalSalary += p.salary();
int youngest = Integer.MAX_VALUE;
for (Person p : people) if (p.age() < youngest) youngest = p.age();
```

Replace Loop with Pipeline

Motivation. Collection pipelines (`filter`, `map`, `reduce`) describe the processing as a series of named operations, which is easier to read than a loop. See the Loops smell.

```
// Before
List<String> result = new ArrayList<>();
for (String line : lines) {
    if (line.isBlank() || line.startsWith("#")) continue;
    result.add(line.split(",")[1].trim());
}
// After
List<String> result = lines.stream()
        .filter(l -> !l.isBlank() && !l.startsWith("#"))
        .map(l -> l.split(",")[1].trim())
        .toList();
```

Remove Dead Code

Motivation. Unused code still costs readers time ("is this called somewhere?"). Delete it — version control remembers it if you ever need it back. Do not comment it out.

```
// Before
if (false) { legacyDiscount(); }
private void legacyDiscount() { /* unused since 2019 */ }
// After
// (gone)
```

7.3.4 Organizing Data (book chapter 9)

Data structures play an important role; these refactorings improve how data is named and shared.

Split Variable ***(aliases: Remove Assignments to Parameters, Split Temp)***

Motivation. A variable (other than a loop counter or an accumulator) assigned more than once usually has more than one responsibility. Give each responsibility its own variable (ideally `final`). The 1st-ed "Remove Assignments to Parameters" is a special case: do not reuse a parameter as a local.

```java
// Before
double temp = 2 * (height + width);
System.out.println(temp);
temp = height * width;
System.out.println(temp);
// After
final double perimeter = 2 * (height + width);
System.out.println(perimeter);
final double area = height * width;
System.out.println(area);
```

Rename Field

Motivation. Field names explain the data structure; they deserve as much care as function names. Encapsulate first if the field is widely used, then rename. (For records, the accessor name changes too.)

```java
// Before
record Organization(String nm, String country) { }
// After
record Organization(String name, String country) { }
```

Replace Derived Variable with Query

Motivation. Mutable data that is *computed from* other data can drift out of sync. Compute it on demand instead. Exception: if the source data is immutable, a stored derived value is safe (e.g. a record computed once).

```java
// Before
class ProductionPlan {
    private double production;
    private final List<Adjustment> adjustments = new ArrayList<>();
    void apply(Adjustment a) { adjustments.add(a); production += a.amount(); }  // two updates to keep in sync
    double production() { return production; }
}
// After
class ProductionPlan {
    private final List<Adjustment> adjustments = new ArrayList<>();
    void apply(Adjustment a) { adjustments.add(a); }
    double production() { return adjustments.stream().mapToDouble(Adjustment::amount).sum(); }
}
```

Change Reference to Value · inverse: Change Value to Reference

Motivation. If an inner object does not need identity (being tracked as one specific object) (two telephone numbers with the same digits are "the same"), make it an immutable **value object**: replace it wholesale instead of mutating it, and compare by value (`equals` / `hashCode`). Values are safe to share and to use across threads. Java `record`s are ideal.

```java
// Before
class TelephoneNumber { String areaCode; String number; void setAreaCode(String a) { areaCode = a; } }
person.telephone().setAreaCode("020");
// After
record TelephoneNumber(String areaCode, String number) { }                 // immutable, equals by value
person.setTelephone(new TelephoneNumber("020", person.telephone().number()));
```

Change Value to Reference · inverse: Change Reference to Value

Motivation. If many objects hold *copies* of the same logical entity (every order holds its own `Customer` copy) and that entity needs to be updated, a change to one copy is not seen by the others. Share **one** reference instead, usually via a **repository** (an object that stores domain objects and looks them up, usually by ID) that hands out the single instance per ID.

```
// Before
Order(String customerId) { this.customer = new Customer(customerId); }      // each order its own copy
// After
Order(String customerId, CustomerRepository repo) { this.customer = repo.findOrCreate(customerId); }
```

7.3.5 Simplifying Conditional Logic (book chapter 10)

Conditionals are where much of a program's complexity hides.

Decompose Conditional

Motivation. A complex `if`/`else` mixes *why* (the condition) and *what* (each branch). Extract the condition and each branch into well-named functions. A special case of Extract Function.

```
// Before
if (!date.isBefore(plan.summerStart()) && !date.isAfter(plan.summerEnd()))
    charge = quantity * plan.summerRate();
else
    charge = quantity * plan.regularRate() + plan.regularServiceCharge();
// After
charge = isSummer(date) ? summerCharge() : regularCharge();
```

Consolidate Conditional Expression

Motivation. Several checks that all lead to the same result are really one condition. Combine them with `&&`/`||` and extract the result into a named function. (Only when the checks have no side effects and truly form one decision.)

```
// Before
if (employee.seniority() < 2) return 0;
if (employee.monthsDisabled() > 12) return 0;
if (employee.isPartTime()) return 0;
// After
if (isNotEligibleForDisability(employee)) return 0;
boolean isNotEligibleForDisability(Employee e) {
    return e.seniority() < 2 || e.monthsDisabled() > 12 || e.isPartTime();
}
```

Replace Nested Conditional with Guard Clauses

Motivation. When one branch is the normal case and the others are unusual, check the unusual cases first and return immediately (**guard clauses**). The normal path then reads straight down, without deep nesting. ("One exit point" is not a rule worth keeping if it hurts clarity.)

```
// Before
double payAmount(Employee e) {
    double result;
    if (e.isSeparated()) result = 0;
    else { if (e.isRetired()) result = 0; else { result = normalPay(e); } }
    return result;
}
// After
double payAmount(Employee e) {
    if (e.isSeparated()) return 0;
    if (e.isRetired()) return 0;
    return normalPay(e);
}
```

Replace Conditional with Polymorphism

Motivation. When a switch on a type appears in several places (Repeated Switches), or when there is a base behaviour with variants, create a class per case and let dynamic dispatch (the runtime choosing which class's method to run from the object's actual type) pick the behaviour. Adding a new case means adding a class, not

editing every switch. This is how you arrive at **Strategy** or **State** (7.6) — State gives each state of an object its own class, which supplies the behaviour for that state. The worked example's step 5 does exactly this.

```
// Before
double speed(Bird b) {
    return switch (b.type()) {
        case "EUROPEAN" -> 35;
        case "AFRICAN"  -> 40 - 2 * b.numberOfCoconuts();
        case "PARROT"   -> b.isNailed() ? 0 : 10 + b.voltage() / 10.0;
        default -> throw new IllegalArgumentException(b.type());
    };
}
// After
sealed interface Bird permits EuropeanSwallow, AfricanSwallow, NorwegianBlueParrot { double speed(); }
record EuropeanSwallow() implements Bird { public double speed() { return 35; } }
record AfricanSwallow(int numberOfCoconuts) implements Bird { public double speed() { return 40 - 2 *
numberOfCoconuts; } }
record NorwegianBlueParrot(boolean isNailed, int voltage) implements Bird {
    public double speed() { return isNailed ? 0 : 10 + voltage / 10.0; }
}
```

Introduce Special Case ***(alias: Introduce Null Object)***

Motivation. Many clients check for the same special value (usually `null`, or an "unknown customer") and do the same thing. Create a **special-case object** that answers those questions itself. The **Null Object** pattern is the most common form. See 7.6 for a runnable example.

```
// Before
String name = (customer == null) ? "occupant" : customer.name();
Plan plan  = (customer == null) ? Plan.BASIC : customer.plan();
// After
final class UnknownCustomer implements Customer {
    public String name() { return "occupant"; }
    public Plan plan()   { return Plan.BASIC; }
}
String name = customer.name();          // repository returns UnknownCustomer instead of null
```

(Java's `Optional<T>` is a related tool: it makes "may be absent" visible in the type, but callers still decide what to do. A special case object *centralises* that decision.)

Introduce Assertion

Motivation. Some code only works if a condition holds (e.g. a discount rate is never negative). Make the assumption explicit with an assertion. An assertion documents the assumption and catches programmer errors early; the program must be correct *without* it. In Java, `assert` is disabled by default (enable with `java -ea`), so do not use it to validate external input — use exceptions for that.

```
// Before
double applyDiscount(double amount) {
    // discountRate should never be negative here
    return amount - discountRate * amount;
}
// After
double applyDiscount(double amount) {
    assert discountRate >= 0 : "discountRate must not be negative";
    return amount - discountRate * amount;
}
```

7.3.6 Refactoring APIs (book chapter 11)

Modules and their functions are the building blocks; APIs are the joints. These make APIs easier to understand and use.

Separate Query from Modifier

Motivation. A function that returns a value should have no observable side effects — then you can call it anywhere, as often as you like, safely. This is **Command–Query Separation** (Bertrand Meyer). If a function both returns something and changes state, split it into a query and a modifier.

```
// Before
String alertForMiscreant(List<String> people) {
    for (String p : people) {
        if (p.equals("Don") || p.equals("John")) { setOffAlarms(); return p; }
    }
    return "";
}
// After
String findMiscreant(List<String> people) {                        // query - no side effects
    return people.stream().filter(p -> p.equals("Don") || p.equals("John")).findFirst().orElse("");
}
void alertForMiscreant(List<String> people) {                       // modifier
    if (!findMiscreant(people).isEmpty()) setOffAlarms();
}
```

Parameterize Function ***(alias: Parameterize Method)***

Motivation. Several functions with very similar logic that differ only in some literal values can become one function with a parameter.

```
// Before
void tenPercentRaise(Person p)  { p.setSalary(p.salary() * 1.10); }
void fivePercentRaise(Person p) { p.setSalary(p.salary() * 1.05); }
// After
void raise(Person p, double factor) { p.setSalary(p.salary() * (1 + factor)); }
```

Remove Flag Argument ***(alias: Replace Parameter with Explicit Methods)***

Motivation. A **flag argument** (a boolean or enum literal that the caller passes to choose which code path runs) makes calls unreadable: what does `book(customer, true)` mean? Provide an explicit function per path.

```
// Before
void setDimension(String name, double value) { if (name.equals("height")) height = value; else if
(name.equals("width")) width = value; }
LocalDate deliveryDate(Order o, boolean isRush) { ... }
deliveryDate(order, true);
// After
void setHeight(double value) { height = value; }
void setWidth(double value)  { width = value; }
LocalDate rushDeliveryDate(Order o)    { ... }
LocalDate regularDeliveryDate(Order o) { ... }
```

Preserve Whole Object

Motivation. If you pull several values out of one object only to pass them to a function, pass the whole object. The function can then take whatever it needs, and signatures stay stable when needs change. (Don't do it if you want to keep the function independent of that object's type.)

```
// Before
int low = room.daysTempRange().low();
int high = room.daysTempRange().high();
if (!plan.withinRange(low, high)) alerts.add("room temperature out of range");
// After
if (!plan.withinRange(room.daysTempRange())) alerts.add("room temperature out of range");
```

Replace Parameter with Query ***(alias: Replace Parameter with Method)*** **· inverse: Replace Query with Parameter**

Motivation. If the function can easily get a value itself (from its own object, or from another parameter), the caller should not have to pass it. Removing the parameter simplifies every call. (Don't do it if it would add an

unwanted dependency.)

```
// Before
double finalPrice() { return discountedPrice(basePrice(), discountLevel()); }
double discountedPrice(double base, int discountLevel) { return discountLevel == 2 ? base * 0.9 : base * 0.95; }
// After
double finalPrice() { return discountedPrice(basePrice()); }
double discountedPrice(double base) { return discountLevel() == 2 ? base * 0.9 : base * 0.95; }
```

Replace Query with Parameter · inverse: Replace Parameter with Query

Motivation. If a function reaches out to a global, a singleton or a mutable field, it is harder to test and not **referentially transparent** (same inputs do not always give the same output). Pass the value in as a parameter instead — the caller takes on the dependency.

```
// Before
double targetTemperature(HeatingPlan plan) {
    double current = Thermostat.INSTANCE.currentTemperature();        // hidden global dependency
    return Math.clamp(current, plan.min(), plan.max());
}
// After
double targetTemperature(HeatingPlan plan, double currentTemperature) {
    return Math.clamp(currentTemperature, plan.min(), plan.max());      // Math.clamp: Java 21+
}
```

Remove Setting Method

Motivation. If a field should not change after construction, remove its setter and set it in the constructor (make it `final`). The class then clearly communicates immutability.

```
// Before
class Person { private String id; void setId(String id) { this.id = id; } }
// After
class Person { private final String id; Person(String id) { this.id = id; } String id() { return id; } }
```

Replace Constructor with Factory Function *(alias: Replace Constructor with Factory Method)*

Motivation. Constructors have limitations: they must return a new instance of exactly that class, their name is fixed, and `new` is needed. A static factory method (a `static` method that creates and returns an instance) can have an intention-revealing name, return a subclass or cached instance, and hide construction details. (Joshua Bloch's *Effective Java*, Item 1, makes the same argument. JDK examples: `List.of`, `Integer.valueOf`, `LocalDate.of`.)

```
// Before
Employee leadEngineer = new Employee(document.leadEngineer(), "E");
// After
static Employee createEngineer(String name) { return new Employee(name, "E"); }
Employee leadEngineer = Employee.createEngineer(document.leadEngineer());
```

Replace Function with Command *(alias: Replace Method with Method Object)* · inverse: Replace Command with Function

Motivation. Wrap a function in its own object (a **command**, with usually one `execute()` method). The object can hold state across steps, support undo, be queued, and — most commonly in refactoring — lets you break a big function with many local variables into small methods that share those variables as fields.

```
// Before
int score(Candidate c, MedicalExam exam, ScoringGuide guide) {
    int result = 0; int healthLevel = 0; boolean highMedicalRisk = false;
    // ... 60 lines using result, healthLevel, highMedicalRisk
    return result;
}
// After
final class Scorer {
    private final Candidate candidate; private final MedicalExam exam; private final ScoringGuide guide;
    private int result; private int healthLevel; private boolean highMedicalRisk;
    Scorer(Candidate c, MedicalExam e, ScoringGuide g) { candidate = c; exam = e; guide = g; }
    int execute() { scoreSmoking(); scoreCertification(); return result - Math.max(healthLevel - 5, 0); }
    private void scoreSmoking() { /* uses fields, no parameter passing */ }
    private void scoreCertification() { /* ... */ }
}
int score(Candidate c, MedicalExam exam, ScoringGuide guide) { return new Scorer(c, exam, guide).execute(); }
```

Replace Command with Function · inverse: Replace Function with Command

Motivation. If a command object is simple and adds nothing a function couldn't do, turn it back into a function. Commands are powerful but cost extra complexity.

```
// Before
final class ChargeCalculator {
    private final Customer customer; private final int usage;
    ChargeCalculator(Customer c, int usage) { this.customer = c; this.usage = usage; }
    double charge() { return customer.rate() * usage; }
}
double monthCharge = new ChargeCalculator(customer, usage).charge();
// After
static double charge(Customer customer, int usage) { return customer.rate() * usage; }
double monthCharge = charge(customer, usage);
```

7.3.7 Dealing with Inheritance (book chapter 12)

Inheritance is powerful and easy to misuse. These refactorings move features up and down a hierarchy and replace inheritance with delegation (composition — one object holding another and forwarding work to it) where needed.

Pull Up Method · inverse: Push Down Method

Motivation. Duplicate methods in sibling subclasses belong in the superclass. If they are similar but not identical, first make them identical (Parameterize Function), or use a Template Method (7.6) — a base-class method that fixes an algorithm's steps and lets subclasses fill some in.

```
// Before
class Salesman extends Employee { String name() { return name; } }
class Engineer extends Employee { String name() { return name; } }
// After
class Employee { String name() { return name; } }
```

Pull Up Field · inverse: Push Down Field

Motivation. Subclasses developed independently often have the same field (maybe with different names). Rename to match, then move the field to the superclass.

```
// Before
class Salesman extends Employee { protected String name; }
class Engineer extends Employee { protected String name; }
// After
class Employee { protected String name; }
```

Pull Up Constructor Body

Motivation. Constructors in subclasses that repeat the same initialisation should call a superclass constructor that does it. In Java 21 `super(...)` must be the first statement of a constructor (Java 25 relaxed this with flexible constructor bodies, JEP 513 — a JDK Enhancement Proposal), so the common code goes into the superclass constructor.

```
// Before
class Manager extends Employee {
    Manager(String name, String id, int grade) { this.name = name; this.id = id; this.grade = grade; }
}
// After
class Employee { Employee(String name, String id) { this.name = name; this.id = id; } }
class Manager extends Employee {
    Manager(String name, String id, int grade) { super(name, id); this.grade = grade; }
}
```

Push Down Method · inverse: Pull Up Method

Motivation. If a superclass method is only relevant to one (or a few) subclasses, move it down to them. Callers must then know they have that subclass — only do it when they do.

```
// Before
class Employee { int quota() { ... } }                    // only salesmen have a quota
// After
class Salesman extends Employee { int quota() { ... } }
```

Push Down Field · inverse: Pull Up Field

Motivation. A field used by only one subclass should live in that subclass.

```
// Before
class Employee { protected int quota; }
// After
class Salesman extends Employee { private int quota; }
```

Replace Type Code with Subclasses *(aliases: Extract Subclass, Replace Type Code with State/Strategy)* · inverse: Remove Subclass

Motivation. A type code field (`"engineer"`, `"manager"`) that drives behaviour is a hint that you need subclasses; then conditionals can become polymorphism. Two ways: **direct inheritance** (subclass the class itself) or **indirect** (the class holds a separate type object, e.g. `EmployeeType`, which is subclassed — needed if the type can change at runtime or the class is already subclassed for another reason; this is the old "Replace Type Code with State/Strategy").

```
// Before
class Employee { String type; Employee(String name, String type) { ... } }
// After (direct)
abstract sealed class Employee permits Engineer, Manager, Salesman { ... }
static Employee create(String name, String type) {
    return switch (type) {
        case "engineer" -> new Engineer(name);
        case "manager"  -> new Manager(name);
        case "salesman" -> new Salesman(name);
        default -> throw new IllegalArgumentException("Employee cannot be of type " + type);
    };
}
```

Remove Subclass *(alias: Replace Subclass with Fields)* · inverse: Replace Type Code with Subclasses

Motivation. Subclasses that no longer differ in behaviour (e.g. they differ only in a constant) are not worth their cost. Replace them with a field in the superclass.

```
// Before
abstract class Person { abstract String genderCode(); }
class Male extends Person   { String genderCode() { return "M"; } }
class Female extends Person { String genderCode() { return "F"; } }
// After
class Person {
    private final String genderCode;
    Person(String name, String genderCode) { ...; this.genderCode = genderCode; }
    String genderCode() { return genderCode; }
}
```

Extract Superclass

Motivation. Two classes doing similar things have duplicated fields and methods. Create a common superclass and pull the shared parts up. (Alternative: Extract Class and use delegation. Fowler notes you can start with inheritance and switch to delegation later with Replace Superclass with Delegate if it becomes a problem.)

```
// Before
class Department { String name; double totalAnnualCost() { ... } int headCount() { ... } }
class Employee   { String name; double annualCost() { ... } String id() { ... } }
// After
abstract class Party { protected String name; abstract double annualCost(); }
class Department extends Party { ... }
class Employee extends Party { ... }
```

Collapse Hierarchy

Motivation. When a subclass and its superclass are no longer different enough to be worth keeping separate, merge them. A cure for Lazy Element and Speculative Generality.

```
// Before
class Employee { ... }
class Salesman extends Employee { }          // adds nothing any more
// After
class Employee { ... }
```

Replace Subclass with Delegate

Motivation. Inheritance has two limits: you can vary only **one** axis (a person cannot be subclassed by both age-group and income-level), and subclasses are tightly coupled to their parent. Delegation (composition) handles both: the varying behaviour moves to a separate delegate object that can be changed at runtime. This is "favour object composition over class inheritance" (GoF — the "Gang of Four" authors of the 1994 *Design Patterns* book), and the core of the **State** and **Strategy** patterns.

```
// Before
class Booking { double basePrice() { return show.price(); } }
class PremiumBooking extends Booking { @Override double basePrice() { return super.basePrice() +
extras.premiumFee(); } }
// After
class Booking {
    private PremiumDelegate premiumDelegate;           // null unless premium - can be set at runtime
    void bePremium(Extras extras) { premiumDelegate = new PremiumDelegate(this, extras); }
    double basePrice() {
        double result = show.price();
        return premiumDelegate == null ? result : premiumDelegate.extendBasePrice(result);
    }
}
```

Replace Superclass with Delegate ***(alias: Replace Inheritance with Delegation)***

Motivation. If a subclass uses only part of its superclass, or the superclass's methods do not make sense for it (Refused Bequest, broken Liskov substitution), stop inheriting and hold an instance instead, forwarding only what you need. Classic example: a `Stack` that extends a list type (the JDK's `java.util.Stack extends Vector` is often cited).

```
// Before
class Scroll extends CatalogItem { ... }     // but a scroll is a physical copy, not a catalogue entry
// After
class Scroll {
    private final CatalogItem catalogItem;   // delegate
    String title() { return catalogItem.title(); }
    boolean hasTag(String tag) { return catalogItem.hasTag(tag); }
    LocalDate lastCleaned;                   // scroll's own data
}
```

7.3.8 Extra refactorings on refactoring.com

The online catalogue (web edition) lists a few more refactorings that are not among the 61 book chapters' entries. They are worth knowing:

Replace Control Flag with Break ***(alias: Remove Control Flag)***

Motivation. A boolean "found" flag that only exists to stop a loop is clumsy. Use `break`, `continue` or `return`.

```
// Before
boolean found = false;
for (String p : people) {
    if (!found && p.equals("Don")) { sendAlert(); found = true; }
}
// After
for (String p : people) {
    if (p.equals("Don")) { sendAlert(); break; }
}
```

Replace Error Code with Exception

Motivation. Returning special codes (`-1`, `null`) for errors makes every caller check them — and callers forget. Throw an exception so errors cannot be silently ignored and the normal path stays clean.

```
// Before
int withdraw(double amount) { if (amount > balance) return -1; balance -= amount; return 0; }
// After
void withdraw(double amount) {
    if (amount > balance) throw new InsufficientFundsException(amount, balance);
    balance -= amount;
}
```

Replace Exception with Precheck ***(alias: Replace Exception with Test)***

Motivation. Exceptions are for *exceptional* behaviour. If the caller can easily check the condition first, check it instead of catching an exception.

```
// Before
double valueAt(int i) { try { return values[i]; } catch (ArrayIndexOutOfBoundsException e) { return 0; } }
// After
double valueAt(int i) { return (i >= 0 && i < values.length) ? values[i] : 0; }
```

Replace Magic Literal ***(alias: Replace Magic Number with Symbolic Constant)***

Motivation. A literal like `9.81` or `"STD"` with special meaning should get a name, so readers know what it means and there is one place to change it. (Don't bother when the meaning is obvious, e.g. `0` as an initial sum.) The worked example's step 4 does this.

```
// Before
double potentialEnergy(double mass, double height) { return mass * 9.81 * height; }
// After
static final double STANDARD_GRAVITY = 9.81;
double potentialEnergy(double mass, double height) { return mass * STANDARD_GRAVITY * height; }
```

Return Modified Value

Motivation. When a function modifies a variable passed in or shared, make it *return* the new value instead and let the caller assign it. The data flow becomes visible.

```
// Before
double totalAscent = 0;
calculateAscent();                      // secretly updates the field totalAscent
// After
double totalAscent = calculateAscent();
double calculateAscent() {
    double result = 0;
    for (int i = 1; i < points.size(); i++) {
        double diff = points.get(i).elevation() - points.get(i - 1).elevation();
        result += Math.max(diff, 0);
    }
    return result;
}
```

1st-edition names you may still hear

1st-edition name	2nd-edition name
Extract Method / Inline Method	Extract Function / Inline Function
Introduce Explaining Variable / Inline Temp	Extract Variable / Inline Variable
Rename Method, Add Parameter, Remove Parameter	Change Function Declaration
Self-Encapsulate Field / Encapsulate Field	Encapsulate Variable
Replace Record with Data Class	Encapsulate Record
Replace Data Value with Object, Replace Type Code with Class	Replace Primitive with Object
Move Method	Move Function
Consolidate Duplicate Conditional Fragments	Slide Statements
Split Temp, Remove Assignments to Parameters	Split Variable
Introduce Null Object	Introduce Special Case
Parameterize Method	Parameterize Function
Replace Parameter with Explicit Methods	Remove Flag Argument
Replace Parameter with Method	Replace Parameter with Query
Replace Constructor with Factory Method	Replace Constructor with Factory Function
Replace Method with Method Object	Replace Function with Command
Extract Subclass, Replace Type Code with State/Strategy	Replace Type Code with Subclasses
Replace Subclass with Fields	Remove Subclass
Replace Inheritance with Delegation	Replace Superclass with Delegate
Remove Control Flag	Replace Control Flag with Break (web)
Replace Magic Number with Symbolic Constant	Replace Magic Literal (web)
Replace Exception with Test	Replace Exception with Precheck (web)

7.4 Smell → refactorings lookup table

Use this when you have named a smell and need to choose a cure. **Bold** = the usual first move.

Smell	Group	Refactorings that cure it
Mysterious Name	2nd-ed extra	**Change Function Declaration**, Rename Variable, Rename Field
Duplicated Code	Dispensables	**Extract Function**, Slide Statements, Pull Up Method *(also useful, not in Fowler's list: Replace Inline Code with Function Call, Substitute Algorithm)*
Long Function	Bloaters	**Extract Function**, Replace Temp with Query, Introduce Parameter Object, Preserve Whole Object, Replace Function with Command, Decompose Conditional, Replace Conditional with Polymorphism, Split Loop
Long Parameter List	Bloaters	Replace Parameter with Query, **Preserve Whole Object**, **Introduce Parameter Object**, Remove Flag Argument, Combine Functions into Class
Global Data	2nd-ed extra	**Encapsulate Variable** (then shrink its scope)
Mutable Data	2nd-ed extra	**Encapsulate Variable**, Split Variable, Slide Statements, Extract Function, Separate Query from Modifier, Remove Setting Method, Replace Derived Variable with Query, Combine Functions into Class, Combine Functions into Transform, Change Reference to Value
Divergent Change	Change Preventers	**Split Phase**, Move Function, Extract Function, **Extract Class**
Shotgun Surgery	Change Preventers	**Move Function**, **Move Field**, Combine Functions into Class, Combine Functions into Transform, Split Phase, Inline Function, Inline Class
Feature Envy	Couplers	**Move Function**, Extract Function
Data Clumps	Bloaters	**Extract Class**, **Introduce Parameter Object**, Preserve Whole Object
Primitive Obsession	Bloaters	**Replace Primitive with Object**, Replace Type Code with Subclasses, Replace Conditional with Polymorphism, Extract Class, Introduce Parameter Object
Repeated Switches	OO Abusers	**Replace Conditional with Polymorphism**
Loops	2nd-ed extra	**Replace Loop with Pipeline**
Lazy Element	Dispensables	**Inline Function**, **Inline Class**, Collapse Hierarchy
Speculative Generality	Dispensables	Collapse Hierarchy, Inline Function, Inline Class, Change Function Declaration, Remove Dead Code
Temporary Field	OO Abusers	**Extract Class**, Move Function, Introduce Special Case
Message Chains	Couplers	**Hide Delegate**, Extract Function, Move Function
Middle Man	Couplers	**Remove Middle Man**, Inline Function, Replace Superclass with Delegate, Replace Subclass with Delegate
Insider Trading	Couplers	**Move Function**, **Move Field**, Hide Delegate, Replace Subclass with Delegate, Replace Superclass with Delegate
Large Class	Bloaters	**Extract Class**, Extract Superclass, Replace Type Code with Subclasses
Alternative Classes with Different Interfaces	OO Abusers	**Change Function Declaration**, Move Function, Extract Superclass
Data Class	Dispensables	**Encapsulate Record**, Remove Setting Method, Move Function, Extract Function, Split Phase
Refused Bequest	OO Abusers	Push Down Method, Push Down Field, **Replace Subclass with Delegate**, **Replace Superclass with Delegate**
Comments	Dispensables	**Extract Function**, Change Function Declaration, Introduce Assertion

And the reverse view — which **design principle** each family of smells violates (links to Chapters 4–6):

Smell family	Principle it violates
Divergent Change, Large Class	Single Responsibility Principle
Repeated Switches, Shotgun Surgery	Open/Closed Principle
Refused Bequest	Liskov Substitution Principle
Long Parameter List with flags, fat interfaces	Interface Segregation / clean function design
Global Data, Mutable Data	Encapsulation / information hiding (control who can change what)
Hard-wired `new` of concrete dependencies	Dependency Inversion
Duplicated Code	DRY (Don't Repeat Yourself)
Speculative Generality	YAGNI
Message Chains, Insider Trading	Law of Demeter / encapsulation
Feature Envy, Data Class	"Tell, Don't Ask" — put behaviour with data

---

7.5 Worked example — from messy to clean in six compiling steps

The starting point

A courier company prints invoices. Each shipment has a **service type** (`STD` standard, `EXP` express, `FRG` fragile), a weight and a distance.

Tariffs:

Type	Charge	Loyalty points
STD	5 + 1.2 per kg, plus 0.05 per km beyond 100 km	1 per full 100 km
EXP	12 + 2.0 per kg, plus 0.10 per km beyond 50 km	1 per full 100 km, +2 bonus
FRG	8 + 1.5 per kg + 3 handling; ×1.2 if heavier than 10 kg	1 per full 100 km

The new feature request: "We also need an HTML invoice for the web portal, and next quarter we are adding an OVERNIGHT service."

The current code (step 0, abridged — full file in 7.8):

```
static String print(Inv inv) {
    double tot = 0;
    int pts = 0;
    int unused = 0;                                  // dead code
    StringBuilder r = new StringBuilder("Invoice for " + inv.cust + "\n");
    for (Shp s : inv.list) {
        double amt = 0;
        switch (s.t) {
            case "STD": amt = 5 + s.kg * 1.2;       if (s.km > 100) amt += (s.km - 100) * 0.05; break;
            case "EXP": amt = 12 + s.kg * 2.0;      if (s.km > 50)  amt += (s.km - 50) * 0.10;  break;
            case "FRG": amt = 8 + s.kg * 1.5 + 3;   if (s.kg > 10)  amt = amt * 1.2;            break;
            default: throw new IllegalArgumentException("unknown type: " + s.t);
        }
        pts += s.km / 100;
        if ("EXP".equals(s.t)) pts += 2;
        r.append("  ").append(s.t).append(" ").append(s.kg).append("kg ")
         .append(s.km).append("km: ").append(String.format(Locale.ROOT, "%.2f", amt)).append("\n");
        tot += amt;
    }
    r.append("Amount owed: ").append(String.format(Locale.ROOT, "%.2f", tot)).append("\n");
    r.append("Points earned: ").append(pts).append("\n");
    return r.toString();
}
```

Smells spotted.

Smell	Where
Mysterious Name	`Shp`, `Inv`, `t`, `kg`, `km`, `amt`, `tot`, `pts`, `r`
Long Function	`print` calculates charges, calculates points, and formats — three jobs
Divergent Change	HTML output would force copying the whole function; a new tariff means editing the formatting function
Repeated Switches (waiting to happen)	The type code `"EXP"` is checked in two places already
Primitive Obsession	The service type is a `String`; any typo compiles
Magic literals	`5`, `1.2`, `100`, `0.05`, `12`, ...
Data Class / Mutable Data	Public mutable fields in `Shp` and `Inv`
Dead code	`int unused`

Adding HTML now would mean duplicating everything. So we do **preparatory refactoring** first: make the change easy, then make the easy change.

The safety net

Before touching anything we write a **characterisation check** — `lld.ch07.worked.Main`. It runs step 0 to record the "golden" output, then runs every later step and compares the output **byte for byte**. The fixture (the fixed test input data) includes boundary cases (exactly 100 km for STD, exactly 10 kg for FRG) because boundaries are where refactorings most often break behaviour. In a real project this would be a JUnit test (JUnit is the standard Java testing framework); here it is a plain `main` so it runs with the JDK (Java Development Kit — the compiler and runtime) alone.

Each step lives in its own package (`step0` … `step5`) so you can compile and diff them (compare them line by line). After *every* step the checker prints `SAME output`.

Step 1 — Extract Function, Rename Variable/Field, Remove Dead Code

- **Rename Field**: `t → type`, `kg → weightKg`, `km → distanceKm`; classes `Shp → Shipment`, `Inv → Invoice`.
- **Rename Variable**: `tot → totalAmount`, `pts → loyaltyPoints`, `r → result`.
- **Extract Function** ×3: the switch becomes `amountFor(shipment)`, the points logic becomes `pointsFor(shipment)`, the formatting becomes `money(amount)`.
- **Remove Dead Code**: `unused` is gone.

```
for (Shipment shipment : invoice.shipments) {
    double thisAmount = amountFor(shipment);
    loyaltyPoints += pointsFor(shipment);
    result.append(...).append(money(thisAmount)).append("\n");
    totalAmount += thisAmount;
}
```

The switch itself was *moved*, not changed. Moving before changing is a key habit: two small safe steps instead of one risky one.

Step 2 — Inline Variable, Split Loop, Replace Temp with Query, Replace Loop with Pipeline, Slide Statements

The loop still does three jobs (print a line, add to total, add points). We:

1. **Inline Variable** `thisAmount` — call `amountFor(shipment)` directly.
2. **Split Loop** — one loop for printing, one for the total, one for points.
3. **Replace Temp with Query** — the total and the points become `totalAmount(invoice)` and `totalPoints(invoice)`.
4. **Replace Loop with Pipeline** — those two queries become streams.
5. **Slide Statements** — the declarations disappear; each value is computed where it is used.

```
static double totalAmount(Invoice invoice) {
    return invoice.shipments.stream().map(Main::amountFor).reduce(0.0, Double::sum);
}
static int totalPoints(Invoice invoice) {
    return invoice.shipments.stream().mapToInt(Main::pointsFor).sum();
}
```

A subtle trap. The obvious pipeline is `mapToDouble(...).sum()`. But `DoubleStream.sum()` may use compensated summation, so it can differ from a plain left-to-right loop in the last bit of a `double`. That is a (tiny) behaviour change. `reduce(0.0, Double::sum)` on a sequential stream adds in encounter order — exactly like the loop. (For `int`, addition is exact, so `IntStream.sum()` is safe.) Performance note: we now call `amountFor` twice per shipment — the kind of cost Fowler says to ignore until a profiler shows it matters.

Step 3 — Split Phase, Encapsulate Record, Encapsulate Collection, Combine Functions into Transform

Now the key preparatory move. Calculation and formatting are two **phases**. We split them with an intermediate data structure:

- `StatementData` (a record) — everything the renderer needs: customer, one `Line` per shipment with its computed amount, total, points.
- `StatementCalculator.calculate(Invoice)` — phase 1, a **transform** (Combine Functions into Transform): raw invoice in, enriched data out.
- `TextRenderer.render(StatementData)` — phase 2. It knows nothing about tariffs.
- `Shipment` and `Invoice` become **records** (Encapsulate Record — no more public mutable fields), and `Invoice` copies its list with `List.copyOf` (Encapsulate Collection).

```
return new TextRenderer().render(new StatementCalculator().calculate(invoice));
```

Step 4 — Replace Primitive with Object, Replace Magic Literal

- **Replace Primitive with Object**: the `String` type code becomes `enum ServiceType { STANDARD("STD"), EXPRESS("EXP"), FRAGILE("FRG") }` with `fromCode(String)`. An unknown code now fails *at the boundary* (when the shipment is created) instead of deep inside the calculation. It is the same exception type and message, and in this program shipments are always built and printed together, so the observable behaviour is unchanged; if some caller created invoices without ever printing them, moving the failure earlier would be a behaviour change to check first. The `"STD"` strings survive only where data enters the system and where it is printed.
- **Replace Magic Literal**: every tariff number gets a name (`STD_FREE_KM`, `FRG_HEAVY_FACTOR`, ...).
- The switch becomes a **switch expression** over the enum; with no `default` branch, the compiler checks it is exhaustive.

```
return switch (s.type()) {
    case STANDARD -> STD_BASE + s.weightKg() * STD_PER_KG
            + (s.distanceKm() > STD_FREE_KM ? (s.distanceKm() - STD_FREE_KM) * STD_PER_EXTRA_KM : 0);
    case EXPRESS  -> ...
    case FRAGILE  -> { double base = ...; yield s.weightKg() > FRG_HEAVY_KG ? base * FRG_HEAVY_FACTOR : base; }
};
```

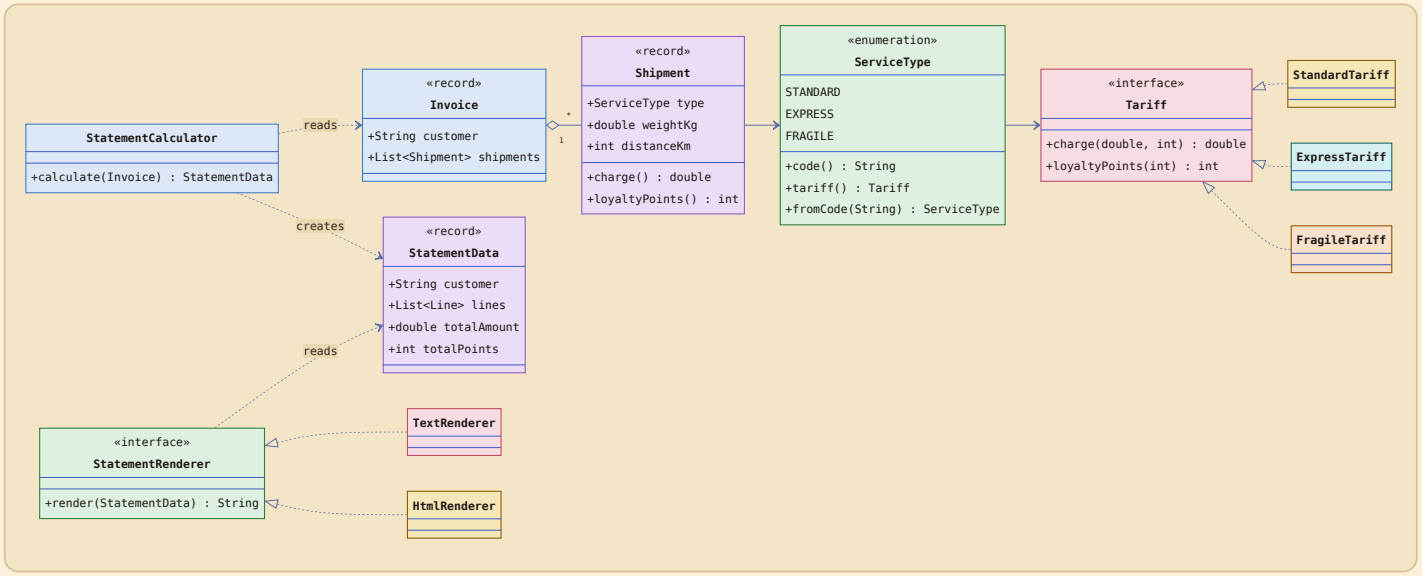
(Is `x + 0` the same as the old "`if` not taken"? For `double`, adding `+0.0` leaves any value unchanged except `-0.0`, which cannot occur here. The checker confirms it.)

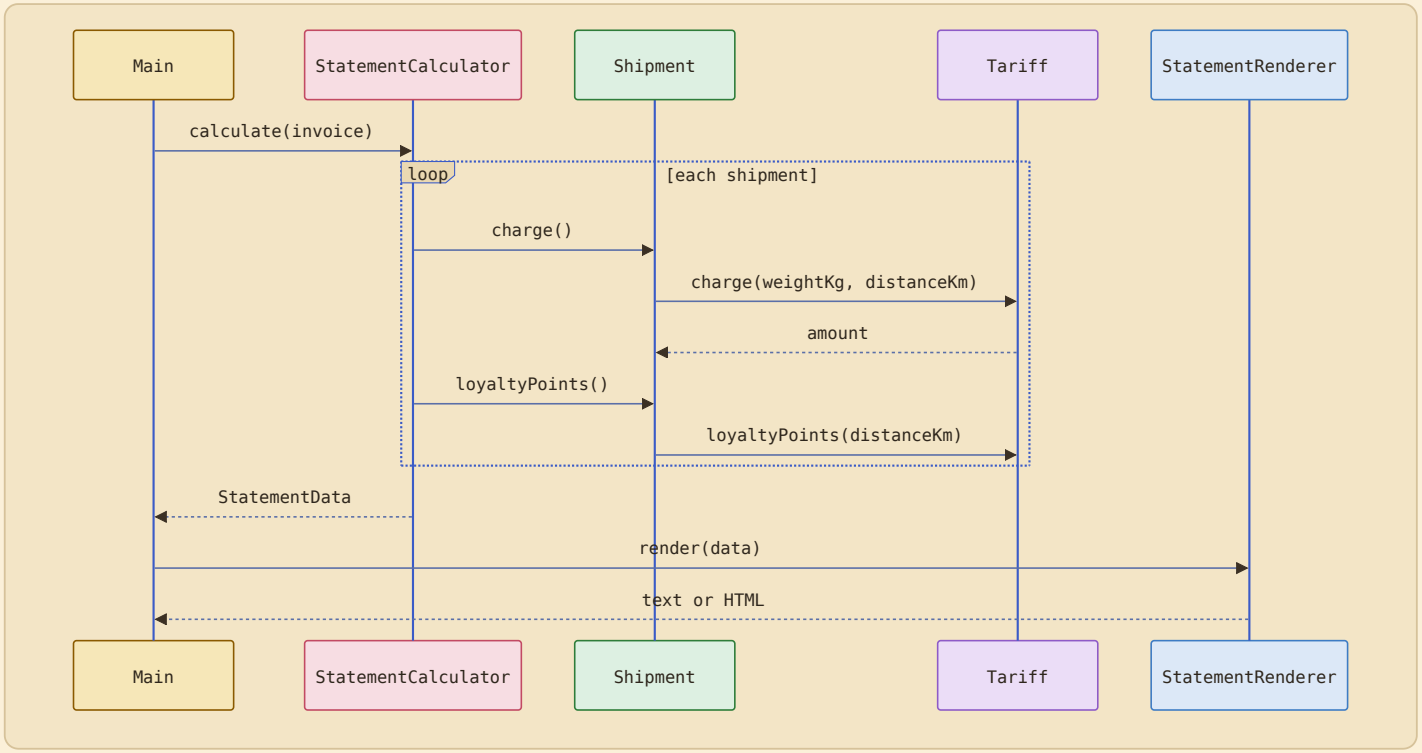
Step 5 — Replace Conditional with Polymorphism, Move Function, then the new feature

- **Replace Conditional with Polymorphism**: each switch branch becomes a class implementing `sealed interface Tariff { double charge(double weightKg, int distanceKm); default int loyaltyPoints(int distanceKm) }`. `ExpressTariff` overrides `loyaltyPoints` to add its bonus — the second `"EXP"` check disappears too. Each enum constant holds its `Tariff` (a **Strategy**).
- **Move Function**: `Shipment.charge()` and `Shipment.loyaltyPoints()` — the calculator no longer reaches into shipment data (Feature Envy cured).
- `StatementCalculator` has **no conditionals left**.

Then — wearing the *adding function* hat now — the new feature is easy:

- Extract a `StatementRenderer` interface; `TextRenderer` implements it.
- Add `HtmlRenderer` — about 15 lines, reusing phase 1 unchanged.
- Adding OVERNIGHT next quarter = one new `Tariff` record, one new enum constant, and one more name in `Tariff`'s `permits` list (a sealed interface must list every implementation). The calculator and the renderers do not change (Open/Closed Principle for the calculation and rendering code).





What changed, step by step

Step	Refactorings	Smells removed
1	Extract Function ×3, Rename Variable, Rename Field, Remove Dead Code	Mysterious Name, part of Long Function, dead code
2	Inline Variable, Split Loop, Replace Temp with Query, Replace Loop with Pipeline, Slide Statements	Long Function (loop doing 3 jobs), Loops
3	Split Phase, Combine Functions into Transform, Encapsulate Record, Encapsulate Collection	Divergent Change, Data Class, Mutable Data
4	Replace Primitive with Object, Replace Magic Literal	Primitive Obsession, magic numbers
5	Replace Conditional with Polymorphism, Move Function, (then Extract interface for renderers)	Repeated Switches, Feature Envy

Checker output (`java lld.ch07.worked.Main`):

```
Golden output from step 0:
Invoice for Asha Traders
  STD 4.0kg 250km: 17.30
  EXP 2.5kg 80km: 20.00
  FRG 12.0kg 40km: 34.80
  STD 1.0kg 90km: 6.20
  STD 0.5kg 100km: 5.60
  FRG 10.0kg 150km: 26.00
Amount owed: 109.90
Points earned: 6
---
step0 (messy original)         SAME output
step1 extract + rename         SAME output
step2 split loop + pipeline    SAME output
step3 split phase              SAME output
step4 primitive -> object      SAME output
step5 polymorphism (final)     SAME output
All steps preserve behaviour.
```

What we deliberately did NOT do. Money is still a `double`. Switching to `BigDecimal` (or the `Money` type from `code/smells`) would change rounding in some cases — that is a *behaviour change*, so it belongs under the "adding function" hat, with its own tests and a product decision about rounding rules. Refactoring and behaviour changes are kept apart.

7.6 Refactoring toward patterns

What it is

Design patterns (Chapters 8–11) are not only designed up front. Very often you **arrive at a pattern by refactoring** when the code asks for it. Joshua Kerievsky's book *Refactoring to Patterns* (2004) catalogues these moves; many are compositions of Fowler's small refactorings. The idea: do not force patterns in early (Speculative Generality); refactor *toward* a pattern when a smell appears, and sometimes *away* from one when it is no longer pulling its weight.

How it works

> **Key term — patterns in this table not met earlier in this chapter** (all are covered in Chapters 8–11). **Factory**: an object or method whose only job is creating other objects; a **Builder** assembles one complex object step by step. **Observer**: subscribers register with an object and are notified automatically when it changes. **Bridge**: separates an abstraction from its implementation so the two can vary independently. **Composite**: a tree structure in which single items and groups of items are treated the same way.

Smell you see	Refactor toward	Via (Fowler's steps)
A switch/if-chain choosing an algorithm (e.g. discount by customer tier)	**Strategy**	Extract Function per branch → Replace Conditional with Polymorphism (Kerievsky: *Replace Conditional Logic with Strategy*)
Methods that check a status field and change it (`if status == PAID then ...`)	**State**	Replace Type Code with Subclasses (indirect, via a state object) → Replace Conditional with Polymorphism (Kerievsky: *Replace State-Altering Conditionals with State*)
`if (x == null)` repeated at many call sites	**Null Object / Special Case**	Introduce Special Case (Kerievsky: *Introduce Null Object*)
Sibling subclasses with the same algorithm skeleton but different steps	**Template Method**	Extract Function in each → Pull Up Method (Kerievsky: *Form Template Method*)
Many constructors with confusing boolean/int parameters	**Factory Method / Creation Methods**	Replace Constructor with Factory Function (Kerievsky: *Replace Constructors with Creation Methods*)
Many `new ConcreteX()` calls scattered; clients should not know which class	**Factory**	Replace Constructor with Factory Function + Move Function to a factory class (Kerievsky: *Encapsulate Classes with Factory*)
Complex object (in Kerievsky's refactoring, a Composite tree) built step by step with many calls in the right order	**Builder**	Kerievsky: *Encapsulate Composite with Builder*
A function too big to decompose because of many shared locals; or you need undo/queueing	**Command**	Replace Function with Command
Embellishment code (logging, caching) mixed into a core class	**Decorator**	Kerievsky: *Move Embellishment to Decorator*
Many objects polling one object for changes; hard-coded notification	**Observer**	Kerievsky: *Replace Hard-Coded Notifications with Observer*
Two classes with different interfaces doing the same job	**Adapter**	Change Function Declaration / Extract Superclass; wrap third-party code (Kerievsky: *Extract Adapter*, *Unify Interfaces with Adapter*)
A switch on a type code to create objects	**Factory + polymorphism**	Replace Type Code with Subclasses + Replace Constructor with Factory Function
Subclass explosion for combinations of features	**Strategy / Decorator / Bridge**	Replace Subclass with Delegate
A pattern that no longer earns its keep (one strategy, one decorator)	*Remove the pattern*	Inline Class, Collapse Hierarchy (Kerievsky: *Inline Singleton* and similar "away from" moves)

The runnable package `lld.ch07.towardpatterns` shows five of these with the **before** code and the **after** code side by side, and checks that both produce the same results. (The prices and loan amounts there are `double` only to keep the before/after comparison short; in production code use `BigDecimal` or a `Money` type.)

Replace Conditional Logic with Strategy

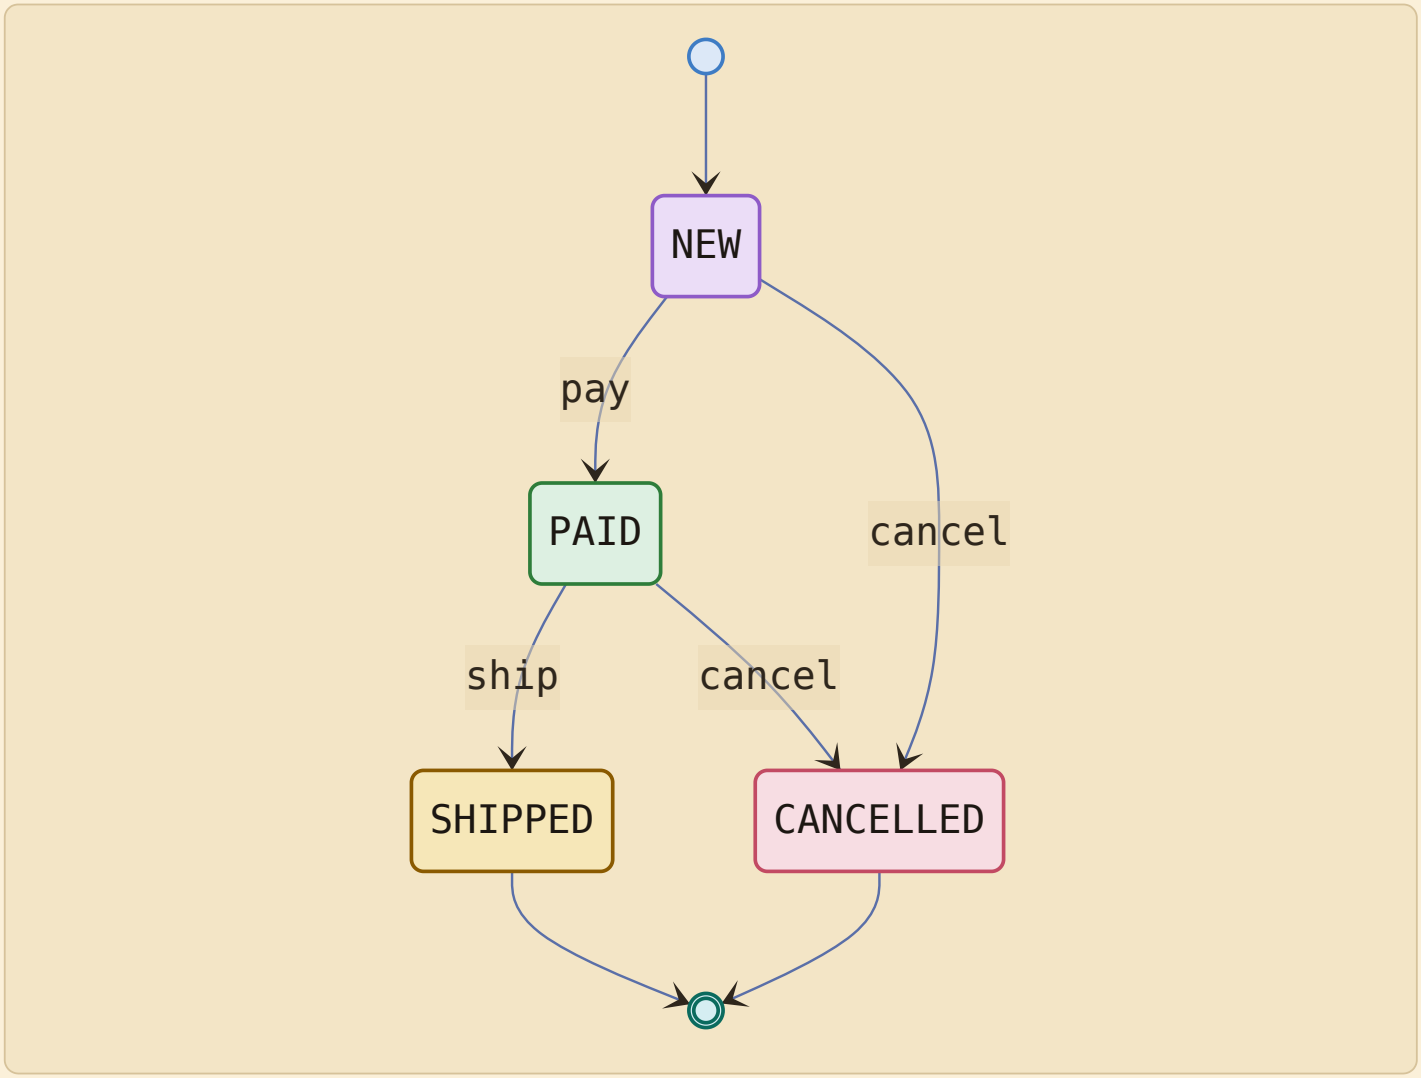
Before: a `switch (tier)` that every new customer tier must edit. **After:** a `DiscountPolicy` functional interface (an interface with a single abstract method, so a lambda — a short inline function — can implement it), one policy per tier (lambdas here; classes if a policy grows), stored in an `EnumMap` (a map whose keys are enum constants). New tiers are *registered*, not coded into a switch.

```
@FunctionalInterface
interface DiscountPolicy { double apply(double amount); }

double price(Tier tier, double amount) {
    return policies.getOrDefault(tier, fallback).apply(amount);
}
```

Replace State-Altering Conditionals with State

Before: every method checks `status` strings and changes them — the rules of the lifecycle are scattered across methods. **After:** each state is an enum constant implementing `OrderState`; it overrides only the moves it allows. Default methods (interface methods with a built-in body) reject everything else. `Order` just delegates: `state = state.pay(this)`.



```
enum States implements OrderState {
    NEW {
        @Override public OrderState pay(Order o)    { o.log("paid"); return PAID; }
        @Override public OrderState cancel(Order o) { o.log("cancelled"); return CANCELLED; }
    },
    PAID {
        @Override public OrderState ship(Order o)   { o.log("shipped"); return SHIPPED; }
        @Override public OrderState cancel(Order o) { o.log("cancelled"); return CANCELLED; }
    },
    SHIPPED, CANCELLED
}
```

Strategy vs State: they have the same class structure. The difference is intent — a **strategy** is usually chosen by the client and stays fixed; a **state** changes *itself* as the object moves through its lifecycle.

Introduce Special Case (Null Object)

Before: `(c == null) ? "occupant" : c.name()` in every client. **After:** `find(id)` returns an `UnknownCustomer` that answers `"occupant"` and `"basic"` itself. Clients have no null checks.

Form Template Method

Before: `legacyCsv` and `legacyMarkdown` repeat the same skeleton (header, one row per item, footer). **After:** an abstract `Exporter.export()` (declared `final`) holds the skeleton once and calls abstract `header()`, `row()`, `footer()` steps; `CsvExporter` and `MarkdownExporter` fill them in.

Replace Constructors with Creation Methods

Before: `new LegacyLoan(5000, false, 12)` — what does `false` mean? **After:** a private constructor plus `Loan.termLoan(5000, 12)` and `Loan.revolver(2000)`.

Output (`java lld.ch07.towardpatterns.Main`):

```
Strategy:        GOLD 250 -> 200.0, NEW 250 -> 240.0 | same as switch: true
State:           cannot ship when NEW; paid; cannot pay when PAID; shipped; cannot cancel when SHIPPED; | same as
if-chains: true
Special Case:    Hello Ravi on premium / Hello occupant on basic | same: true
Template Method: CSV and Markdown exporters | same: true
Factory:         term 5000.0/12, revolver 2000.0/0 | same: true
All pattern refactorings preserve behaviour.
```

Small smell cures (package `lld.ch07.smells`)

A separate runnable package shows the cures for several smells from 7.2 as real code: `Money` (Primitive Obsession), `DateRange` (Data Clumps), and `Order` with `shippingCity()` (Message Chains → Hide Delegate), `Line.total()` (Feature Envy → Move Function) and a read-only `lines()` view (Mutable Data → Encapsulate Collection).

Output (`java lld.ch07.smells.Main`):

```
double 0.1+0.2       = 0.30000000000000004
Money  0.10+0.20     = USD 0.30
mixing currencies    -> currency mismatch: USD vs EUR
booking contains 3rd = true, overlaps other = true
ship to Bengaluru, total INR 301.00
outsider tried lines().clear() -> UnsupportedOperationException (collection is encapsulated)
```

7.7 Putting it together

Trade-offs

Benefit	Cost / risk
Code easier to read and change; features get faster over time (Design Stamina)	Takes time now; the pay-off is later and hard to measure
Bugs become visible	Without tests, you can introduce bugs
Design can evolve with requirements (less up-front guessing)	Renames and moves cause merge conflicts on long-lived branches
Small steps are safe and can stop at any point	Small steps feel slow to beginners (they get fast with practice and IDE support)
More small classes and methods, each easy to understand	More indirection — too much creates Middle Men and Lazy Elements
Removes duplication	Premature abstraction (before the Rule of Three) can create the *wrong* abstraction, which is costlier than duplication

When not to use it

(Summary of 7.1.4.) Do not refactor code you do not need to touch; do not refactor without a safety net (add tests first); do not refactor instead of a rewrite when the code does not work at all; do not break published interfaces without a migration path; do not mix refactoring with behaviour changes in the same step.

Common mistakes

Mistake	Why it is a problem	Do this instead
Calling any code change "refactoring"	Behaviour changes hide inside "refactoring" commits; reviewers relax	Keep refactoring commits separate from feature/bug-fix commits
Big-bang refactoring (days with broken code)	High risk, merge pain, no way to stop halfway	Tiny steps, compile and test after each, commit often
Refactoring without tests	Silent behaviour changes	Write characterisation tests first; use IDE-automated refactorings
Debugging a failed refactoring step	Wastes time	Revert and redo in smaller steps
Tests coupled to private implementation	Every refactoring breaks tests	Test behaviour through public APIs
Text search-and-replace for renames	Changes strings, comments, unrelated symbols	IDE Rename (symbol-aware) — and check reflection/config/serialisation
Abstracting on the first duplication	Wrong abstraction; many flags later	Rule of Three
Changing rounding/ordering "while you're there" (e.g. `DoubleStream.sum()` vs loop, `toList()` vs mutable `ArrayList`)	Subtle behaviour changes	Know the exact semantics of the replacement API
Adding patterns everywhere "for flexibility"	Speculative Generality	Refactor toward a pattern when a smell demands it
Refactoring sprints as the main approach	Business sees refactoring as a separate, optional cost	Opportunistic refactoring inside every feature

Real-world examples

- **IntelliJ IDEA, Eclipse, VS Code (Java extension)** — automated Rename, Extract Method, Inline, Change Signature, Move, Pull Up / Push Down: these are direct implementations of catalogue entries.
- **OpenRewrite** — open-source engine for automated, large-scale source refactoring with "recipes"; used, for example, to migrate codebases between Spring Boot (a popular Java application framework) versions or from JUnit 4 to JUnit 5.
- **Google** — Error Prone with Refaster templates, used for large automated changes across its monorepo (one giant repository holding most of the company's code).
- **JDK history.** `java.util.Stack extends Vector` and `java.util.Properties extends Hashtable` are classic, often-cited cases of inheritance where delegation would have been better (Refused Bequest). For new code, the JDK docs recommend `ArrayDeque` (via the `Deque` interface) over `Stack`. `Date` → `java.time` (Java 8) shows Primitive Obsession/Mutable Data being replaced by immutable value types (`LocalDate`, `Instant`, `Duration`) — a new API alongside the old one rather than an in-place refactor, because the old API is published.
- **Deprecation as migration mechanics.** The JDK and Spring mark old methods `@Deprecated` (Java 9 added `forRemoval`) and keep them delegating for several releases — exactly *Change Function Declaration* with migration mechanics.
- **Java language features that support refactoring**: records (Encapsulate Record, value objects), `sealed` interfaces + switch pattern matching (safe type hierarchies), streams (Replace Loop with Pipeline), `Optional` (making absence explicit), `List.copyOf` / `Collections.unmodifiableList` (Encapsulate Collection).
- **Strangler Fig in industry.** Many companies that split a monolith (an application built and deployed as one unit) into services (Fowler's own write-ups describe this pattern) route one feature at a time from the old system to the new, instead of a big-bang rewrite.

In the interview

30-second answer — "What is refactoring?" "Refactoring is changing the internal structure of code to make it easier to understand and modify, without changing its observable behaviour. You do it in very small steps — each one compiles and passes the tests — so the system is never broken. You use code smells like Long Function, Duplicated Code or Repeated Switches to find where to refactor, and named refactorings like

> Extract Function, Move Function or Replace Conditional with Polymorphism to fix them. Tests are the safety net. The goal is economic: clean code lets you add features faster."

Follow-ups (with answers)

- **Q: How do you refactor code that has no tests?** A: Treat it as legacy code. First write characterisation tests that record current behaviour. If the code is hard to test, break dependencies at a seam — for example, pass an interface through the constructor instead of calling `new` inside. Until tests exist, use only IDE-automated, symbol-aware refactorings. Sprout Method/Class lets me add new, tested code without first cleaning everything.
- **Q: Refactor or rewrite?** A: Default to refactoring — small safe steps and the system keeps working. Consider a rewrite only when the code really does not work or the platform must change, and even then use a Strangler Fig approach to replace it piece by piece.
- **Q: Doesn't refactoring hurt performance?** A: Rarely in a way that matters: small methods are inlined by the JIT, and most time is spent in a small part of the code. I refactor for clarity, then profile and optimise the real hot spots, which is easier in well-factored code.
- **Q: What would you refactor in this code?** (In a machine-coding round.) A: Name smells and cures: "`processOrder` is a Long Function — I'd Extract Function for validation, pricing and persistence. The switch on `vehicleType` appears in three places — Repeated Switches — I'd Replace Conditional with Polymorphism, giving a Strategy per vehicle type. `double price` is Primitive Obsession — a `Money` value object. And `getParkingLot().getFloor(1).getSpot(3)` is a Message Chain — Hide Delegate."
- **Q: When do you remove duplication?** A: Rule of Three. After three occurrences the shape of what varies is clear, so the abstraction is likely right. Earlier abstraction risks the wrong abstraction.
- **Q: Difference between Divergent Change and Shotgun Surgery?** A: Divergent Change: one class changes for many different reasons → split it. Shotgun Surgery: one reason to change touches many classes → gather the code into one place.
- **Q: How do you get from a switch statement to the Strategy or State pattern?** A: Extract each branch into a function, then Replace Conditional with Polymorphism: create an interface with one implementation per case and let the object hold the right implementation. If the choice is fixed by the client, it's Strategy; if the object moves between cases itself, it's State.
- **Q: Is a data class always bad?** A: No. Immutable records used as values, DTOs or the output of a Split Phase are fine. The smell is a *mutable* class with getters/setters whose behaviour lives in other classes.
- **Q: How do you rename a public API method used by other teams?** A: Migration mechanics of Change Function Declaration: add the new method, make the old one delegate to it and mark it `@Deprecated`, migrate callers over time, then remove the old one. For REST APIs, versioning or expand/contract.

Self-check

1. **Q:** Is fixing a bug while tidying the method one refactoring? **A:** No. The bug fix changes behaviour. Do the refactoring and the fix as separate steps (two hats), ideally separate commits.
2. **Q:** A method prints a banner, sums orders, sets a due date and prints details. Which smell and which refactoring? **A:** Long Function; Extract Function for each block (and maybe Split Loop / Replace Temp with Query).
3. **Q:** `book(hotel, from, to, 2, 1, true)` — which smells? **A:** Long Parameter List, Data Clumps (`from`, `to` and the two guest counts), a flag argument (`true`). Cures: Introduce Parameter Object (`Stay`, `Guests`), Remove Flag Argument (or replace the boolean with an explicit enum such as `MealPlan`).
4. **Q:** What is the inverse of Hide Delegate, and when do you use it? **A:** Remove Middle Man — when a class has become mostly forwarding methods.
5. **Q:** Why did the worked example use `reduce(0.0, Double::sum)` instead of `DoubleStream.sum()`? **A:** `DoubleStream.sum()` may use compensated summation and can differ from a plain loop in the last bit; `reduce` on a sequential stream adds left to right like the loop, so behaviour is preserved.
6. **Q:** What is a characterisation test? **A:** A test that records what existing code currently does (right or wrong), so a refactoring that changes behaviour is detected.
7. **Q:** Which smell does `class Stack extends ArrayList` have, and what is the cure? **A:** Refused Bequest (it inherits list operations that break stack rules, violating Liskov). Replace Superclass with Delegate — hold a `Deque` instead.

8. **Q:** Which refactoring turns a status-checking `if` chain into the State pattern? **A:** Replace Type Code with Subclasses (via a state object) followed by Replace Conditional with Polymorphism (Kerievsky: Replace State-Altering Conditionals with State).
9. **Q:** Name the five refactoring.guru smell groups. **A:** Bloaters, Object-Orientation Abusers, Change Preventers, Dispensables, Couplers.
10. **Q:** What is preparatory refactoring? **A:** Refactoring just before a feature so that the feature becomes easy to add — "make the change easy, then make the easy change". Step 3 (Split Phase) of the worked example did this for HTML output.
11. **Q:** When is a comment not a smell? **A:** When it explains *why* (a decision, a trade-off, a reference, a warning), not *what* the code does.
12. **Q:** What does Separate Query from Modifier enforce? **A:** Command–Query Separation: functions that return values have no observable side effects.
13. **Q:** A Java IDE rename of a field broke the JSON response. Was it a refactoring? **A:** It was meant to be, but the JSON field name (observable behaviour) changed, so behaviour was not preserved. Check serialisation, reflection and config when renaming.

TL;DR

- **Refactoring = small, behaviour-preserving changes** to internal structure, done continuously, with tests after every step. Two hats: never refactor and change behaviour at the same time.
- **When:** Rule of Three, preparatory ("make the change easy, then make the easy change"), comprehension, litter-pickup, during code review. Mostly opportunistic, rarely planned. **Not** for code you never touch, and not without a safety net.
- **Smells** tell you *where*: 24 in the 2nd edition — Mysterious Name, Duplicated Code, Long Function, Long Parameter List, Global Data, Mutable Data, Divergent Change, Shotgun Surgery, Feature Envy, Data Clumps, Primitive Obsession, Repeated Switches, Loops, Lazy Element, Speculative Generality, Temporary Field, Message Chains, Middle Man, Insider Trading, Large Class, Alternative Classes with Different Interfaces, Data Class, Refused Bequest, Comments. Groups: Bloaters, OO Abusers, Change Preventers, Dispensables, Couplers.
- **Refactorings** tell you *how*: 61 named ones in seven families; the everyday core is Extract/Inline Function, Rename, Move Function, Extract Class, Split Phase, Replace Conditional with Polymorphism.
- **Performance:** refactor first, then profile and optimise hot spots. **Rewrite** only rarely, and then with a Strangler Fig. **Legacy code** = code without tests → characterisation tests, seams, sprout/wrap.
- **Patterns** are often reached by refactoring: switch → Strategy/State, null checks → Null Object, duplicated skeleton → Template Method, confusing constructors → Factory methods.

7.8 Full source code and output

How to compile and run (Java 21, standard library only):

```
cd chapters/07-refactoring/code
javac --release 21 -d /tmp/lld_07 $(find . -name '*.java')
java -cp /tmp/lld_07 lld.ch07.worked.Main           # characterisation check over all six steps
java -cp /tmp/lld_07 lld.ch07.worked.step5.Main     # final design + new HTML feature
java -cp /tmp/lld_07 lld.ch07.towardpatterns.Main   # refactoring toward patterns
java -cp /tmp/lld_07 lld.ch07.smells.Main           # small smell cures
```

Packages: `lld.ch07.worked` (checker), `lld.ch07.worked.step0` … `step5` (each has its own `Main`; steps 0–4 print the text invoice only), `lld.ch07.towardpatterns`, `lld.ch07.smells`. All 9 `Main` classes compile and run.

Worked example — characterisation check

```java
// File: code/worked/Main.java
package lld.ch07.worked;

import java.util.LinkedHashMap;
import java.util.Map;
import java.util.function.Supplier;

/**
 * Characterisation check - the safety net for the whole worked example.
 * Every step must print exactly what the messy STEP 0 printed. If one byte differs,
 * that step was not a refactoring (it changed behaviour) and we exit with an error.
 */
public class Main {

    public static void main(String[] args) {
        Map<String, Supplier<String>> steps = new LinkedHashMap<>();
        steps.put("step0 (messy original)", lld.ch07.worked.step0.Main::run);
        steps.put("step1 extract + rename", lld.ch07.worked.step1.Main::run);
        steps.put("step2 split loop + pipeline", lld.ch07.worked.step2.Main::run);
        steps.put("step3 split phase", lld.ch07.worked.step3.Main::run);
        steps.put("step4 primitive -> object", lld.ch07.worked.step4.Main::run);
        steps.put("step5 polymorphism (final)", lld.ch07.worked.step5.Main::run);

        String golden = lld.ch07.worked.step0.Main.run();
        System.out.print("Golden output from step 0:\n" + golden);
        System.out.println("---");
        boolean allSame = true;
        for (Map.Entry<String, Supplier<String>> e : steps.entrySet()) {
            boolean same = golden.equals(e.getValue().get());
            allSame &= same;
            System.out.printf("%-30s %s%n", e.getKey(), same ? "SAME output" : "DIFFERENT output!");
        }
        if (!allSame) {
            System.err.println("A step changed behaviour - that was not a refactoring.");
            System.exit(1);
        }
        System.out.println("All steps preserve behaviour.");
    }
}
```

Worked example — step 0 (messy original)

```java
// File: code/worked/step0/Main.java
package lld.ch07.worked.step0;

import java.util.ArrayList;
import java.util.List;
import java.util.Locale;

/** STEP 0 - the messy starting point. It works, but it smells. */
public class Main {

        System.out.print(run());
        System.out.println("--- new feature: HTML statement ---");
        System.out.print(new HtmlRenderer().render(new StatementCalculator().calculate(sampleInvoice())));
    }
}
```

Output (`java -cp /tmp/lld_07 lld.ch07.worked.step5.Main`):

```
Invoice for Asha Traders
  STD 4.0kg 250km: 17.30
  EXP 2.5kg 80km: 20.00
  FRG 12.0kg 40km: 34.80
  STD 1.0kg 90km: 6.20
  STD 0.5kg 100km: 5.60
  FRG 10.0kg 150km: 26.00
Amount owed: 109.90
Points earned: 6
--- new feature: HTML statement ---
<h1>Invoice for Asha Traders</h1>
<table>
  <tr><td>STD</td><td>4.0kg</td><td>250km</td><td>17.30</td></tr>
  <tr><td>EXP</td><td>2.5kg</td><td>80km</td><td>20.00</td></tr>
  <tr><td>FRG</td><td>12.0kg</td><td>40km</td><td>34.80</td></tr>
  <tr><td>STD</td><td>1.0kg</td><td>90km</td><td>6.20</td></tr>
  <tr><td>STD</td><td>0.5kg</td><td>100km</td><td>5.60</td></tr>
  <tr><td>FRG</td><td>10.0kg</td><td>150km</td><td>26.00</td></tr>
</table>
<p>Amount owed: <b>109.90</b></p>
<p>Points earned: <b>6</b></p>
```

Output of `lld.ch07.worked.Main` is shown in 7.5. Steps 0–4 each print the same text invoice as the first nine lines above.

Chapter 8 — Design Patterns: Introduction & Creational Patterns

What you will learn. What a design pattern is and where the idea came from, the full Gang of Four catalogue of 23 patterns, the object-oriented principles that sit underneath all of them, how to choose a pattern (and how to *not* choose one), the anti-patterns that come from overusing them, and then — in depth — the five creational patterns (Singleton, Factory Method, Abstract Factory, Builder, Prototype), the Simple Factory idiom, and the Object Pool bonus pattern.

How to read it. Part A is the map. Part B walks through each creational pattern with the same template: *what it is → the problem → how it works → Java code (with real output) → trade-offs → when not to use it → common mistakes → real-world examples → interview answers → self-check → TL;DR*. The chapter ends with one big comparison table.

Code. Everything lives in `chapters/08-patterns-creational/code/lld/ch08/<pattern>/`. Each package (a named folder of related Java classes that also acts as a namespace) has a `Main` (the class whose `main` method the program starts from). Compile and run all of them with:

```
cd chapters/08-patterns-creational/code
javac --release 21 -d /tmp/lld_08 $(find . -name '*.java')
java -cp /tmp/lld_08 lld.ch08.singleton.Main        # or .simplefactory / .factorymethod / .abstractfactory / .builder / .prototype / .objectpool
```

Part A — Design patterns: the big picture

8.1 What is a design pattern?

What it is

A **design pattern** is a named, reusable description of a good solution to a problem that keeps showing up in software design. It is not a library and not a piece of code you paste in. It is closer to a *recipe* you adapt to your kitchen.

Everyday analogy. Think about building houses. Every builder has to decide where to put the front door so people can move through the house easily. Over hundreds of houses, builders learned which placements work. If someone wrote that experience down as a guideline — "put the door here, for these reasons, and this is what you give up" — that guideline would be a pattern. A design pattern is the same thing for code: the combined experience of many developers, written down so you do not have to rediscover it.

Two words you will see everywhere:

- **Intent** — the one-sentence purpose of a pattern ("ensure a class has only one instance").
- **Participants** — the roles (classes/interfaces — an **interface** is a type that lists method signatures without bodies, which classes then implement) that take part in the pattern, such as *Creator*, *Product*, *Client*.

The problem it solves

Without patterns, every team solves the same recurring problems (how to create objects without hard-coding classes, how to add behaviour without editing old code, how to notify many listeners) from scratch, each in a slightly different, slightly buggy way. Patterns fix that in seven ways:

Benefit	What it means in practice
Solve common design problems	You start from a proven solution that has been refined over years.
Avoid reinventing the wheel	Less time designing, fewer surprises.
Readability and maintainability	Code that follows a known shape is easier for the next person to understand.
Shared vocabulary	Saying "this is a Factory" or "use an Observer" replaces a paragraph of explanation. This is the biggest win in interviews.
Best practices built in	Patterns embody good principles (loose coupling — parts know little about each other; open/closed — extend without editing), so code tends to be more testable.
Adaptability and scalability	Many patterns exist precisely so code can absorb change later.
Faster development	Tested paradigms speed up design decisions.

How it works

Every classic pattern description has four essential parts (this is how the Gang of Four book frames them):

1. **Name** — a word or two that becomes part of the team's vocabulary.
2. **Problem** — when to apply it: the situation and the forces in tension.
3. **Solution** — the participants, their responsibilities and how they collaborate. It is abstract: a *template*, not concrete code.
4. **Consequences** — the costs and benefits. A pattern without its trade-offs is only half a pattern.

You then **adapt** the template to your language and your problem. Two correct implementations of the same pattern can look quite different.

When not to use it

Patterns must be used with judgement. Not every problem needs one. Forcing a pattern where it is not needed adds classes, indirection (extra layers you must step through to reach the code that does the real work) and confusion — which is worse than having no pattern at all. We come back to this in 8.6 Anti-patterns.

TL;DR

A design pattern = **name + problem + solution template + consequences**. It is shared experience, not copy-paste code. Its biggest value is vocabulary and proven trade-offs; its biggest risk is overuse.

8.2 A short history: from buildings to the "Gang of Four"

Year	Event	Why it matters
1977	Architect **Christopher Alexander** publishes *A Pattern Language*, a catalogue of solutions for towns and buildings.	The idea of a "pattern" as a named, reusable solution comes from architecture, not software.
1987	**Kent Beck** and **Ward Cunningham** experiment with applying pattern languages to programming (user-interface design in Smalltalk, an early object-oriented language).	First bridge from architecture to software.
1994	**Erich Gamma, Richard Helm, Ralph Johnson and John Vlissides** publish *Design Patterns: Elements of Reusable Object-Oriented Software*. The four authors are nicknamed the **Gang of Four (GoF)**.	Catalogues **23 patterns** in three categories, with C++ and Smalltalk examples. This is the book people mean when they say "GoF patterns".
2004	*Head First Design Patterns* (Freeman & Robson, with Sierra and Bates) teaches the same patterns in Java with pictures and stories (the pizza store for factories, the chocolate boiler for Singleton, the Starbuzz coffee shop for Decorator).	Made the GoF catalogue approachable, and put the **OO principles** behind patterns front and centre.

The GoF book states two principles that run through the whole catalogue:

1. **Program to an interface, not an implementation.** Variables and parameters should be typed by abstractions (interfaces or abstract classes that say *what* something does, not *how*), so callers do not care which concrete class (an ordinary, fully implemented class you can create with `new`) they get.
2. **Favour object composition over class inheritance.** Build behaviour by *holding* other objects ("has-a"), not only by extending classes ("is-a"). Composition is "black-box" reuse; inheritance exposes a parent's internals to its children.

Creational patterns are what make principle 1 practical: if code must not name concrete classes, *someone* still has to create those objects — and creational patterns decide who and how.

8.3 The three categories and all 23 GoF patterns

What it is

The GoF grouped patterns by **purpose** — what problem family they address:

Category	Question it answers	In one line
Creational	*How do objects get made?*	Control object creation so the system does not depend on concrete classes or on the messy details of construction.
Structural	*How are objects put together?*	Compose classes and objects into larger structures while keeping them flexible — simple ways to realise relationships between entities.
Behavioral	*How do objects talk and share work?*	Assign responsibilities and design communication between objects, so you think about how objects are connected instead of about raw control flow.

The GoF also used a second axis, **scope**:

- **Class patterns** use inheritance, fixed at compile time (when the compiler translates the source code, before the program runs) (Factory Method, class Adapter, Template Method, Interpreter).
- **Object patterns** use composition, changeable at run time (while the program is running) (almost everything else).

The full catalogue

#	Pattern	Category	Intent in one line	Chapter
1	**Abstract Factory**	Creational	Create *families* of related objects without naming their concrete classes.	8
2	**Builder**	Creational	Build a complex object step by step, separating construction from the final representation.	8
3	**Factory Method**	Creational	Let subclasses decide which concrete class to instantiate through an overridable creation method.	8
4	**Prototype**	Creational	Create new objects by copying a pre-configured instance.	8
5	**Singleton**	Creational	Ensure a class has exactly one instance and give a global access point to it.	8
6	**Adapter** (also called Wrapper)	Structural	Convert one interface into another that clients expect.	9
7	**Bridge**	Structural	Split an abstraction from its implementation so both can vary independently.	9
8	**Composite**	Structural	Treat individual objects and trees of objects uniformly.	9
9	**Decorator**	Structural	Attach extra responsibilities to an object dynamically by wrapping it.	9
10	**Facade**	Structural	Give a simple, unified entry point to a complex subsystem.	9
11	**Flyweight**	Structural	Share common (intrinsic) state to support huge numbers of fine-grained objects cheaply.	9
12	**Proxy**	Structural	Provide a stand-in that controls access to another object (lazy, remote, protective…).	9
13	**Chain of Responsibility**	Behavioral	Pass a request along a chain of handlers until one handles it.	10/11
14	**Command**	Behavioral	Turn a request into an object so it can be queued, logged or undone.	10/11
15	**Interpreter**	Behavioral	Represent a small language's grammar as classes and evaluate sentences in it.	10/11
16	**Iterator**	Behavioral	Traverse a collection without exposing how it is stored.	10/11
17	**Mediator**	Behavioral	Centralise complex communication between objects in one mediator object.	10/11
18	**Memento**	Behavioral	Capture and restore an object's state without breaking encapsulation (keeping internals private).	10/11
19	**Observer**	Behavioral	Notify many dependents automatically when one object changes.	10/11
20	**State**	Behavioral	Let an object change behaviour when its internal state changes, as if it changed class.	10/11
21	**Strategy**	Behavioral	Make a family of algorithms interchangeable behind one interface.	10/11
22	**Template Method**	Behavioral	Fix an algorithm's skeleton in a base class and let subclasses fill in steps.	10/11
23	**Visitor**	Behavioral	Add new operations to a set of classes without changing those classes.	10/11

Count check: 5 creational + 7 structural + 11 behavioral = **23**. (Some course lists show ten behavioral patterns and leave out Interpreter, which is rarely used in practice — it is still one of the 23.)

Not in the GoF 23 but you will meet them: *Simple Factory* (an idiom), *Object Pool* (covered at the end of this chapter), *Dependency Injection* (handing an object the things it needs from outside instead of letting it create them), *Null Object*, *Repository*, *MVC* (Model–View–Controller, which splits an app into data, display and input handling; Head First calls it a "compound pattern" built from Observer, Strategy and Composite).

Self-check

- **Q:** Which creational pattern is a *class* pattern (uses inheritance) rather than an object pattern? **A:** Factory Method — subclasses override the creation method.
- **Q:** How many behavioral GoF patterns are there? **A:** Eleven.

8.4 The OO principles behind every pattern

Patterns are not magic; they are principles applied to recurring situations. *Head First Design Patterns* collects these principles as it goes; together with SOLID (Chapter 4 — five object-oriented design rules: Single responsibility, Open–closed, Liskov substitution, Interface segregation, Dependency inversion) they explain *why* each pattern is shaped the way it is.

Principle (plain words)	What it means	Patterns that apply it (examples)
Encapsulate what varies	Find the part of the code that changes and put it behind its own abstraction, separate from what stays the same.	Factory Method (the created type varies), Strategy, State, Builder
Favour composition over inheritance	Get behaviour by holding objects, not only by subclassing.	Abstract Factory (client *holds* a factory), Strategy, Decorator
Program to interfaces, not implementations	Depend on the supertype. Callers should not care which concrete class they get.	Every creational pattern returns an interface type
Strive for loosely coupled designs between objects that interact	Objects should know as little about each other as possible.	Observer, Mediator, factories
Open–Closed Principle — open for extension, closed for modification	Add new behaviour by adding code, not by editing tested code.	Factory Method (new product = new subclass), Decorator
Dependency Inversion — depend on abstractions, not concrete classes	High-level code and low-level code both depend on interfaces.	The core of all factory patterns: the client never calls `new ConcreteThing()`
Least Knowledge ("only talk to your friends")	A method should call only its own object, its parameters, objects it creates and its fields.	Facade
Hollywood Principle ("don't call us, we'll call you")	High-level components decide when low-level ones run.	Template Method, Factory Method (the base class calls the subclass's hook), frameworks/IoC (inversion of control)
Single Responsibility — one reason to change	Each class does one job.	Builder (construction separated from the product), Iterator

Why creational patterns exist, in one sentence: Dependency Inversion says "do not depend on concrete classes", but `new PdfDocument()` *is* a dependency on a concrete class — so creational patterns move that `new` somewhere controlled (a factory, a subclass, a builder, a prototype, a container).

8.5 How to pick a pattern

The problem it solves

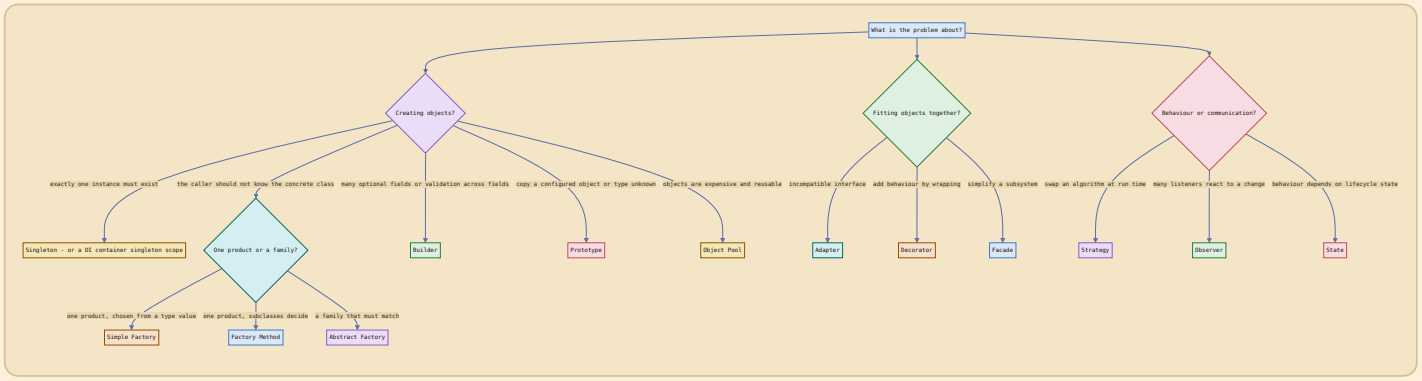
Beginners often learn 23 patterns and then look for places to use them. That is backwards. You should start from a **signal** in the requirements and only then reach for the pattern that answers it.

How it works

1. **Name the problem first**, in plain words: "the pricing rule will change", "there must be exactly one of these", "the constructor has ten arguments".
2. **Decide the category**: is it about *creating*, *structuring*, or *communicating/behaving*?

3. **Match the signal** to a pattern using the tables below.
4. **Check the cost**: how many classes does it add? Is there a simpler option (an enum — a type with a fixed list of named constants; a lambda — a short unnamed function; a constructor; a DI container — a framework that creates objects and hands them their dependencies)?
5. **Say what you rejected and why.** In an interview this is worth as much as the pattern you picked.

The flowchart below is a decision guide for the creational family plus the most common neighbours.



The six patterns that come up in almost every LLD interview

Six patterns turn up again and again in an object-oriented design round. Knowing their names pays off twice: a single word replaces a long explanation, and it signals to the interviewer that you have met this kind of problem before. The flip side matters more — dropping a pattern into a place that does not need it costs you more than never having heard of it. So learn each one together with its **signal**: the clue in the problem statement that says it fits.

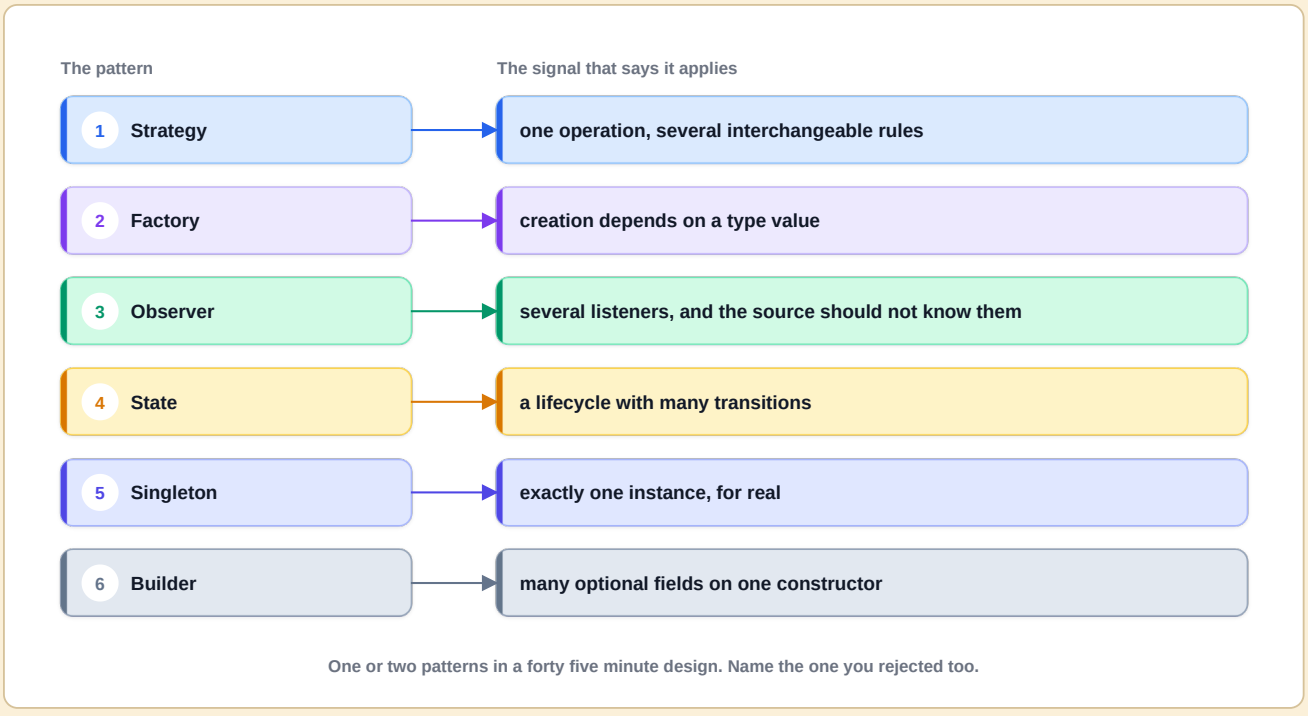


Figure — the six interview patterns and the signal that tells you each one applies (course diagram)

As the figure above shows, each pattern is paired with a trigger, not a place to force it in:

Pattern	The signal	Where it typically applies	Use it when	Do not use it when
Strategy	A single operation comes in several swappable versions, and which one runs is decided at run time	Pricing, matching, sorting, ranking, routing	There is one operation with several interchangeable rules	Only one rule exists and nothing hints at a second
Factory	Something has to be created, and the caller should not care which concrete class it gets	Turning a type value into a vehicle, spot, payment or notification	The class to create depends on a type value	Only one concrete class exists
Observer	One object changes and several others must react, without the changing object knowing who they are	Display boards, notifications, live updates, event logs	There are several listeners the source should stay ignorant of	There is a single listener the source already has a reference to
State	What an object does depends on its current status, and the allowed moves between statuses are fixed	Tickets, orders, bookings, loans — anything with a lifecycle	The lifecycle has many states and transitions	Three or four states can be handled by one guarded method
Singleton	The program genuinely needs one and only one instance	The top-level object, e.g. `ParkingLot`, `Library`	There really must be exactly one	All you want is an easy global handle
Builder	Many fields are optional and the constructor keeps getting longer	A book copy, a booking, a search query	Lots of optional fields	A handful of required fields

How each signal shows up in a parking-lot or library design:

- **Strategy.** At first the price is simply "per hour". Later the business wants a weekend tariff and a monthly pass too. With no pattern, the fee method grows a `switch` that someone has to edit whenever a tariff appears. Strategy instead defines an **interface** (a type that lists method signatures without bodies) named `ParkingRate`, whose one method turns hours into an amount; `HourlyRate`, `WeekendRate` and `MonthlyPass` implement it, and the lot holds a reference to the one currently in force. Adding a tariff means writing one class and editing nothing. Use this when the interviewer asks near the end, "what if the pricing rules change?" — the follow-up you will hear more than any other.
- **Factory.** At some point a string or enum value has to turn into a `Vehicle` object. If that conversion lives inside the entrance panel, the panel must know every vehicle type and changes whenever a type is added. Hand the job to a factory instead: it receives the type and gives back the right object, so the panel simply asks for "a vehicle". The factory becomes the single registration point for new types — the Open–Closed Principle in practice. Keep it lean: in a 45-minute round a creation method on a class you already have is normally enough; one factory class per vehicle type is more structure than the time allows.
- **Observer.** When a spot is taken, every display board on that floor must refresh. The naive version has the floor recompute its counts and push them to its single board. With Observer the spot is the *subject*, and boards, entrance panels and floor portals *subscribe* to it; on each status change the spot notifies all subscribers without knowing what they are. Adding another board needs no change to the spot. Contrast the library: when a reserved book is returned, exactly one member must be told — a direct method call is enough, because a single listener does not justify Observer.
- **State.** A parking ticket goes active → paid → closed; a book copy can be available, reserved, on loan or lost. Without the pattern every method opens with "if status is…", and the rules about which move is legal end up scattered through the class. State gives each status its own small class that knows the legal next steps, so an illegal move cannot even be written, rather than merely being absent. Be candid about the cost: with four states and three transitions, an `enum` plus one method with a guard reads more easily. Reach for State when the transition table is big, and explain why.
- **Singleton.** A car park is one physical place, so the design has one `ParkingLot`; a private constructor plus one accessor enforce that. Interviewers nearly always probe two points, so raise them yourself: fetching the instance must be correct when several threads (independent paths of execution running at the same time inside one program) ask at once (use a lock — a guard that lets only one thread at a time run a piece of code — or create it eagerly), and a singleton is global state (data that any part of the program can read and change) that makes tests harder — which is why many teams create one instance and pass it around instead. Stating that trade-off earns more credit than naming the pattern.

- **Builder.** A `BookItem` needs a barcode, price, format, purchase date, publication date and rack — an eight-argument constructor is easy to call wrongly, because two neighbouring `String` parameters can be exchanged and the compiler says nothing. A builder names every field and produces the finished object at the end. Bring it up once a constructor in your design passes about six arguments, then move on: it improves readability, it does not change the structure.

Rules of thumb for the interview:

- **One or two patterns** in a 45-minute design is the right number, placed exactly where their signal appears. If you count six, the design has probably drifted away from the requirements.
- **Compare out loud.** For example: "Strategy for the rates, because a second tariff is clearly coming; no State for the ticket, because a single guard handles three statuses." Explaining the pattern you *rejected* shows as much judgement as the one you chose — and that comparison is the real reason to learn the names.

8.6 Anti-patterns: when patterns go wrong

What it is

An **anti-pattern** is a common "solution" that looks reasonable but reliably causes more problems than it solves. Knowing them is how you avoid misusing real patterns.

Anti-pattern	What it looks like	Why it hurts	The fix
God Object (God class, the Blob)	One class knows and does almost everything: `SystemManager` with 80 methods and 40 fields.	Violates Single Responsibility. Every change touches it, merge conflicts (clashing edits by different people to the same lines) everywhere, impossible to test in isolation.	Split by responsibility (Extract Class — Chapter 7), push behaviour to the objects that own the data.
Golden Hammer	"When all you have is a hammer, everything looks like a nail." The team's favourite tool or pattern is applied to every problem.	The solution is forced onto problems it does not fit, e.g. every object is a Singleton, every `if` becomes a Strategy.	Start from the problem's signal (8.5), not from the tool.
Pattern overuse ("patternitis")	Factories that create one class, interfaces with one implementation "just in case", five layers of indirection for a CRUD (create, read, update, delete) screen.	More classes, more hops to read, no benefit. Fowler calls the underlying smell **Speculative Generality** (building for imagined future needs).	Apply YAGNI ("You Aren't Gonna Need It", Chapter 5): add the pattern when the *second* variant actually arrives. Refactor towards a pattern, do not start from one.
Singletonitis	Singletons used as convenient global variables.	Hidden dependencies, order-dependent tests, hard to replace.	Dependency injection; pass the object in (8.8).
Cargo-cult patterns	Copying a pattern's structure without understanding its intent (e.g. a "Builder" that only copies fields with no validation, a "Factory Method" that is really a switch).	Ceremony with none of the guarantees.	Know the *intent*: what property does the pattern give you? If you cannot name it, drop it.

TL;DR

Patterns are a vocabulary, not a checklist. The God Object comes from ignoring design; the Golden Hammer and pattern overuse come from over-applying it.

Part B — Creational patterns

8.7 Creational patterns at a glance

What it is

Creational patterns control *how objects are created*, so that the rest of the system is not tied to the concrete classes or the construction details. They hide *which* class is instantiated, *how* it is assembled, and sometimes *whether* a new object is made at all.

Using them lets a system:

- be **independent** of how its objects are created, composed and represented;
- **hide the complexity** of creation (long setup, validation, choosing a subtype);
- keep **flexibility** about *what* gets created, *who* creates it, *how*, and *when*.

Pattern	Intent in one line
Singleton	Exactly one instance of a class, with one global way to reach it.
Factory Method	A base class defines a creation method; subclasses decide which concrete class it returns.
Abstract Factory	One factory object creates a whole *family* of related objects that must match.
Builder	Assemble one complex object step by step; the same construction process can produce different representations.
Prototype	Create new objects by cloning a prototypical instance.
Simple Factory (idiom)	One method with a switch/registry decides which class to create.
Object Pool (bonus)	Reuse a bounded set of expensive objects instead of creating and destroying them.

8.8 Singleton

What it is

The **Singleton** pattern restricts a class to **exactly one instance** (per process — one running program — or, strictly, per class loader — the part of the JVM, the Java Virtual Machine that runs compiled Java code, which loads classes into memory) and gives every caller **one well-known way to reach it**.

Everyday analogy. A country has one official government. Whoever needs "the government" — a citizen, a company, a foreign embassy — reaches the same one through a known channel. Nobody is allowed to set up a second one.

Terms used below:

- **Instance** — one object created from a class.
- **Eager initialization** — create the object as soon as the class is loaded.
- **Lazy initialization** — create it only the first time someone asks for it.
- **Thread-safe** — gives correct results even when many threads call it at the same moment.

GoF intent and participants. Intent: guarantee that a class never has more than one instance, and give every client a well-known way to reach it. There is a single participant, **Singleton**, which (a) defines a class-level operation (`getInstance()`) that lets clients reach the unique instance and (b) is usually responsible for creating that instance itself. Clients simply call that operation.

The problem it solves

A few things in a program really are "one per process": the settings loaded from a file when the app starts, the pool of database connections (a set of open connections kept ready for reuse), the registry that collects metrics (counters and timings the app records about itself). Let every module create its own and you end up with many copies of the settings, the same file parsed many times, and metrics split across registries whose totals no one can combine.

Picture a `ConfigStore` filled from a settings file: the cloud region to talk to, the retry count, the timeout (how long to wait before giving up). The billing service reads it, so does the nightly reporting job, so does

the mailer. If each of them builds a private copy, the file is parsed three times, and a value one service changes never reaches the other two.

A plain global variable looks like the easy fix, but it has two problems. Tests all share it, so a test's result can depend on which test happened to run before it. And *some* code has to assign it before anyone reads it — get the start-up order wrong and a caller finds `null` (Java's "no object here" value). Singleton moves both jobs into the class: **the class decides how many instances may exist and creates the one it allows**, on demand. Callers never assign anything, so there is no ordering mistake to make.

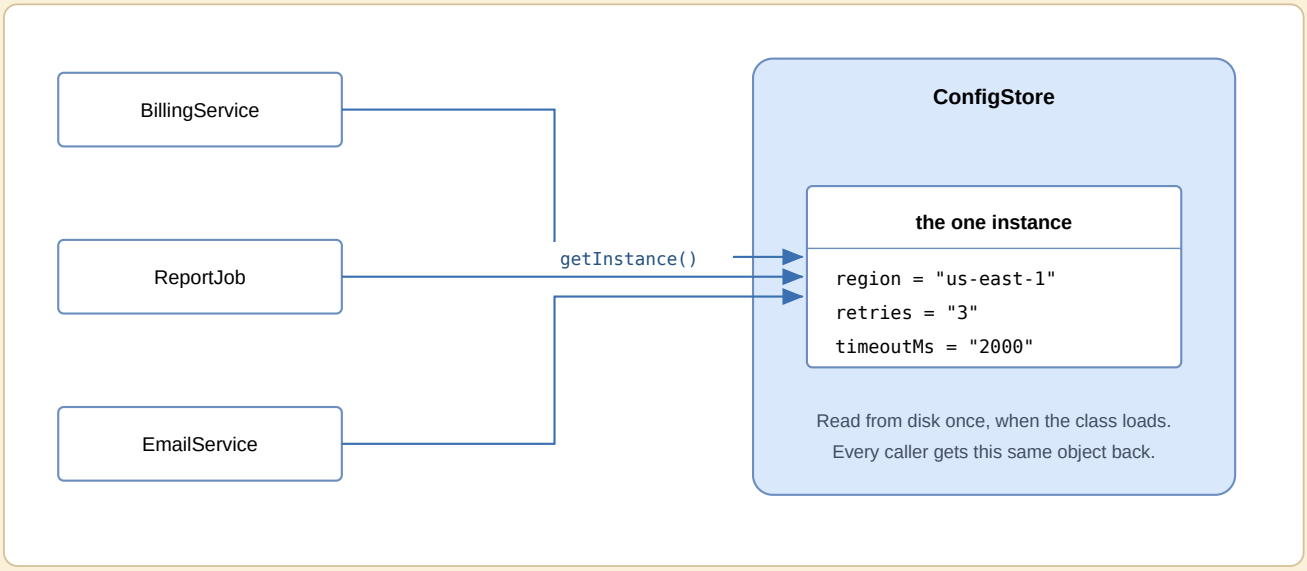

Figure — BillingService, ReportJob and EmailService all call getInstance() and receive the same ConfigStore, which was read from disk once (course diagram)

In the figure, none of the three services constructs a `ConfigStore`; each one asks the class for it and gets back the very same object, whose settings were loaded a single time.

How it works

1. Make the **constructor** `private`, so code outside the class cannot write `new ConfigStore()`. That access modifier (the `public` / `protected` / `private` keyword that says who may use a member) is the whole enforcement mechanism; make the constructor public and any caller can create a second one.
2. Keep the single instance in a `private static` **field** — static because it is owned by the class itself, not by whichever object asks for it.
3. Expose a `public static getInstance()` method. It has to be static: a caller has no instance yet (getting one is the whole point), so it can only call something on the class.
4. Inside `getInstance()`, return the stored instance, creating it first if needed (and doing that creation safely when threads are involved).
5. Add ordinary instance methods (`get`, `set`, …) for the actual work.

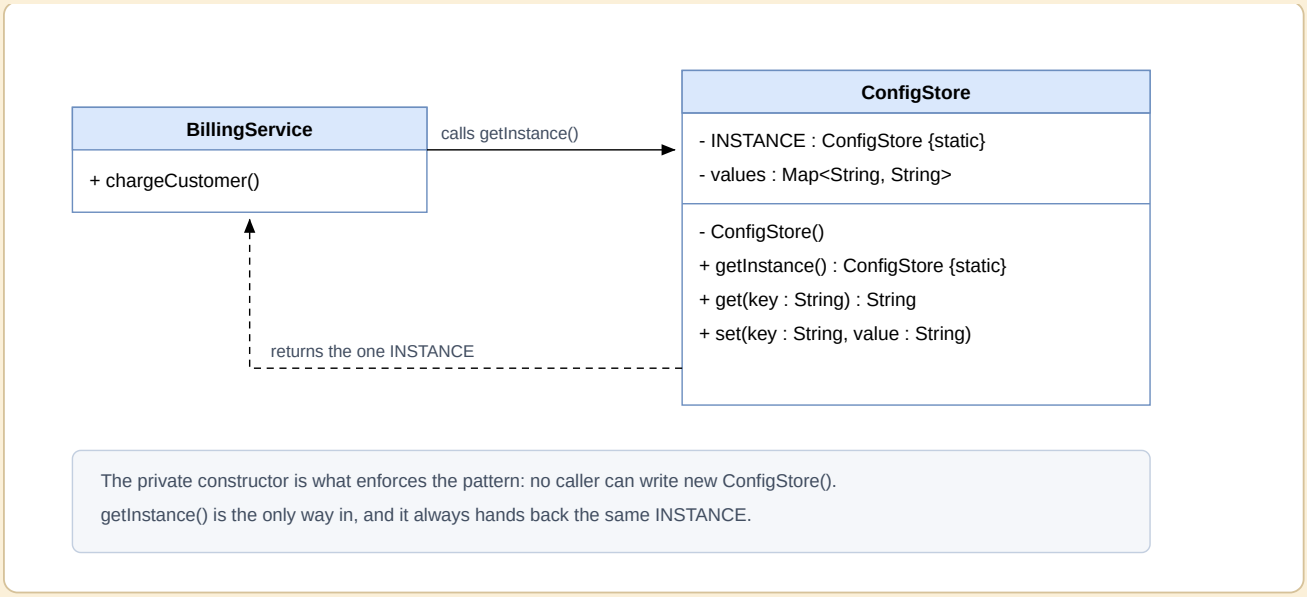

Figure — ConfigStore with a private static INSTANCE, a private constructor and a static getInstance(); BillingService only calls getInstance() (course diagram)

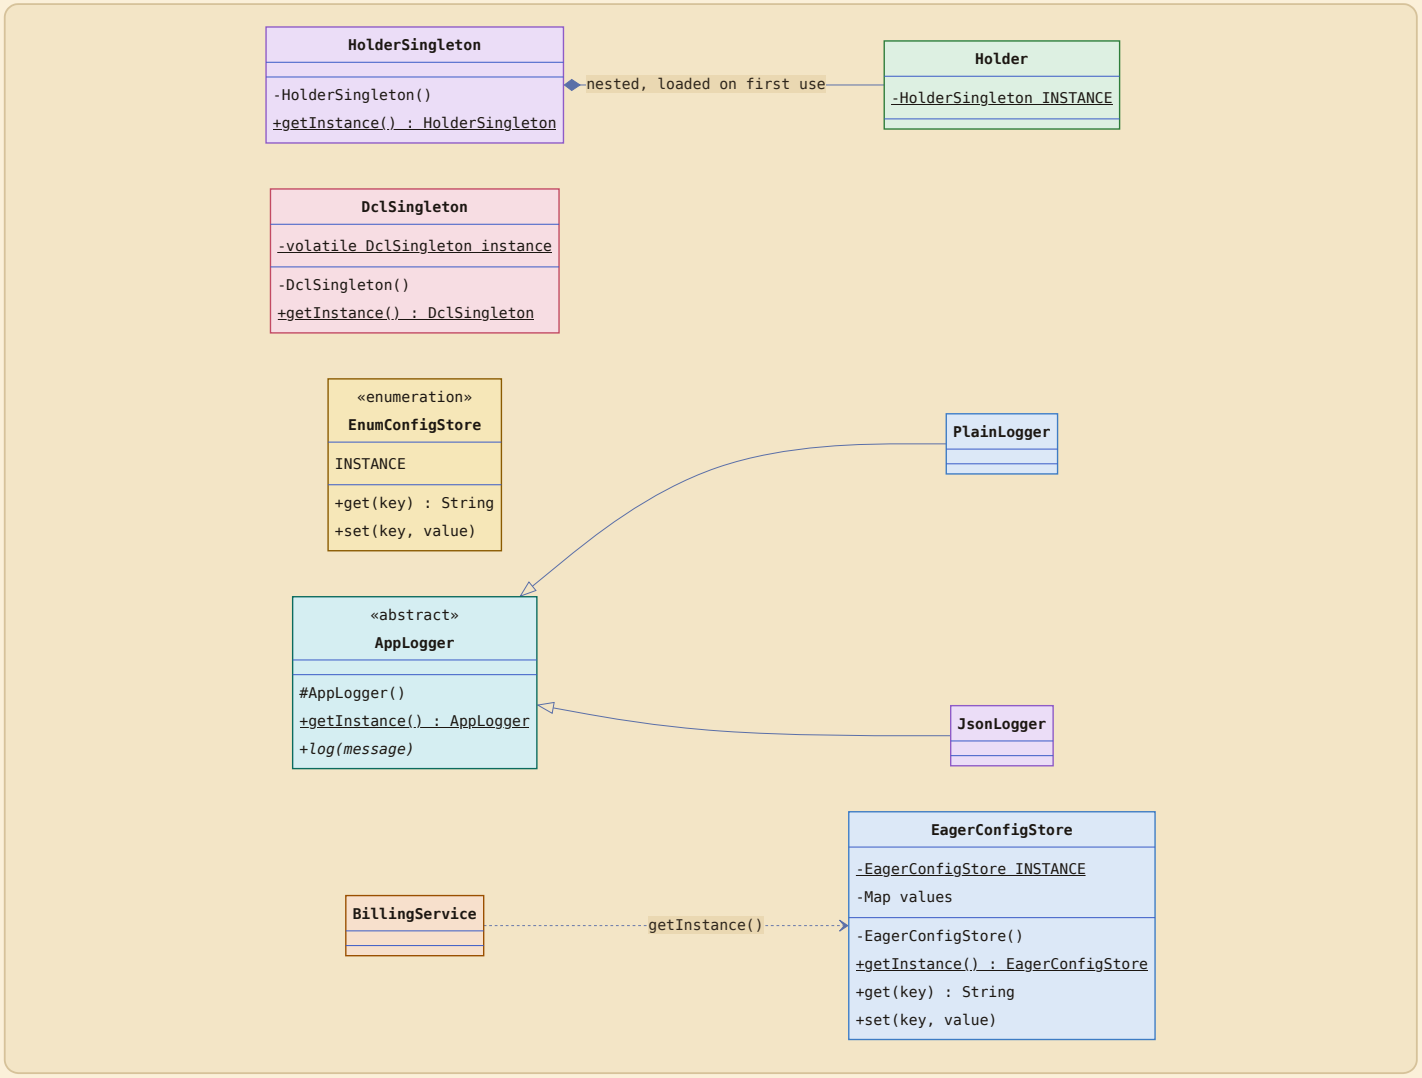
Our Java design (all the variants in the code package):



The six ways to write a Singleton in Java

Two terms in the table: **serialization** turns an object into bytes so it can be saved or sent (and **deserialization** rebuilds an object from those bytes); **reflection** is Java's ability to inspect and call a class's members — even private ones — at run time. "Contention" means many threads competing for the same lock.

#	Variant	Lazy?	Thread-safe?	Cost on each call	Survives serialization / reflection?	Verdict
1	**Eager** `static final` field	No (built when the class is initialized)	Yes — the JVM initializes a class exactly once	None	No / No (needs defences)	Default choice when construction is cheap
2	**Naive lazy** `if (instance == null)`	Yes	**No**	None	No / No	Never in multi-threaded code
3	`synchronized` **getInstance()**	Yes	Yes	A lock on *every* call	No / No	Correct but slow under contention
4	**Double-checked locking** + `volatile`	Yes	Yes (Java 5+)	One volatile read	No / No	When the instance depends on run-time input
5	**Bill Pugh / holder idiom**	Yes	Yes — class-loading guarantee	None	No / No	Best lazy option in plain Java
6	`enum` **with one constant**	No (created when the enum class initializes)	Yes	None	**Yes / Yes** (JVM guarantees)	Shortest and most robust; recommended by *Effective Java* (Joshua Bloch's best-practice book)

Let us walk through each one.

1 — Eager. The `static final` field is assigned while the class is being *initialized*. In Java that happens on the class's first active use — typically the first `getInstance()` call, but also the first access to any other static method or non-constant static field of the class — not at JVM start-up. The Java Language Specification (§12.4.2) guarantees that initialization runs exactly once, under an internal lock, even if many threads trigger it at the same moment, and that every thread afterwards sees the fully built object — so you get thread safety without writing any. The only cost: the object is built as soon as the class is touched for *any* reason, even if that code path never needs the instance. If the constructor opens a file or a socket (an endpoint of a network connection), that may matter.

2 — Naive lazy (broken). "Create on first use" is written as *check, then act*:

```
// Do NOT use this in multi-threaded code.
public static ConfigStore getInstance() {
    if (instance == null) {            // two threads can both see null here...
        instance = new ConfigStore();  // ...and both construct
    }
    return instance;
}
```

Nothing stops thread A and thread B from both reading `null` before either has stored its object. Each then constructs its own store, and whatever one caller writes into its copy never shows up in the other's. Run it in a single-threaded test and it behaves perfectly, which is exactly why the bug slips through review. Our demo starts eight threads at the same instant: the naive version built **more than one** object (eight in the run shown below).

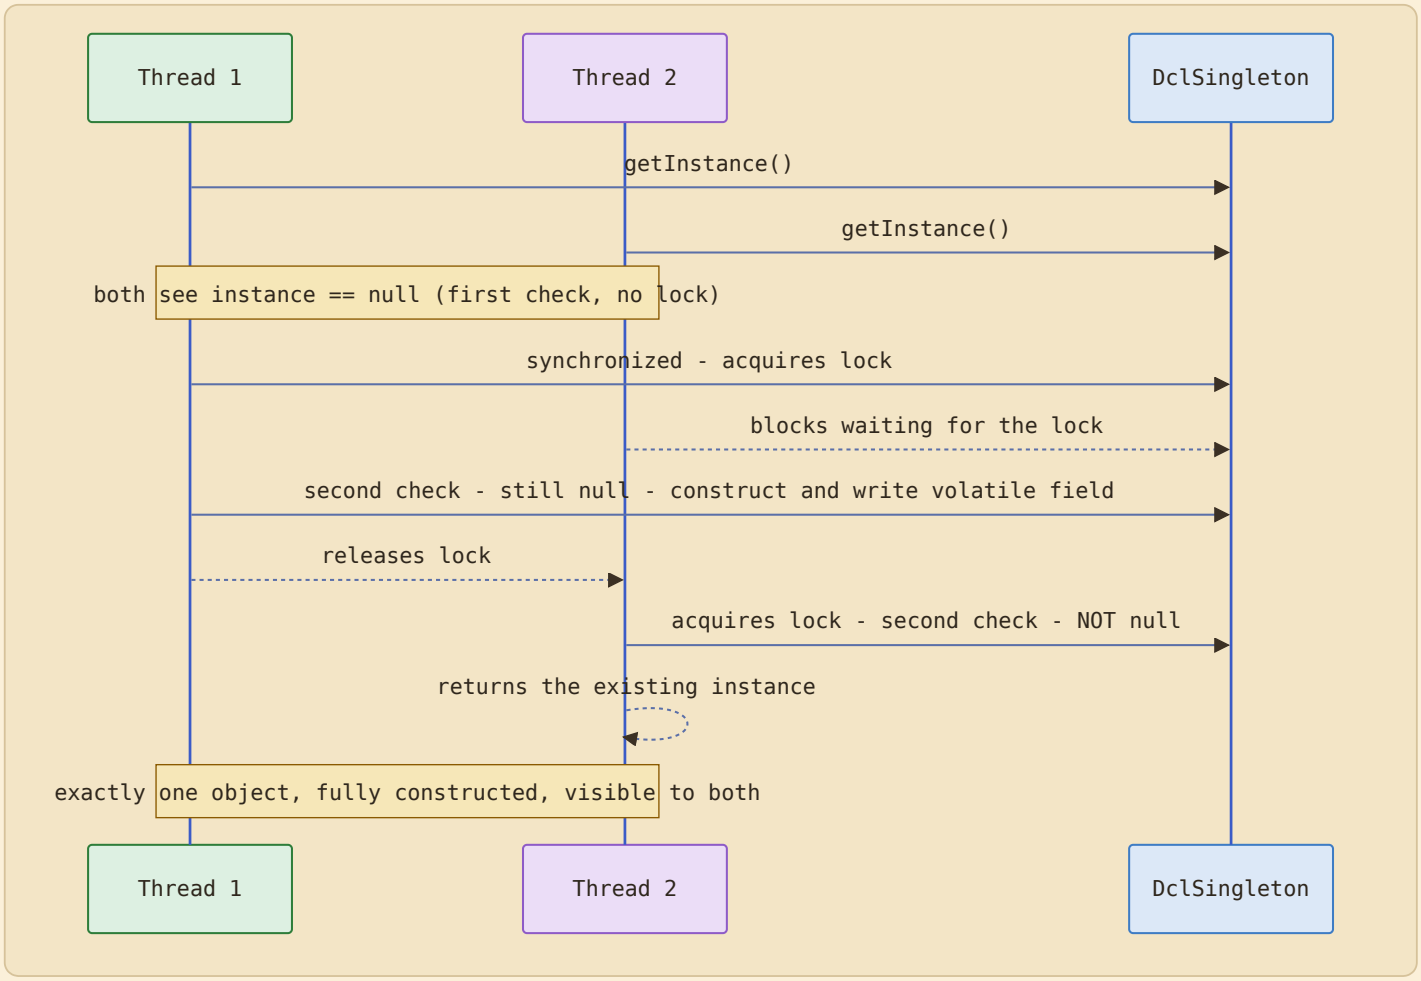
3 — `synchronized` **method.** Putting `synchronized` on `getInstance()` fixes the race (a **race condition**: a bug whose outcome depends on the unlucky timing of threads) — only one thread can be inside at a time. But the lock is taken on *every* call, forever, even though it is only needed for the first one.

4 — Double-checked locking (DCL). Check *without* the lock first (fast path), and only if the instance is missing, take the lock and **check again** (another thread may have created it while you waited):

- The second check is what prevents two constructions.
- The field **must be** `volatile` (a Java keyword that makes each write to the field immediately visible to every thread and forbids reordering around it). Creating an object is really three steps — allocate memory, run the constructor, store the reference. Without `volatile`, the Java Memory Model (the rules for when one thread's writes become visible to other threads) allows another thread to see the stored reference *before* the

constructor's writes are visible, i.e. a half-built object. A `volatile` write/read creates a **happens-before** relationship: everything the constructor did is visible to any thread that reads the reference. (Before Java 5's memory model, DCL was broken even with `volatile`.)

- Copying the field into a local variable (`local`) means the common path reads the volatile field only once — a small optimization shown in *Effective Java*.



5 — Bill Pugh / initialization-on-demand holder. Put the instance in a private *nested* class (a class declared inside another class). The JVM does not initialize `Holder` until `getInstance()` first touches `Holder.INSTANCE`, so creation is lazy; and class initialization is guaranteed to run once and be safely published (made visible to other threads only once fully built), so it is thread-safe with **no locks and no `volatile`**. Named after Bill Pugh, who led the work on the Java memory model. This is the usual choice for a lazy singleton.

6 — Enum. `enum EnumConfigStore { INSTANCE; ... }`. The JVM guarantees each enum constant exists once; `Constructor.newInstance` refuses to create enum objects; and enum serialization is special-cased to return the existing constant. It is the shortest correct version. Limits: an enum cannot extend another class (it can implement interfaces), and it is created when the enum class initializes rather than truly on demand.

Which one to pick. Default to **eager**: fewest lines and no race is possible; its only drawback matters when construction is costly. Switch to the **holder** idiom once you have *measured* a start-up cost worth avoiding. Choose **double-checked locking** when building the instance needs a value that only exists at run time (a holder's static initializer cannot take a parameter) — and always declare the field `volatile`. Choose **enum** when you also want serialization and reflection safety without writing any defensive code.

Breaking a Singleton — and the fixes

A `private` constructor is a *language* rule, not a JVM guarantee. There are three classic ways around it:

Attack	How it creates a second instance	Fix
Reflection	`getDeclaredConstructor().setAccessible(true).newInstance()` calls the private constructor.	Throw from the constructor if the instance already exists (reliable for eager/holder, racy for lazy). Or use an **enum** — the JVM refuses.
Serialization	`ObjectInputStream.readObject()` builds a new object without calling your constructor.	Add `private Object readResolve() { return INSTANCE; }` — the deserialized copy is replaced by the real one. Mark instance fields `transient` (skipped by serialization) if they should not travel. Or use an **enum**.
Cloning	If the class (or a parent) implements `Cloneable` and exposes `clone()`, `clone()` copies the object.	Override `clone()` to throw `CloneNotSupportedException` (or return `INSTANCE`). If no ancestor is `Cloneable`, `Object.clone()` is `protected` and this attack does not apply.
Multiple class loaders	Each class loader loads its own copy of the class, so each has its own "single" instance (common in app servers and plugin systems).	Load the class from a shared parent loader, or let a container own the instance.
Multiple processes / servers	A singleton is one per JVM. On four servers you have four.	Use an external coordinator (database, Redis — an in-memory data store, ZooKeeper — a coordination service) for anything that must be unique system-wide, e.g. ID generation or locks.

Our demo attacks an undefended singleton and a hardened one, then the enum (see output).

Subclassing a Singleton

The GoF book notes a singleton *can* be subclassed if its constructor is `protected` rather than `private`, and `getInstance()` decides **once, at run time**, which subclass becomes "the" instance. `AppLogger` below picks `PlainLogger` or `JsonLogger` from a system property (a key=value setting passed to the JVM at launch, e.g. `-Dlog.format=json`). With a `private` constructor (the usual case) the class cannot be subclassed at all — so the flexibility is only there if you design for it.

The dependency-injection alternative

In modern code the best singleton is often **not a Singleton class at all**. Write a normal class with a public constructor, create **one** instance at start-up (the *composition root*), and **pass it in** through constructors. "One instance" becomes a wiring decision, not a property baked into the class.

- Dependencies become visible in constructors (no hidden `getInstance()` calls).
- Tests pass a fake (a simple stand-in object written for tests) (`new BillingService(testConfig)`) — no reset hooks needed.
- Spring, Guice, Micronaut, Dagger, NestJS and friends (dependency-injection frameworks) do exactly this: in Spring every bean (an object that Spring creates and manages) is **singleton-scoped by default**, meaning *one shared instance per bean definition per container* (`ApplicationContext`) — not one per JVM, and without any private constructor. Two contexts in one JVM hold two instances, and nothing stops other code calling `new` on the class. Spring's opposite, `prototype` **scope**, creates a fresh instance on every lookup.

Java implementation

```java
// File: code/lld/ch08/singleton/EagerConfigStore.java
package lld.ch08.singleton;

import java.util.Map;
import java.util.concurrent.ConcurrentHashMap;

/** 1. Eager: the instance is created when the class is initialised. Thread-safe for free. */
public final class EagerConfigStore {

    private static final EagerConfigStore INSTANCE = new EagerConfigStore();

    private final Map<String, String> values = new ConcurrentHashMap<>();

    private EagerConfigStore() {                        // private: nobody else can call new
        System.out.println("  [EagerConfigStore] reading settings from disk (runs once)");
        values.put("region", "us-east-1");
        values.put("retries", "3");
    }

    public static EagerConfigStore getInstance() { return INSTANCE; }

    public String get(String key)             { return values.get(key); }
    public void set(String key, String value) { values.put(key, value); }
}
```

```java
// File: code/lld/ch08/singleton/LazyVariants.java
package lld.ch08.singleton;

import java.util.concurrent.atomic.AtomicInteger;

/** 2. Naive lazy: NOT thread-safe. Two threads can both see null and both construct. */
final class NaiveLazySingleton {
    static final AtomicInteger CONSTRUCTED = new AtomicInteger();
    private static NaiveLazySingleton instance;

    private NaiveLazySingleton() {
        CONSTRUCTED.incrementAndGet();
        try { Thread.sleep(20); } catch (InterruptedException e) { Thread.currentThread().interrupt(); }
    }

    static NaiveLazySingleton getInstance() {
        if (instance == null) {                 // check ...
            instance = new NaiveLazySingleton(); // ... then act: a race window
        }
        return instance;
    }
}

/** 3. Synchronized lazy: correct, but every call pays for the lock. */
final class SynchronizedLazySingleton {
    static final AtomicInteger CONSTRUCTED = new AtomicInteger();
    private static SynchronizedLazySingleton instance;

    private SynchronizedLazySingleton() {
        CONSTRUCTED.incrementAndGet();
        try { Thread.sleep(20); } catch (InterruptedException e) { Thread.currentThread().interrupt(); }
    }

    static synchronized SynchronizedLazySingleton getInstance() {
        if (instance == null) instance = new SynchronizedLazySingleton();
        return instance;
    }
}

/** 4. Double-checked locking: lock only on the first calls. volatile is mandatory. */
final class DclSingleton {
    static final AtomicInteger CONSTRUCTED = new AtomicInteger();
    private static volatile DclSingleton instance;

    private DclSingleton() {
        CONSTRUCTED.incrementAndGet();
        try { Thread.sleep(20); } catch (InterruptedException e) { Thread.currentThread().interrupt(); }
    }

    static DclSingleton getInstance() {
        DclSingleton local = instance;          // one volatile read on the fast path
        if (local == null) {                    // 1st check, no lock
            synchronized (DclSingleton.class) {
                local = instance;
                if (local == null) {            // 2nd check, under the lock
                    local = new DclSingleton();
                    instance = local;           // volatile write publishes a fully built object
                }
            }
        }
        return local;
    }
}

/** 5. Bill Pugh / initialization-on-demand holder: lazy, lock-free, thread-safe via class loading. */
final class HolderSingleton {
    static final AtomicInteger CONSTRUCTED = new AtomicInteger();
```

```
    private HolderSingleton() {
        CONSTRUCTED.incrementAndGet();
        System.out.println("  [HolderSingleton] constructed on first getInstance()");
    }

    private static final class Holder {          // not initialised until first touched
        private static final HolderSingleton INSTANCE = new HolderSingleton();
    }

    static HolderSingleton getInstance() { return Holder.INSTANCE; }
}
```

```
// File: code/lld/ch08/singleton/EnumConfigStore.java
package lld.ch08.singleton;

import java.util.Map;
import java.util.concurrent.ConcurrentHashMap;

/** 6. Enum singleton: shortest form, safe against reflection and serialization by the JVM itself. */
public enum EnumConfigStore {
    INSTANCE;

    private final Map<String, String> values = new ConcurrentHashMap<>(Map.of("region", "us-east-1"));

    public String get(String key)             { return values.get(key); }
    public void set(String key, String value) { values.put(key, value); }
}
```

```
// File: code/lld/ch08/singleton/BreakableSingleton.java
package lld.ch08.singleton;

import java.io.Serializable;

/** A parent that (unwisely) exposes a public clone(). Children inherit it. */
class CloneableBase implements Cloneable {
    @Override
    public Object clone() throws CloneNotSupportedException { return super.clone(); }
}

/** A classic eager singleton with NO defences. Reflection, serialization and cloning all break it. */
public final class BreakableSingleton extends CloneableBase implements Serializable {
    private static final long serialVersionUID = 1L;
    public static final BreakableSingleton INSTANCE = new BreakableSingleton();

    private BreakableSingleton() { }
}
```

```java
// File: code/lld/ch08/singleton/HardenedSingleton.java
package lld.ch08.singleton;

import java.io.Serial;
import java.io.Serializable;

/** The same singleton with the three classic defences. */
public final class HardenedSingleton extends CloneableBase implements Serializable {
    @Serial private static final long serialVersionUID = 1L;
    public static final HardenedSingleton INSTANCE = new HardenedSingleton();

    private HardenedSingleton() {
        // Defence 1 - reflection: refuse a second construction.
        // (Works reliably with eager init, because INSTANCE is set during class init.)
        if (INSTANCE != null) {
            throw new IllegalStateException("Singleton already exists - use INSTANCE");
        }
    }

    // Defence 2 - serialization: replace whatever was deserialized with the real instance.
    @Serial
    private Object readResolve() { return INSTANCE; }

    // Defence 3 - cloning: override the inherited public clone() and refuse.
    @Override
    public Object clone() throws CloneNotSupportedException {
        throw new CloneNotSupportedException("Singleton cannot be cloned");
    }
}
```

```java
// File: code/lld/ch08/singleton/AppLogger.java
package lld.ch08.singleton;

/**
 * GoF note: a Singleton may be subclassed if the constructor is protected.
 * getInstance() decides ONCE, at run time, which subclass becomes "the" instance.
 */
public abstract class AppLogger {

    protected AppLogger() { }                           // protected, not private

    private static final class Holder {
        private static final AppLogger INSTANCE =
                "json".equals(System.getProperty("log.format")) ? new JsonLogger() : new PlainLogger();
    }

    public static AppLogger getInstance() { return Holder.INSTANCE; }

    public abstract void log(String message);
}

final class PlainLogger extends AppLogger {
    @Override public void log(String message) { System.out.println("  LOG " + message); }
}

final class JsonLogger extends AppLogger {
    @Override public void log(String message) { System.out.println("  {\"log\":\"" + message + "\"}"); }
}
```

```java
// File: code/lld/ch08/singleton/DiAlternative.java
package lld.ch08.singleton;

import java.util.Map;

/** The dependency-injection alternative: "one instance" is decided by the wiring code, not the class. */
interface Config {
    String get(String key);
}

record MapConfig(Map<String, String> values) implements Config {
    public String get(String key) { return values.get(key); }
}

final class BillingService {
    private final Config config;                        // dependency is visible in the constructor
    BillingService(Config config) { this.config = config; }
    String charge(int cents) { return "charged " + cents + " cents in " + config.get("region"); }
}

final class ReportJob {
    private final Config config;
    ReportJob(Config config) { this.config = config; }
    String run() { return "report for " + config.get("region"); }
}
```

```java
// File: code/lld/ch08/singleton/Main.java
package lld.ch08.singleton;

import java.io.*;
import java.lang.reflect.Constructor;
import java.util.*;
import java.util.concurrent.*;
import java.util.function.Supplier;

public class Main {

    public static void main(String[] args) throws Exception {

        }
    }
}
```

Explaining the parts:

- `EagerConfigStore` — the classic shape: private constructor, `static final INSTANCE`, `getInstance()`. Section 1 of `Main` shows why anyone wants this: `reports` updates the region and `billing` immediately reads the new value, even though neither holds a reference to the other — they share the one store.
- `LazyVariants.java` — each constructor sleeps 20 ms to widen the race window, and counts how many times it ran. The `race(...)` helper releases eight threads at once with a `CountDownLatch`.
- `HolderSingleton` — prints "constructed so far: 0" before first use, proving laziness.
- `BreakableSingleton` vs `HardenedSingleton` — identical except for the three defences (constructor guard, `readResolve`, throwing `clone`).
- `AppLogger` — a subclassable singleton using a holder; `DiAlternative.java` — the DI version with no singleton code at all.

Output:

```
== 1. Eager singleton: every caller shares one store ==
  [EagerConfigStore] reading settings from disk (runs once)
  billing reads region = us-east-1
  after reports.set, billing reads = eu-west-1
  same object? true

== 2-4. Lazy variants hit by 8 threads at the same instant ==
  naive lazy (unsafe)      constructor ran 8 time(s), callers saw 8 distinct object(s)
  synchronized lazy        constructor ran 1 time(s), callers saw 1 distinct object(s)
  double-checked locking   constructor ran 1 time(s), callers saw 1 distinct object(s)

== 5. Bill Pugh holder: nothing built until first use ==
  constructed so far: 0
  [HolderSingleton] constructed on first getInstance()
  constructed now: 1, same? true

== 6. Enum singleton ==
  retries = 5

== 7. Breaking a naive singleton ==
  reflection    -> new object, same? false
  serialization -> same? false
  clone         -> same? false

== 8. The hardened version ==
  reflection    -> blocked: Singleton already exists - use INSTANCE
  serialization -> same? true
  clone         -> blocked: Singleton cannot be cloned

== 9. Enum resists reflection and serialization ==
  reflection    -> blocked: Cannot reflectively create enum objects
  serialization -> same? true

== 10. Subclassable singleton (protected constructor) ==
  LOG chosen subclass = PlainLogger

== 11. DI alternative: one instance created by the composition root ==
  charged 499 cents in ap-south-1
  report for ap-south-1
  in a test: charged 1 cents in test-region
```

(The naive-lazy line is a race, so its count varies from run to run — anything above 1 is the bug.)

Trade-offs

Pros	Cons
Controlled access — the class guarantees a single instance and there is exactly one documented door to it.	**Global state** — in practice it tends to become shared mutable (changeable) state that anything can change, with all the classic problems that brings.
You choose when it is built — eagerly (simplest) or lazily on first request (cheaper start-up).	**Awkward to test** — replacing it with a fake needs a reset/injection hook, and that hook then ships in production code (the code running the live system real users depend on) where someone may misuse it.
Right fit for a shared resource — a pool, a cache or a device handle, where a second copy would be a bug.	**Invisible dependencies** — a class that calls `getInstance()` internally does not show that dependency in its constructor, so readers and tests cannot see it.
Setup cost paid once — the expensive initialization runs once per process instead of once per caller.	**Uniqueness ends at the process** (strictly, the class loader) — it cannot coordinate anything across machines, which surprises people who try.
Subclassing is possible if designed in — with a `protected` constructor, `getInstance()` can pick a subclass at run time (see `AppLogger`). With a `private` constructor, as in most examples, it cannot.	**Hard to undo** — by the time you want an ordinary class back, `getInstance()` calls are scattered everywhere. It also mixes two jobs (SRP — Single Responsibility Principle): managing its own lifecycle *and* doing its real work.

Often confused with:

Looks like	The actual difference
Static utility class (`Math`)	A class with only static members is not an object: it cannot implement an interface or be handed to a method as an argument. A Singleton *is* an object, so it can hide behind an interface and a test can substitute another implementation. That difference is the main argument for a Singleton over a static class.
Prototype	The intents point in opposite directions: Singleton caps the count at one, Prototype exists to churn out many copies.
DI container singleton scope	Achieves the same "one shared instance" with a better mechanism: the container manages the lifecycle, classes still declare what they need in their constructors, and tests swap in replacements freely.
Multiton / registry (`Logger.getLogger(name)`)	One instance *per key*, not one per class.

In other languages: in Python, a module's top-level code runs only once, so an object created at module level is already shared by every importer (the hand-written `__new__` version has the same check-then-act race as Java's naive lazy form and needs a `threading.Lock` with a double check). In JavaScript/TypeScript, exporting an object that is already constructed gives the same effect; because a single event loop (the one loop that runs JavaScript tasks one after another) never interleaves two synchronous blocks of code, no locking is needed — but each Web Worker (a background thread in the browser) has its own separate memory, so each gets its own copy. In Go, a package-level variable initialized through `sync.Once`. In C++, a function-local `static` (the "Meyers Singleton") is created on first call and the language standard guarantees that happens once even under concurrent calls. In Java, the single-element `enum` is the shortest thread-safe form and, unlike the field-based versions, survives serialization without extra code.

When not to use it

No creational pattern is misapplied more often than this one.

- **The real motive is convenience.** Wanting to reach an object from anywhere is not a design requirement — a constructor or method parameter delivers it just as well, and this motive explains most of the singletons that should never have existed.
- **It holds mutable state that tests read or write.** All tests then share that state, and you get the maddening case of a test that passes in isolation but fails when the whole suite (all the tests together) runs.
- **A framework already manages lifecycles.** In Spring, Guice, NestJS and similar containers, declare the class with singleton scope and write no singleton code at all.

- **More than one process is involved.** Each JVM has its own instance, so four servers means four "singletons". Relying on one for a distributed lock (a lock shared by several machines) or for unique IDs is a **correctness bug**, not a matter of style.

Common mistakes

- Using the **naive lazy** version in a web server or any multi-threaded code.
- Writing double-checked locking **without** `volatile`.
- Forgetting that `implements Serializable` silently breaks the guarantee unless you add `readResolve()`.
- Putting **mutable state** in a singleton without thread-safe structures (our `ConfigStore` uses `ConcurrentHashMap` because many threads may `set` concurrently).
- Adding a `public static void reset()` "for tests" — it will be called in production one day.
- Assuming "one instance" means one in the whole system (it is one per JVM / class loader).

Real-world examples

- **JDK** (Java Development Kit — Java's compiler, tools and standard library)**:** `Runtime.getRuntime()` is the textbook case: `Runtime` has a private constructor and a single static instance for the whole JVM. `java.awt.Desktop.getDesktop()` also hands back one shared instance. `Collections.emptyList()` returns one shared immutable (unchangeable after creation) constant — singleton-*like* caching of an immutable value rather than the full pattern. `Logger.getLogger(name)` (java.util.logging) returns one shared logger per name — a registry (multiton), one instance per key.
- **Not singletons, despite the name `getInstance()`:** `Calendar.getInstance()`, `NumberFormat.getInstance()` and `Cipher.getInstance(...)` return a **new object on every call** — they are static factory methods (see 8.9). A method called `getInstance` proves nothing; what matters is whether only one instance can ever exist.
- **Spring:** beans are singleton-scoped by default — one per bean definition per `ApplicationContext`, managed by the container rather than by a private constructor. This is the DI alternative in production; it is "one per container", not "one per JVM".
- **Everyday infrastructure:** connection pools (HikariCP's pool is usually one per data source), metrics registries (Micrometer's global registry), feature-flag clients (switches that turn features on or off without redeploying) — each stands for something that truly exists once (one pool of sockets, one set of counters). Ask that question before choosing the pattern. The browser's `window` object is a singleton per page.
- **Head First's example:** a chocolate factory's boiler controller — there is one physical boiler, so two controller objects could both try to fill it and overflow it. Their fix walks through the same lazy → synchronized → double-checked / eager progression you saw above.

In the interview

> **30-second answer:** "Singleton guarantees one instance per JVM (strictly, per class loader) with a single access point: private constructor, static accessor. I'd use eager initialization — the class loader makes it thread-safe for free — or the holder idiom if construction is expensive. If it must survive serialization or reflection I'd use an enum. But it's global state with hidden dependencies, so in a Spring app I'd just make it a singleton-scoped bean and inject it."

Follow-ups:

- *Q: Why is the naive lazy version broken?* — A: It is check-then-act without synchronization; two threads can both see `null` and both construct.
- *Q: Why does DCL need `volatile`?* — A: Without it the reference can be published before the constructor's writes are visible, so another thread might use a half-initialized object. `volatile` gives a happens-before edge between the write and later reads.
- *Q: Why is the holder idiom thread-safe without locks?* — A: The JVM initializes a class once and publishes its static fields safely; the nested class is only initialized on first access.
- *Q: How can a singleton be broken?* — A: Reflection, serialization, cloning, multiple class loaders. Fixes: constructor guard, `readResolve`, throwing `clone`, or just use an enum.
- *Q: Singleton vs static class?* — A: A singleton is an object: it can implement interfaces, be passed around, be lazily created and be mocked (replaced in a test by a fake that records how it was called). A static class can do none of that.

- *Q: Is Singleton an anti-pattern?* — A: It is often *used* as one (glorified global). It is fine for genuinely single resources; prefer DI to enforce "one instance" from outside.
- *Q: How do you make a unique ID generator across 10 servers?* — A: Not with a Singleton — it is one per JVM. Use a database sequence (a database counter that hands out increasing numbers), a Snowflake-style ID (timestamp + machine id + counter), or UUIDs (128-bit randomly generated IDs that practically never repeat).

Self-check

- **Q:** Which single keyword enforces the pattern? **A:** `private` on the constructor.
- **Q:** Which Java variant is lazy, lock-free and thread-safe? **A:** The Bill Pugh holder idiom.
- **Q:** Which variant resists both reflection and serialization with no extra code? **A:** The single-element enum.
- **Q:** What does `readResolve` do? **A:** It replaces the object produced by deserialization with the one you return — the real instance.
- **Q:** In Spring, how many instances of a default bean exist? **A:** One per application context (container), not one per JVM.

TL;DR

Private constructor + static accessor = one instance per JVM. Prefer **eager**, then **holder**, then **enum** (bullet-proof); **DCL needs** `volatile`; never naive lazy. Know the four ways to break it. Mention the costs (global state, hidden deps, tests) and that DI singleton scope is usually the better tool.

8.9 Simple Factory (an idiom, not a GoF pattern)

What it is

A **Simple Factory** is one class (usually one static method) that takes a type value — a string or enum — and returns the matching object, typed as a common interface. It is extremely common and often the right answer, but it is **not** one of the 23 GoF patterns. *Head First* calls it a programming idiom rather than a real pattern.

Everyday analogy. A vending machine: you press "B3" and a snack comes out. You do not know or care how the machine picks and releases the item — you only know you asked for B3.

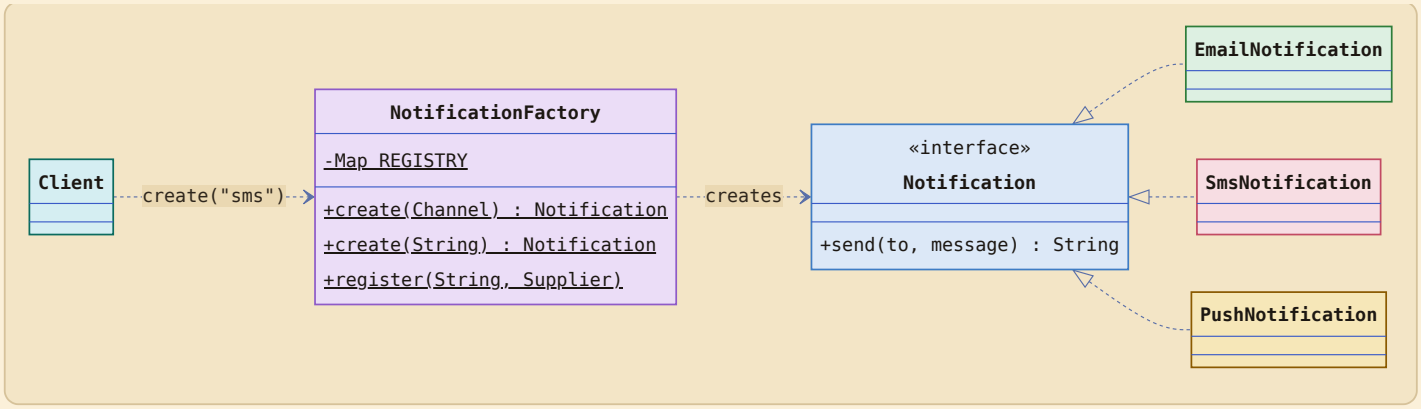
The problem it solves

Without it, the `if/else` or `switch` that turns `"sms"` into `new SmsNotification()` is copied into every place that needs a notification. A new channel means hunting down every copy. A simple factory **centralizes** that decision in one place, and callers depend only on the `Notification` interface.

Important: it **centralizes** the decision; it does not **remove** it. Adding a channel still means editing the factory, and the factory still knows every type. The registry version below softens this — new types are *registered* at start-up rather than coded into a switch.

How it works

1. Define a product **interface** (`Notification`).
2. Write the concrete classes (`EmailNotification`, `SmsNotification`, `PushNotification`).
3. Write one `create(type)` method that maps the type to a concrete class — with an exhaustive `switch` over an enum, or with a `Map<String, Supplier<Notification>>` registry (a lookup table from type names to `Supplier`s; a `Supplier` is Java's built-in "give me a new value" function type).
4. Callers call `create(...)` and hold the result as the interface. They never write `new ConcreteClass()`.
5. Reject unknown types loudly (`IllegalArgumentException`).



Java implementation

```java
// File: code/lld/ch08/simplefactory/Notification.java
package lld.ch08.simplefactory;

/** The product interface every caller programs against. */
public interface Notification {
    String send(String to, String message);
}

record EmailNotification() implements Notification {
    public String send(String to, String message) { return "EMAIL to " + to + ": " + message; }
}

record SmsNotification() implements Notification {
    public String send(String to, String message) { return "SMS to " + to + ": " + message; }
}

record PushNotification() implements Notification {
    public String send(String to, String message) { return "PUSH to " + to + ": " + message; }
}
```

```java
// File: code/lld/ch08/simplefactory/NotificationFactory.java
package lld.ch08.simplefactory;

import java.util.Map;
import java.util.Locale;
import java.util.concurrent.ConcurrentHashMap;
import java.util.function.Supplier;

/** Simple Factory (an idiom, not a GoF pattern): one static method owns the "which class?" decision. */
public final class NotificationFactory {

    public enum Channel { EMAIL, SMS, PUSH }

    private NotificationFactory() { }

    /** Version 1: a switch. Adding a channel means editing this method (and the enum). */
    public static Notification create(Channel channel) {
        return switch (channel) {                       // exhaustive switch: the compiler checks every enum value
            case EMAIL -> new EmailNotification();
            case SMS   -> new SmsNotification();
            case PUSH  -> new PushNotification();
        };
    }

    /** Version 2: a registry of suppliers. New types are registered, not coded into a switch. */
    private static final Map<String, Supplier<? extends Notification>> REGISTRY = new ConcurrentHashMap<>(Map.of(
            "email", EmailNotification::new,
            "sms", SmsNotification::new,
            "push", PushNotification::new));

    public static void register(String type, Supplier<? extends Notification> supplier) {
        REGISTRY.put(type.toLowerCase(Locale.ROOT), supplier);
    }

    public static Notification create(String type) {
        Supplier<? extends Notification> s = REGISTRY.get(type.toLowerCase(Locale.ROOT));
        if (s == null) throw new IllegalArgumentException("Unknown notification type: " + type);
        return s.get();
    }
}
```

```java
// File: code/lld/ch08/simplefactory/Main.java
package lld.ch08.simplefactory;

public class Main {
    public static void main(String[] args) {
        System.out.println("== Simple Factory with an enum switch ==");
        for (NotificationFactory.Channel c : NotificationFactory.Channel.values()) {
            Notification n = NotificationFactory.create(c);      // caller never writes "new XxxNotification"
            System.out.println("  " + n.send("ada", "Your order shipped"));
        }

        System.out.println("\n== Simple Factory with a registry (string keys from config) ==");
        System.out.println("  " + NotificationFactory.create("SMS").send("+91-98xxxx", "OTP 4821"));
        try {
            NotificationFactory.create("whatsapp");
        } catch (IllegalArgumentException e) {
            System.out.println("  rejected: " + e.getMessage());
        }
        // A new channel is registered at start-up - the factory's code is not edited.
        NotificationFactory.register("whatsapp", () -> (to, msg) -> "WHATSAPP to " + to + ": " + msg);
        System.out.println("  " + NotificationFactory.create("whatsapp").send("grace", "Table for 2 confirmed"));
    }
}
```

- The enum `switch` has **no** `default`: the Java compiler checks that every `Channel` value is covered, so adding `WHATSAPP` to the enum without handling it is a compile error. That is a nice safety net.
- The registry version maps lower-cased names to **constructor references** (`EmailNotification::new` — shorthand for "call this constructor"). `register(...)` lets start-up code add a channel without touching the factory. Because `Notification` has one abstract method, a lambda can implement it (an interface with exactly one abstract method is called a *functional interface*).
- `Locale.ROOT` avoids surprising lower-casing in some locales (language-and-region settings) (the Turkish dotless "i" problem).

Output:

```
== Simple Factory with an enum switch ==
  EMAIL to ada: Your order shipped
  SMS to ada: Your order shipped
  PUSH to ada: Your order shipped

== Simple Factory with a registry (string keys from config) ==
  SMS to +91-98xxxx: OTP 4821
  rejected: Unknown notification type: whatsapp
  WHATSAPP to grace: Table for 2 confirmed
```

Trade-offs

Simple Factory	Factory Method (next section)
One method, usually a switch	The decision is spread across subclasses, one each
Adding a type = edit the factory	Adding a type = add a class
No inheritance needed	Needs a creator subclass per product
Not a GoF pattern	A GoF pattern

Which to use: when the list of types is short, rarely changes and is selected by a configuration value, a Simple Factory is the shorter, clearer choice and is perfectly respectable. Move to Factory Method when new types will be contributed by *other* developers — perhaps in separate modules — who should be able to add them without modifying your class.

When not to use it

- There is only **one** concrete class — just call the constructor.
- The objects differ only in **data**, not behaviour — use one class with a field.

Common mistakes

- Calling a switch-based factory a "Factory Method" in an interview.
- A `default` branch that silently returns `null` or a "default" object instead of failing.
- Letting the factory grow into a God class that also configures, caches and logs.

Real-world examples

These are **static factory methods** (Joshua Bloch, *Effective Java* item 1): named static methods that return an instance, possibly of a hidden subclass. They are Simple-Factory style, **not** the GoF Factory Method — there is no Creator class whose subclasses override a creation hook — and **not** Singletons: most return a new object on each call.

- `Calendar.getInstance()` — returns a **new** `GregorianCalendar` on every call in most locales (a different calendar for a few, such as Japanese imperial or Buddhist). The name suggests Singleton; it is not one.
- `NumberFormat.getInstance()` / `getCurrencyInstance(locale)` — also a fresh (locale-specific, usually `DecimalFormat`) object per call.
- `EnumSet.noneOf(type)` — returns a `RegularEnumSet` (≤ 64 constants, one `long` bit-vector) or a `JumboEnumSet`; you never see either class.
- `List.of(...)`, `Map.of(...)`, `Optional.of(...)`, `Integer.valueOf(...)`, `Path.of(...)`.
- `Executors.newFixedThreadPool(n)`, `Executors.newVirtualThreadPerTaskExecutor()` — return configured `ExecutorService` implementations (Java's thread-pool interface for running tasks on reusable threads).

- **Spring:** `@Bean` methods (`@Bean` is an annotation — a `@` tag on code that a framework reads) in a `@Configuration` class are factory methods the container calls to create beans.

In the interview

30-second answer: "A simple factory is one method that maps a type value to a concrete class and returns it as an interface. It centralizes the switch so callers don't depend on concrete classes. It's an idiom, not a GoF pattern — adding a type still edits the factory. If I want new types without editing it, I use a registry of suppliers or Factory Method."

- *Q: Is it Open–Closed?* — A: Not strictly: the factory is edited for each new type. A registry makes it open for extension via registration.
- *Q: Static factory method vs constructor?* — A: Static factories have names, can cache/return existing instances (`Integer.valueOf`), and can return subtypes. Constructors cannot.

Self-check

- **Q:** What does a Simple Factory centralize but not remove? **A:** The switch (knowledge of every concrete type).
- **Q:** Why does the enum `switch` have no `default`? **A:** So the compiler flags any unhandled enum constant.

TL;DR

One `create(type)` method, returns an interface. Great default for small, stable sets of types. Not GoF. Registry of `Supplier`s = extensible variant.

8.10 Factory Method

What it is

Factory Method defines a method for creating an object in a base class, but lets **subclasses decide which concrete class** that method returns. The base class then uses the created object without ever naming its concrete type.

Everyday analogy. A franchise restaurant chain writes one operations manual: take the order, *prepare the dish*, serve, bill. Every branch follows the manual exactly, but "prepare the dish" is left to each branch — the New York branch makes a thin-crust pizza, the Chicago branch a deep-dish one. (This is exactly *Head First*'s pizza-store example: `PizzaStore.orderPizza()` is fixed, and each regional store overrides `createPizza()`.)

Terms:

- **Product** — the interface of the object being created (`Document`).
- **Concrete product** — an implementation (`PdfDocument`).
- **Creator** — the base class that declares the factory method and contains the shared logic (`ReportGenerator`).
- **Concrete creator** — a subclass that overrides the factory method (`PdfReportGenerator`).

GoF intent and participants. Intent: declare an operation that creates an object, but leave the choice of concrete class to subclasses — the base class postpones instantiation to them. The four participants are **Product** (the interface of the objects created), **ConcreteProduct** (implements Product), **Creator** (declares the factory method returning a Product, may supply a default implementation, and — crucially — *calls* it from its own operations) and **ConcreteCreator** (overrides the factory method to return a ConcreteProduct).

> **Factory Method is not a "static factory method".** The word "factory" is overloaded. A *static factory method* (`List.of`, `Integer.valueOf`, `Calendar.getInstance`) and a *Simple Factory* (`NotificationFactory.create(type)`, 8.9) are **one static method that decides** what to return. They cannot be overridden (static methods are not polymorphic — a call cannot be redirected to a subclass's version at run time), and there is no Creator hierarchy. The GoF **Factory Method** is an **instance method, overridden in subclasses**, that the base class itself calls. If there is no inheritance and no overriding, it is not this pattern.

The problem it solves

Plenty of classes must create an object whose exact type they should not decide: a report generator needs a document, a parser needs tree nodes, a notification service needs messages. Once `ReportGenerator` contains `new PdfDocument()`, it is hard-wired to PDF, and supporting HTML means reopening a class that is finished and tested.

Our `ReportGenerator` does four things: gather the rows, create a document from them, render it, and announce the file name. **Only the "create a document" step cares about the output format**; the other three are identical for PDF, HTML or CSV. The first instinct is a `switch` on a format string. That holds up until a second method needs the same `switch`, then a third — and from then on each new format means hunting down every copy.

Factory Method instead leaves a deliberate **gap** in the base class: the complete procedure lives there, but at the moment a document is needed it calls an abstract method that the base class does not implement. Every subclass supplies just that one method.

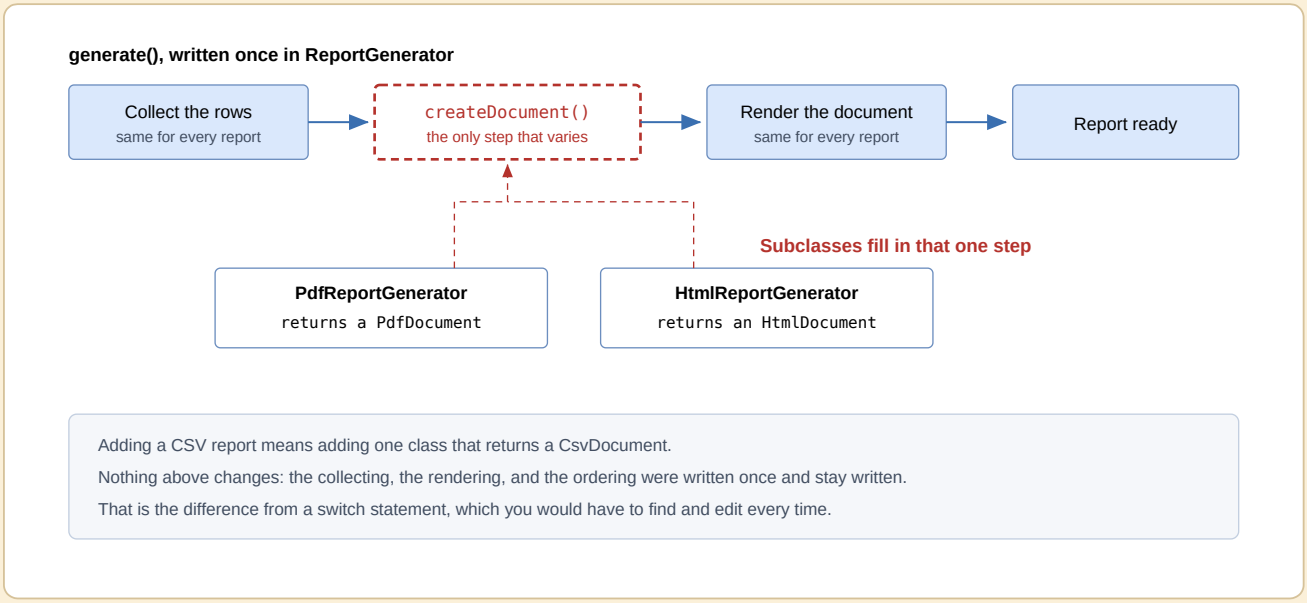


Figure — generate() is written once in ReportGenerator; only createDocument() varies, filled in by PdfReportGenerator or HtmlReportGenerator (course diagram)

In the figure, gathering, rendering and announcing are inherited unchanged; supporting CSV only requires one more subclass whose override returns a `CsvDocument`. Compare that with a `switch`, which has to be located and edited for every new format.

How it works

1. Define the **product interface** (`Document`: `render(rows)`, `fileName()`).
2. Write **concrete products** (`PdfDocument`, `HtmlDocument`, later `CsvDocument`).
3. Write the **creator** as an abstract class with an **abstract, `protected` factory method** (`createDocument()`). `protected` signals that it is an extension point meant for subclasses rather than something outside callers invoke — they call `generate()`.
4. Write the **shared logic** in the creator (`generate()`), calling `createDocument()` where it needs a product. It depends only on `Document`.
5. Write one **concrete creator** per product, overriding only the factory method. That override is the *only* place a concrete type is named.
6. The **client** picks a creator once and then works entirely through `ReportGenerator` and `Document`.

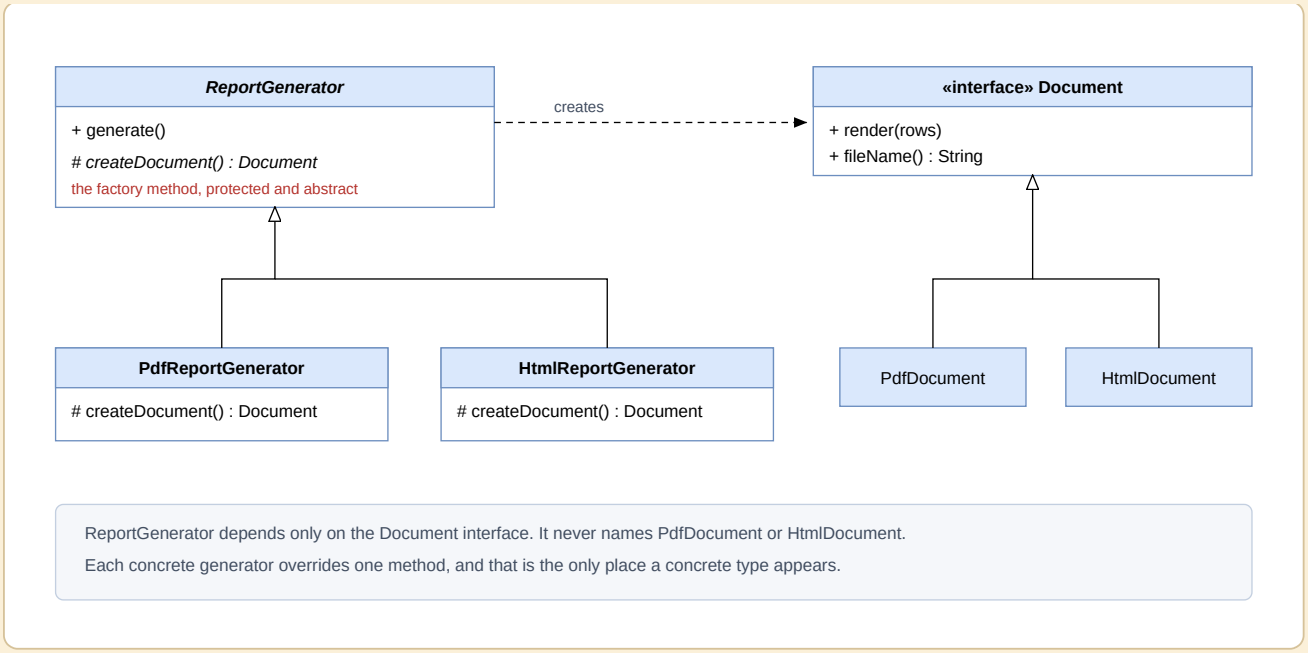

Figure — ReportGenerator declares the protected factory method createDocument(); each concrete generator overrides it to return its own Document (course diagram)

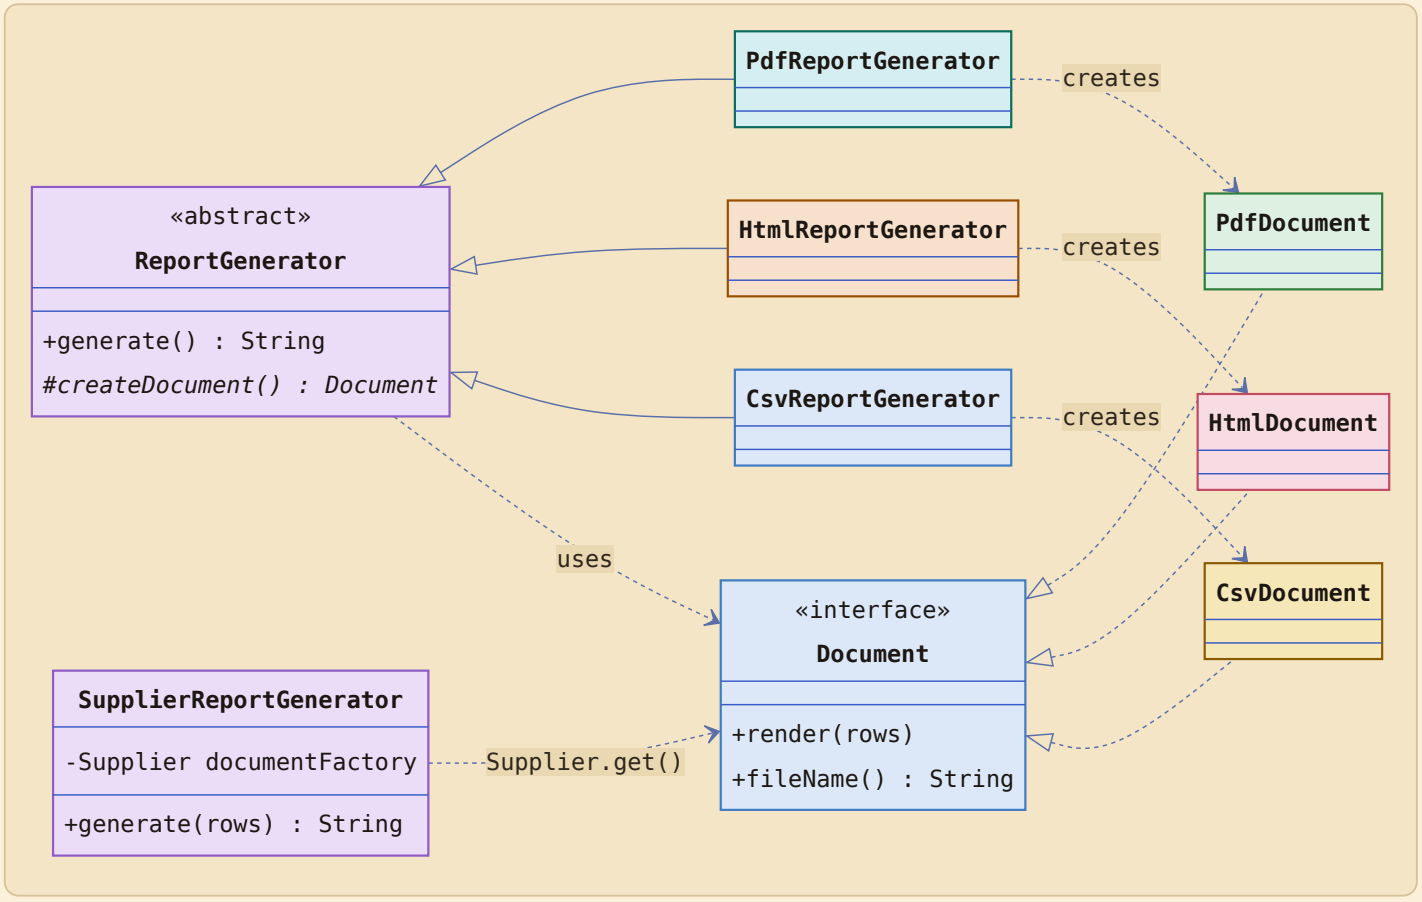

Java implementation

```java
// File: code/lld/ch08/factorymethod/Document.java
package lld.ch08.factorymethod;

import java.util.List;

/** Product: the only document type ReportGenerator knows about. */
public interface Document {
    void render(List<String> rows);
    String fileName();
}

final class PdfDocument implements Document {
    public void render(List<String> rows) { System.out.println("  Rendering as PDF: " + rows.size() + " rows"); }
    public String fileName() { return "sales.pdf"; }
}

final class HtmlDocument implements Document {
    public void render(List<String> rows) { System.out.println("  Rendering as HTML table: " + rows.size() + "
rows"); }
    public String fileName() { return "sales.html"; }
}

/** Added later - no existing class had to change. */
final class CsvDocument implements Document {
    public void render(List<String> rows) { rows.forEach(r -> System.out.println("  csv> " + r)); }
    public String fileName() { return "sales.csv"; }
}
```

```java
// File: code/lld/ch08/factorymethod/ReportGenerator.java
package lld.ch08.factorymethod;

import java.util.List;

/** Creator: writes the whole procedure once and leaves one hole - the factory method. */
public abstract class ReportGenerator {

    /** The factory method. Protected: a hook for subclasses, not public API. */
    protected abstract Document createDocument();

    /** The template that USES the factory method. It never names a concrete document. */
    public final String generate() {
        System.out.println("  Collecting rows for the monthly sales report...");
        List<String> rows = List.of("north,120", "south,95", "east,140");
        Document document = createDocument();
        document.render(rows);
        System.out.println("  Report ready: " + document.fileName());
        return document.fileName();
    }
}

final class PdfReportGenerator extends ReportGenerator {
    @Override protected Document createDocument() { return new PdfDocument(); }
}

final class HtmlReportGenerator extends ReportGenerator {
    @Override protected Document createDocument() { return new HtmlDocument(); }
}

final class CsvReportGenerator extends ReportGenerator {
    @Override protected Document createDocument() { return new CsvDocument(); }
}
```

```java
// File: code/lld/ch08/factorymethod/SupplierReportGenerator.java
package lld.ch08.factorymethod;

import java.util.List;
import java.util.function.Supplier;

/** The modern, composition-based variant: pass the "factory method" in as a Supplier. */
public final class SupplierReportGenerator {
    private final Supplier<? extends Document> documentFactory;

    public SupplierReportGenerator(Supplier<? extends Document> documentFactory) {
        this.documentFactory = documentFactory;
    }

    public String generate(List<String> rows) {
        Document d = documentFactory.get();
        d.render(rows);
        return d.fileName();
    }
}
```

```java
// File: code/lld/ch08/factorymethod/Main.java
package lld.ch08.factorymethod;

import java.util.List;

public class Main {
    public static void main(String[] args) {
        // The client picks a creator once, then only talks to ReportGenerator and Document.
        for (ReportGenerator g : List.of(new PdfReportGenerator(), new HtmlReportGenerator(), new
CsvReportGenerator())) {
            System.out.println("== " + g.getClass().getSimpleName() + " ==");
            g.generate();
        }

        System.out.println("\n== Supplier-based variant (composition instead of subclassing) ==");
        SupplierReportGenerator gen = new SupplierReportGenerator(HtmlDocument::new);
        System.out.println("  produced " + gen.generate(List.of("west,77")));

        // A test can plug in a fake product with a lambda - no subclass needed.
        SupplierReportGenerator testGen = new SupplierReportGenerator(() -> new Document() {
            public void render(List<String> rows) { System.out.println("  (fake) captured " + rows); }
            public String fileName() { return "fake.txt"; }
        });
        System.out.println("  produced " + testGen.generate(List.of("row-1")));
    }
}
```

- `generate()` is `final`: subclasses may change *what* is created, not the procedure. Notice it never mentions PDF, HTML or CSV.
- `CsvDocument` + `CsvReportGenerator` were "added later" — **no existing class was edited** (Open–Closed Principle).
- `SupplierReportGenerator` is the modern alternative: pass a `Supplier<Document>` (a function that creates a product) instead of subclassing. It composes better and a test can supply a lambda.

Output:

```
== PdfReportGenerator ==
  Collecting rows for the monthly sales report...
  Rendering as PDF: 3 rows
  Report ready: sales.pdf
== HtmlReportGenerator ==
  Collecting rows for the monthly sales report...
  Rendering as HTML table: 3 rows
  Report ready: sales.html
== CsvReportGenerator ==
  Collecting rows for the monthly sales report...
  csv> north,120
  csv> south,95
  csv> east,140
  Report ready: sales.csv

== Supplier-based variant (composition instead of subclassing) ==
  Rendering as HTML table: 1 rows
  produced sales.html
  (fake) captured [row-1]
  produced fake.txt
```

All three generators print an identical "Collecting rows…" line, since that code exists only once, in `ReportGenerator`; the rendering line is the only thing that changes.

Trade-offs

Pros	Cons
Extensible without edits — supporting another product means writing another class; no existing class is reopened.	**More classes** — every product type needs its own creator subclass, which is a lot of files for a small feature.
Common procedure in one place — everything around the creation step is written once in the base class.	**Indirection** — the concrete type is not visible where it is used; you have to find out which subclass you are holding.
Built-in test seam (a spot where a test can plug in its own object) — a test can subclass the creator and hand back a fake product.	**Relies on inheritance** — Java allows one superclass, and inheritance combines less flexibly than passing in a function.
Nobody holds the full list of types — no class has to know every format.	**Tempting too early** — with only one product type it is all cost and no benefit.

Often confused with:

Looks like	The actual difference
Simple Factory	One static `create` method with a `switch`. Not a GoF pattern, and frequently the better choice for small stable sets. It gathers the `switch` into one place instead of eliminating it.
Abstract Factory	Factory Method produces **one** product and varies it by **subclassing** the creator. Abstract Factory produces a **family** of products and is varied by **passing in** a different factory object (composition). Abstract Factories are often built out of factory methods.
Template Method	Same mechanism (a base-class method calls an overridable hook), different goal: Template Method lets subclasses vary a *step of an algorithm*; Factory Method lets them vary *which object gets created*. Factory Method can be seen as a special case of Template Method — `generate()` here *is* a template method.
Builder	Factory Method chooses a type in a single call; Builder assembles one complex object across many calls.
"Static factory method" (`List.of`)	A named static method used instead of a constructor, *Effective Java* style. It cannot be overridden, so it is not this pattern — only the word "factory" is shared.

In other languages (and modern Java): wherever functions are values, you can hand the creator a *creation function* instead of subclassing it. Python: `ReportGenerator(create_document=PdfDocument)` (a class is callable). JavaScript/TypeScript: pass `() => new PdfDocument()` into the constructor, and a test passes its own arrow

function (JavaScript's short `() => ...` function syntax). Java: a `Supplier<Document>` field, as in `SupplierReportGenerator`. This is usually the better default because it needs no new class; keep the subclassing form for framework base classes that other teams extend — which is where the pattern was born.

When not to use it

- **There is one product type and no second one on the horizon.** Just call the constructor, and introduce the pattern on the day a second type actually appears. Adding it earlier is the most frequent over-design in the whole creational group.
- **The base class has no shared work of its own.** If `generate()` did nothing except call `createDocument()`, the abstract class would be an interface wearing a costume. The pattern pays only when real logic is written once in the creator.
- **Types differ by data, not by behaviour.** If a configuration string picks the type and the types do not behave differently, a `Map` from string to constructor reference (`Map<String, Supplier<Document>>`) is shorter than a subclass per type.
- **You need several objects that must match.** That is Abstract Factory's job.

Common mistakes

- Making the factory method **public** — it becomes part of the API (Application Programming Interface — the methods others are meant to call) and callers bypass the shared procedure.
- Calling the base class's factory method from its **constructor** — the subclass's fields are not initialized yet when the override runs.
- Calling a switch-in-one-method a Factory Method. (A learner asked exactly this about a code sample: if one method decides with `if/switch`, it is a *simple factory*; if subclasses override a creation hook used by shared base-class logic, it is a *factory method*.)

Real-world examples

- **JDK:** `Iterable.iterator()` / `Collection.iterator()` — the interface declares the creation method (Creator), and `ArrayList`, `LinkedList`, `HashSet`… (ConcreteCreators) each return their own `Iterator` implementation (ConcreteProduct); the enhanced `for` loop and every method written against `Iterator` (Product) never learn which one. `AbstractList` implements `iterator()` on top of its abstract `get(int)` — the template/factory mix in action.
- **JDK XML (as a building block):** `DocumentBuilderFactory.newDocumentBuilder()` and `TransformerFactory.newTransformer()` are abstract methods that each parser implementation's factory subclass overrides — factory methods living inside what, as a whole, is an Abstract Factory (8.11). Note that `DocumentBuilderFactory.newInstance()` itself is a *static* factory method, not a Factory Method.
- **Spring:** `FactoryBean<T>.getObject()` — a bean whose job is to create another object (e.g. proxies, `SqlSessionFactoryBean` in MyBatis-Spring). Spring's `AbstractApplicationContext` also exposes overridable creation hooks for subclasses.
- **Frameworks:** Android's `Fragment.onCreateView()` — you override a `create…` hook the framework calls. JUnit/TestNG (Java testing frameworks) fixture (shared test setup) base classes with overridable `create…` methods.

In the interview

30-second answer: "Factory Method puts a creation hook in a base class. The base class writes the whole procedure once against a product interface; each subclass overrides the protected factory method to return its concrete product. New types are new classes, so it's Open–Closed. It only pays off when there's genuine shared logic in the base class — otherwise a constructor or a simple factory is simpler. In modern Java I'd often pass a `Supplier` instead of subclassing."

- *Q: Difference from Simple Factory?* — A: Simple Factory = one (static) method with a switch that knows every type. Factory Method = subclasses override an instance hook that the base class calls; nothing knows the full list. Raise this distinction yourself before you are asked — calling a `switch` a "Factory Method" is a classic slip interviewers listen for.
- *Q: Difference from Abstract Factory?* — A: One product via inheritance vs a family of matched products via a factory object passed in.
- *Q: Why protected?* — A: It is an extension point for subclasses, not something callers should invoke directly.

- *Q: How do you test `generate()`?* — A: Subclass the creator in the test (or pass a `Supplier`) and return a fake `Document` that records calls.

Self-check

- **Q:** Where is the only place a concrete product class is named? **A:** Inside each concrete creator's override of the factory method.
- **Q:** What must exist in the base class for this pattern to be worthwhile? **A:** Shared logic that uses the product (here, `generate()`).
- **Q:** Which principle does adding `CsvReportGenerator` demonstrate? **A:** Open–Closed.

TL;DR

Base class = procedure + abstract `protected createX()`; subclasses decide the concrete type. One product, varied by inheritance. Worth it only with shared logic and multiple (growing) product types; `Supplier` is the lightweight modern form.

8.11 Abstract Factory

What it is

Abstract Factory provides an interface for creating **families of related objects** that must be used together, without the client naming any concrete class. Choosing a family = choosing a factory; everything created afterwards automatically matches.

Everyday analogy. Furniture showrooms sell matching sets. If you pick the "Victorian" catalogue, the chair, sofa and table you order all come in the Victorian style. You cannot accidentally get a modern chair with a Victorian sofa, because you ordered from one catalogue. (The course summary uses the GUI (graphical user interface) version: one factory per OS (operating system) theme — Windows or macOS — producing buttons, checkboxes and scrollbars that belong together. *Head First* uses a pizza *ingredient* factory per region: New York dough, sauce and cheese vs Chicago dough, sauce and cheese.)

Terms:

- **Family** — a set of products designed to work together (Postgres connection + Postgres query builder; Postgres is short for PostgreSQL, a popular open-source database, and a query builder is an object that writes the SQL text for you).
- **Abstract product** — an interface per product kind (`Connection`, `QueryBuilder`).
- **Abstract factory** — an interface with one `create…` method per product kind (`StorageFactory`).
- **Concrete factory** — implements *every* create method for one family (`PostgresFactory`).

GoF intent and participants. Intent: offer one interface through which a client creates a whole set of related or interdependent objects, without naming their concrete classes. Participants: **AbstractFactory** (declares one creation operation per product kind — `StorageFactory`), **ConcreteFactory** (implements those operations for one family — `PostgresFactory`), **AbstractProduct** (the interface for one kind of product — `Connection`, `QueryBuilder`), **ConcreteProduct** (a product of one family, created by the matching concrete factory — `PostgresQueryBuilder`) and **Client** (uses *only* the AbstractFactory and AbstractProduct types — `ReportService`). GoF also notes that an application usually needs just one ConcreteFactory per family, which is why it is often made a Singleton (though passing it in is better).

The problem it solves

Certain objects are only correct alongside partners from the same variant. A Postgres connection needs a Postgres-flavoured query builder: Postgres wraps identifiers (table and column names) in double quotes, MySQL in backticks. A macOS-styled button should sit next to a macOS-styled checkbox. A test run wants a fake payment client, a fake mailer *and* a fake clock — never a mixture of fake and real.

When each of those objects is constructed independently, nothing prevents a bad combination. Pairing a `PostgresConnection` with a `MySqlQueryBuilder` compiles without a murmur; the mistake only surfaces later as an SQL (the standard language for querying relational databases) syntax error from the server, with a stack trace (the list of method calls that were active when the error happened) that points nowhere near the two lines that made the wrong choice.

This is also what separates it from Factory Method: Factory Method varies **one** product, Abstract Factory varies a **set** of products that must stay consistent.

Abstract Factory hands responsibility for the **entire set to one object**. Each concrete factory can only return members of its own family, so writing a mismatched pair is no longer possible through the factory. Remember the pattern by what it guarantees: *it does not help you choose the right combination — it removes the ability to build a wrong one.*

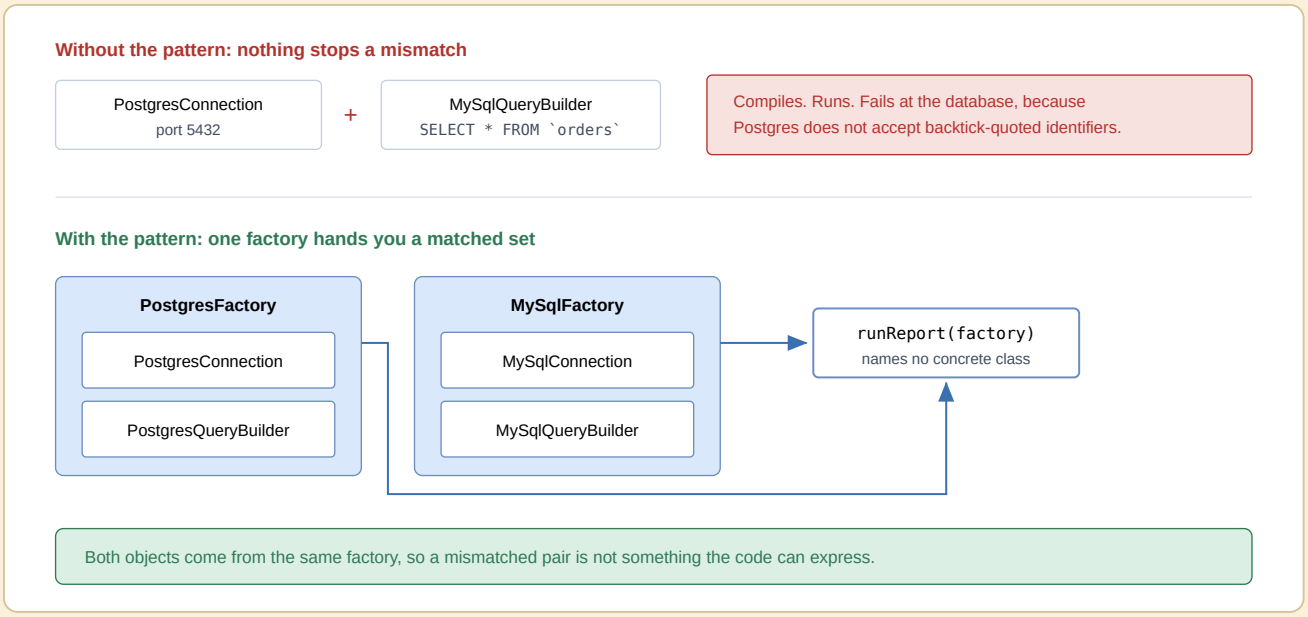

Figure — without the pattern a PostgresConnection can be paired with a MySqlQueryBuilder and fail at the database; with it, each factory hands out a matched set (course diagram)

The upper half of the figure shows the failure — the code compiles and starts, and then Postgres rejects the table name wrapped in backticks. The lower half shows the cure: `runReport(factory)` obtains both objects from one factory.

How it works

1. Identify the **product kinds** in the family and give each an interface (`Connection`, `QueryBuilder`).
2. Write the **abstract factory** interface with one creation method per product kind.
3. For each variant, write the **concrete products** and a **concrete factory** that implements *every* method and returns only that family's products (Java's covariant return types (an override may declare a more specific return type than the method it overrides) let `PostgresFactory.createConnection()` declare `PostgresConnection`, documenting the family).
4. The **client** receives a factory (composition, usually via its constructor) and only uses the abstract types.
5. Choose the concrete factory **once**, at the **composition root** — the spot close to `main` where the application wires its concrete parts together — and pass it down.

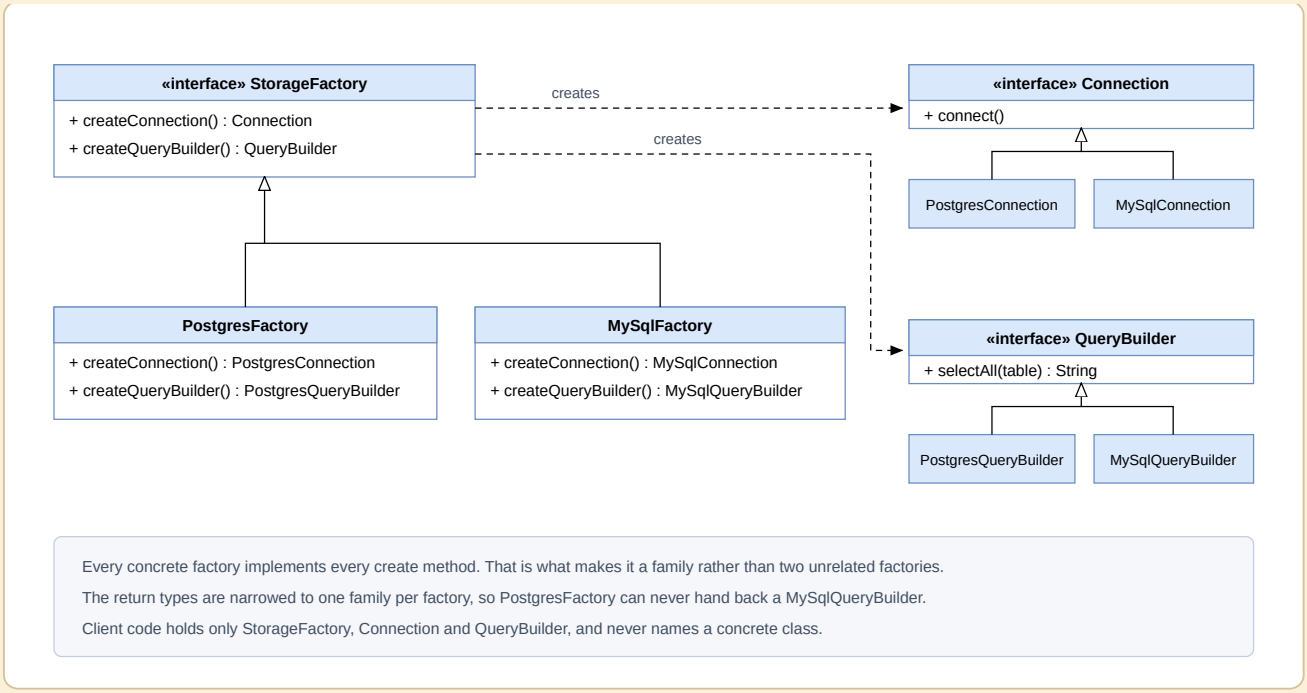

Figure — StorageFactory with createConnection() and createQueryBuilder(); PostgresFactory and MySqlFactory each create their own Connection and QueryBuilder (course diagram)

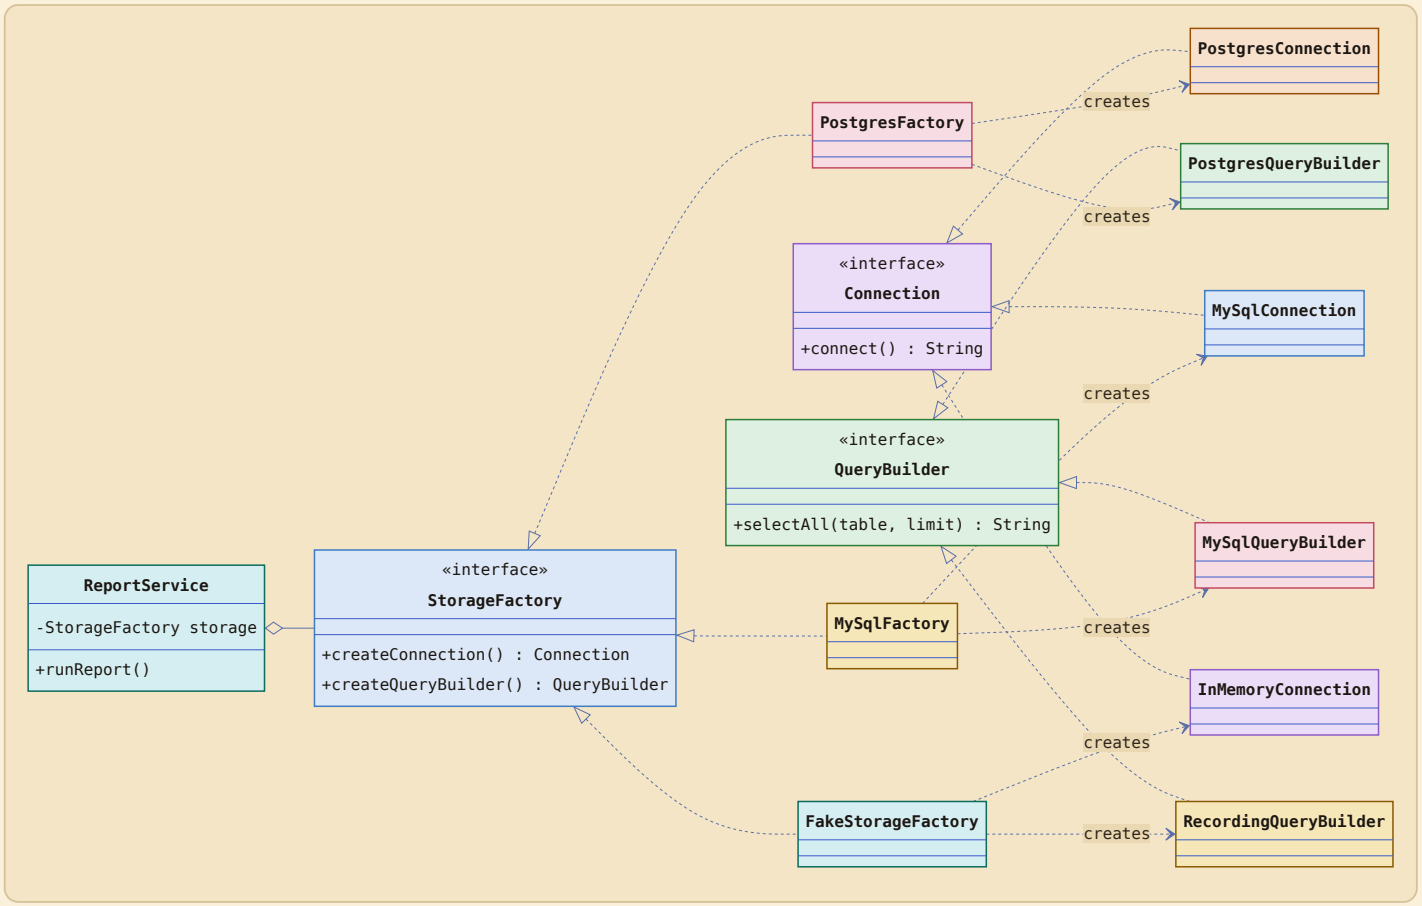
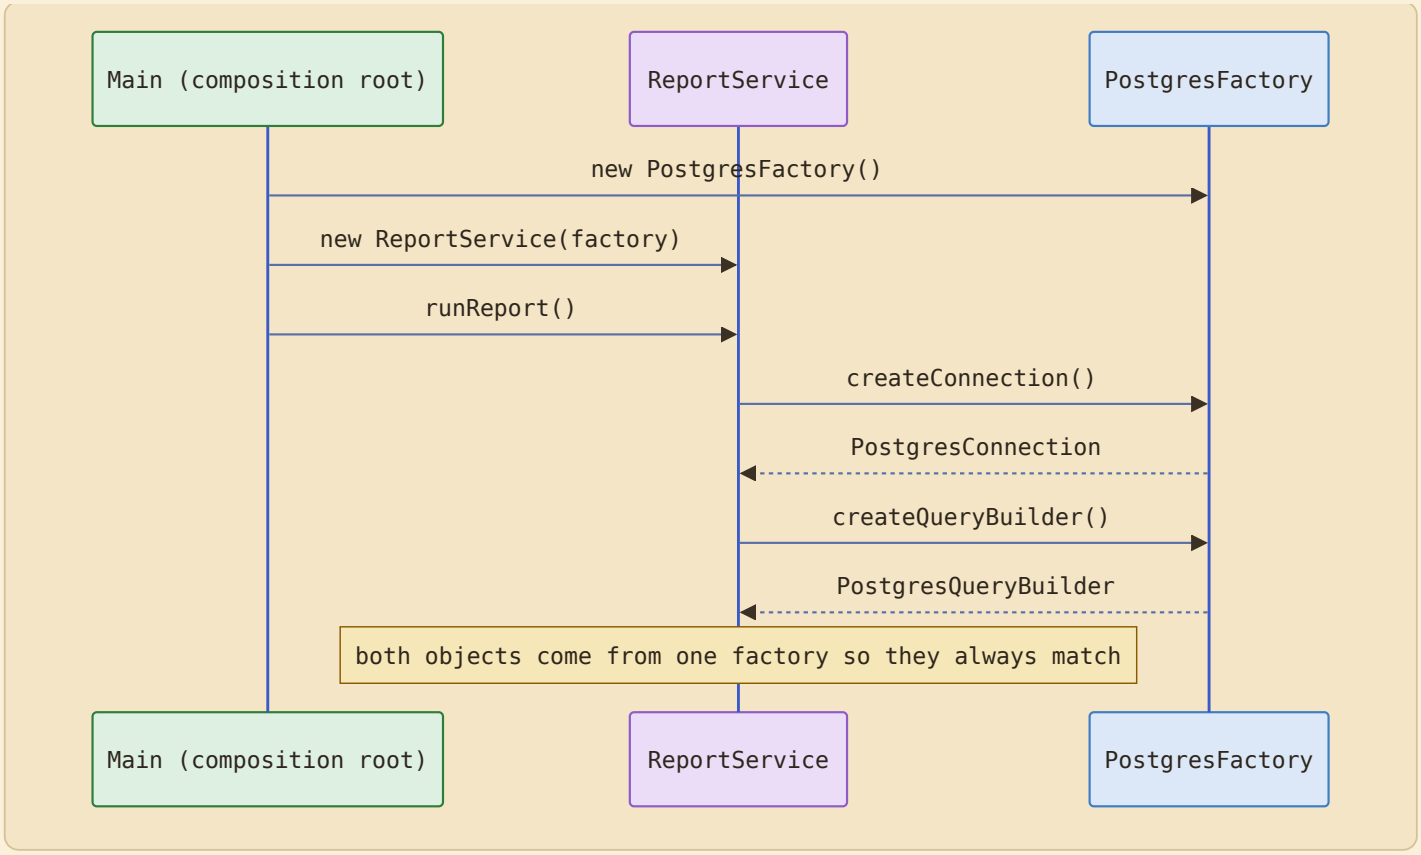
Note in the figure above that every concrete factory implements *every* create method — that is what makes it a family rather than two unrelated factories. (A learner pointed out that an older café example showed factories returning only one product each; a correct Abstract Factory must return **all** products of its family.)





Main (composition root)
ReportService
PostgresFactory
new PostgresFactory()
new ReportService(factory)
runReport()
createConnection()
PostgresConnection
createQueryBuilder()
PostgresQueryBuilder
both objects come from one factory so they always match
Main (composition root)
ReportService
PostgresFactory

Java implementation

```
// File: code/lld/ch08/abstractfactory/Products.java
package lld.ch08.abstractfactory;

/** Abstract product 1. */
interface Connection {
    String connect();
}

/** Abstract product 2. Must agree with the Connection about the SQL dialect. */
interface QueryBuilder {
    String selectAll(String table, int limit);
}

// ---- Postgres family ----
final class PostgresConnection implements Connection {
    public String connect() { return "connected to postgres://localhost:5432/app"; }
}
final class PostgresQueryBuilder implements QueryBuilder {
    public String selectAll(String table, int limit) {
        return "SELECT * FROM \"" + table + "\" LIMIT " + limit;      // Postgres quotes with double quotes
    }
}

// ---- MySQL family ----
final class MySqlConnection implements Connection {
    public String connect() { return "connected to mysql://localhost:3306/app"; }
}
final class MySqlQueryBuilder implements QueryBuilder {
    public String selectAll(String table, int limit) {
        return "SELECT * FROM `" + table + "` LIMIT " + limit;        // MySQL quotes with backticks
    }
}

// ---- Fake family for tests ----
final class InMemoryConnection implements Connection {
    public String connect() { return "connected to in-memory store (no network)"; }
}
final class RecordingQueryBuilder implements QueryBuilder {
    public String selectAll(String table, int limit) { return "[recorded] selectAll(" + table + ", " + limit + ")";
}
}
```

```java
// File: code/lld/ch08/abstractfactory/StorageFactory.java
package lld.ch08.abstractfactory;

/** Abstract factory: one creation method per product in the family. */
public interface StorageFactory {
    Connection createConnection();
    QueryBuilder createQueryBuilder();
}

/** Concrete factories implement EVERY method and return only their own family (covariant return types). */
final class PostgresFactory implements StorageFactory {
    @Override public PostgresConnection createConnection()     { return new PostgresConnection(); }
    @Override public PostgresQueryBuilder createQueryBuilder() { return new PostgresQueryBuilder(); }
}

final class MySqlFactory implements StorageFactory {
    @Override public MySqlConnection createConnection()     { return new MySqlConnection(); }
    @Override public MySqlQueryBuilder createQueryBuilder() { return new MySqlQueryBuilder(); }
}

final class FakeStorageFactory implements StorageFactory {
    @Override public Connection createConnection()     { return new InMemoryConnection(); }
    @Override public QueryBuilder createQueryBuilder() { return new RecordingQueryBuilder(); }
}
```

```java
// File: code/lld/ch08/abstractfactory/ReportService.java
package lld.ch08.abstractfactory;

/** Client: holds only the abstract factory and abstract products. It cannot mix families. */
public final class ReportService {
    private final StorageFactory storage;

    public ReportService(StorageFactory storage) { this.storage = storage; }

    public void runReport() {
        Connection connection = storage.createConnection();
        QueryBuilder queries = storage.createQueryBuilder();
        System.out.println("  " + connection.connect());
        System.out.println("  " + queries.selectAll("orders", 10));
    }
}
```

```java
// File: code/lld/ch08/abstractfactory/Main.java
package lld.ch08.abstractfactory;

public class Main {

    /** Composition root: the ONE place that chooses the family. */
    static StorageFactory chooseFactory(String db) {
        return switch (db) {
            case "postgres" -> new PostgresFactory();
            case "mysql"    -> new MySqlFactory();
            case "fake"     -> new FakeStorageFactory();
            default -> throw new IllegalArgumentException("unknown db " + db);
        };
    }

    public static void main(String[] args) {
        String fromEnv = System.getenv().getOrDefault("DB", "postgres");
        for (String db : new String[] { fromEnv, "mysql", "fake" }) {
            System.out.println("== Using " + db + " ==");
            new ReportService(chooseFactory(db)).runReport();   // ReportService never changes
        }
    }
}
```

- `ReportService` contains **no branch** on the database — the SQL differs purely because the factory differs.
- `chooseFactory(...)` is the **composition root** and holds the program's only `switch` on the database. Had we put that `switch` inside `runReport`, it would merely have been relocated, and every other class that later needs a connection would sprout a duplicate of it.
- `FakeStorageFactory` shows the most valuable use: swap the **whole environment** for tests with one line.

Output (with no `DB` environment variable set — an environment variable is a named setting the operating system passes to a program):

```
== Using postgres ==
  connected to postgres://localhost:5432/app
  SELECT * FROM "orders" LIMIT 10
== Using mysql ==
  connected to mysql://localhost:3306/app
  SELECT * FROM `orders` LIMIT 10
== Using fake ==
  connected to in-memory store (no network)
  [recorded] selectAll(orders, 10)
```

Trade-offs

Pros	Cons
Wrong combinations cannot be written — the family is fixed once, when the factory is chosen.	**Many types** — one interface per product kind plus one class per product per family adds up fast.
One switch for a whole environment — real ↔ fake, Postgres ↔ MySQL, light ↔ dark theme.	**New product kinds are expensive** — the factory interface grows, and every concrete factory must be edited.
Client never names a concrete class — it depends only on abstractions (Dependency Inversion).	**Another layer to trace** — to know what was actually created you must find out which factory was picked.
Test seam — a single fake factory stands in for everything outside the process.	**Pointless with one family** — with a single variant it is pure ceremony.

The asymmetry to remember: adding a new **family** (e.g. `SqliteFactory`) is easy and Open–Closed; adding a new **product kind** (e.g. `createMigrationRunner()`) is hard, because every factory must change.

Abstract Factory vs Factory Method

	Factory Method	Abstract Factory
Creates	**One** product	A **family** of related products
Mechanism	**Inheritance** — subclass overrides a method	**Composition** — client holds a factory object
Who chooses the concrete type	The subclass of the creator	The concrete factory passed in
Shape	One abstract method in a class that has other logic	An interface whose *only* job is creation (several methods)
Guarantees	New types without editing the creator	Products from one factory are always compatible
Adding a new variant	New creator subclass + new product	New factory + one new product per kind
Adding a new product kind	n/a	Edit the interface and **every** factory
Relationship	—	Each `create…` method in a concrete factory is often itself a factory method
Typical example	`Collection.iterator()`	`DocumentBuilderFactory`, UI toolkits, DB dialects

Often confused with: *Builder* (Abstract Factory returns several finished products immediately; Builder assembles one product step by step and hands it over at the end); a *DI container* (same outcome through a more general mechanism — Spring profiles or Guice modules bind a whole set of implementations as configuration; if you

already have a container, prefer it); a *Facade* over several factories (a Facade simplifies an existing interface, whereas Abstract Factory guarantees consistency — similar shapes, unrelated purposes).

In other languages: in Python or JavaScript, a plain dictionary/object of creation functions — `{"connection": PostgresConnection, "queries": PostgresQueryBuilder}` — already acts as a factory, no classes needed. In Java, a `record` (Java's short syntax for an immutable data class) with several `Supplier` fields (`record StorageKit(Supplier<Connection> connection, Supplier<QueryBuilder> queries)`) is often shorter than an interface plus one class per family. With a DI container, write the pattern by hand only when you are building the framework, not when using one.

When not to use it

- **The objects do not belong together.** A "factory" exposing `createLogger()` and `createInvoice()` is a grab-bag of unrelated dependencies, not a matched set — inject them separately.
- **There is only one variant** and no second is expected: an interface plus a single implementation is cost without benefit.
- **The set of product kinds keeps growing** (beyond roughly five or six) — each new kind edits every factory; a container or registry scales better.
- **Your DI container already does it** (Spring `@Profile`, Guice modules, NestJS providers) — that *is* this pattern, expressed as configuration instead of code.

Common mistakes

- A concrete factory that implements only some methods, or returns products from another family.
- Choosing the factory deep in the call stack (the chain of method calls that led to the current one) instead of once at the composition root.
- Making the factory a Singleton by reflex — pass it in instead.

Real-world examples

- **JDK:** `javax.xml.parsers.DocumentBuilderFactory`, `javax.xml.transform.TransformerFactory`, `XPathFactory` — the abstract factory class is what client code holds; the static `newInstance()` locates one implementation (e.g. the JDK's built-in Xerces/Xalan-based ones, or Saxon if configured), and that concrete factory hands out objects belonging to the same implementation (`TransformerFactory` creates both `Transformer` and `Templates`). Swapping the implementation swaps the whole set. JDBC's (Java Database Connectivity, Java's standard database API) `java.sql.Connection` acts as a factory for a driver-specific (a driver is the library that talks to one particular database) family: `createStatement()`, `prepareStatement()`, `prepareCall()`, `createBlob()` all return objects of the same driver.
- **UI toolkits:** the original GoF example — a factory per look-and-feel producing matching widgets. Swing's pluggable look-and-feel follows the same idea.
- **ORMs:** Hibernate's `Dialect` bundles database-specific SQL generation, type mapping and identifier quoting that must agree with each other. (An ORM — object-relational mapper — is a library that maps classes to database tables so you rarely write SQL by hand.)
- **Spring:** `@Profile("test")` vs `@Profile("prod")` configurations swap a whole set of beans (fake mailer, fake payments, in-memory DB) together.
- **Cloud SDKs:** switching between AWS and GCP clients in a multi-cloud abstraction (SDK = software development kit, a provider's client library; AWS and GCP are Amazon's and Google's cloud platforms) (storage client + queue client + secrets client per provider).

In the interview

> **30-second answer:** "Abstract Factory is an interface with one create method per product in a family; each concrete factory returns a matched set. The client holds only the factory and the abstract products, so it can't mix, say, a Postgres connection with a MySQL query builder. I pick the factory once at the composition root. The cost is that adding a new product kind means editing every factory."

- *Q: Factory Method vs Abstract Factory?* — A: One product via inheritance vs a family via composition; Abstract Factory often uses factory methods internally.
- *Q: How would you add SQLite?* — A: `SqliteConnection`, `SqliteQueryBuilder`, `SqliteFactory`, and one line in the composition root. Nothing else changes.

- *Q: How would you add a `MigrationRunner` product?* — A: Add `createMigrationRunner()` to the interface and implement it in every factory — this is the pattern's weak spot.
- *Q: How is this used in tests?* — A: A fake factory returns in-memory/recording products, so one line swaps the entire outside world.

Self-check

- **Q:** What property does Abstract Factory guarantee? **A:** Products from one factory are always from the same family — mismatches cannot be expressed.
- **Q:** What is the composition root? **A:** The one place near start-up where concrete choices (like which factory) are made and passed down.
- **Q:** Which change is easy and which is hard? **A:** New family = easy; new product kind = edit every factory.

TL;DR

One factory object → a matched family of products. Chosen once, passed down. Easy to add families, hard to add product kinds. Prefer a DI container's profiles if you already have one.

8.12 Builder

What it is

Builder separates the *construction* of a complex object from the object itself. A separate builder object collects the values **one named step at a time**, and a final `build()` call produces the finished — usually **immutable** — product. The GoF phrasing adds that the same construction process can create different representations.

Everyday analogy. Ordering a custom meal at a fast-food counter (the course's example) or a sandwich at Subway: bread → cheese → vegetables → sauce, each step named, many optional, and only at the end do you get the finished sandwich. Nobody hands the cashier a row of ten unlabelled values.

Terms:

- **Product** — the object being built (`HttpRequest`).
- **Builder** — collects the values and has `build()`.
- **Fluent interface** — each method returns `this` so calls can be chained: `.method("POST").timeoutSeconds(5)`.
- **Director** — optional class that knows a *recipe* (the order of steps) and runs it on a builder.
- **Immutable** — cannot change after creation (all fields `final`, no setters).

Two different "Builders" share the name — know both:

	GoF Builder (1994)	**Bloch's Builder (*Effective Java*, item 2)**
Problem it targets	One *construction process* should be able to produce *different representations* (the GoF example: one RTF reader converting a document to plain ASCII, TeX, or an editable text widget)	A constructor with many optional parameters (telescoping constructors) and the wish for an immutable, validated object
Participants	**Builder** (abstract interface with one method per part, e.g. `buildParagraph()`), **ConcreteBuilder** (implements the parts for one representation, keeps the result, exposes `getResult()`), **Director** (runs the construction steps through the Builder interface), **Product** (the complex object being built — its type can differ per ConcreteBuilder)	One product class plus one `static` nested `Builder` class: fluent setters that return `this`, and `build()` that validates and calls the product's private constructor. No Director, no abstract Builder interface
What varies	*Which* ConcreteBuilder is plugged in — the steps stay the same, the output type/format differs	Only the *values* the caller supplies
Examples	The GoF RTF converter; a report exporter whose one traversal drives a PDF builder, an HTML builder or a CSV builder	`HttpRequest.newBuilder()`, `Locale.Builder`, Lombok `@Builder`, this chapter's `HttpRequest.Builder`

Most code you will see (and write) is Bloch's fluent builder; interviews often expect you to *name* the GoF participants too. The two ideas overlap in the core insight — separate the step-by-step assembly from the finished object.

The problem it solves

A class keeps collecting fields, and most of them are optional. Its constructor grows until a call site looks like this:

```
new HttpRequest(url, "GET", headers, null, 30, 3, true, false, null);
```

A reader cannot tell what this does. Which of the `null`s is the body? What does the first `true` switch on? If someone exchanges the two booleans, the compiler accepts it, and the mistake only shows up in production — for example as requests that follow redirects although they were meant not to.

The two usual "fixes" are both bad:

Approach	What goes wrong
Telescoping constructors — one overload per useful combination: `Pizza(size)`, `Pizza(size, crust)`, `Pizza(size, crust, cheese)`, …	The number of overloads explodes with every field; call sites are still positional and unreadable; two parameters of the same type are easy to swap.
JavaBeans style — empty constructor + setters (methods that each change one field)	The object exists in a **half-built** state; nothing stops use before it is ready; it **cannot be immutable**; no single place to validate rules that span several fields.

Builder fixes both: every value is **named** at the call site, optional fields have **defaults**, the product can be **immutable**, and `build()` is **one gate** that can refuse to create an invalid object. Our API adopts the rule "a GET must not carry a body" (HTTP — the request/response protocol of the web, see System Design Fundamentals — gives a GET, its "read this resource" request, no defined meaning for a body — RFC 9110 §9.3.1, the official HTTP standard — and many servers and proxies (middlemen that forward requests) reject or drop it). That rule involves two fields at once (`method` and `body`), so no single setter can enforce it; `build()` is the natural place for it.

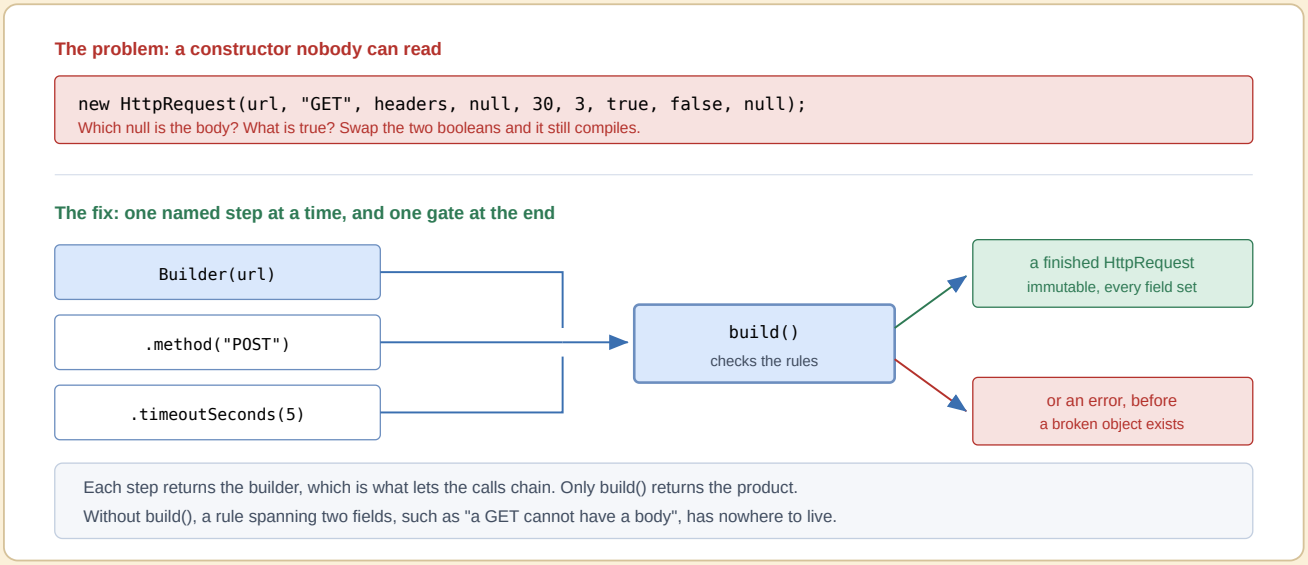


Figure — the unreadable positional constructor versus named builder steps that end in one build() gate which validates and returns an immutable HttpRequest or an error (course diagram)

In the figure, every step hands back the builder itself (which is what lets the calls chain), and only `build()` hands back a product — or throws, so an invalid request never comes into existence.

How it works

1. Make the product's fields `final` and its constructor `private`, taking the builder. Nobody can build a half-filled product directly.
2. Create a `static` `nested` `Builder` class with the same fields, mutable, each optional one with a **default**.

3. Take **required** values in the builder's constructor (or factory method `builder(url)`) so they cannot be forgotten.
4. Give every setter-like method a **name that says what it sets** and have it `return this`.
5. Write `build()`: validate cross-field rules, **copy mutable collections**, and call the private product constructor. Every other builder method returns the builder; `build()` alone returns the product.
6. Optionally add a **Director** for reusable recipes, a `toBuilder()` for copy-and-modify, or a **staged builder** so the compiler enforces required steps.

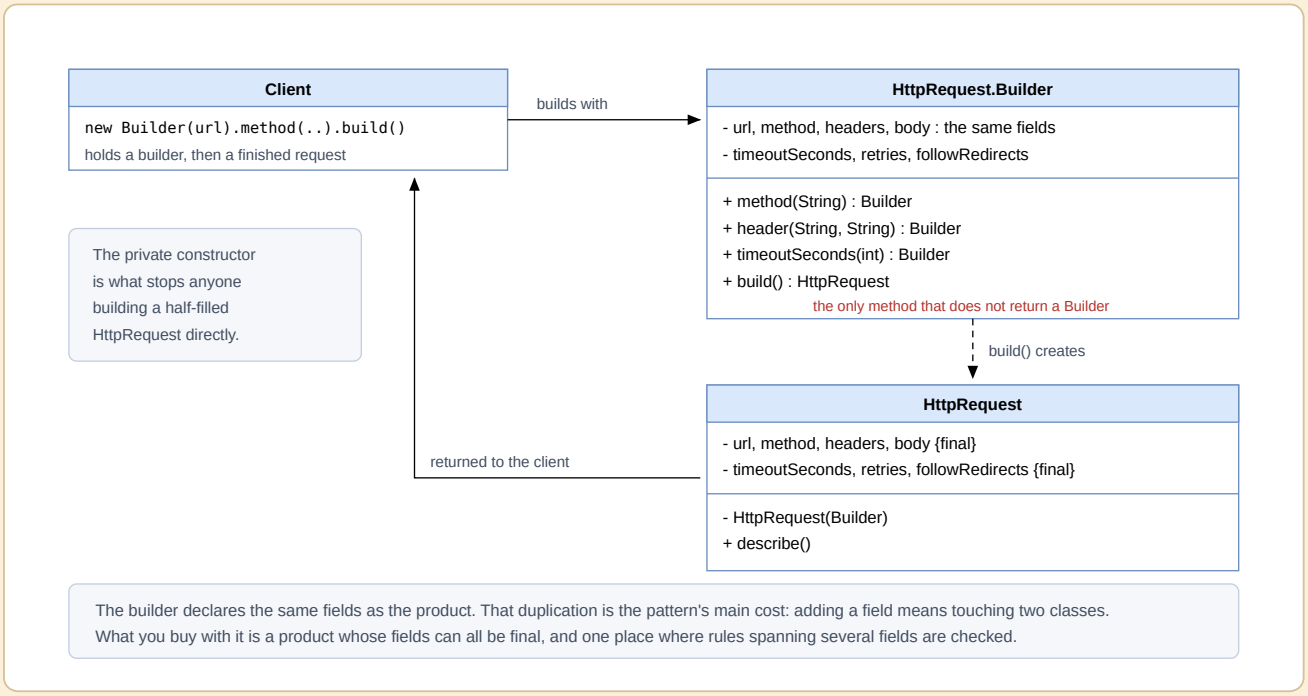

Figure — HttpRequest with final fields and a private constructor; HttpRequest.Builder with the same mutable fields, setters returning Builder, and build() returning HttpRequest (course diagram)

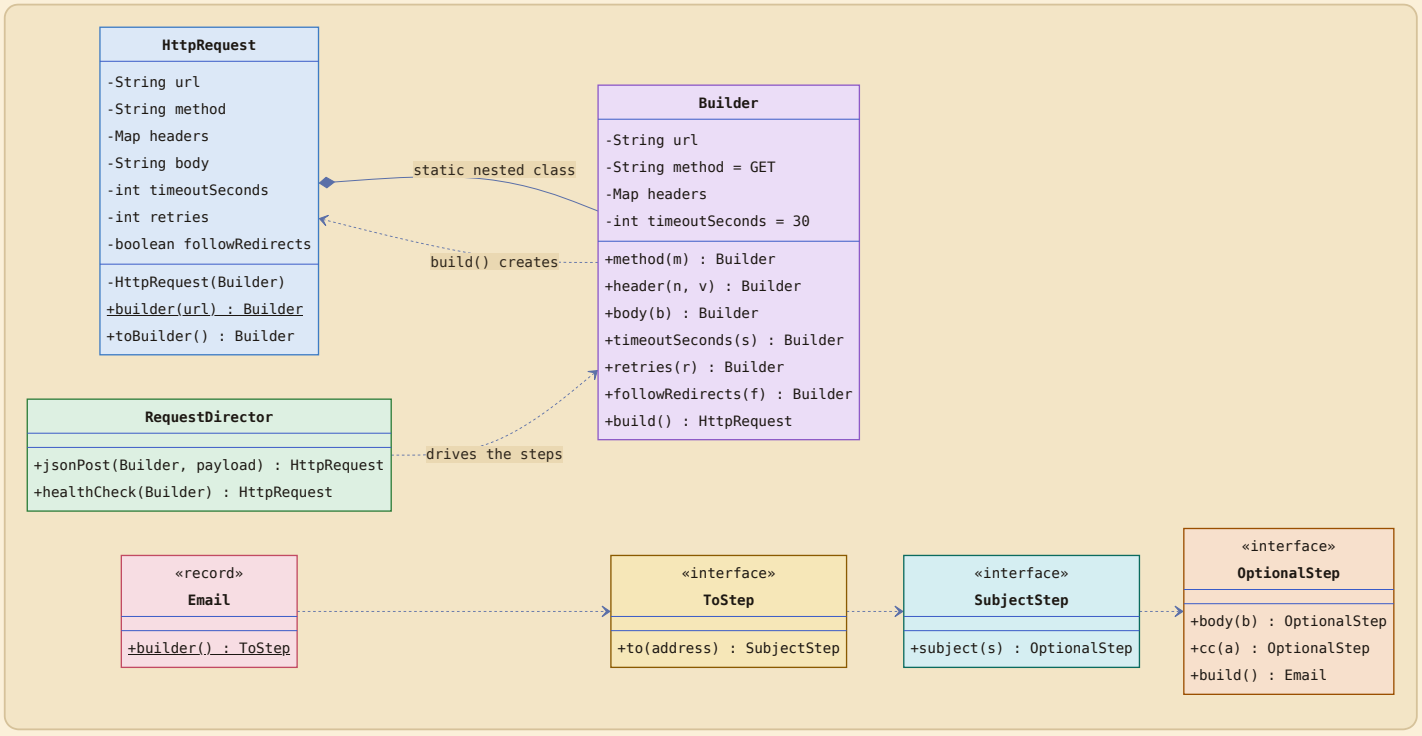
The diagram also exposes the price: the builder repeats every field of the product, so each new field must be added in two places. In exchange, the product has no setters, all of its fields are `final`, and every instance passes through one validation point.



The Director — and why you rarely see one

The GoF version has a fourth participant, the **Director**: a class that knows the **order of steps** and runs them on whichever builder it is given. It exists to make a *sequence* reusable — if many places build "a JSON POST with our usual headers and timeout", that recipe deserves a name, and the Director is its home. (In the GoF book's example, one director — an RTF reader — drives different builders that output plain text or TeX: same process, different representations.)

Day to day you will mostly see the **fluent** builder, because what changes between call sites is normally the *values*, not the order of steps. If only values change, a Director adds nothing a caller could not write as one chained expression. **A quick test:** will this Director ever be given a *different* kind of builder? If so, it separates the recipe from the thing being built and is worth keeping. If not, remove it and let callers chain the calls themselves. (Our `RequestDirector` is deliberately simplified: it only accepts `HttpRequest.Builder`, so it shows the "named recipe" half of the idea. A full GoF Director would be typed against an abstract Builder interface with several implementations.)

The staged (step) builder

When some steps are required or must come in order, encode it in the **types**: each step returns an interface exposing only the legal next calls. `Email.builder()` returns a `ToStep` (only `to(...)`), which returns a `SubjectStep` (only `subject(...)`), which returns an `OptionalStep` that finally has `build()`. Now `Email.builder().build()` **does not compile**. This is the answer to "how would you stop a caller forgetting a required field?" — heavier than most code needs, but good to know.

Lombok-style builders and records

- **Lombok** `@Builder` (Lombok is a library that writes Java boilerplate for you at compile time) generates all of this from an annotation: a static `builder()` method, a nested builder class with one method per field, and `build()`. `@Builder(toBuilder = true)` adds `toBuilder()` for copy-and-modify; `@Singular` generates `header(name, value)`-style methods that add to collections. Lombok's builder does **not** validate by default — you add validation in the constructor it calls.
- **Java records** give you the immutable product for free. A record plus a static nested builder (like `Email`) is now a common shape. Put validation in the record's compact constructor (a constructor with no parameter list that runs on every creation) so it runs however the record is created.
- **Immutability checklist:** `final` class or private constructor, `final` fields, no setters, defensive copies (private copies, so outside code cannot change your internals) of mutable inputs (`Map.copyOf`, `List.copyOf`), and getters that do not leak mutable internals.

Java implementation

```java
// File: code/lld/ch08/builder/TelescopingPizza.java
package lld.ch08.builder;

/** The PROBLEM: telescoping constructors. Each new optional field adds another overload. */
public final class TelescopingPizza {
    private final String size;          // required
    private final String crust;         // optional
    private final boolean cheese;       // optional
    private final boolean olives;       // optional
    private final boolean jalapenos;    // optional

    public TelescopingPizza(String size) { this(size, "regular"); }
    public TelescopingPizza(String size, String crust) { this(size, crust, true); }
    public TelescopingPizza(String size, String crust, boolean cheese) { this(size, crust, cheese, false); }
    public TelescopingPizza(String size, String crust, boolean cheese, boolean olives) {
        this(size, crust, cheese, olives, false);
    }
    public TelescopingPizza(String size, String crust, boolean cheese, boolean olives, boolean jalapenos) {
        this.size = size; this.crust = crust; this.cheese = cheese; this.olives = olives; this.jalapenos =
jalapenos;
    }

    @Override public String toString() {
        return "Pizza[size=" + size + ", crust=" + crust + ", cheese=" + cheese
               + ", olives=" + olives + ", jalapenos=" + jalapenos + "]";
    }
}
```

```java
// File: code/lld/ch08/builder/HttpRequest.java
package lld.ch08.builder;

import java.util.LinkedHashMap;
import java.util.Map;
import java.util.Objects;

/** Product: immutable. Only the nested Builder can create one. */
public final class HttpRequest {
    private final String url;
    private final String method;
    private final Map<String, String> headers;
    private final String body;
    private final int timeoutSeconds;
    private final int retries;
    private final boolean followRedirects;

    private HttpRequest(Builder b) {
        this.url = b.url;
        this.method = b.method;
        this.headers = Map.copyOf(b.headers);      // defensive, unmodifiable copy
        this.body = b.body;
        this.timeoutSeconds = b.timeoutSeconds;
        this.retries = b.retries;
        this.followRedirects = b.followRedirects;
    }

    public static Builder builder(String url) { return new Builder(url); }

        RequestDirector director = new RequestDirector();
        System.out.println("  " + director.jsonPost(HttpRequest.builder("https://api.example.com/payments"), "
{\"amount\":499}"));
        System.out.println("  " + director.healthCheck(HttpRequest.builder("https://api.example.com/health")));

        System.out.println("\n== Staged builder: the compiler enforces required steps ==");
        Email email = Email.builder()
                .to("ada@example.com")          // must come first
                .subject("Welcome")             // then this
                .body("Glad to have you")       // optional, any order
                .cc("team@example.com")
                .build();
        System.out.println("  " + email);
        // Email.builder().build();   // does not compile: ToStep has no build()
    }
}
```

- `TelescopingPizza` is the anti-example: five constructors for five fields, and the call `("large", "thin", true, false, true)` hides which boolean means what.
- In `HttpRequest`, the constructor does `Map.copyOf(b.headers)`. Without that copy, building twice from one builder would hand both products **the same map**, and a header added later would appear in the earlier product. The "reuse" demo proves `first` did not pick up `X-Debug`. `Map.copyOf` is also unmodifiable, which is why `headers().put(...)` throws.
- `build()` enforces four rules, including the cross-field one (GET + body).
- `toBuilder()` gives Lombok-style "same as this, but…" copies.

Output:

```
== The problem: telescoping constructors ==
  Pizza[size=large, crust=thin, cheese=true, olives=false, jalapenos=true]

== Fluent builder: every value is named ==
  GET https://api.example.com/orders headers={Accept=application/json} timeout=30s retries=3 followRedirects=true
  POST https://api.example.com/orders headers={Content-Type=application/json} body={"item":"widget"} timeout=5s
retries=0 followRedirects=false

== build() refuses broken objects ==
  rejected: a GET request cannot have a body

== Reusing a builder does not leak state into earlier products ==
  first headers  = {X-Trace=1}
  second headers = {X-Debug=true, X-Trace=1}

== Product is immutable ==
  headers().put -> UnsupportedOperationException

== toBuilder(): copy-and-change, like Lombok @Builder(toBuilder = true) ==
  POST https://api.example.com/orders headers={Content-Type=application/json} body={"item":"widget"} timeout=60s
retries=0 followRedirects=false

== Director: named recipes over any builder ==
  POST https://api.example.com/payments headers={Accept=application/json, Content-Type=application/json} body=
{"amount":499} timeout=5s retries=3 followRedirects=true
  HEAD https://api.example.com/health headers={} timeout=1s retries=0 followRedirects=false

== Staged builder: the compiler enforces required steps ==
  Email[to=ada@example.com, subject=Welcome, body=Glad to have you, cc=[team@example.com]]
```

Trade-offs

Pros	Cons
Self-describing call sites — each value is labelled where it is passed, so parameter order no longer matters.	**Duplicated fields** — the builder repeats every field of the product; a new field means two edits.
Immutable products — all fields can be `final` because they are fixed before the object exists; safe to share between threads.	**Forgettable last step** — omit `build()` and you are holding a builder, not the object you wanted.
A home for validation — rules that involve several fields are checked in `build()`.	**Easily overused** — for a value object (a small object defined only by its values, like `Money`) with three fields it only adds noise.
Free optional fields — defaults sit in the builder, callers mention only what they change.	**Reuse pitfall** — building twice from one builder can leave two products sharing one mutable collection unless it is copied.
Different representations (GoF) — a Director can drive different ConcreteBuilders through the same steps.	One extra short-lived object per construction — almost never measurable.

Often confused with:

Looks like	The actual difference
Factory Method	Chooses *which type* to create, in a single call. Builder assembles *one known type* over a series of calls.
Abstract Factory	Hands back several finished products straight away. Builder hands back one product after a sequence of steps.
Fluent interface	Chaining is merely a calling style. A chained API that modifies and returns the *same* object (a jQuery chain, a `StringBuilder`-style mutator used as the result itself) has no separate finished product, so on its own it is not the Builder pattern.
Prototype	Prototype begins with a ready-made object and duplicates it; Builder begins with nothing and fills values in. Both are ways around a huge constructor — one starts from the end result, the other from scratch.

In other languages: Python and Kotlin (and C#) have **named arguments with defaults** — `HttpRequest(url, method="POST", timeout=5)` — which already make call sites readable; Python's `@dataclass(frozen=True)` and Kotlin's `data class` (with `.copy(...)`) supply the immutable product. Use a builder there only for cross-field validation or staged construction. JavaScript/TypeScript usually pass an options object: `new HttpRequest({ url, method: "POST" })`.

When not to use it

- **A few fields, all required.** A plain constructor is shorter and just as clear — this is the misuse you will see most.
- **The language has named/default arguments** — see above.
- **The builder merely copies fields**, validates nothing, and the product is mutable anyway — that is an extra class with no payoff. Either add the validation or remove the builder.
- **The object is mutable and lives only inside one method** — ordinary setters are fine there.

Common mistakes

- Setters that **don't return the builder** (breaks chaining). Every step returns `Builder`; only `build()` returns the product.
- **No validation** in `build()`.
- **Sharing mutable collections** between the builder and the products.
- Making the product constructor public (then nobody has to use the builder or its validation).
- Using a Director when the order never varies.

Real-world examples

- **JDK:** `StringBuilder` (append repeatedly, `toString()` once); `java.net.http.HttpClient.newBuilder()` and `HttpRequest.newBuilder()` (Java 11+); `Locale.Builder`; `Calendar.Builder` (Java 8+); `Stream.builder()`; `Thread.ofVirtual().name("w").start(task)` — the `Thread.Builder` API in Java 21; `ProcessBuilder`.
- **Spring:** `UriComponentsBuilder`, `ResponseEntity.ok().header(...).body(...)`, `WebClient.builder()`, `MockMvcRequestBuilders.get("/x").param(...)`, Spring Security's `HttpSecurity` DSL (domain-specific language — a mini-language built for one job).
- **Libraries:** OkHttp `Request.Builder`; Protocol Buffers generated messages (immutable messages + generated builders); Guava `ImmutableList.builder()`; Lombok `@Builder`; test-data builders like `aUser().withEmail("x@y.com").build()`.

In the interview

30-second answer: "When a constructor has many optional parameters, I use a Builder: required values in the builder's constructor, one named method per optional field that returns the builder, and `build()` that validates cross-field rules and creates an immutable product through a private constructor. I'd mention the classic Director but usually skip it because only values vary. For tiny objects or languages with named arguments, I wouldn't bother."

- *Q: Why not setters?* — A: Half-built objects, no immutability, nowhere for cross-field validation.
- *Q: How do you enforce required fields?* — A: Take them in the builder's constructor, validate in `build()`, or use a staged builder so the compiler enforces them.

- *Q: Is `StringBuilder` a GoF Builder?* — A: Not in the full GoF structure (no Director, one representation), but it is the everyday example of the idea: accumulate parts step by step, produce the final `String` once.
- *Q: Is the built object thread-safe?* — A: The product is, if immutable. The builder itself is not — do not share a builder across threads.

Self-check

- **Q:** What is the only builder method that does not return the builder? **A:** `build()`.
- **Q:** What bug does copying the headers map in `build()`/the constructor prevent? **A:** Two products built from one builder sharing (and mutating) the same map.
- **Q:** When is a Director worth it? **A:** When the same recipe (order of steps) is reused, possibly with different builders.

TL;DR

Named steps + defaults + one validating `build()` → immutable product. Solves telescoping constructors and half-built JavaBeans. Director optional; staged builder for compile-time required steps; Lombok/records remove the boilerplate.

8.13 Prototype

What it is

Prototype creates new objects by **copying an existing, already-configured object** (the prototype) instead of building from scratch. The object itself offers a `copy()` method, so the caller does not need to know its concrete class.

Everyday analogy. A photocopier, or cell division: you do not rebuild a document or a cell from raw materials — you duplicate one that already exists and then change what differs. Another: a company's contract template. Legal drafted it once; each new contract is a copy with the name and date changed.

Terms:

- **Prototype** — the original object that gets copied.
- **Clone / copy** — the new object produced.
- **Shallow copy** — copies the fields; if a field is a reference, the copy points to the *same* object.
- **Deep copy** — copies the fields *and* the objects they point to, so nothing mutable is shared.
- **Copy constructor** — a constructor that takes another instance of the same class and copies it.
- **Prototype registry** — a map of named, pre-configured prototypes you ask for copies of.

GoF intent and participants. Intent: use a ready-configured instance as the model for the kind of object you want, and make new objects by copying that model. Participants: **Prototype** (declares the operation that copies itself — our `Shape` with `copy()`), **ConcretePrototype** (implements that copy operation — `Circle`, `Rectangle`, `Group`, or `NotificationTemplate`, which plays both roles) and **Client** (asks a prototype to copy itself instead of calling a constructor — `Main`, or `ShapeRegistry`, which GoF calls a *prototype manager*).

The problem it solves

There are two versions of the problem:

1. **Construction is expensive.** Initialization might load a file, hit a database, parse a template or fill in dozens of default values. Suppose a `NotificationTemplate` is parsed from disk at start-up; every welcome email differs from it only in the subject line and one added channel. Re-parsing the file for each recipient repeats the slowest work for nothing.
2. **You do not know the concrete class** — the more important case in practice. The code holds a reference typed as `Shape` or `Template` and needs *one more of the same*. Writing `new` is impossible, because you do not know which class name to write. Asking the object to copy itself solves it: the object always knows its own class. No factory or `switch` is needed to work the type out, and the copy starts from values that are already correct, so it skips the expensive setup.

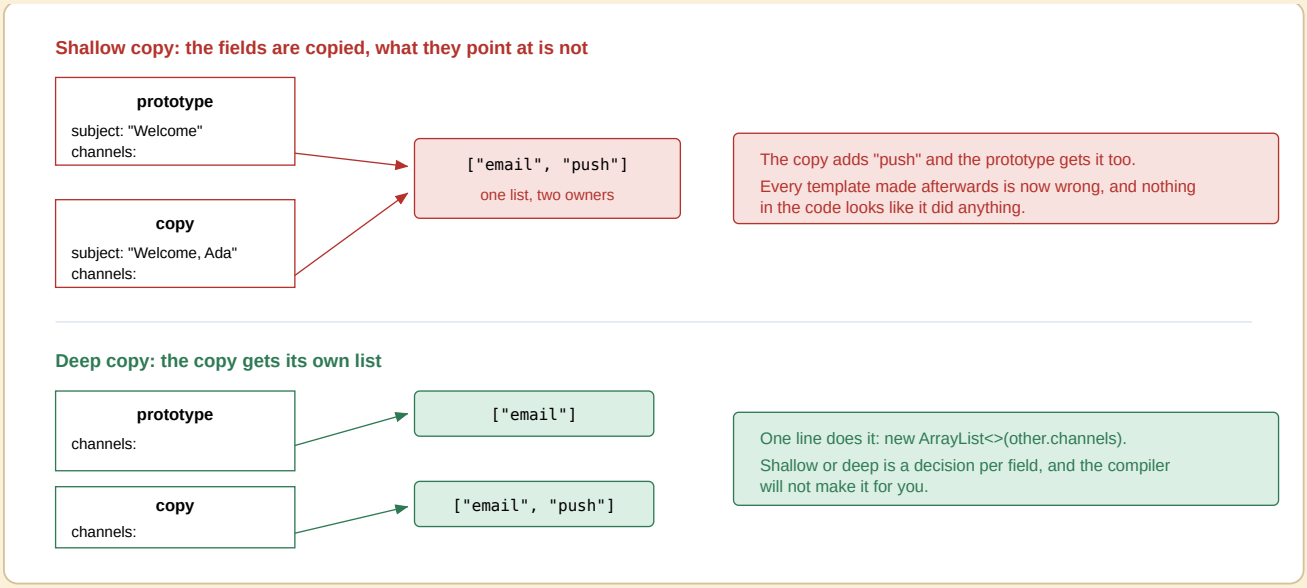

Figure — a shallow copy shares the channels list with the prototype, so adding "push" to the copy corrupts the prototype; a deep copy gets its own list (course diagram)

The figure highlights the one decision in this pattern that really needs thought: **how far down the object graph (every object reachable by following references from this one) the copy reaches.** The structure itself is simple: two entrances to the class — an ordinary constructor that does the expensive work, and a copy path that does none of it.

How it works

1. Give the class two ways in: the **normal constructor** (expensive setup) and a **copy path** that does none of it.
2. Implement the copy path, preferably as a **private copy constructor** `NotificationTemplate(NotificationTemplate other)`.
3. For each field, decide: immutable (share it — `String`, records of immutables) or mutable (copy it — `new ArrayList<>(other.channels)`), and recurse for nested mutable objects.
4. Expose a public `copy()` returning a new, independent instance.
5. If clients hold several unrelated types, add a **prototype interface** (`Shape { Shape copy(); }`) so they can copy polymorphically.
6. Optionally keep a **registry** of named prototypes that always hands out copies, never the original.

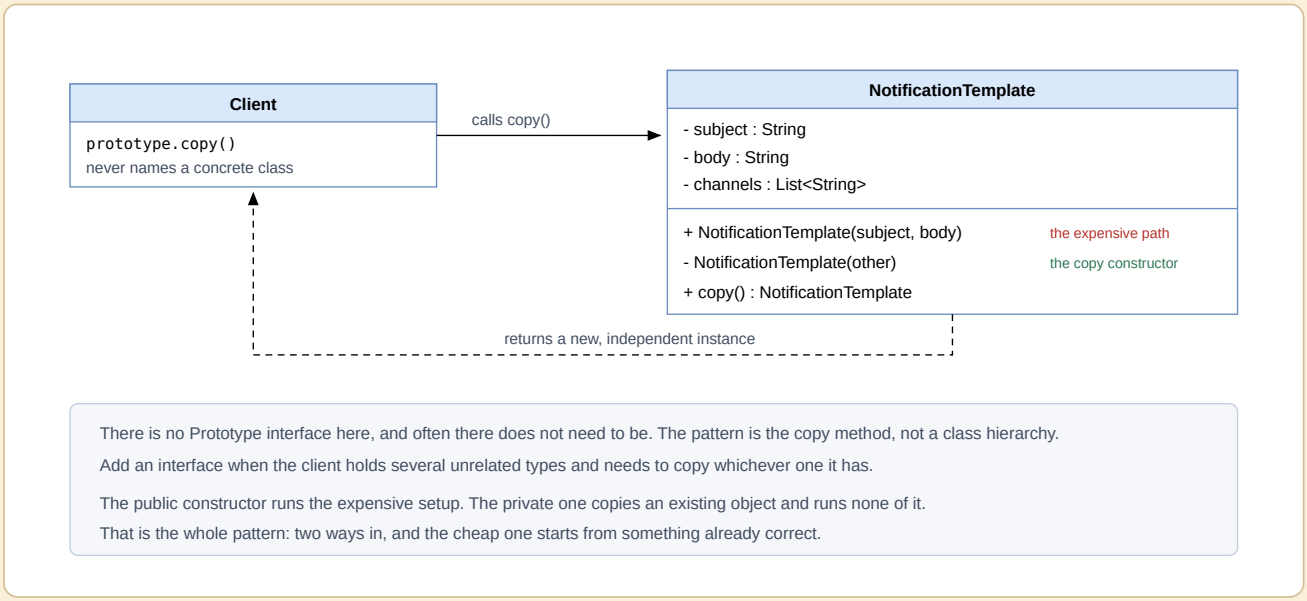

Figure — NotificationTemplate is both prototype and product: a public expensive constructor, a private copy constructor, and copy() that the Client calls (course diagram)

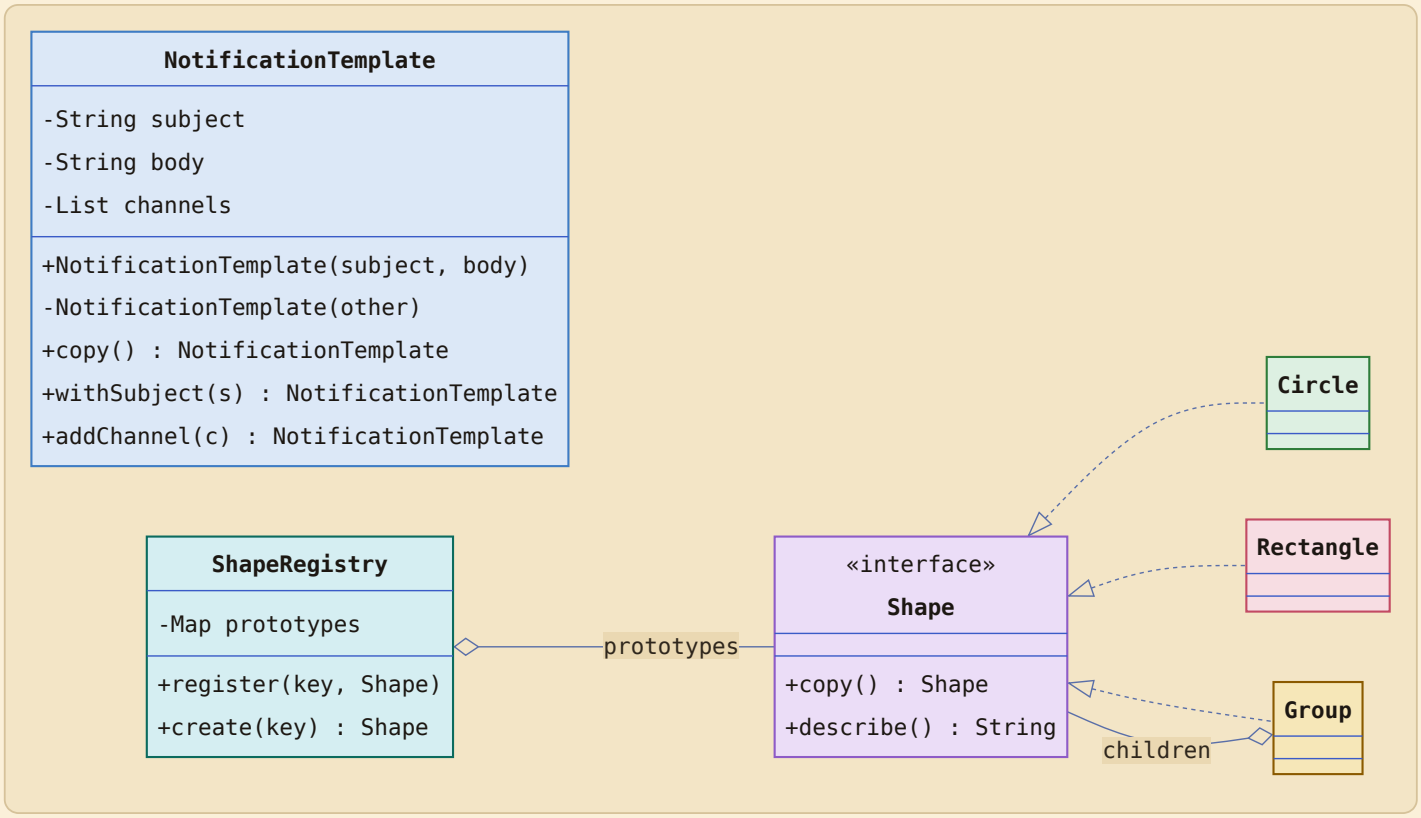
Notice in the class diagram that there is **no separate creator class and no Prototype interface** — unlike the other creational patterns, the product creates its own copies. What makes it Prototype is the copy method, not a

class hierarchy. Introduce a Prototype interface (like `Shape` below) only when the client holds several unrelated types and must copy whichever it happens to have.



Shallow vs deep copy

	Shallow copy	Deep copy
Primitives (`int`, `double`, `boolean`…), `String`, other immutables	Copied / safely shared	Copied / safely shared
Mutable fields (lists, maps, objects)	**Shared** — both objects point to the same one	**Duplicated** — each has its own
Cost	Cheap	Proportional to the size of the object graph
Risk	Changing the copy silently changes the original	Cycles, copying things you meant to share (caches), copying resources
Java default	`Object.clone()`	You write it (per field)

Suppose the copy constructor had written `this.channels = other.channels`. Both templates would then point at a single list, so adding "push" to the copy silently adds it to the prototype too — and **every later copy inherits the stray channel**, although no line of code visibly touched the prototype. That shared-mutable-collection bug is the one you will meet most often with this pattern. The cure is one line per mutable field — `new ArrayList<>(other.channels)` — i.e. a copy one level deeper. Had the list contained mutable objects instead of `String`s, those would need copying as well, and so on down the graph. **The depth of the copy is a design choice you make field by field**; neither Java nor the compiler will make it for you.

Three related traps:

- **A new field added without updating the copy** — the copy quietly drops it; no compiler error, and usually no test catches it, so the drift can go unnoticed for months.
- **Copying something that owns a resource** (connection, file handle) — two objects now think they own it and both try to close it.
- **Cycles** — a naive recursive deep copy of objects that point to each other never terminates. Real deep-copy utilities track visited objects.

Why Java's `Cloneable` is a trap

Java's built-in version of Prototype is `Object.clone()` + the `Cloneable` interface, and it is widely considered broken (*Effective Java*, item 13):

- `Cloneable` is a **marker interface with no methods** — it does not declare `clone()`. It only changes the behaviour of `Object.clone()` (without it, `clone()` throws `CloneNotSupportedException`).
- `Object.clone()` is **`protected`**, so you must override it as `public` to make it usable.
- It makes a **shallow** field-by-field copy.
- It **creates the object without running any constructor**, so constructor validation and invariants (rules that must always hold for the object) are skipped.
- To deep-copy you must reassign fields after `super.clone()` — which is **impossible for `final` fields**.
- It throws a **checked** exception (one the compiler forces you to catch or declare) you have to catch even when it cannot happen.

Prefer a copy constructor or a static copy factory (`static Foo copyOf(Foo other)`). It is ordinary code, runs your validation, works with `final` fields, and its behaviour is visible where you wrote it. The exception is arrays: `array.clone()` works well for primitive arrays.

Java implementation

```java
// File: code/lld/ch08/prototype/NotificationTemplate.java
package lld.ch08.prototype;

import java.util.ArrayList;
import java.util.List;

/** Prototype via a copy constructor: one expensive path, one cheap copy path. */
public final class NotificationTemplate {
    static int parses = 0;

    private String subject;
    private final String body;
    private final List<String> channels;

    /** The expensive path (imagine parsing a template file). */
    public NotificationTemplate(String subject, String body) {
        parses++;
        System.out.println("  Parsing template from disk... (expensive)");
        this.subject = subject;
        this.body = body;
        this.channels = new ArrayList<>(List.of("email"));
    }

    /** The copy path: no parsing. Deep-copies the mutable list. */
    private NotificationTemplate(NotificationTemplate other) {
        this.subject = other.subject;              // String is immutable -> sharing is safe
        this.body = other.body;
        this.channels = new ArrayList<>(other.channels);  // NEW list -> the copy owns its own
    }

    public NotificationTemplate copy() { return new NotificationTemplate(this); }

    public NotificationTemplate withSubject(String s) { this.subject = s; return this; }
    public NotificationTemplate addChannel(String c) { channels.add(c); return this; }

    @Override public String toString() { return "subject=\"" + subject + "\" channels=" + channels; }
}
```

```java
// File: code/lld/ch08/prototype/Shapes.java
package lld.ch08.prototype;

import java.util.ArrayList;
import java.util.List;

/** Prototype interface: lets code copy an object whose concrete class it does not know. */
interface Shape {
    Shape copy();
    String describe();
}

final class Circle implements Shape {
    private final int radius;
    private final String color;
    Circle(int radius, String color) { this.radius = radius; this.color = color; }
    private Circle(Circle other) { this(other.radius, other.color); }            // copy constructor
    @Override public Circle copy() { return new Circle(this); }                  // covariant return
    @Override public String describe() { return color + " circle r=" + radius; }
}

final class Rectangle implements Shape {
    private final int w, h;
    private final String color;
    Rectangle(int w, int h, String color) { this.w = w; this.h = h; this.color = color; }
    @Override public Rectangle copy() { return new Rectangle(w, h, color); }
    @Override public String describe() { return color + " rectangle " + w + "x" + h; }
}

/** A composite prototype: deep copy must copy the children too. */
final class Group implements Shape {
    private final List<Shape> children = new ArrayList<>();
    Group add(Shape s) { children.add(s); return this; }
    @Override public Group copy() {
        Group g = new Group();
        for (Shape s : children) g.add(s.copy());       // recursive deep copy
        return g;
    }
    @Override public String describe() { return "group" + children.stream().map(Shape::describe).toList(); }
    int size() { return children.size(); }
}
```

```java
// File: code/lld/ch08/prototype/ShapeRegistry.java
package lld.ch08.prototype;

import java.util.HashMap;
import java.util.Map;

/** Prototype registry (a.k.a. prototype manager): named, pre-configured objects handed out as copies. */
final class ShapeRegistry {
    private final Map<String, Shape> prototypes = new HashMap<>();

    void register(String key, Shape prototype) { prototypes.put(key, prototype); }

    Shape create(String key) {
        Shape p = prototypes.get(key);
        if (p == null) throw new IllegalArgumentException("no prototype named " + key);
        return p.copy();                                  // never hand out the original
    }
}
```

```java
// File: code/lld/ch08/prototype/CloneablePitfall.java
package lld.ch08.prototype;

import java.util.ArrayList;
import java.util.List;

/** Why Cloneable is risky: Object.clone() is shallow, so mutable fields are shared. */
class ShallowPlaylist implements Cloneable {
    String name;
    List<String> songs = new ArrayList<>();

    @Override
    public ShallowPlaylist clone() {
        try {
            return (ShallowPlaylist) super.clone();       // field-by-field copy: 'songs' reference is shared
        } catch (CloneNotSupportedException e) {
            throw new AssertionError(e);                  // cannot happen: we implement Cloneable
        }
    }
}

/** The fixed clone(): deep-copy each mutable field by hand. (It cannot do this for a final field.) */
class DeepPlaylist implements Cloneable {
    String name;
    List<String> songs = new ArrayList<>();

    @Override
    public DeepPlaylist clone() {
        try {
            DeepPlaylist copy = (DeepPlaylist) super.clone();
            copy.songs = new ArrayList<>(songs);          // re-assigning is why 'songs' cannot be final
            return copy;
        } catch (CloneNotSupportedException e) {
            throw new AssertionError(e);
        }
    }
}
```

```java
// File: code/lld/ch08/prototype/Main.java
package lld.ch08.prototype;

public class Main {
    public static void main(String[] args) {
        System.out.println("== Copy instead of re-parsing ==");
        NotificationTemplate prototype = new NotificationTemplate("Welcome", "Hello there");
        NotificationTemplate ada = prototype.copy().withSubject("Welcome, Ada").addChannel("push");
        NotificationTemplate grace = prototype.copy().withSubject("Welcome, Grace").addChannel("sms");
        System.out.println("  ada       : " + ada);
        System.out.println("  grace     : " + grace);
        System.out.println("  prototype : " + prototype + "   <- unchanged (deep copy of the list)");
        System.out.println("  templates parsed: " + NotificationTemplate.parses);

        System.out.println("\n== Cloneable pitfall: shallow copy shares the list ==");
        ShallowPlaylist p1 = new ShallowPlaylist();
        p1.name = "Road trip"; p1.songs.add("Song A");
        ShallowPlaylist p2 = p1.clone();
        p2.songs.add("Song B");
        System.out.println("  original songs after editing the CLONE: " + p1.songs + "   <- bug");

        DeepPlaylist d1 = new DeepPlaylist();
        d1.name = "Road trip"; d1.songs.add("Song A");
        DeepPlaylist d2 = d1.clone();
        d2.songs.add("Song B");
        System.out.println("  deep clone -> original " + d1.songs + ", copy " + d2.songs);

        System.out.println("\n== Polymorphic copy: the caller only knows 'Shape' ==");
        Shape unknown = args.length > 0 ? new Rectangle(2, 3, "green") : new Circle(5, "red");
        Shape twin = unknown.copy();
        System.out.println("  copied a " + twin.getClass().getSimpleName() + ": " + twin.describe()
                + ", same object? " + (twin == unknown));

        System.out.println("\n== Prototype registry ==");
        ShapeRegistry registry = new ShapeRegistry();
        registry.register("button-bg", new Rectangle(120, 40, "blue"));
        registry.register("avatar", new Circle(24, "grey"));
        registry.register("badge", new Group().add(new Circle(8, "gold")).add(new Rectangle(30, 10, "gold")));
        Shape b1 = registry.create("badge");
        Shape b2 = registry.create("badge");
        System.out.println("  " + registry.create("button-bg").describe());
        System.out.println("  " + registry.create("avatar").describe());
        System.out.println("  " + b1.describe() + ", two badges distinct? " + (b1 != b2));
    }
}
```

- "Parsing template from disk" prints **once** although three templates exist — the copies skipped the expensive setup.
- The prototype still has only `[email]` — each copy owns its list.
- `ShallowPlaylist` shows the `Cloneable` bug: editing the clone changed the original. `DeepPlaylist` fixes it, but only because `songs` is not `final`.
- `Circle.copy()` returns `Circle` (a covariant return type) — handy when you know the type, while `Shape` callers still get a `Shape`.
- `Group.copy()` recursively copies its children — a deep copy of a composite.
- `ShapeRegistry.create()` always returns `p.copy()`, never the stored prototype, so callers cannot corrupt it.

Output:

```
== Copy instead of re-parsing ==
  Parsing template from disk... (expensive)
  ada       : subject="Welcome, Ada" channels=[email, push]
  grace     : subject="Welcome, Grace" channels=[email, sms]
  prototype : subject="Welcome" channels=[email]   <- unchanged (deep copy of the list)
  templates parsed: 1

== Cloneable pitfall: shallow copy shares the list ==
  original songs after editing the CLONE: [Song A, Song B]   <- bug
  deep clone -> original [Song A], copy [Song A, Song B]

== Polymorphic copy: the caller only knows 'Shape' ==
  copied a Circle: red circle r=5, same object? false

== Prototype registry ==
  blue rectangle 120x40
  grey circle r=24
  group[gold circle r=8, gold rectangle 30x10], two badges distinct? true
```

Trade-offs

Pros	Cons
Costly setup is paid once — the prototype does the parsing/loading; each copy is cheap.	**Every class carries copy code** — and it falls out of date as soon as someone adds a field and forgets the copy.
Create without naming a class — the only option when all you hold is an interface.	**Shallow vs deep must be decided per field** — a wrong call makes two objects secretly share state.
New kinds at run time — configured prototypes can be registered and copied without compiling a class for each (fewer subclasses).	**Cyclic graphs** need special care, or a naive deep copy recurses forever.
Saved starting points — users can keep a template, a filter or a layout and begin new work from it.	**Hazardous for objects with identity** — primary keys (unique row IDs in a database), handles and connections must not be duplicated.
	Uneven language support — some languages offer no built-in cloning, and Java's built-in one (`Cloneable`) is flawed, so you write the copy logic yourself.

Often confused with:

Looks like	The actual difference
Factory Method	Creates a fresh object from nothing, with the type chosen by a subclass. Prototype duplicates an existing instance, so the type comes along automatically.
Builder	Builder puts an object together from parts the caller supplies; Prototype takes a finished object and adjusts only what differs.
Copy constructor	The usual *implementation*. It becomes the pattern when callers use a polymorphic `copy()` without knowing the concrete type.
Object Pool	A pool lends out **existing** objects and takes them back, so identity is reused. Prototype produces **new** objects, so identity is never shared.
Spring `prototype` scope	Despite the name, Spring creates a **new instance** via the constructor on every `getBean()` — it does not clone anything.
JavaScript prototypes	JS prototypal inheritance (the prototype chain) is a language feature for sharing behaviour, not this pattern.

In other languages: Python has `copy.copy()` / `copy.deepcopy()` built in, and `dataclasses.replace(obj, subject="x")` returns a modified copy. JavaScript's spread `{...original, subject: "x"}` is a *shallow* copy (same trap as above), while `structuredClone()` deep-copies plain data. Kotlin/Scala `data class` gives `.copy(subject = "x")`. In C++ the copy constructor is part of the language, and the "rule of zero" means the compiler-generated one copies every member correctly as long as the class owns no raw resources. In Java, a `record` is a natural copy point (all

components are available to a copy constructor or a `withX(...)` method), and a hand-written copy constructor is still preferred to `Cloneable`.

When not to use it

- **Creating from scratch is cheap** — a constructor is clearer and has no copy semantics to get wrong.
- **The object has identity** — duplicating something that holds a database primary key, a socket or an open file yields an object that *looks* fine but is not. Two rows sharing one ID is a far worse bug than a slow constructor.
- **The object graph is large** — a deep copy may cost more than rebuilding and may duplicate things you meant to share, such as a cache.
- **The object is immutable** — no one can change it, so just share the same instance.

Common mistakes

- Shallow-copying a mutable collection (the classic bug).
- Implementing `Cloneable` and trusting `super.clone()`.
- Forgetting to update the copy constructor when adding a field.
- Handing out the registry's original prototype instead of a copy.

Real-world examples

- **JDK:** `Object.clone()` and arrays' `clone()`; `ArrayList.clone()` and `HashMap.clone()` (documented as **shallow** — elements are not copied); copy constructors everywhere: `new ArrayList<>(collection)`, `new HashMap<>(map)`, `new TreeMap<>(sortedMap)`, `new EnumMap<>(enumMap)`; `List.copyOf(...)` for immutable snapshots.
- **Game engines:** Unity's `Instantiate(prefab)` clones a configured "prefab" object to spawn enemies, bullets and so on — load the model, stats and animations once, then copy it for each of the hundreds of enemies on a level.
- **Products:** "Duplicate" in Google Docs/Slides/Figma, "Save as template" / "Use template" in Notion or Jira, saved search filters and report layouts.
- **Tests:** a valid base fixture copied and nudged per test.

In the interview

> **30-second answer:** "Prototype creates objects by copying a configured instance through a `copy()` method on the object. It saves expensive setup and — the deeper reason — it lets me create an object when I only hold an interface. The main decision is shallow vs deep copy per field; sharing a mutable list is the classic bug. In Java I'd write a copy constructor rather than use `Cloneable`, and I'd refuse to copy anything with identity like a DB id or a connection."

- *Q: Why avoid `Cloneable`?* — A: No `clone()` in the interface, protected `Object.clone()`, shallow by default, skips constructors, cannot deep-copy `final` fields, checked exception.
- *Q: How do you deep-copy an object graph with cycles?* — A: Keep an identity map from original → copy; before copying an object, check the map and reuse the copy if it exists.
- *Q: Prototype vs Spring prototype scope?* — A: Spring's scope just means "new instance per request for the bean" — it constructs, it does not clone.
- *Q: Serialization-based deep copy?* — A: Possible (serialize then deserialize) but slow, needs everything `Serializable`, and bypasses constructors — a last resort.

Self-check

- **Q:** What is the difference between shallow and deep copy? **A:** Shallow copies references (mutable parts are shared); deep also copies what they point to.
- **Q:** Why can't `DeepPlaylist` make `songs` final? **A:** `clone()` must reassign it after `super.clone()`, which is impossible for a final field.
- **Q:** What should a prototype registry return? **A:** A copy of the stored prototype, never the original.

TL;DR

Copy a configured object instead of building one — saves setup and works when you only know the interface. Decide shallow vs deep per field. Copy constructors, not `Cloneable`. Never copy things with identity.

8.14 Bonus — Object Pool

What it is

An **Object Pool** keeps a **bounded set of reusable objects**. Instead of creating an object, using it once and throwing it away, a client **borrows** one from the pool (`acquire`), uses it, and **returns** it (`release`) so the next client can reuse it. It is not one of the GoF 23, but it is a well-known creational pattern.

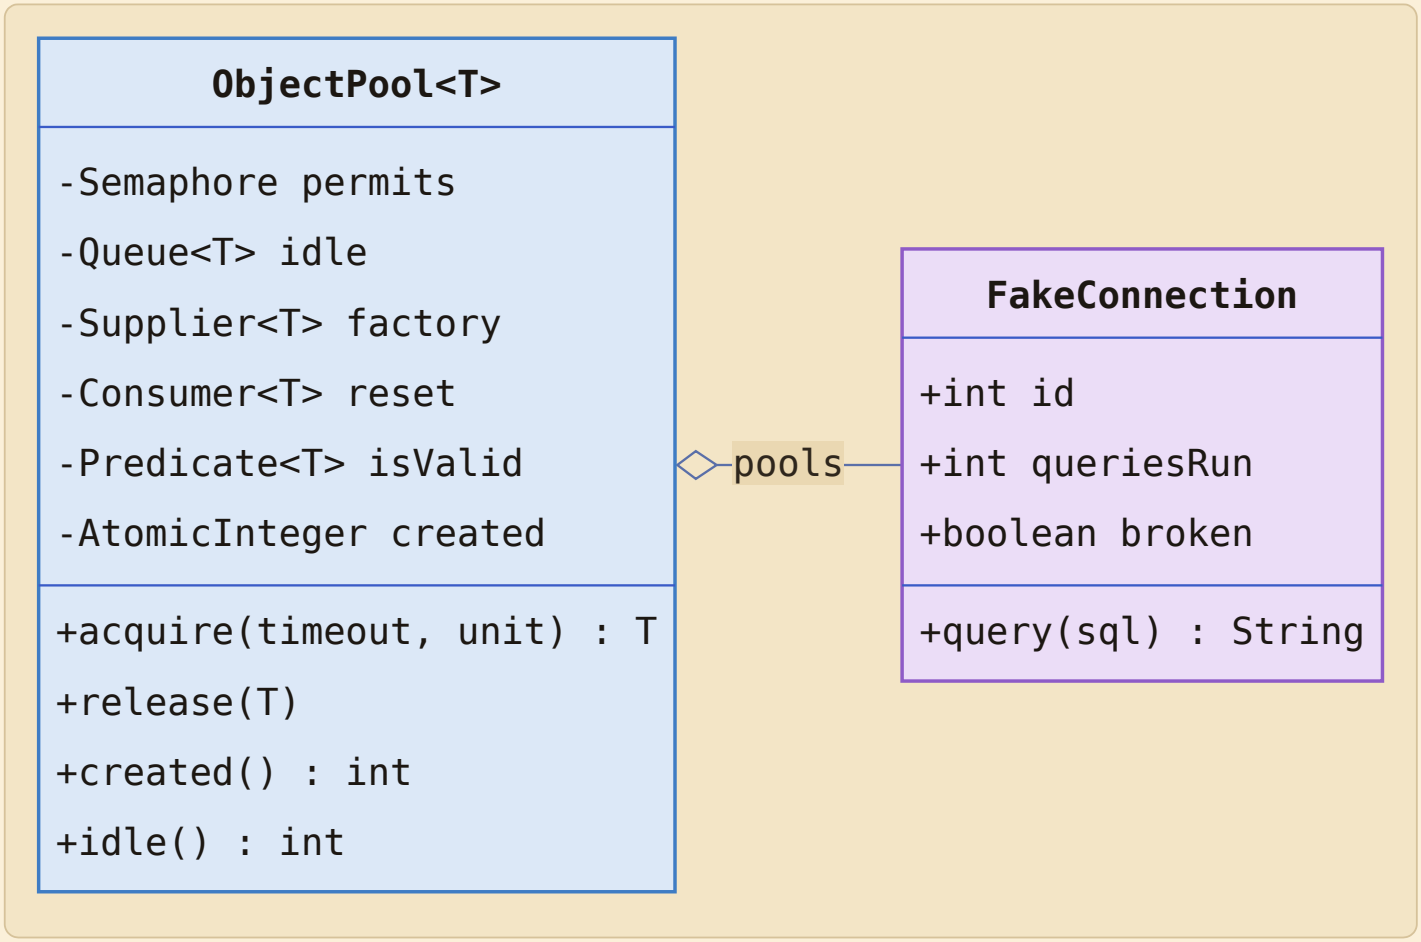
Everyday analogy. A library, or a bike-sharing dock. There are a fixed number of bikes. You take one, ride, and dock it again. If all are out, you wait (or give up after a while). Nobody builds a new bike for every ride.

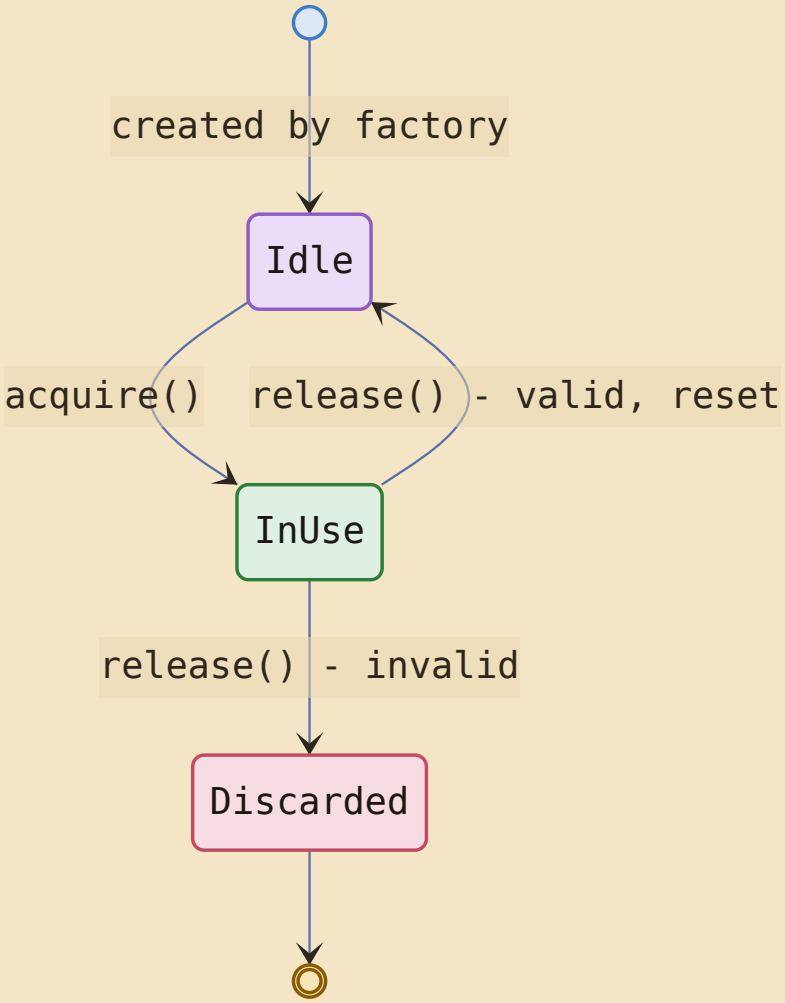
The problem it solves

Some objects are **expensive to create** (a database connection needs a TCP handshake — the back-and-forth that opens a network connection — then TLS, the encryption layer behind `https`, then authentication, proving who you are; see System Design Fundamentals) and/or **limited** (the database accepts only so many connections). Creating one per request is slow and can overwhelm the server. A pool pays the creation cost a few times and **caps** the total.

How it works

1. Keep an **idle queue** (a first-in, first-out waiting line) of ready objects, a count of how many are alive, and a cap on how many may be lent out at once (here a `Semaphore` — a counter of permits that a thread must take before going on and hand back afterwards — with one permit per object).
2. **acquire()**: wait (with a timeout) for a free slot; then take an idle object if there is one, otherwise create a new one. If no slot frees up before the timeout, fail.
3. The client uses the object and **always releases it in a `finally` block** (code that always runs, even if an exception was thrown) — a leaked (never returned) object is gone from the pool forever.
4. **release()**: **validate** the object (is the connection still alive?); if broken, discard it so a fresh one can be made later; otherwise **reset** its state (clear per-borrower data) and put it back. Either way, free the slot.
5. Make all of this **thread-safe** — pools exist *because* many threads compete.





created by factory
Idle
acquire()
release() - valid, reset
InUse
release() - invalid
Discarded

Java implementation

```java
// File: code/lld/ch08/objectpool/ObjectPool.java
package lld.ch08.objectpool;

import java.util.concurrent.ConcurrentLinkedQueue;
import java.util.concurrent.Semaphore;
import java.util.concurrent.TimeUnit;
import java.util.concurrent.atomic.AtomicInteger;
import java.util.function.Consumer;
import java.util.function.Predicate;
import java.util.function.Supplier;

/**
 * A bounded, thread-safe object pool.
 * A Semaphore holds one permit per object that may be lent out, so at most maxSize objects
 * are ever borrowed at once. Objects are created lazily, handed out with acquire(), and
 * returned with release().
 */
public final class ObjectPool<T> {
    private final Semaphore permits;                              // one permit = one object may be borrowed
    private final ConcurrentLinkedQueue<T> idle = new ConcurrentLinkedQueue<>();
    private final Supplier<T> factory;        // how to make a new object
    private final Consumer<T> reset;          // how to clean an object before reuse
    private final Predicate<T> isValid;       // is a returned object still usable?
    private final AtomicInteger created = new AtomicInteger();    // objects currently alive (idle + borrowed)

    public ObjectPool(int maxSize, Supplier<T> factory, Consumer<T> reset, Predicate<T> isValid) {
        if (maxSize <= 0) throw new IllegalArgumentException("maxSize must be positive");
        this.permits = new Semaphore(maxSize, true);              // fair: waiters are served in order
        this.factory = factory;
        this.reset = reset;
        this.isValid = isValid;
    }

    /** Borrow an object, waiting up to the timeout if all are in use. */
    public T acquire(long timeout, TimeUnit unit) throws InterruptedException {
        if (!permits.tryAcquire(timeout, unit)) {
            throw new IllegalStateException("pool exhausted: timed out after " + timeout + " " + unit);
        }
        // Holding a permit guarantees we are within the cap: reuse an idle object or create one.
        T obj = idle.poll();
        if (obj != null) return obj;
        try {
            obj = factory.get();

    static final class FakeConnection {
        private static final AtomicInteger IDS = new AtomicInteger();
        final int id = IDS.incrementAndGet();
        int queriesRun = 0;
        boolean broken = false;
        String query(String sql) { queriesRun++; return "conn#" + id + " ran: " + sql; }
    }

    public static void main(String[] args) throws Exception {
        ObjectPool<FakeConnection> pool = new ObjectPool<>(
                3,
                () -> { System.out.println("  (opening a new connection - expensive)"); return new
FakeConnection(); },
                c -> c.queriesRun = 0,              // reset per-borrower state
                c -> !c.broken);                    // validate on return

        System.out.println("== 10 tasks on 6 threads share at most 3 connections ==");
        List<Integer> usedIds = new CopyOnWriteArrayList<>();
        try (ExecutorService workers = Executors.newFixedThreadPool(6)) {
            List<Future<?>> futures = new ArrayList<>();
            for (int i = 0; i < 10; i++) {
                final int task = i;
                futures.add(workers.submit(() -> {
                    FakeConnection c = pool.acquire(2, TimeUnit.SECONDS);
                    try {                                       // ALWAYS release in finally
                        c.query("SELECT " + task);
                        usedIds.add(c.id);
                        Thread.sleep(20);
                    } finally {
                        pool.release(c);
                    }
                    return null;
                }));
            }
            for (Future<?> f : futures) f.get();
        }
        System.out.println("  tasks finished: " + usedIds.size()
                + ", connections ever created: " + pool.created()
                + ", distinct connections used: " + usedIds.stream().distinct().count());

        System.out.println("\n== A broken connection is discarded, not reused ==");
        FakeConnection c = pool.acquire(1, TimeUnit.SECONDS);
        c.broken = true;
        pool.release(c);
        System.out.println("  created after discarding: " + pool.created() + ", idle: " + pool.idle());

        System.out.println("\n== Exhaustion: borrowers wait, then time out ==");
        List<FakeConnection> held = new ArrayList<>();
        for (int i = 0; i < 3; i++) held.add(pool.acquire(1, TimeUnit.SECONDS));
        try {
            pool.acquire(100, TimeUnit.MILLISECONDS);
        } catch (IllegalStateException e) {
            System.out.println("  " + e.getMessage());
        }
        held.forEach(pool::release);
        System.out.println("  after returning all: idle = " + pool.idle());
```

```
    }
}
```

- A **`Semaphore`** with `maxSize` permits enforces the cap: a borrower must obtain a permit first (`tryAcquire(timeout)` waits with a deadline), so no more than `maxSize` objects can ever be out at once — however many threads race. Holding a permit then means "reuse an idle object if there is one, otherwise it is safe to create one".
- `release()` returns the permit in a `finally` block, **even when the object is discarded** — so a borrower waiting for a slot wakes up and can create a replacement. (A design that only waits on the idle queue would leave that waiter stuck until its timeout although capacity is free.) If the factory throws, `acquire()` gives its permit back too, so a failed creation never shrinks the pool.
- `ConcurrentLinkedQueue` holds the idle objects; handing an object from one thread to another through a concurrent queue (and the semaphore) also makes the previous borrower's writes visible to the next one.
- Validation + reset on `release()` keep broken or dirty objects out.
- `Main` runs 10 tasks on 6 threads with a pool of 3: only 3 connections are ever opened.

Output:

```
== 10 tasks on 6 threads share at most 3 connections ==
  (opening a new connection - expensive)
  (opening a new connection - expensive)
  (opening a new connection - expensive)
  tasks finished: 10, connections ever created: 3, distinct connections used: 3

== A broken connection is discarded, not reused ==
  created after discarding: 2, idle: 2

== Exhaustion: borrowers wait, then time out ==
  (opening a new connection - expensive)
  pool exhausted: timed out after 100 MILLISECONDS
  after returning all: idle = 3
```

Trade-offs

Pros	Cons
Avoids repeated expensive creation	Complexity: sizing, validation, timeouts, leak detection
Caps resource usage (protects the DB)	Leaked (never released) objects shrink the pool until it deadlocks (everyone waits forever)
Predictable latency (time per request) after warm-up	Stale state if reset is incomplete — one user's data leaks to the next
	For cheap objects it is **slower** than `new` — modern JVM allocation and GC (garbage collection — the JVM's automatic memory clean-up) are very fast

When not to use it

- For **cheap** objects (small value objects, `StringBuilder`s) — the JVM allocates them faster than a pool can hand them out.
- For **virtual threads** (Java 21; lightweight threads managed by the JVM, cheap enough to create by the million) — they are cheap by design; create one per task instead of pooling them.
- When a **well-tested library** exists — use HikariCP, Apache Commons Pool 2 or your framework's pool rather than writing your own in production.

Common mistakes

- Not releasing in `finally` (or not using try-with-resources (Java's `try (...)` form that closes things automatically) wrappers).
- Not resetting borrower state.
- Unbounded waits — always use a timeout.
- Returning the same object twice (double release). In our teaching pool that would put one object in the idle queue twice *and* add an extra permit, silently raising the cap; production pools track which objects are

currently borrowed and reject a second release.

Real-world examples

- **Database connection pools:** HikariCP (Spring Boot's default), Apache DBCP, c3p0.
- **Thread pools:** `ThreadPoolExecutor` / `Executors.newFixedThreadPool` reuse worker threads.
- **Apache Commons Pool 2** `GenericObjectPool` (used by Jedis for Redis connections).
- **Netty** `PooledByteBufAllocator` pools buffers to reduce GC pressure.
- Not pools, though often confused: the `String` intern pool and the `Integer` cache (-128..127) share immutable instances — that is **Flyweight** (Chapter 9), nothing is borrowed or returned.

In the interview

> **30-second answer:** "An object pool reuses a bounded set of expensive objects like DB connections. acquire takes an idle one, creates one if under the cap, or waits with a timeout; release validates, resets and returns it. It must be thread-safe, and clients must release in finally. For cheap objects it's counter-productive, and in production I'd use HikariCP."

- *Q: How do you size a pool?* — A: From measured concurrency and downstream limits (the capacity of the services you call, e.g. the database); HikariCP's guidance is that small pools (roughly core-count scale) often beat big ones, because the database can only do so much in parallel.
- *Q: How do you detect leaks?* — A: Record who borrowed each object and when; log if held longer than a threshold (HikariCP's `leakDetectionThreshold` does this).

Self-check

- **Q:** Object Pool vs Flyweight? **A:** Pool lends mutable objects exclusively and takes them back; Flyweight shares immutable objects among everyone at once.
- **Q:** Why validate on release? **A:** So broken objects (dead connections) are discarded instead of handed to the next borrower.

TL;DR

Borrow → use → return (in `finally`). Bounded, thread-safe, validated, reset. Worth it only for expensive or limited resources; use a mature library in production.

8.15 Creational patterns compared

At a glance

Pattern	Distinctive feature	Use when	Course example	JDK / Spring example	Pros	Cons
Singleton	Only one instance of the class exists	One shared resource: configuration, pool, registry	One `ConfigStore` (or one DB connection pool)	`Runtime.getRuntime()`, Spring singleton-scoped beans	Global access; single initialization	Hurts unit testing (testing one class on its own); hidden dependencies; global state
Simple Factory *(idiom)*	One method maps a type value to a class	Small, stable set of types chosen by config	Notification by channel	`Calendar.getInstance()`, `EnumSet.noneOf`, `@Bean` methods	Short, centralizes the switch	Edit it for every new type
Factory Method	Subclasses decide the created type via an overridable method	Shared procedure, varying product; others will add types	PDF / HTML report generator (documents of different types — PDF, Word, HTML…)	`Collection.iterator()`, Spring `FactoryBean`	Open–Closed; decouples creator from products	More classes; needs subclasses
Abstract Factory	Creates *families* of related objects without concrete classes	Products must be compatible; swap a whole set at once	Postgres vs MySQL storage; Windows vs macOS widgets	`DocumentBuilderFactory`, JDBC `Connection`, Spring profiles	Guarantees compatibility; Open–Closed for families	Complex; adding a product kind edits every factory
Builder	Separates construction of a complex object from its representation	Many optional fields, validation, immutability, step-by-step control	`HttpRequest`; building a custom meal	`StringBuilder`, `HttpClient.newBuilder()`, `UriComponentsBuilder`	Step-by-step, readable, immutable, validated	Verbose for simple objects; field duplication; Director optional
Prototype	Creates objects by copying an existing one	Setup is expensive, or only the interface is known	`NotificationTemplate`; cloning a customized car configuration	Copy constructors, `ArrayList.clone()`, Unity `Instantiate`	Skips setup; fewer subclasses; runtime-configured kinds	Deep copy is hard; `Cloneable` is broken; identity issues
Object Pool *(bonus)*	Reuses a bounded set of objects	Expensive or limited resources	DB connections	HikariCP, `ThreadPoolExecutor`	Fast reuse; caps load	Leaks, stale state, pointless for cheap objects

Pick by the question you are asking

You are asking…	Pattern
"How do I make sure there is only one?"	Singleton (or DI singleton scope)
"How do I avoid `new ConcreteClass()` scattered around?"	Simple Factory
"How do I let subclasses/plug-ins decide what to create?"	Factory Method
"How do I make sure these objects always match?"	Abstract Factory
"How do I make this 10-argument constructor readable and safe?"	Builder
"How do I make another one of *this*, cheaply or without knowing its class?"	Prototype
"How do I stop creating and destroying this expensive thing?"	Object Pool

How they combine

- An **Abstract Factory** is often implemented with **Factory Methods**, may use **Prototypes** (a factory configured with prototype objects it copies), and is frequently a **Singleton** (one factory per family) — though passing it in is better.
- A **Builder** can use a **Factory** to pick which parts to build, and a **Director** can be a Singleton-like stateless (keeps no data between calls) service.
- Designs often *start* with Factory Method (simple, subclass-based) and *evolve* towards Abstract Factory, Prototype or Builder as more flexibility is needed.

8.16 Chapter self-check

1. **Q:** Name the three GoF categories and how many patterns each has. **A:** Creational 5, Structural 7, Behavioral 11 = 23.
2. **Q:** Which two principles does the GoF book put at the centre? **A:** Program to an interface, not an implementation; favour composition over inheritance.
3. **Q:** What is the Golden Hammer? **A:** Applying a favourite tool/pattern to every problem regardless of fit.
4. **Q:** Why must the DCL field be `volatile`? **A:** To prevent another thread from seeing a reference to a not-yet-fully-constructed object (it creates a happens-before edge).
5. **Q:** Simple Factory vs Factory Method in one line? **A:** A switch in one method vs a creation hook overridden by subclasses.
6. **Q:** Factory Method vs Abstract Factory in one line? **A:** One product by inheritance vs a family of matching products by composition.
7. **Q:** Builder's single most important method, and why? **A:** `build()` — the one gate that validates cross-field rules and creates the immutable product.
8. **Q:** What is the classic Prototype bug? **A:** A shallow copy sharing a mutable collection with the original.
9. **Q:** Why is `enum` the most robust Java singleton? **A:** The JVM guarantees one instance per constant and blocks reflective creation and serialization duplicates.
10. **Q:** In an interview, how many patterns should a 45-minute design use? **A:** Usually one or two — and name the one you rejected.

8.17 Chapter TL;DR

- **Patterns** are named, proven solution templates with trade-offs — vocabulary first, code second. GoF (1994) catalogued 23 in three categories.
- **Pick from the signal, not the catalogue.** One or two patterns per interview design; always state the cost and the alternative.
- **Singleton** — one per JVM; eager / holder / enum; DCL needs `volatile`; prefer DI.
- **Simple Factory** — one `create(type)`; idiom, not GoF.
- **Factory Method** — base-class procedure + subclass-chosen product.
- **Abstract Factory** — one factory, one matching family; chosen at the composition root.

- **Builder** — named steps, one validating `build()`, immutable product.
- **Prototype** — copy a configured object; decide shallow vs deep; avoid `Cloneable`.
- **Object Pool** — borrow/return expensive objects; use a real library in production.

Chapter 9 — Structural Design Patterns

> **Where this fits.** Chapter 8 was about *creating* objects. This chapter is about *putting objects together*: how to connect, wrap, nest and share them so that larger structures stay flexible. Chapters 10–11 then cover how objects *talk to each other* (behavioral patterns).

What you will learn

#	Pattern	One-line intent	Everyday analogy
9.1	Adapter	Translate a class's interface into the one your code already uses	A travel plug adapter
9.2	Bridge	Separate two independently varying dimensions into two hierarchies joined by a reference	A TV remote (control) and the TV (device) are sold separately
9.3	Composite	Treat one object and a tree of objects the same way	A folder can hold files and other folders
9.4	Decorator	Add behaviour to one object at run time by wrapping it	Toppings on a coffee
9.5	Facade	One simple entry point in front of a complicated subsystem	A hotel concierge
9.6	Flyweight	Share the repeating part of many objects to save memory	One font glyph "e" reused for every "e" on a page
9.7	Proxy	A stand-in with the same interface that controls access	A receptionist who decides whether you may see the manager
9.8	Comparison	Adapter vs Decorator vs Proxy vs Facade vs Bridge	—

How to run every example in this chapter

```
cd chapters/09-patterns-structural/code
javac --release 21 -d /tmp/lld_09 $(find . -name '*.java')
java -cp /tmp/lld_09 lld.ch09.adapter.Main     # or bridge, composite, decorator, facade, flyweight, proxy
```

All seven `Main` classes compile with Java 21 (standard library only — the classes that ship with Java itself) and run. The output printed under each example is the real output of that program.

> **Code-style note.** Every top-level type has its own file, as in a real codebase, and the types are package-private (visible only to classes in the same package — a package being a named folder of related classes) because each example lives in one package. Where a section shows several short files in a row, read them top to bottom: interface first, then implementations, then `Main`. The whole folder compiles with `javac --release 21 -Xlint:all` with **zero warnings**.

9.0 What structural patterns are

What it is

A **design pattern** is a named, reusable solution to a design problem that keeps coming back. The "Gang of Four" (GoF) book — *Design Patterns: Elements of Reusable Object-Oriented Software* (Gamma, Helm, Johnson, Vlissides, 1994) — sorted its 23 patterns into three families:

Family	Question it answers	Examples
Creational (Ch. 8)	How do I create objects?	Singleton, Factory Method, Builder
Structural (this chapter)	**How do I combine classes and objects into bigger structures?**	**Adapter, Bridge, Composite, Decorator, Facade, Flyweight, Proxy**
Behavioral (Ch. 10–11)	How do objects share work and talk?	Strategy, Observer, Command

Structural patterns help you combine small objects and classes into larger, more complex structures while keeping those structures flexible and efficient. Used well, they:

- **simplify complex structures** (a Facade hides many steps; a Composite hides nesting),
- **promote reuse** (an Adapter lets you reuse a class whose interface does not fit),
- **improve flexibility by decoupling** classes from each other — i.e. reducing how much each one depends on the others' details (Bridge, Decorator, Proxy),
- **improve maintainability**, because the relationships between entities are clear and each change stays local.

There are many structural patterns, but the seven the GoF named — and that interviewers ask about — are **Adapter, Bridge, Composite, Decorator, Facade, Flyweight and Proxy**.

Three words you need first

- **Composition** ("has-a"): an object holds a reference to another object and uses it. Almost every structural pattern is built on composition.
- **Delegation**: forwarding a call to the object you hold. `wrapper.pay()` calls `inner.charge()`.
- **Interface** (in the design sense): the set of methods a caller can use on an object. In Java this is often, but not always, an `interface` type.

> **Key insight.** Four of these patterns (Adapter, Decorator, Proxy, Facade) have the *same physical shape*: one object holds another and forwards calls to it. What tells them apart is **intent** — what changes as the call passes through. Keep this in mind; section 9.8 puts them side by side.

9.1 Adapter Pattern

What it is

The **Adapter** pattern lets your code use a class whose methods have the "wrong" shape — one you are not able to change — by placing a small translator class between the two. GoF's intent: *convert the interface of a class into another interface clients expect; Adapter lets classes work together that couldn't otherwise because of incompatible interfaces.*

Analogy: your laptop charger has a US plug; the hotel wall in India has a different socket. You do not rewire the wall or cut the plug — you put a small travel adapter in between.

GoF also calls it **Wrapper**. Vocabulary:

Term	Meaning
Target	The interface your code wants to use (`PaymentGateway`).
Adaptee	The existing class with the "wrong" interface (`StripeClient`). You usually do not own it.
Adapter	The class that implements the Target and translates calls to the Adaptee (`StripeGateway`).
Client	Code that uses the Target (`checkout`).

The problem it solves

The shape your code calls and the shape the other component offers do not match. Typical cases:

- your checkout wants to call `pay(Money)`, but the payment SDK (software development kit — the vendor's ready-made client library) only offers `charge(amountInCents, currencyCode)`;

- an old service answers in XML, yet every consumer after it works with JSON (XML and JSON are two common text formats for structured data);
- the analytics library asks for `track(String, Map)`, while your code naturally produces an `Event` object.

The key constraint: **the other side is not yours to change.** It may be a third-party library (code written and owned by an outside company or project), a service owned by another team, or code with dozens of existing callers. Bending *your* code to its shape means touching every call site (each place in the code that calls the method) — and repeating the whole exercise the day that vendor is swapped out.

A concrete version: the checkout has to support Stripe now and perhaps PayPal in a few months (both are online payment providers). Stripe expects the amount as a whole number of **cents** plus a **lowercase** currency code; PayPal expects a **decimal string** such as "42.50" plus an **uppercase** code. Your own code would rather reason about a `Money` value than either of those.

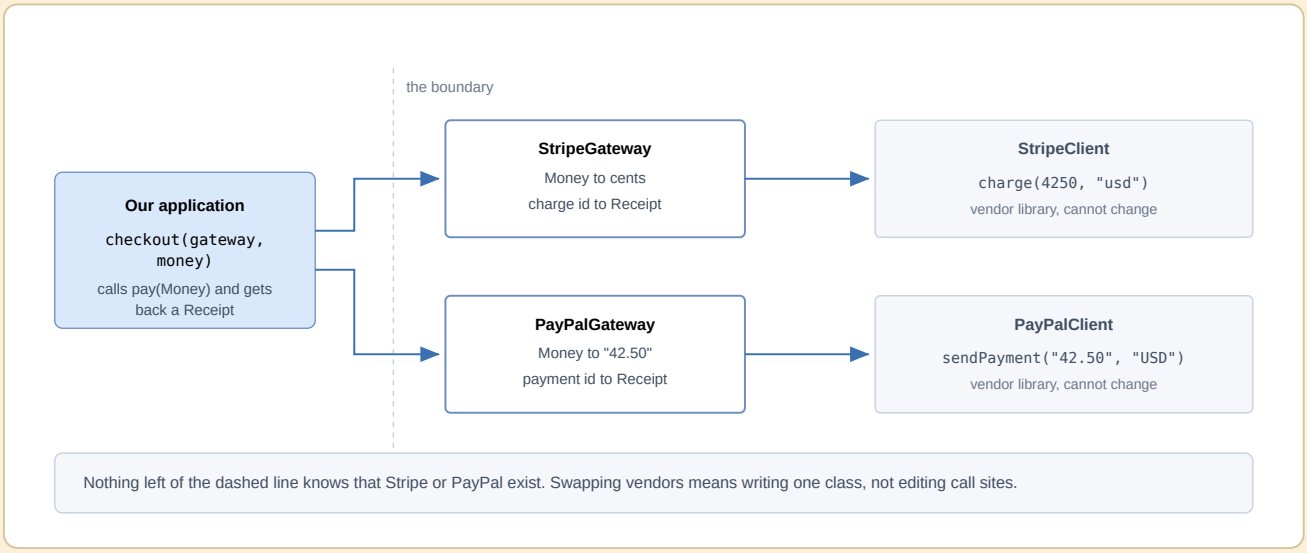

Figure — Two adapters (StripeGateway, PayPalGateway) translate our `pay(Money)` into each vendor's own call; nothing on the application side knows which vendor exists (course diagram)

In the figure above, everything to the left of the dashed boundary talks only in `Money` and `Receipt`. Swapping vendors means writing one new class, not touching call sites.

How it works

1. **Define the Target interface in your own vocabulary** (`PaymentGateway.pay(Money) -> Receipt`). It mentions no vendor.
2. **Write one adapter class per adaptee.** It `implements` the Target and **holds** the vendor object.
3. **Translate inputs**: your types into the vendor's types (`Money` → cents + lowercase code).
4. **Call the adaptee.**
5. **Translate outputs and errors back**: vendor result → `Receipt`; vendor exception → *your* exception.
6. **Client code depends only on the Target**, so it never learns which vendor answered.

> **The rule that makes it work:** the adapter's public methods mention **only your types** — parameters, return values *and* exceptions. The moment `pay` hands back a `StripeCharge`, or lets a `StripeCardException` propagate (travel up, uncaught, to the callers), callers depend on Stripe again and the adapter has decoupled nothing.

Structure

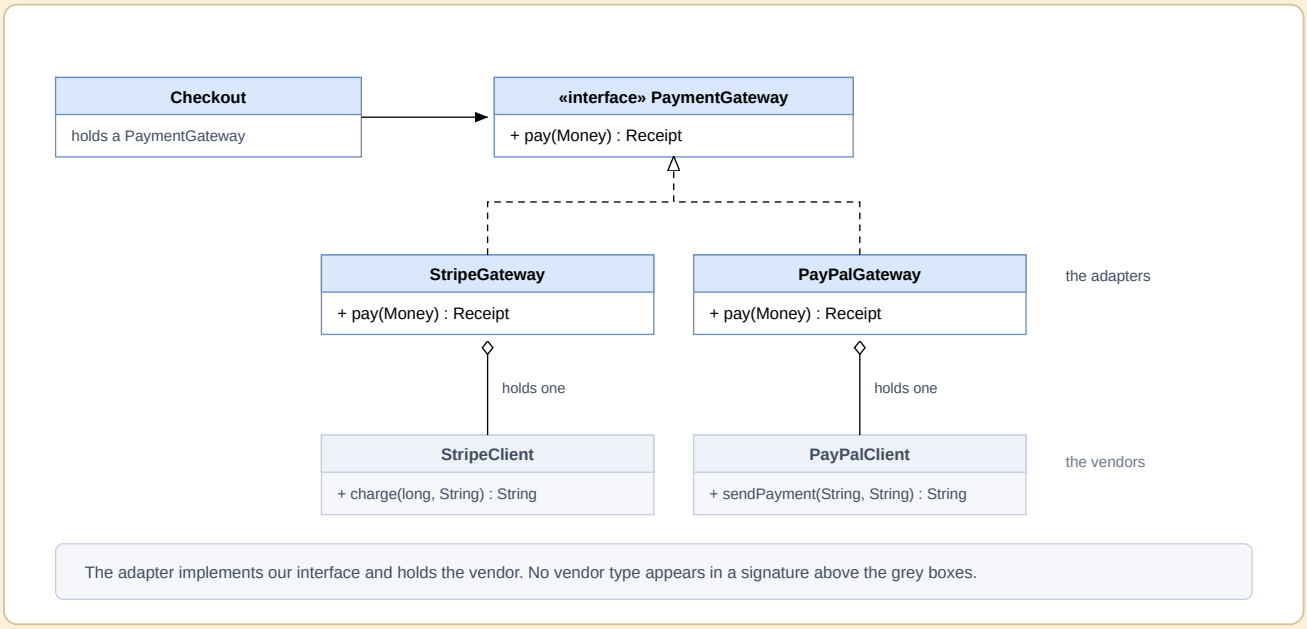

Figure — Adapter class diagram: `Checkout` holds a `PaymentGateway`; `StripeGateway` and `PayPalGateway` implement it and each wrap a vendor client, shown in grey because we do not own them (course diagram)

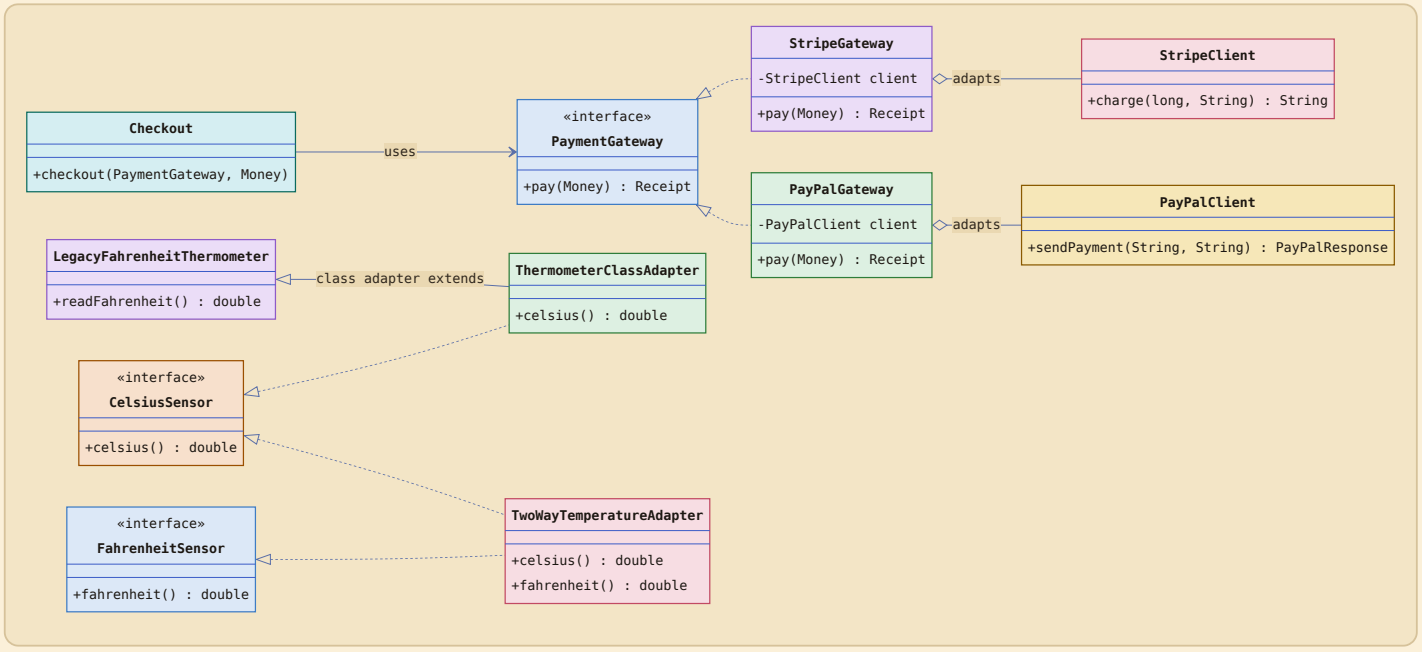
Reading the class diagram above: `PaymentGateway` is the Target, owned by your application; `StripeGateway` and `PayPalGateway` are the Adapters; `StripeClient` and `PayPalClient` are the Adaptees (third-party code); `Checkout` stands for any Client. Every mismatch — method names, parameter types, casing rules — is soaked up inside the two adapter classes, and nothing above them sees it.

Our Java design (including the class and two-way adapters):



Java example

```java
// File: code/lld/ch09/adapter/Money.java
package lld.ch09.adapter;

import java.util.Locale;

/** Our own vocabulary. No vendor type ever appears here. */
record Money(long cents, String currency) {
    Money {
        if (cents < 0) throw new IllegalArgumentException("negative amount");
        currency = currency.toUpperCase(Locale.ROOT);
    }

    /** 4250 cents -> "42.50" */
    String asDecimal() {
        return String.format(Locale.ROOT, "%d.%02d", cents / 100, cents % 100);
    }
}
```

```java
// File: code/lld/ch09/adapter/Receipt.java
package lld.ch09.adapter;

record Receipt(String id, String status) { }
```

```java
// File: code/lld/ch09/adapter/PaymentFailedException.java
package lld.ch09.adapter;

import java.io.Serial;

/** Our exception type: callers never see a vendor exception. */
class PaymentFailedException extends RuntimeException {
    @Serial private static final long serialVersionUID = 1L;

    PaymentFailedException(String message, Throwable cause) { super(message, cause); }
}
```

```java
// File: code/lld/ch09/adapter/PaymentGateway.java
package lld.ch09.adapter;

/** TARGET interface: the shape our application wants to talk to. */
interface PaymentGateway {
    Receipt pay(Money amount);
}
```

```java
// File: code/lld/ch09/adapter/StripeClient.java
package lld.ch09.adapter;

/*
 * ADAPTEES: pretend these come from third-party jars we cannot edit.
 * Note the different method names, argument types and conventions.
 */

/** Stripe-like SDK: integer cents + lowercase currency, throws its own exception. */
final class StripeClient {
    private int next = 1001;

    String charge(long amountInCents, String currencyCode) {
        System.out.printf("  [stripe] charge(%d, \"%s\")%n", amountInCents, currencyCode);
        if (amountInCents > 100_000) throw new StripeCardException("card_declined");
        return "ch_" + next++;
    }
}
```

```java
// File: code/lld/ch09/adapter/StripeCardException.java
package lld.ch09.adapter;

import java.io.Serial;

final class StripeCardException extends RuntimeException {
    @Serial private static final long serialVersionUID = 1L;

    StripeCardException(String code) { super(code); }
}
```

```java
// File: code/lld/ch09/adapter/PayPalClient.java
package lld.ch09.adapter;

/** PayPal-like SDK: decimal string + uppercase currency, returns a response object. */
final class PayPalClient {
    record PayPalResponse(String paymentId, String state) { }

    PayPalResponse sendPayment(String total, String currency) {
        System.out.printf("  [paypal] sendPayment(\"%s\", \"%s\")%n", total, currency);
        return new PayPalResponse("PAY-" + total.replace(".", ""), "approved");
    }
}
```

```java
// File: code/lld/ch09/adapter/StripeGateway.java
package lld.ch09.adapter;

import java.util.Locale;

/** OBJECT ADAPTER: implements our interface, HOLDS the vendor object (composition). */
final class StripeGateway implements PaymentGateway {
    private final StripeClient client;

    StripeGateway(StripeClient client) { this.client = client; }

    @Override
    public Receipt pay(Money amount) {
        try {
            String chargeId = client.charge(amount.cents(), amount.currency().toLowerCase(Locale.ROOT));
            return new Receipt(chargeId, "SUCCEEDED");
        } catch (StripeCardException e) {               // translate the vendor's error too
            throw new PaymentFailedException("Stripe declined: " + e.getMessage(), e);
        }
    }
}
```

```java
// File: code/lld/ch09/adapter/PayPalGateway.java
package lld.ch09.adapter;

final class PayPalGateway implements PaymentGateway {
    private final PayPalClient client;

    PayPalGateway(PayPalClient client) { this.client = client; }

    @Override
    public Receipt pay(Money amount) {
        PayPalClient.PayPalResponse r = client.sendPayment(amount.asDecimal(), amount.currency());
        String status = "approved".equals(r.state()) ? "SUCCEEDED" : "FAILED";
        return new Receipt(r.paymentId(), status);
    }
}
```

```java
// File: code/lld/ch09/adapter/CelsiusSensor.java
package lld.ch09.adapter;

/** Target used by our new weather dashboard. */
interface CelsiusSensor {
    double celsius();
}
```

```java
// File: code/lld/ch09/adapter/FahrenheitSensor.java
package lld.ch09.adapter;

/** Interface used by an old US reporting module. */
interface FahrenheitSensor {
    double fahrenheit();
}
```

```java
// File: code/lld/ch09/adapter/LegacyFahrenheitThermometer.java
package lld.ch09.adapter;

/** A legacy class we cannot change. It is NOT final, so a class adapter can extend it. */
class LegacyFahrenheitThermometer {
    private final double reading;

    LegacyFahrenheitThermometer(double reading) { this.reading = reading; }

    public double readFahrenheit() { return reading; }
}
```

```java
// File: code/lld/ch09/adapter/ThermometerClassAdapter.java
package lld.ch09.adapter;

/**
 * CLASS ADAPTER: inherits from the adaptee and implements the target.
 * Works in Java only because the target is an interface (no multiple class inheritance).
 */
final class ThermometerClassAdapter extends LegacyFahrenheitThermometer implements CelsiusSensor {
    ThermometerClassAdapter(double fahrenheit) { super(fahrenheit); }

    @Override
    public double celsius() { return (readFahrenheit() - 32) * 5.0 / 9.0; }
    // Downside: readFahrenheit() is still public on this object -> the adaptee's API leaks.
}
```

```java
// File: code/lld/ch09/adapter/TwoWayTemperatureAdapter.java
package lld.ch09.adapter;

/**
 * TWO-WAY ADAPTER: implements BOTH interfaces, so the same object can be handed to
 * new code (wants Celsius) and old code (wants Fahrenheit).
 */
final class TwoWayTemperatureAdapter implements CelsiusSensor, FahrenheitSensor {
    private final double celsius;

    private TwoWayTemperatureAdapter(double celsius) { this.celsius = celsius; }

    static TwoWayTemperatureAdapter from(CelsiusSensor s) {
        return new TwoWayTemperatureAdapter(s.celsius());
    }

    static TwoWayTemperatureAdapter from(FahrenheitSensor s) {
        return new TwoWayTemperatureAdapter((s.fahrenheit() - 32) * 5.0 / 9.0);
    }

    @Override public double celsius()    { return celsius; }
    @Override public double fahrenheit() { return celsius * 9.0 / 5.0 + 32; }
}
```

```java
// File: code/lld/ch09/adapter/Main.java
package lld.ch09.adapter;

import java.io.BufferedReader;
import java.io.ByteArrayInputStream;
import java.io.IOException;
import java.io.InputStreamReader;
import java.nio.charset.StandardCharsets;
import java.util.Arrays;
import java.util.List;

public class Main {

    /** Client code: talks only to OUR interface and never names a vendor. */
    static void checkout(PaymentGateway gateway, Money amount) {
        try {
            Receipt r = gateway.pay(amount);
            System.out.println("  receipt " + r.id() + " " + r.status());
        } catch (PaymentFailedException e) {
            System.out.println("  payment failed -> " + e.getMessage());
        }
    }

    public static void main(String[] args) throws IOException {
        System.out.println("== Object adapters (payment) ==");
        Money amount = new Money(4250, "usd");
        checkout(new StripeGateway(new StripeClient()), amount);
        checkout(new PayPalGateway(new PayPalClient()), amount);
        checkout(new StripeGateway(new StripeClient()), new Money(250_000, "USD"));

        System.out.println("== Class adapter ==");
        CelsiusSensor s = new ThermometerClassAdapter(98.6);
        System.out.printf("  98.6F -> %.1fC%n", s.celsius());

        System.out.println("== Two-way adapter ==");
        FahrenheitSensor oldSensor = () -> 212.0;
        TwoWayTemperatureAdapter both = TwoWayTemperatureAdapter.from(oldSensor);
        CelsiusSensor forNewCode = both;
        FahrenheitSensor forOldCode = both;
        System.out.printf("  new code sees %.1fC, old code sees %.1fF%n",
                forNewCode.celsius(), forOldCode.fahrenheit());

        System.out.println("== JDK adapters ==");
        String[] array = {"a", "b", "c"};
        List<String> view = Arrays.asList(array);   // adapts array -> List, no copy
        array[0] = "z";
        System.out.println("  Arrays.asList sees array change: " + view);
        try {
            view.add("d");
        } catch (UnsupportedOperationException e) {
            System.out.println("  cannot resize an array-backed list: UnsupportedOperationException");
        }
        var bytes = new ByteArrayInputStream("héllo".getBytes(StandardCharsets.UTF_8));
        // InputStreamReader adapts a byte stream (InputStream) to a char stream (Reader)
        try (var reader = new BufferedReader(new InputStreamReader(bytes, StandardCharsets.UTF_8))) {
            System.out.println("  InputStreamReader decoded: " + reader.readLine());
        }
    }
}
```

Output:

```
== Object adapters (payment) ==
  [stripe] charge(4250, "usd")
  receipt ch_1001 SUCCEEDED
  [paypal] sendPayment("42.50", "USD")
  receipt PAY-4250 SUCCEEDED
  [stripe] charge(250000, "usd")
  payment failed -> Stripe declined: card_declined

== Two-way adapter ==
  new code sees 100.0C, old code sees 212.0F
== JDK adapters ==
  Arrays.asList sees array change: [z, b, c]
  cannot resize an array-backed list: UnsupportedOperationException
  InputStreamReader decoded: héllo
```

What each part does

- `Money`, `Receipt`, `PaymentGateway`, `PaymentFailedException` — **our** vocabulary. The compact constructor (a constructor with no parameter list that runs on every creation) of the `Money` record (Java's short syntax for a data class whose fields cannot change) normalises the currency to upper case once, so every adapter can rely on it.
- `StripeClient`, `PayPalClient` — the **adaptees**. Different method names, argument types, casing and error styles. We treat them as untouchable.
- `StripeGateway` — an **object adapter**. It converts `Money` into `(cents, "usd")`, converts the returned charge id into a `Receipt`, and converts `StripeCardException` into `PaymentFailedException`. The third call in the output shows that translation: the client sees *our* error type.
- `PayPalGateway` — the same idea with a different translation (`Money.asDecimal()` → "42.50"; `"approved"` → `"SUCCEEDED"`).
- `checkout(...)` — the **client**. One function, two completely different vendors, and no `if (stripe)` branch anywhere.
- The JDK section shows two adapters you already use: `Arrays.asList` and `InputStreamReader`.

Object adapter vs class adapter

GoF describes two ways to build an adapter:

	Object adapter (composition)	**Class adapter (inheritance)**
How	Adapter *holds* an adaptee instance and implements the Target	Adapter *extends* the adaptee class and implements the Target
In our code	`StripeGateway`, `PayPalGateway`	`ThermometerClassAdapter extends LegacyFahrenheitThermometer implements CelsiusSensor`
Works when adaptee is `final`?	Yes	**No** — you cannot extend a final class (our `StripeClient` is `final`)
Can adapt a whole family (adaptee + subclasses)?	Yes — pass any subclass instance in	No — bound to one concrete class at compile time (fixed when the code is compiled)
Can override adaptee behaviour?	Harder — you would have to subclass the adaptee and adapt that subclass	Yes (it is a subclass)
Leaks the adaptee's API (its public methods)?	No — only the Target methods are visible	**Yes** — every public adaptee method (e.g. `readFahrenheit()`) is also on the adapter
Java constraint	none	Java has no multiple class inheritance (extending two classes at once), so the **Target must be an interface**

Rule of thumb: prefer the **object adapter**. It follows "favour composition over inheritance", works with final classes, can wrap several objects, and does not inherit methods you did not want. Use a class adapter only when you must override some adaptee behaviour and the adaptee is designed for extension.

Two-way adapter

A **two-way adapter** implements *both* interfaces, so the same object can be given to clients of either side. GoF mentions it for the case where two different clients need to view one object in two different ways.

In the code, `TwoWayTemperatureAdapter implements CelsiusSensor, FahrenheitSensor`. It can be built from either kind of sensor. New dashboard code sees `100.0C`; old US reporting code sees `212.0F` — the same object. This is handy during a **migration** (gradually moving code from an old system to a new one): old and new modules can share one object while you gradually move callers across.

Adapter vs Facade vs Decorator vs Proxy (quick view)

Pattern	What happens to the interface	What happens to the behaviour
Adapter	**Translated** — the client sees your interface, the wrapped object keeps its own	Same work, just re-expressed
Decorator	Kept identical on both sides	**Extended** — extra work runs around the call
Proxy	Kept identical	Same work, but **gated** — it may be postponed, served from a cache (a store of earlier results kept for quick reuse) or rejected
Facade	**Replaced** — a single simpler interface stands in for many	Same work, fewer calls for the client

In one line each: translating shapes → **Adapter**; adding work, same shape → **Decorator**; guarding access, same shape and same work → **Proxy**; one simple door in front of several objects → **Facade**.

A useful test: *adapters exist because someone else picked the interface.* Imagine the vendor rewrote its API tomorrow to match yours exactly — if your class would then have no reason to exist, it was an Adapter. The other three exist because you decided to add something. Bridge can be drawn with the same boxes, but its timing is reversed: a Bridge is planned *before* the classes exist so two hierarchies never fuse; an Adapter is bolted on *after* to reconcile two things that already exist.

Trade-offs

Pros	Cons
The foreign format is contained — only one class knows the vendor's conventions.	**An extra class and an extra call** — stack traces (the list of calls printed when an error happens) gain a frame (one entry in that list) whose only job is conversion.
Changing vendor is local — supporting PayPal beside Stripe means adding a class, not editing callers (Open/Closed Principle — open for extension, closed for modification).	**Conversions can drop information**, and callers cannot see that anything was lost.
Easy to test — faking your own one-method interface is far simpler than faking a vendor SDK.	**Two data models must stay aligned** — each vendor API change forces a mapping change.
Your code keeps its own language (`Money`, `Receipt` rather than cents and charge ids); conversion has a single home (Single Responsibility — one reason to change per class).	**Logic tends to creep in** — retries (automatically re-trying a failed call) and pricing rules drift into the adapter unless reviews stop them.

When not to use it

- **Both sides are yours.** Change one interface so they match. An adapter between two pieces of code you own is overhead you pay forever for a mismatch you could simply remove.
- **The two models really disagree.** When mapping one to the other drops data or forces guesses, the "adapter" grows into a mini-application with bugs of its own; redraw the boundary instead.
- **You want extra behaviour, not a translation.** That job belongs to a Decorator.
- **The conversion happens in exactly one place.** A few inline lines read better than a new class.

Common mistakes

- **Leaking vendor types** (`StripeCharge` return type, `StripeCardException` escaping). Then nothing is decoupled.
- **Putting business logic in the adapter** (discount rules, retries). Adapters translate; they do not decide.
- **Choosing a class adapter by default** — it exposes the adaptee's whole API and breaks on `final` classes.

- **One giant adapter for many vendors** with `if (vendor == STRIPE)` inside — that is the branch the pattern was meant to remove. One adapter per adaptee.
- **Silently dropping information** (e.g. vendor's "pending" state mapped to "SUCCEEDED"). Map every case deliberately.

Real-world examples

- **`java.util.Arrays.asList(T...)`** adapts an array to the `List` interface *without copying* — writes go through to the array (as the output shows) and the list cannot grow, so `add` throws `UnsupportedOperationException`.
- **`java.io.InputStreamReader` / `OutputStreamWriter`** adapt byte streams (raw bytes read one after another) to character streams (text) using a charset (the rule that maps bytes to characters, e.g. UTF-8).
- **`java.util.Collections.enumeration(Collection)`** adapts a modern `Collection` to the legacy (old but still supported) `Enumeration` interface. (*Head First Design Patterns* builds the reverse, an Enumeration-to-Iterator adapter.)
- **SLF4J providers/bindings** — SLF4J (Simple Logging Facade for Java) is one logging API, with an adapter module for each backend (the library that actually writes the log lines) (Logback, Log4j, `java.util.logging`).
- **JDBC (and ODBC) drivers** (JDBC is Java's standard database API; a driver is the library for one particular database) adapt each database's own wire protocol (the exact bytes it sends over the network) to the standard `java.sql` interfaces, which is why the same application code runs on several databases.
- **Spring MVC `HandlerAdapter`** lets the `DispatcherServlet` (the central object in Spring MVC, Spring's web framework, that receives every web request) invoke very different kinds of handlers (annotated controllers, `HttpRequestHandler`, etc.) through one interface.
- **Almost every "client" wrapper around a vendor SDK** in a real codebase — if it exists so the rest of the code does not import the SDK, it is an adapter.

In modern languages

- **First-class functions** (functions that can be stored in variables and passed around like values): if the Target has a single method, a **lambda** (a short unnamed function) is a complete adapter — `PaymentGateway g = m -> new Receipt(stripe.charge(m.cents(), "usd"), "SUCCEEDED");` (our `FahrenheitSensor oldSensor = () -> 212.0;` is the same trick).
- **Python**: duck typing ("if it has the right methods, it fits" — checked when the code runs, never declared) means any object with the expected method names fits, so a small wrapper class — or even a `types.SimpleNamespace` — is enough.
- **TypeScript**: structural typing accepts anything of the right shape, so adapters are frequently plain object literals (objects written inline as `{ ... }`).
- **Go**: interfaces are satisfied implicitly (a type that has the methods automatically counts — no `implements` needed), so the adapter is often just a small named type with one method.

In the interview

> **30-second answer:** "An Adapter converts one interface into another that the client expects. I use it at boundaries I do not control — a vendor SDK, a legacy service. The adapter implements *my* interface, holds the vendor object, and translates inputs, outputs and exceptions, so no vendor type leaks into my code. Swapping vendors becomes one new class. I prefer the object adapter over the class adapter because it uses composition and works with final classes."

Follow-ups

- *Q: Adapter vs Decorator?* — A: Adapter changes the interface and keeps the behaviour. Decorator keeps the interface and changes (adds to) the behaviour.
- *Q: Adapter vs Facade?* — A: An Adapter converts **one** interface to **one** other, usually because you only own one side. A Facade simplifies a **whole subsystem** of several objects into one entry point, usually over code you own.
- *Q: Why not just change the other side?* — A: Say this up front, unprompted: it is a vendor library, another team's API, or code with many callers. That constraint is what justifies the pattern — without it you are pattern-matching out of habit.
- *Q: What ruins an adapter?* — A: A vendor type or vendor exception in the adapter's public signature.
- *Q: How does it help testing?* — A: The checkout depends on a small interface I own, so in tests I pass a fake `PaymentGateway`; I never have to fake the vendor SDK.

- *Q: What is a two-way adapter?* — A: One class implementing both interfaces so it can serve clients of either side, useful during migrations.

Self-check

1. **Q:** Name the four roles in the Adapter pattern. **A:** Target, Adaptee, Adapter, Client.
2. **Q:** Why is `StripeClient` impossible to class-adapt in our code? **A:** It is `final`; a class adapter must extend the adaptee.
3. **Q:** What does `Arrays.asList(arr).add(x)` do, and why? **A:** Throws `UnsupportedOperationException`, because the list is a fixed-size view (adapter) over the array.
4. **Q:** You own both classes and their interfaces differ slightly. Adapter? **A:** No — change the interface; an adapter would be permanent overhead.
5. **Q:** Where should the vendor's exception be handled? **A:** Inside the adapter, translated into your own exception type.

TL;DR

- **Adapter = translator** between the interface you have and the interface you need.
- Implements **your** interface, **holds** the vendor object, translates **in, out and errors**.
- Prefer **object adapter** (composition) over **class adapter** (inheritance). Two-way adapters implement both sides.
- Use at boundaries you **don't control**; skip it when you own both sides.

9.2 Bridge Pattern

What it is

The **Bridge** pattern splits one class that varies in *two independent ways* into **two separate hierarchies** connected by a reference (the "bridge"), so each side can grow on its own.

Analogy: a universal TV remote. Remotes come in kinds (basic, advanced with mute); TVs come in brands (Sony, Samsung). You do not buy a "BasicSonyRemote" — any remote works any TV through a common protocol (an agreed set of signals).

GoF's intent: *decouple an abstraction from its implementation so that the two can vary independently.* GoF also lists **Handle/Body** as another name for it. Its names for the parts — the vocabulary interviewers expect:

Term	Meaning	In our code
Abstraction	The high-level side the client uses; holds a reference to an Implementor	`Notification`
Refined Abstraction	Subclasses of the abstraction	`AlertNotification`, `ReminderNotification`, `DigestNotification`
Implementor	The interface of the low-level side that does the physical work	`Channel`
Concrete Implementor	Real implementations of that low-level work	`EmailChannel`, `SmsChannel`, `PushChannel`

> **Naming trap.** In Bridge, "implementation" is *not* the everyday Java meaning ("a class that implements an interface"). It names the **low-level half of the split** — the side that does the platform-specific, physical work (sending bytes, drawing pixels). The GoF terms are awkward, but they are the ones you will be asked about.

The problem it solves — the class explosion

You have three kinds of notification (alert, reminder, digest) and three delivery channels (email, SMS, push). If both live in **one** inheritance hierarchy you need a class for every combination:

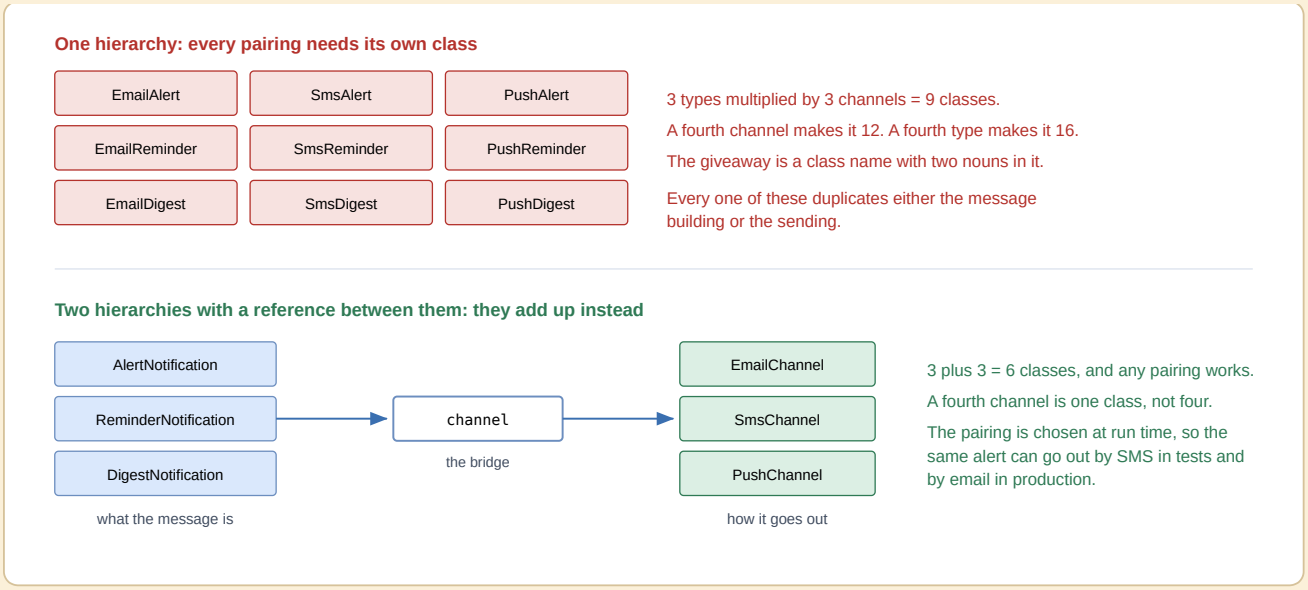

Figure — Top: one hierarchy needs 3 × 3 = 9 classes such as EmailAlert and SmsDigest. Bottom: two hierarchies joined by one `channel` reference need 3 + 3 = 6 (course diagram)

The figure shows the arithmetic. In a single hierarchy the concrete classes **multiply**: 3 × 3 = 9; one more channel gives 12; one more type on top gives 16. With a bridge they **add**: 3 + 3 = 6, and 4 + 4 = 8. (Counts are concrete classes; the `Notification` base and the `Channel` interface are the same in both designs.)

The **smell** (code smell: a surface symptom that hints at a deeper design problem) that points to a missing Bridge is **a class name made of two nouns** — `EmailAlert`, `SmsDigest`, `PushReminder`. Each such class repeats either the "build the message" code or the "send it" code, so changing how SMS delivery works means editing three classes that otherwise have nothing in common.

Splitting the two dimensions has one more pay-off: the pairing becomes a **run-time choice**. The same alert object can be built with an SMS channel in a test and an email channel in production (the live system real users depend on). The code is small; the genuinely hard part is deciding **which dimension is the abstraction and which is the implementation** (see "Getting the split wrong" below).

How it works

1. **Find the two dimensions** that vary independently (what the message *is* vs how it *goes out*).
2. **Make the lower-level dimension an interface** — the Implementor (`Channel.deliver(title, body)`). Keep it small and general.
3. **Make the higher-level dimension an abstract class** — the Abstraction — that **holds a reference** to the Implementor. That field is the bridge.
4. **Refined abstractions** build their own content and **delegate** the physical work across the bridge. They never check which implementor they have.
5. **Pair them at run time**: `new AlertNotification(new SmsChannel(...), ...)`. The same alert can go by SMS in a test and by email in production.

Structure

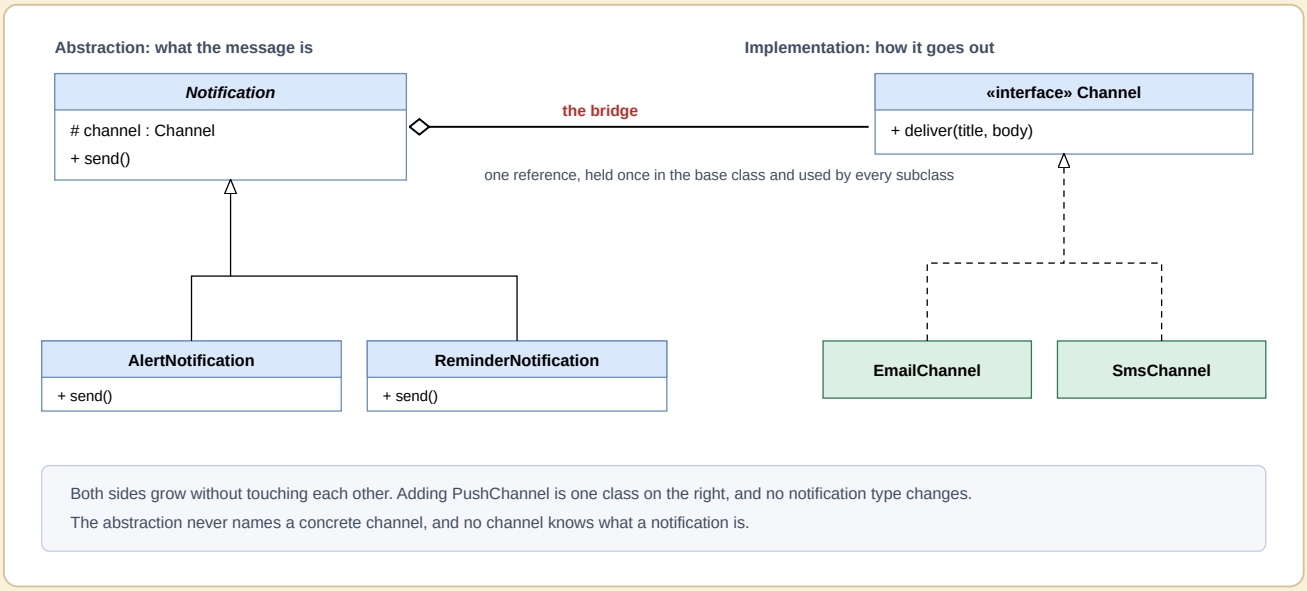

Figure — Bridge class diagram: `Notification` (abstraction) holds a `Channel` (implementor); alert/reminder notifications refine the abstraction; email/SMS channels implement the channel (course diagram)

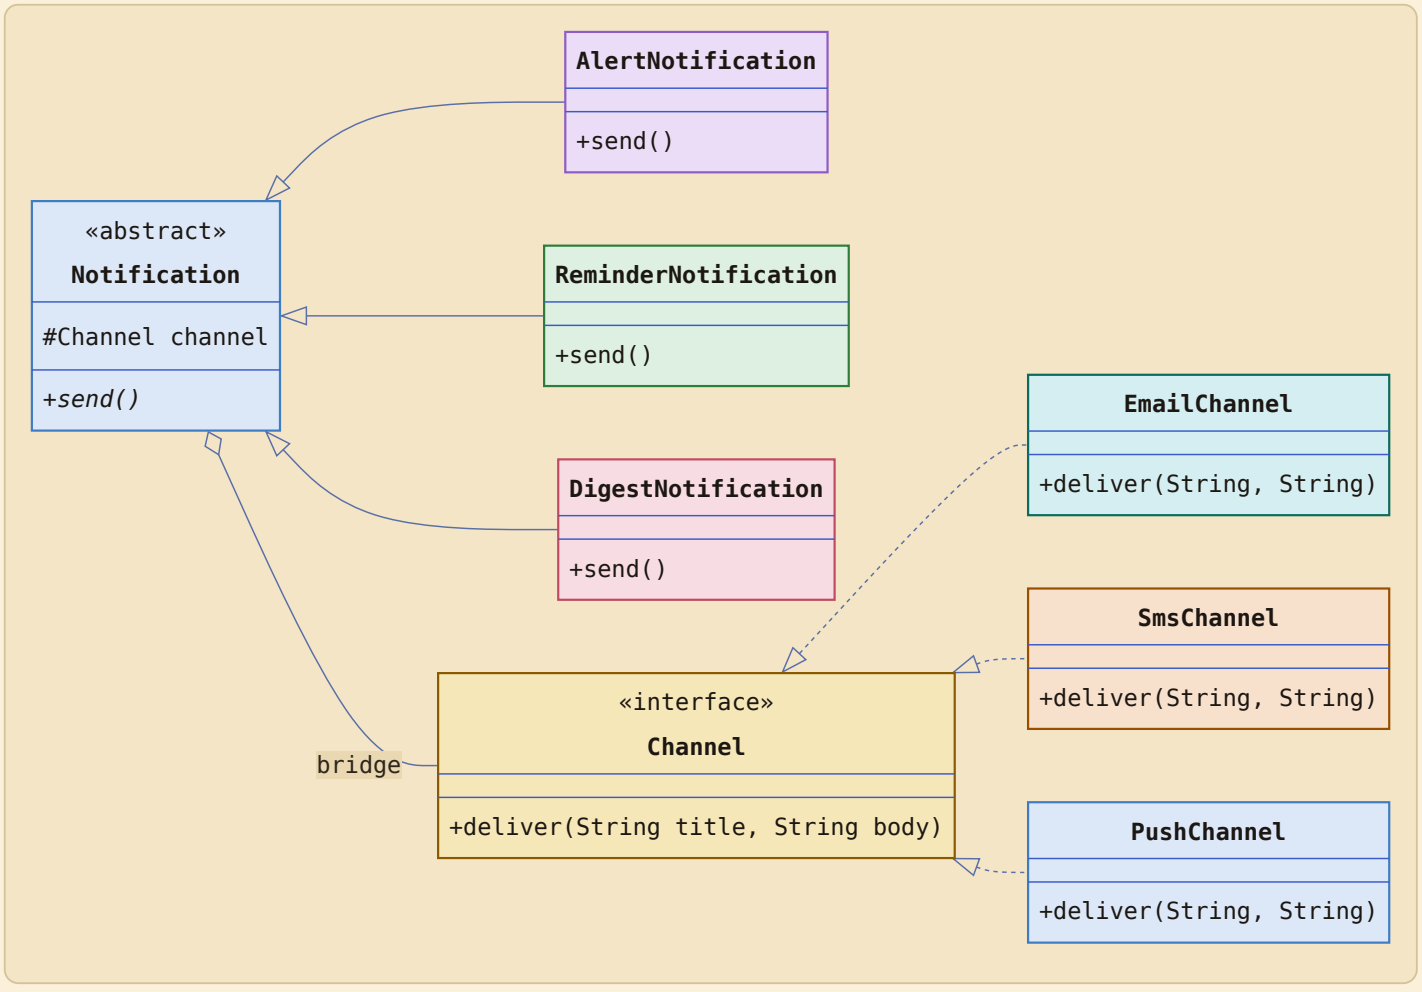
In the class diagram above, the bridge is that one `channel` field: declared once in the base class, used by every subclass. The channel classes know nothing about notifications — neither what an alert is nor that alerts exist.



Java example

```java
// File: code/lld/ch09/bridge/Channel.java
package lld.ch09.bridge;

/**
 * IMPLEMENTOR: the low-level "how it goes out" side.
 * Kept small and general: two plain strings, nothing channel-specific.
 */
interface Channel {
    void deliver(String title, String body);
}
```

```java
// File: code/lld/ch09/bridge/EmailChannel.java
package lld.ch09.bridge;

/** CONCRETE IMPLEMENTORS: none of them knows what an alert or a digest is. */
final class EmailChannel implements Channel {
    private final String address;

    EmailChannel(String address) { this.address = address; }

    @Override
    public void deliver(String title, String body) {
        System.out.println("  [email to " + address + "] Subject: " + title + " | " + body);
    }
}
```

```java
// File: code/lld/ch09/bridge/SmsChannel.java
package lld.ch09.bridge;

final class SmsChannel implements Channel {
    private static final int LIMIT = 40;           // tiny limit so the demo shows truncation
    private final String phone;

    SmsChannel(String phone) { this.phone = phone; }

    @Override
    public void deliver(String title, String body) {
        String text = title + ": " + body;
        if (text.length() > LIMIT) text = text.substring(0, LIMIT - 3) + "...";
        System.out.println("  [sms to " + phone + "] " + text);
    }
}
```

```java
// File: code/lld/ch09/bridge/PushChannel.java
package lld.ch09.bridge;

final class PushChannel implements Channel {
    private final String deviceId;

    PushChannel(String deviceId) { this.deviceId = deviceId; }

    @Override
    public void deliver(String title, String body) {
        System.out.println("  [push to " + deviceId + "] (" + title + ") " + body);
    }
}
```

```java
// File: code/lld/ch09/bridge/Notification.java
package lld.ch09.bridge;

/**
 * ABSTRACTION: the high-level "what the message is" side.
 * The protected 'channel' field IS the bridge.
 */
abstract class Notification {
    protected final Channel channel;

    protected Notification(Channel channel) { this.channel = channel; }

    /** Builds the message, then hands it across the bridge. Never branches on channel type. */
    abstract void send();
}
```

```java
// File: code/lld/ch09/bridge/AlertNotification.java
package lld.ch09.bridge;

/** REFINED ABSTRACTIONS */
final class AlertNotification extends Notification {
    private final String system;
    private final String problem;

    AlertNotification(Channel channel, String system, String problem) {
        super(channel);
        this.system = system;
        this.problem = problem;
    }

    @Override
    void send() { channel.deliver("ALERT " + system, problem + " - act now"); }
}
```

```java
// File: code/lld/ch09/bridge/ReminderNotification.java
package lld.ch09.bridge;

final class ReminderNotification extends Notification {
    private final String what;
    private final String when;

    ReminderNotification(Channel channel, String what, String when) {
        super(channel);
        this.what = what;
        this.when = when;
    }

    @Override
    void send() { channel.deliver("Reminder", what + " at " + when); }
}
```

```java
// File: code/lld/ch09/bridge/DigestNotification.java
package lld.ch09.bridge;

import java.util.List;

final class DigestNotification extends Notification {
    private final List<String> items;

    DigestNotification(Channel channel, List<String> items) {
        super(channel);
        this.items = List.copyOf(items);
    }

    @Override
    void send() { channel.deliver("Daily digest (" + items.size() + ")", String.join("; ", items)); }
}
```

```java
// File: code/lld/ch09/bridge/Main.java
package lld.ch09.bridge;

import java.util.List;

public class Main {
    public static void main(String[] args) {
        Channel email = new EmailChannel("ops@shop.com");
        Channel sms = new SmsChannel("+1-555-0100");
        Channel push = new PushChannel("pixel-7");

        System.out.println("== Any type x any channel, paired at run time ==");
        List<Notification> outbox = List.of(
                new AlertNotification(email, "payments", "error rate 12%"),
                new AlertNotification(sms, "payments", "error rate 12%"),
                new ReminderNotification(push, "Stand-up", "09:30"),
                new DigestNotification(email, List.of("3 orders", "1 refund", "0 incidents")),
                new DigestNotification(sms, List.of("3 orders", "1 refund", "0 incidents")));
        outbox.forEach(Notification::send);

        System.out.println("== Class count ==");
        int types = 3, channels = 3;
        System.out.println("  one hierarchy (type x channel): " + types * channels + " classes");
        System.out.println("  bridge (type + channel):        " + (types + channels) + " classes");
        System.out.println("  with 4 types and 4 channels:    " + 4 * 4 + " vs " + (4 + 4));
    }
}
```

Output:

```
== Any type x any channel, paired at run time ==
  [email to ops@shop.com] Subject: ALERT payments | error rate 12% - act now
  [sms to +1-555-0100] ALERT payments: error rate 12% - act now

  [email to ops@shop.com] Subject: Daily digest (3) | 3 orders; 1 refund; 0 incidents
  [sms to +1-555-0100] Daily digest (3): 3 orders; 1 refund;...
== Class count ==
  one hierarchy (type x channel): 9 classes
  bridge (type + channel):        6 classes
  with 4 types and 4 channels:    16 vs 8
```

What each part does

- `Channel` — the Implementor. Just `deliver(title, body)` with two plain strings, so every channel can support it.
- `EmailChannel`, `SmsChannel`, `PushChannel` — each knows *only* how to deliver. `SmsChannel` truncates long text; that rule lives inside SMS, not in any notification.
- `Notification` — the Abstraction, holding `protected final Channel channel` (the bridge).

- `AlertNotification` etc. — each builds a title and body and calls `channel.deliver(...)`. No `instanceof` (Java's check of an object's concrete type), no `switch` on channel type.
- Adding `SlackChannel` = one new class; adding `PromoNotification` = one new class. Nothing else changes.

Bridge vs Strategy

Written down, the two are **indistinguishable** — an object keeps a reference to an interface and delegates through it. Interviewers and code reviewers both ask about this, so have an answer ready: the difference is the **reason the reference is there**, not how it looks.

	Bridge	Strategy
What varies	A whole **dimension** of the design	**One algorithm** or policy
When chosen	Usually once, at construction, then it stays	Often swapped repeatedly, even per call
Why it exists	To stop two hierarchies multiplying	To make one behaviour replaceable
When decided	Up front, as a structural decision	Later, when a second algorithm appears
Example	`Notification` → `Channel`	`list.sort(comparator)`

Practical test: picture adding one more implementation. If it is *a new kind of thing the system supports* (another delivery channel), you have a Bridge. If it is *one more way to perform a single step* (another compression algorithm), you have a Strategy. When you truly can't decide, relax — the code is identical and either name will be understood. What does matter is not building either one while an axis has only a single member.

Getting the split wrong

Bridge is quick to write but costly to re-cut once both sides have several classes. Two ways it goes wrong:

- **Low-level details leaking up.** An `if (channel instanceof SmsChannel)` inside `AlertNotification` means the bridge is no longer doing its job — that SMS-specific rule should move into `SmsChannel`.
- **An implementor interface shaped around one implementation.** Add `setEmailReplyTo(...)` to `Channel` and every non-email channel must now implement a method it can only throw from. Keep the low-level interface minimal and generic; that is why `deliver` accepts two plain strings instead of a rich message type.

Trade-offs

Pros	Cons
Class counts add rather than multiply — 3 types and 3 channels need 6 classes, not 9.	**Two hierarchies** to understand instead of one.
Each side extends independently (Open/Closed) — a new channel touches no notification class.	**More indirection** — following one call means reading two files.
Pairing picked at run time — real channel in production, fake in tests, per-environment config.	**Hard to undo** — once both sides have implementations, moving the split line is a large refactor (restructuring code without changing what it does).
Platform code kept apart — only one class knows about SMTP (the protocol for sending email) (Single Responsibility).	**Pointless with one member** — a bridge with a single implementor is just an interface plus ceremony.

When not to use it

- **An axis has only one member.** With a single channel the bridge abstracts nothing; introduce it when the second channel actually shows up, not in advance.
- **The axes are not truly independent.** If some combinations are forbidden (e.g. digests must never be sent by SMS), Bridge happily lets you build them, and you end up adding run-time checks that separate subclasses would have made impossible.
- **You can't state in one sentence which side is the abstraction.** Then the design isn't ready — picking the wrong split is more expensive than living with a few extra classes.
- **The second axis is really a behaviour, not a kind of thing.** Use Strategy.

Common mistakes

- Building the bridge "just in case" with a single implementor.
- Letting the abstraction branch on the concrete implementor type.
- Making the implementor interface mirror one specific implementation.
- Confusing Bridge with Adapter: Adapter is **retrofitted** to make existing things fit; Bridge is **designed in** so the two sides never get fused into one hierarchy.

Real-world examples

- **JDBC**: your code uses `java.sql.Connection` / `Statement`; each database driver supplies the implementation. Application code and drivers evolve separately, which is why the same query code can run on PostgreSQL or MySQL. (JDBC is often cited as both Bridge — two independent hierarchies — and Adapter — each driver adapts a native protocol. Both views are fair.)
- **SLF4J and similar logging APIs**: the logging API you call is one side and the backend that actually writes log lines is the other. (SLF4J calls itself a *facade*; the API/backend split underneath is Bridge-shaped.)
- **Window systems and device/graphics drivers**: GoF's own motivating example is a `Window` abstraction whose `WindowImp` implementation is written once per platform (X Window System, IBM Presentation Manager). OS drawing APIs over per-card graphics drivers follow the same idea.
- **`java.awt` peers** (the textbook Java example): each AWT component held a platform-specific peer object that did the actual native drawing.
- **Notification / payment services in most apps**: a `NotificationService` interface with pluggable providers (SES, Twilio, FCM — Amazon's email service, an SMS provider, Google's push-notification service) is this pattern, whether or not anyone called it Bridge.
- **Dependency-injection containers** (frameworks that create objects and hand each one the dependencies it needs) that bind an interface to a different implementation per environment give you Bridge-style pairing that is configured rather than coded.

In modern languages

- **First-class functions**: if the implementor has one method, it can simply be a function — `Notification(channel = send_email)` is the same design without a `Channel` class.
- **Python / JavaScript**: duck typing means the implementor side needs no declared interface — any object with a `deliver` method will do.
- **Go**: a small interface declared by the *consumer*, with implementations in other packages, is ordinary idiomatic (natural, conventional-style) Go — Bridge without the name.
- **DI containers** (Spring, Guice, .NET): the pairing is wired by configuration per environment.

Other patterns it is confused with

Looks like	Actual difference
Strategy	Same code shape; Bridge separates a permanent structural dimension, Strategy makes one algorithm swappable.
Adapter	The class diagrams can look alike, but the timing is reversed: an Adapter is retrofitted to reconcile two things that already exist; a Bridge is planned before the classes are written.
Abstract Factory	Abstract Factory decides *which family of objects gets created*; Bridge describes *how an object hands off work once it exists*. They work well together — a factory commonly supplies the implementor a bridge receives.
Decorator	A Decorator shares the interface of the object inside it and adds behaviour; in a Bridge the two sides have unrelated interfaces and neither one wraps the other.

In the interview

> **30-second answer:** "Bridge separates an abstraction from its implementation so both can vary independently. If notifications vary by type and by channel, one hierarchy needs type × channel classes — 3 × 3 = 9, and 16 with a fourth of each. I split it: a `Notification` hierarchy holding a reference to a `Channel` interface. Now it is type + channel classes — 6, then 8 — and the pairing is chosen at run time. I wouldn't build it while there is only one channel."

Follow-ups

- *Q: How is it different from Strategy?* — A: The code is the same; the intent differs. Bridge splits a permanent dimension decided up front; Strategy makes one algorithm replaceable, often per call.
- *Q: What is the smell that says you need it?* — A: Class names with two nouns (`SmsDigest`) and duplicated code across them.
- *Q: When would you not use it?* — A: With only one channel today — I would add the bridge when the second one lands. Also when some combinations are invalid.
- *Q: Who decides which implementor a notification gets?* — A: Whoever builds it — often a factory or the DI container, configured per environment.

Self-check

1. **Q:** With 5 notification types and 4 channels, how many classes without and with Bridge? **A:** 20 without, 9 with.
2. **Q:** Which field is "the bridge"? **A:** The `Channel channel` reference held by the `Notification` base class.
3. **Q:** An `AlertNotification` checks `channel instanceof SmsChannel`. What is wrong? **A:** Implementation detail has leaked upward; move that behaviour into `SmsChannel`.
4. **Q:** Is Bridge added before or after the classes exist? **A:** Before — it is an up-front structural decision (Adapter is the after-the-fact one).

TL;DR

- **Two dimensions varying → two hierarchies + one reference.** Multiplication becomes addition.
- Abstraction (what) holds Implementor (how). Keep the implementor small and general.
- Same code as Strategy; different intent. Don't build it for one implementor.

9.3 Composite Pattern

What it is

The **Composite** pattern gives an individual item and a whole nested group of items **one common interface**, so code that uses them never needs to check whether it has a **single object** or an **entire tree**.

Analogy: a company org chart. You can ask any manager "what is your team's total salary?" — a manager answers by asking each report and adding up; an individual contributor just answers with their own salary. The question is the same for both.

Term	Meaning	In our code
Component	The shared interface for leaves and containers	`FileSystemNode`, `MenuComponent`
Leaf	An object with no children; does the work itself	`FileNode`, `MenuItem`
Composite	A container that holds children (typed as Component) and delegates to them	`FolderNode`, `Menu`
Client	Code that works with Components only	`report(...)`

GoF's intent in plain words: compose objects into tree structures that represent **part-whole hierarchies**, and let clients treat individual objects and compositions **uniformly**.

The problem it solves

Plenty of data is nested: folders contain files *and* folders; an invoice contains line items *and* bundles that have their own items; a UI (user interface) panel contains widgets (buttons, text boxes and other screen controls) *and* sub-panels. Ask for a total size, a total price or a rendering of the whole thing, and — without the pattern — each operation (`size`, `print`, `search`, `copy`) opens with the same type test:

```
if (node instanceof Folder f) { /* loop over children, recurse */ }
else if (node instanceof File f) { /* read the size */ }
```

That test gets pasted into every operation. Introduce a third kind of node — say a symbolic link (a file-system entry that points to another file or folder) — and you have to hunt down each copy; overlook one and the new node type quietly gets the wrong answer.

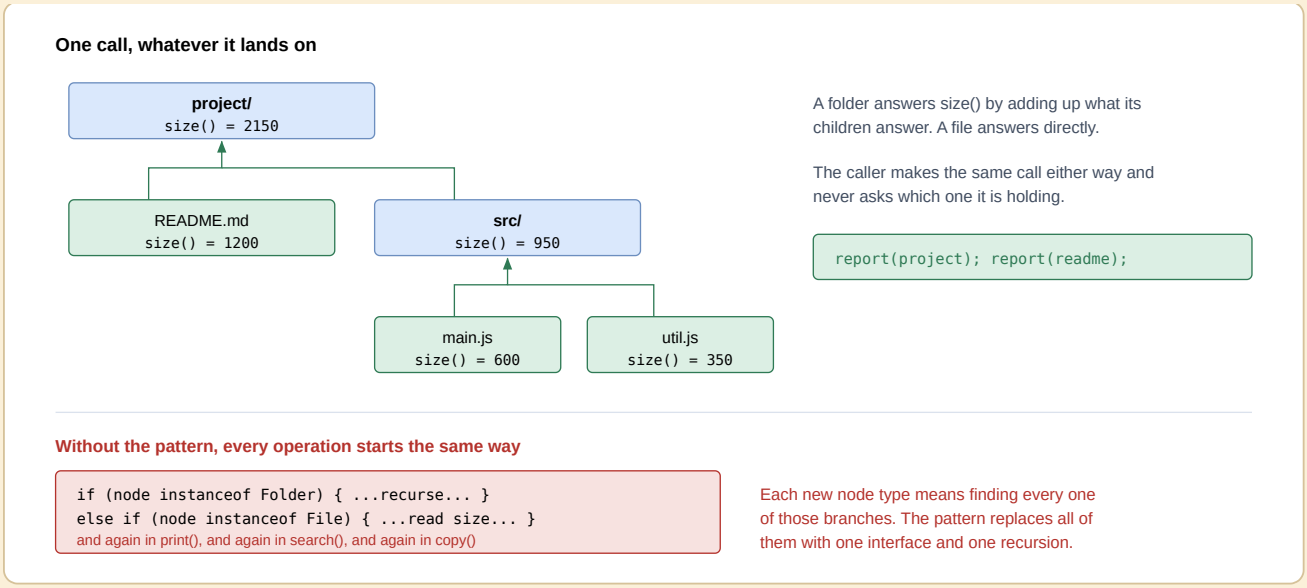

Figure — `size()` on the project folder (2150) is the sum of README.md (1200) and src/ (950), which itself sums main.js and util.js. The caller makes the same call on a tree or a single file (course diagram)

The figure shows the fix: a file answers `size()` with its own byte count, and a folder answers by asking each child and summing. Because a child may be a file or another folder and both respond to the same call, a single piece of recursive code (code that calls itself on the smaller parts) handles any depth. The caller writes `report(project)` or `report(readme)` and never asks which one it holds.

How it works

1. **Define a Component interface** with operations that make sense for *both* leaves and containers (`name()`, `size()`, `print()`).
2. **Leaf** implements them directly (a file returns its own byte count).
3. **Composite** stores a `List<Component>` — the **interface type**, not the leaf type — and implements each operation by **asking each child and combining the results**.
4. Because a child can itself be a composite, the recursion is written **once** and works to any depth.
5. **Clients** hold a `Component` and never type-check.

Structure

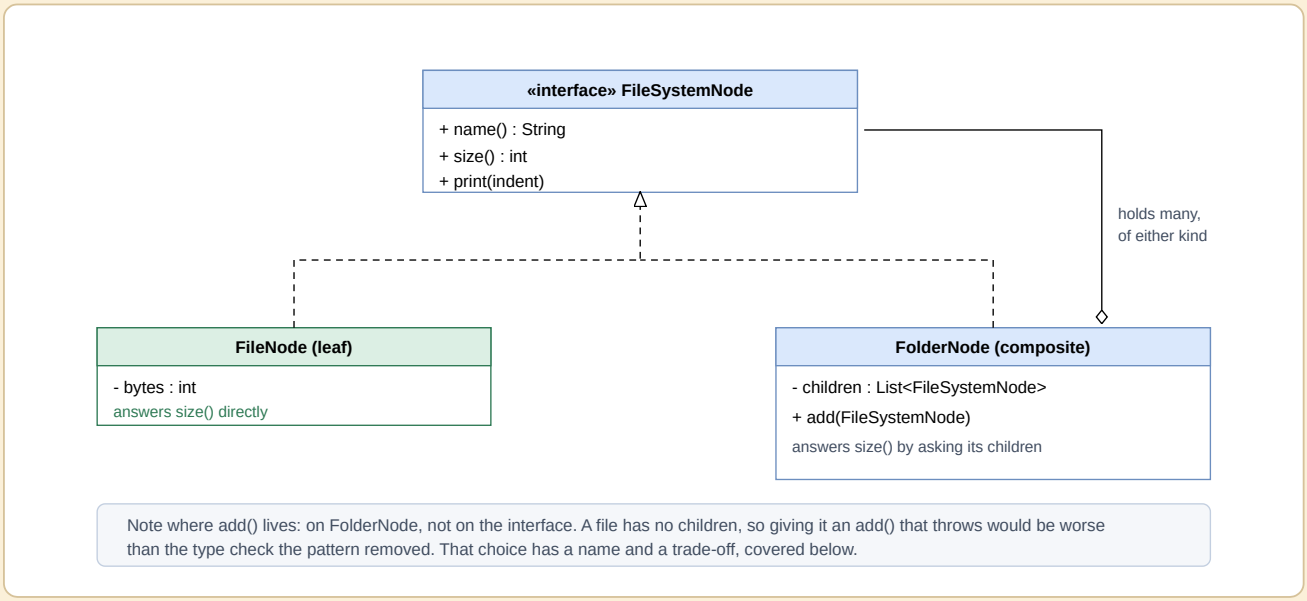

Figure — Composite class diagram: `FileNode` (leaf) and `FolderNode` (composite) implement `FileSystemNode`; the folder holds a list of `FileSystemNode` and has `add()` (course diagram)

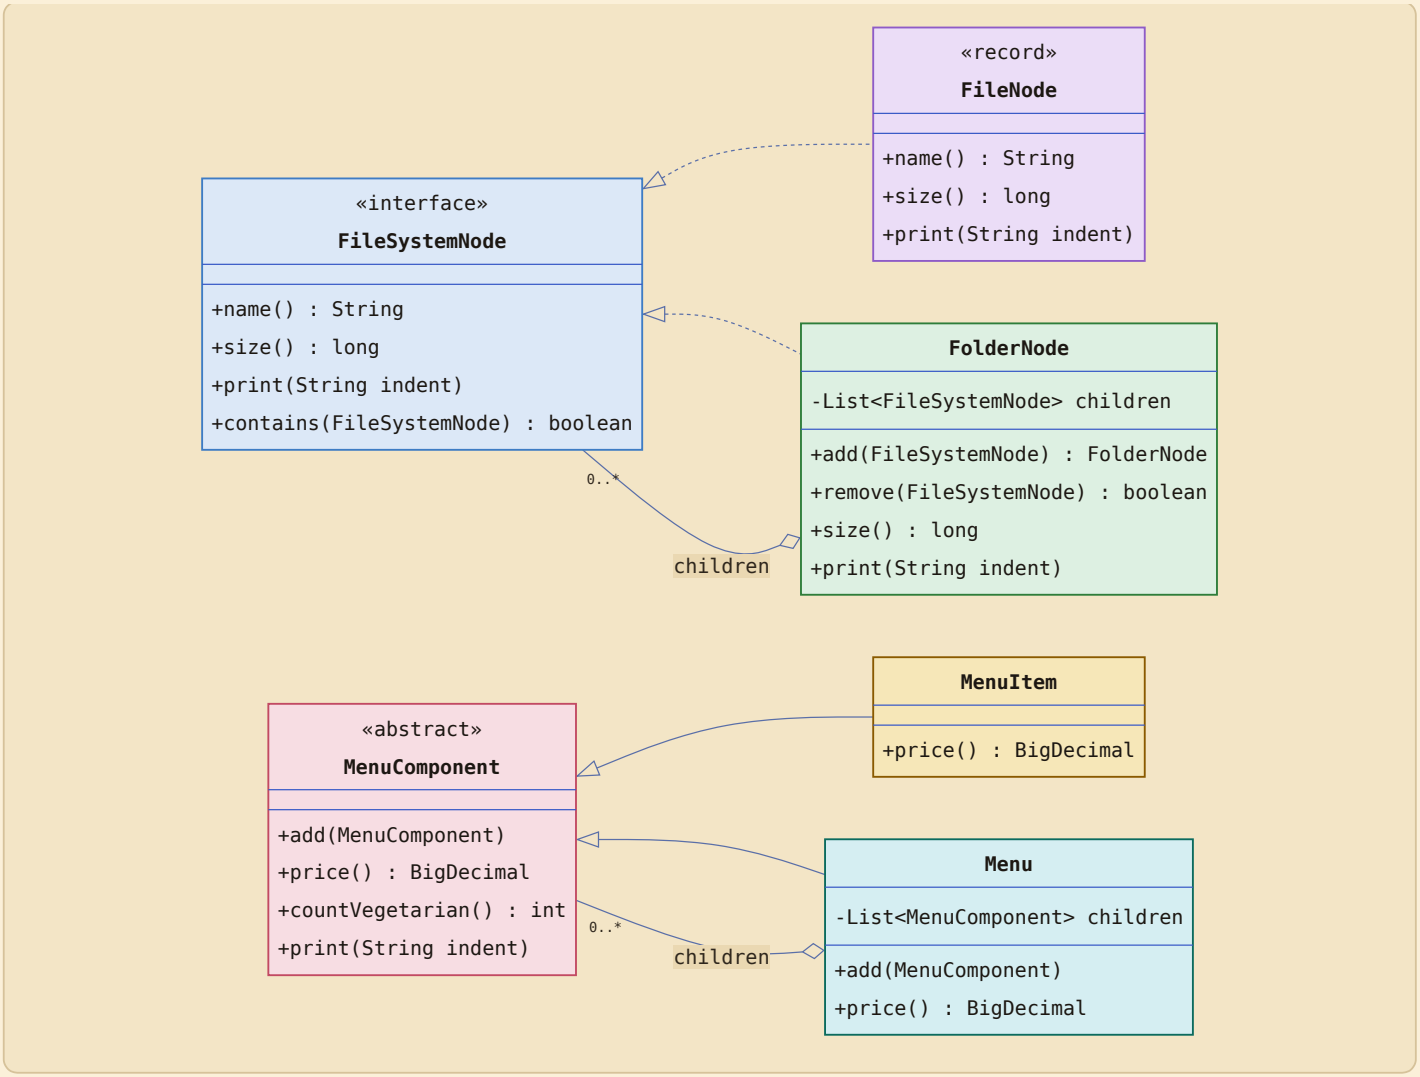
Two details in the class diagram above matter: the folder's child list is typed as the **interface** — that is what lets folders hold folders — and `add()` is declared on `FolderNode` rather than on the shared interface. The second is a deliberate trade-off (the "safe" design), covered right after the code.



Java example

```java
// File: code/lld/ch09/composite/FileSystemNode.java
package lld.ch09.composite;

/**
 * COMPONENT (safe version): only operations that make sense for BOTH leaf and composite.
 * add/remove are NOT here - they live on FolderNode only.
 */
interface FileSystemNode {
    String name();
    long size();
    void print(String indent);

    /** True if 'target' is this node or somewhere below it. Used for the cycle check. */
    default boolean contains(FileSystemNode target) { return this == target; }
}
```

```java
// File: code/lld/ch09/composite/FileNode.java
package lld.ch09.composite;

/** LEAF: no children, answers directly. */
record FileNode(String name, long size) implements FileSystemNode {
    @Override
    public void print(String indent) {
        System.out.println(indent + "- " + name + " (" + size + " B)");
    }
}
```

```java
// File: code/lld/ch09/composite/FolderNode.java
package lld.ch09.composite;

import java.util.ArrayList;
import java.util.Collections;
import java.util.List;

/** COMPOSITE: holds children typed as the INTERFACE, so folders can hold folders. */
final class FolderNode implements FileSystemNode {
    private final String name;
    private final List<FileSystemNode> children = new ArrayList<>();

    FolderNode(String name) { this.name = name; }

    /** Returns this so trees can be built fluently. Rejects cycles at insert time. */
    FolderNode add(FileSystemNode child) {
        if (child.contains(this)) {
            throw new IllegalArgumentException("cycle: " + child.name() + " already contains " + name);
        }
        children.add(child);
        return this;
    }

    boolean remove(FileSystemNode child) { return children.remove(child); }

    List<FileSystemNode> children() { return Collections.unmodifiableList(children); }

    @Override public String name() { return name; }

    /** The recursion lives in ONE place. */
    @Override
    public long size() {
        long total = 0;
        for (FileSystemNode child : children) total += child.size();
        return total;
    }

    @Override
    public void print(String indent) {
        System.out.println(indent + "+ " + name + "/ (" + size() + " B)");
        for (FileSystemNode child : children) child.print(indent + "   ");
    }

    @Override
    public boolean contains(FileSystemNode target) {
        if (this == target) return true;
        for (FileSystemNode child : children) {
            if (child.contains(target)) return true;
        }
        return false;
    }
}
```

```java
// File: code/lld/ch09/composite/MenuComponent.java
package lld.ch09.composite;

import java.math.BigDecimal;

/**
 * COMPONENT (transparent version): child management is on the shared type,
 * so callers never cast - but a leaf must reject it at run time.
 */
abstract class MenuComponent {
    void add(MenuComponent c) { throw new UnsupportedOperationException(name() + " is a leaf"); }

    abstract String name();
    abstract BigDecimal price();            // total price of everything under this node (money: BigDecimal, never
double)
    abstract int countVegetarian();
    abstract void print(String indent);
}
```

```java
// File: code/lld/ch09/composite/MenuItem.java
package lld.ch09.composite;

import java.math.BigDecimal;

final class MenuItem extends MenuComponent {
    private final String name;
    private final BigDecimal price;
    private final boolean vegetarian;

    MenuItem(String name, String price, boolean vegetarian) {
        this.name = name;
        this.price = new BigDecimal(price);     // from a String, so "3.49" is exactly 3.49
        this.vegetarian = vegetarian;
    }

    @Override String name() { return name; }
    @Override BigDecimal price() { return price; }
    @Override int countVegetarian() { return vegetarian ? 1 : 0; }
    @Override void print(String indent) {
        System.out.println(indent + name + (vegetarian ? " (v)" : "") + " $" + price);
    }
}
```

```java
// File: code/lld/ch09/composite/Menu.java
package lld.ch09.composite;

import java.math.BigDecimal;
import java.util.ArrayList;
import java.util.List;

final class Menu extends MenuComponent {
    private final String name;
    private final List<MenuComponent> children = new ArrayList<>();

    Menu(String name) { this.name = name; }

    @Override void add(MenuComponent c) { children.add(c); }
    @Override String name() { return name; }
    @Override BigDecimal price() {
        return children.stream().map(MenuComponent::price).reduce(BigDecimal.ZERO, BigDecimal::add);
    }
    @Override int countVegetarian() { return children.stream().mapToInt(MenuComponent::countVegetarian).sum(); }
    @Override void print(String indent) {
        System.out.println(indent + "[" + name + "]");
        children.forEach(c -> c.print(indent + "  "));
    }
}
```

```java
// File: code/lld/ch09/composite/Main.java
package lld.ch09.composite;

public class Main {

    /** Client: one parameter type, no instanceof anywhere. */
    static void report(FileSystemNode node) {
        System.out.println("  " + node.name() + " -> " + node.size() + " bytes");
    }

    public static void main(String[] args) {
        System.out.println("== Safe composite: file system ==");
        FileNode readme = new FileNode("README.md", 1200);
        FolderNode src = new FolderNode("src")
                .add(new FileNode("main.js", 600))
                .add(new FileNode("util.js", 350));
        FolderNode project = new FolderNode("project").add(readme).add(src);

        project.print("  ");
        report(project);   // a whole tree
        report(readme);    // a single file - same call

        try {
            src.add(project);   // project already contains src -> would loop forever
        } catch (IllegalArgumentException e) {
            System.out.println("  rejected: " + e.getMessage());
        }

        System.out.println("== Transparent composite: restaurant menu ==");
        MenuComponent all = new Menu("All menus");
        MenuComponent breakfast = new Menu("Breakfast");
        MenuComponent desserts = new Menu("Desserts");
        breakfast.add(new MenuItem("Pancakes", "3.49", true));
        breakfast.add(new MenuItem("Bacon & eggs", "4.99", false));
        desserts.add(new MenuItem("Apple pie", "2.59", true));
        breakfast.add(desserts);          // a menu inside a menu
        all.add(breakfast);
        all.add(new MenuItem("Coffee", "1.50", true));

        all.print("  ");
        System.out.println("  total $" + all.price() + ", vegetarian items: " + all.countVegetarian());
        try {
            new MenuItem("Tea", "1.00", true).add(new MenuItem("Milk", "0.20", true));
        } catch (UnsupportedOperationException e) {
            System.out.println("  transparent cost: " + e.getMessage());
        }
    }
}
```

Output:

```
== Safe composite: file system ==
  + project/ (2150 B)
     - README.md (1200 B)
     + src/ (950 B)
        - main.js (600 B)
        - util.js (350 B)
  project -> 2150 bytes
  README.md -> 1200 bytes
  rejected: cycle: project already contains src
== Transparent composite: restaurant menu ==
  [All menus]
    [Breakfast]
      Pancakes (v) $3.49
      Bacon & eggs $4.99
      [Desserts]
        Apple pie (v) $2.59
    Coffee (v) $1.50
  total $12.57, vegetarian items: 3
  transparent cost: Tea is a leaf
```

What each part does

- `FileSystemNode` — the Component. Only operations valid for both files and folders.
- `FileNode` (a `record`) — the Leaf: immutable, answers `size()` directly.
- `FolderNode` — the Composite. `size()` is the four-line recursion and the **only** place in the program that knows a tree can nest. `add()` returns `this` so trees build fluently.
- `contains(...)` + the check in `add()` — **cycle protection** at insert time. Trying to put `project` inside its own child `src` is rejected (see output).
- `MenuComponent` / `Menu` / `MenuItem` — the *transparent* variant (the restaurant-menu example popularised by *Head First Design Patterns*): `add` is on the shared abstract class and a leaf throws.
- `report(...)` — the client, called with a whole tree and with a single file.

Transparent vs safe composite

Where do `add` and `remove` belong? GoF named both answers:

	Transparent	Safe
Where `add/remove` live	On the shared Component	Only on the Composite
Uniformity	Full — every node looks the same; no casts (forcing a value to a more specific type)	Partial — builders must hold a `FolderNode`
Type safety	Weaker — `leaf.add(...)` compiles, then **throws at run time**	Strong — the compiler rejects `file.add(...)`
Our code	`MenuComponent` (`Tea is a leaf` in the output)	`FileSystemNode` / `FolderNode`
Choose when	Callers add children to arbitrary nodes without knowing their type (e.g. a UI editor where anything might be a container)	The tree is built in one place and read in many (most cases)

The transparent version swaps a compile-time guarantee for a possible run-time exception. The safe version keeps the read-side interface small, but any code that builds or edits the tree must hold a `FolderNode` — and code that walks a tree and then wants to insert needs a cast or type check after all. Neither is wrong; in review, check that the choice was **made on purpose**. A throwing `add` that nobody intended is the real defect.

Head First Design Patterns makes an interesting point here: the transparent composite knowingly bends the Single Responsibility Principle (the component both manages children and does work) to gain transparency. That is a conscious design trade-off, not an accident.

Two traps worth knowing

- **Cycles.** If a folder is ever placed inside one of its own descendants, `size()` recurses forever (in Java: `StackOverflowError`, thrown when nested calls use up the call stack — the memory that tracks calls in

progress). **Validate when inserting**, not during traversal (walking through every node) — once you are traversing, you are already stuck. Our `add()` does exactly this.

- **Repeated work.** Our `print()` calls `size()` on every level, so the same subtotals are recomputed again and again — about quadratic (work grows with the square of the depth) for a deep chain. For big real trees, **store each subtree's total** and invalidate upward when a child changes (which needs a parent pointer).

Trade-offs

Pros	Cons
Callers never type-check — the same call works on a leaf or a whole tree.	**The shared interface tends to bloat** with operations that only half-fit one of the two kinds.
The recursion lives in one place, reused by each new operation.	**Weaker type safety** (transparent variant) — the compiler allows adding a child to a leaf.
Adding a node type doesn't touch callers (Open/Closed) — e.g. a `SymlinkNode`.	**Deep trees mean deep call stacks**, and a cycle shows up as endless recursion instead of a clear error.
Nesting comes for free — a composite that stores the interface can store other composites.	**Totals get recomputed** on every call unless you cache them.

When not to use it

- **Nothing nests.** A flat list gains nothing from a shared leaf/container interface.
- **Leaves and containers share little.** A forced common interface fills up with methods that throw, which is worse than the type test it replaced.
- **Deep tree on a hot path.** (A hot path is code that runs so often that its speed matters.) Each level costs a stack frame and likely CPU cache misses (fetching data from slow main memory instead of the processor's fast cache); precomputed totals, or a loop that manages its own work-list instead of recursing, can be faster.
- **The tree is modified while being traversed.** Concurrent changes (made at the same time by another thread) during recursion are dangerous, and Composite offers no protection.

Common mistakes

- Typing the child list as the **leaf** type (`List<FileNode>`) — then folders cannot hold folders.
- Returning the internal mutable child list — callers can bypass `add()` and its cycle check. We return `Collections.unmodifiableList(children)`.
- Adding `add()` to the interface by accident (transparent without meaning to).
- No cycle check.
- Using Composite when a single recursive function with one type check would do — the pattern pays off when **operations multiply**.

Real-world examples

- **The HTML DOM** (Document Object Model — the browser's in-memory tree of page elements) — an element holds child nodes, each possibly an element with children; `textContent` walks the whole subtree.
- **UI toolkits** — in Swing/AWT, `java.awt.Container` *is a* `Component` and holds `Component`s, which is why panels nest without limit. React (a JavaScript UI library) component trees and Android's `ViewGroup` (a `View` that holds `View`s) follow the same idea.
- **File systems** — the example used here.
- **Abstract syntax trees** (the tree a compiler builds from source code) in compilers — an expression node holds sub-expressions; evaluating any node evaluates its subtree.
- `java.io.File` represents both files and directories with one class — a fair illustration of the transparent cost: `listFiles()` returns `null` when called on a regular file.
- **JUnit 3 test suites** (JUnit is the standard Java testing framework; a suite is a named group of tests) — `TestSuite` implements `Test` and holds `Test`s (cases or other suites); running a suite runs everything beneath it. (JUnit 5 keeps the idea as a tree of test descriptors.)
- **Spring's** `CompositeCacheManager` delegates to a list of `CacheManager`s while itself being a `CacheManager`.
- **Invoices / bundles** — an e-commerce "bundle" priced as the sum of its items, which may themselves be bundles.

In modern languages

- **Python / JavaScript**: duck typing — leaf and container just need the same method names; a composite is often a class with a `children` list.
- **Sealed types + pattern matching** (Java 21, Kotlin, Scala, Rust) — a sealed type lists exactly which subtypes may exist, and pattern matching lets a `switch` branch on which subtype it has: a `sealed interface Node permits File, Folder` plus an exhaustive `switch` is a real alternative. The compiler then reports any node type a `switch` forgets — a guarantee Composite does not give. Prefer it when the set of node types is closed.
- **Functional languages**: a recursive algebraic data type (a type defined as "one of these shapes", where a shape may contain the type itself) is Composite with language support; a `fold` (a function that combines all parts of a structure into one result) over it is the recursion written once.
- **Java streams** (a pipeline API for processing collections): `flatMap` (turns each element into several and flattens the result) makes walking a composite read nicely once the structure exists.

Other patterns it is confused with

Looks like	Actual difference
Decorator	Both hold objects of their own interface. A Decorator wraps exactly **one** and adds behaviour; a Composite holds **many** and combines their results.
Iterator	Composite gives the tree a uniform interface; Iterator gives a way to walk it without exposing its structure. Often used together.
Visitor	Composite makes the structure uniform; Visitor adds new operations over it without editing node classes — the usual next step when operations keep multiplying.
A plain recursive function	If one function with one type check does the job, you don't need the pattern. Composite pays off when **many** operations would each repeat that branch.

In the interview

30-second answer: "Composite lets a client treat a single object and a tree of objects the same way. Leaf and container share one interface; the container stores children *typed as that interface* — which is what allows arbitrary nesting — and implements each operation by delegating to its children and combining the results. Its value is what it deletes: the `instanceof` branch in every operation. I choose between the transparent and safe variants depending on whether callers need `add` on arbitrary nodes, I reject cycles on insert, and I cache subtree totals if the tree is large."

Follow-ups

- *Q: Transparent or safe?* — A: Safe if the tree is built in one place and read in many; transparent if callers add children to arbitrary nodes and casts would spread everywhere.
- *Q: What about cycles?* — A: Check on insert: reject `add(child)` if the child already contains the parent.
- *Q: Performance on a big tree?* — A: Cache subtree totals, invalidate upward on change; or use an iterative walk to avoid deep recursion.
- *Q: Composite vs Decorator?* — A: Both hold objects of their own interface. Decorator holds **one** and adds behaviour; Composite holds **many** and combines their results.
- *Q: How do you add a new operation without touching every node?* — A: Use Visitor over the composite structure.

Self-check

1. **Q:** Why must the child list be `List<FileSystemNode>`, not `List<FileNode>`? **A:** So a folder can contain other folders — arbitrary nesting.
2. **Q:** In the transparent variant, what happens when you call `add` on a leaf? **A:** It compiles but throws at run time (`UnsupportedOperationException`).
3. **Q:** Where should a cycle be detected? **A:** At insertion time.
4. **Q:** Name a JDK class that is both a component and a container of components. **A:** `java.awt.Container`.

TL;DR

- **Part-whole trees, one interface.** Leaf answers directly; composite asks children and combines.

- Child list holds the **interface**. Recursion lives in one place.
- **Safe** (add only on composite, compile-time safe) vs **transparent** (add everywhere, run-time throw). Guard against **cycles**; cache big totals.

9.4 Decorator Pattern

What it is

The **Decorator** pattern extends what **a single object** does, **while the program runs**, by enclosing it in a wrapper that implements **the same interface**. The original class is never edited, and you don't need a separate subclass for each mix of extras.

Analogy: ordering coffee. Start with an espresso, add milk, add mocha, add whipped cream. Each topping wraps the drink and adds to its price and description; the result is still "a drink".

Term	Meaning	In our code
Component	The shared interface	`UserRepository`, `Beverage`, `InputStream`
Concrete Component	The real object that does the core work	`DatabaseUserRepository`, `Espresso`
Decorator (base)	Implements the Component, holds a Component, forwards everything	`RepositoryDecorator`, `java.io.FilterInputStream`
Concrete Decorator	Adds one behaviour around the forwarded call	`LoggingRepository`, `CachingRepository`, `Mocha`, `UpperCaseInputStream`

GoF's intent: *attach additional responsibilities to an object dynamically — a flexible alternative to subclassing for extending functionality.* GoF also calls it **Wrapper** (the same nickname as Adapter).

The key property: **a decorator IS-A Component and HAS-A Component.** Since it has the very type it wraps, a decorator can sit around the real object, around another decorator, or around a test double (any stand-in object used in tests — fake, stub or mock), and code that only sees the interface cannot tell which.

The problem it solves

First a repository (an object that loads and saves data, hiding the database behind methods) needs logging, then caching, later retries and metrics (counters and timings the app records about itself). Each caller wants its own mix of these, and sometimes in its own order.

- **Subclassing can't keep up.** A `LoggingCachingRetryingUserRepository` serves one mix only. Four optional concerns give 2^4 = **16** possible mixes, and the class count doubles with every new concern — a class explosion.
- **One class with on/off flags** holds up until a caller wants "everything except the cache". One boolean turns into four, and you end with `new Repo(true, false, true, true)`, which nobody can read.

Decorator gives **each concern its own class** with the component's interface. Four concerns cost **four classes**, and each caller assembles exactly the stack it needs — by wrapping at run time rather than inheriting at compile time. That is the Open/Closed Principle at work: new behaviour arrives as new classes, and existing classes stay untouched.

How it works

1. Start from a **Component interface** (`UserRepository`).
2. Write the **concrete component** that does the real work (`DatabaseUserRepository`).
3. Write an **abstract base decorator** that implements the interface, holds an `inner` of the **interface type**, and **forwards every method** by default.
4. Each **concrete decorator** extends the base and overrides only the methods it changes, doing something **before and/or after** calling `inner`.
5. **Compose by wrapping**: `new Logging(new Caching(new Database()))`. The outermost object is what the caller holds.

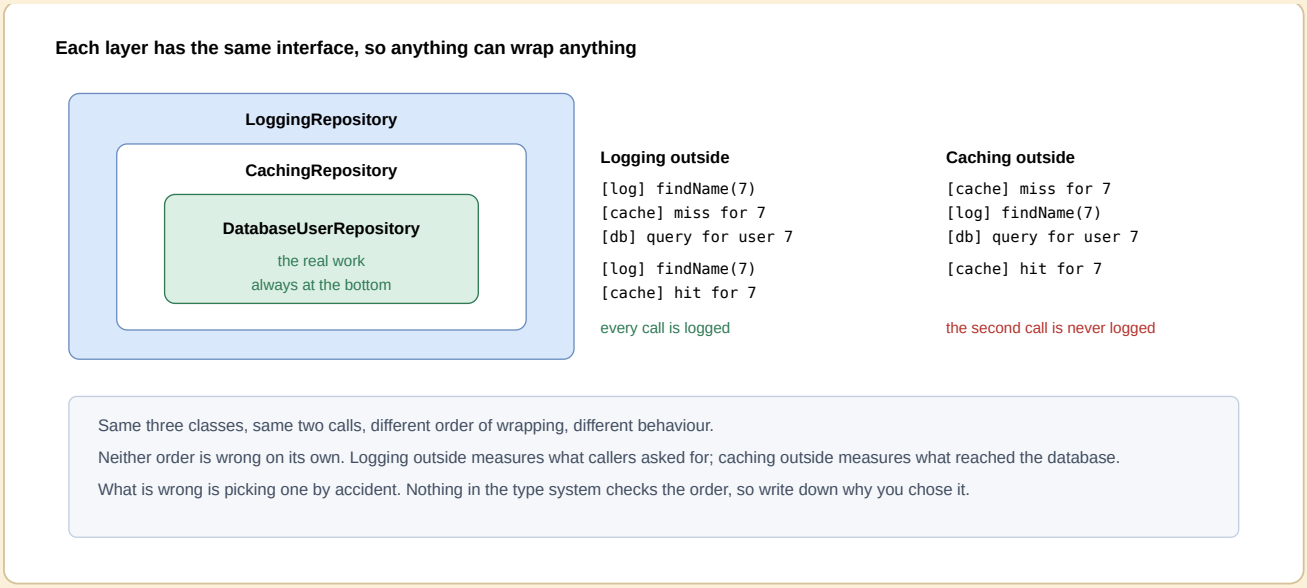


Figure — The same three classes stacked in two orders. Logging outside caching logs every call; caching outside logging means the second call (a cache hit) is never logged (course diagram)

Structure

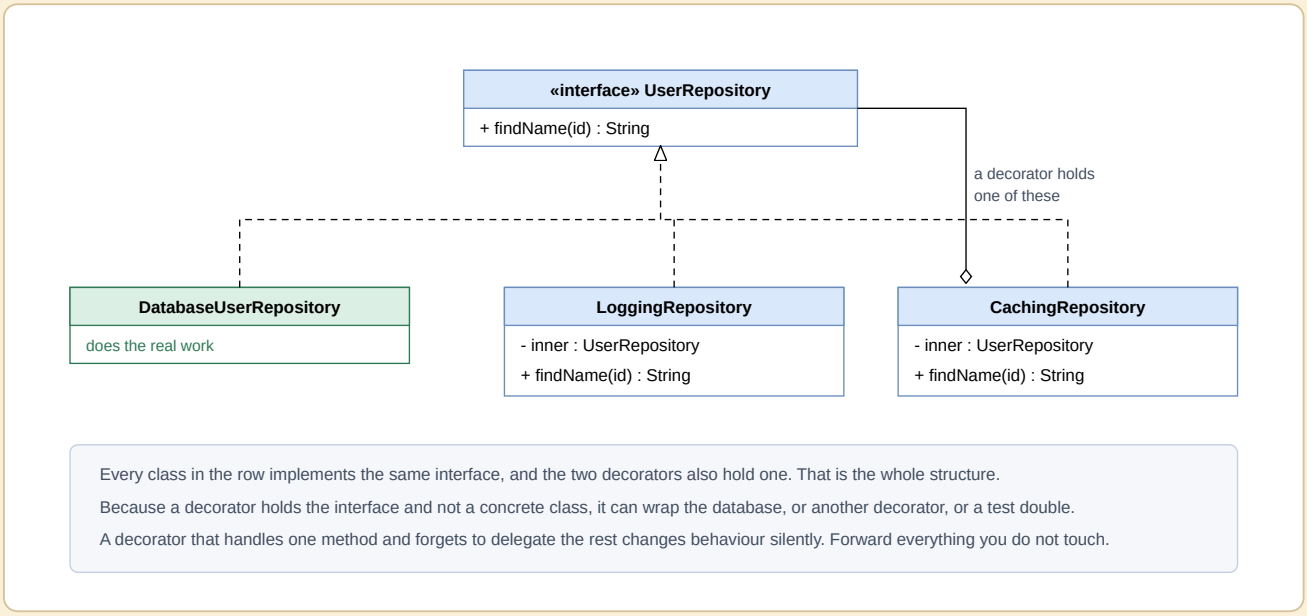

Figure — Decorator class diagram: `DatabaseUserRepository`, `LoggingRepository` and `CachingRepository` all implement `UserRepository`; each decorator holds an `inner` UserRepository (course diagram)

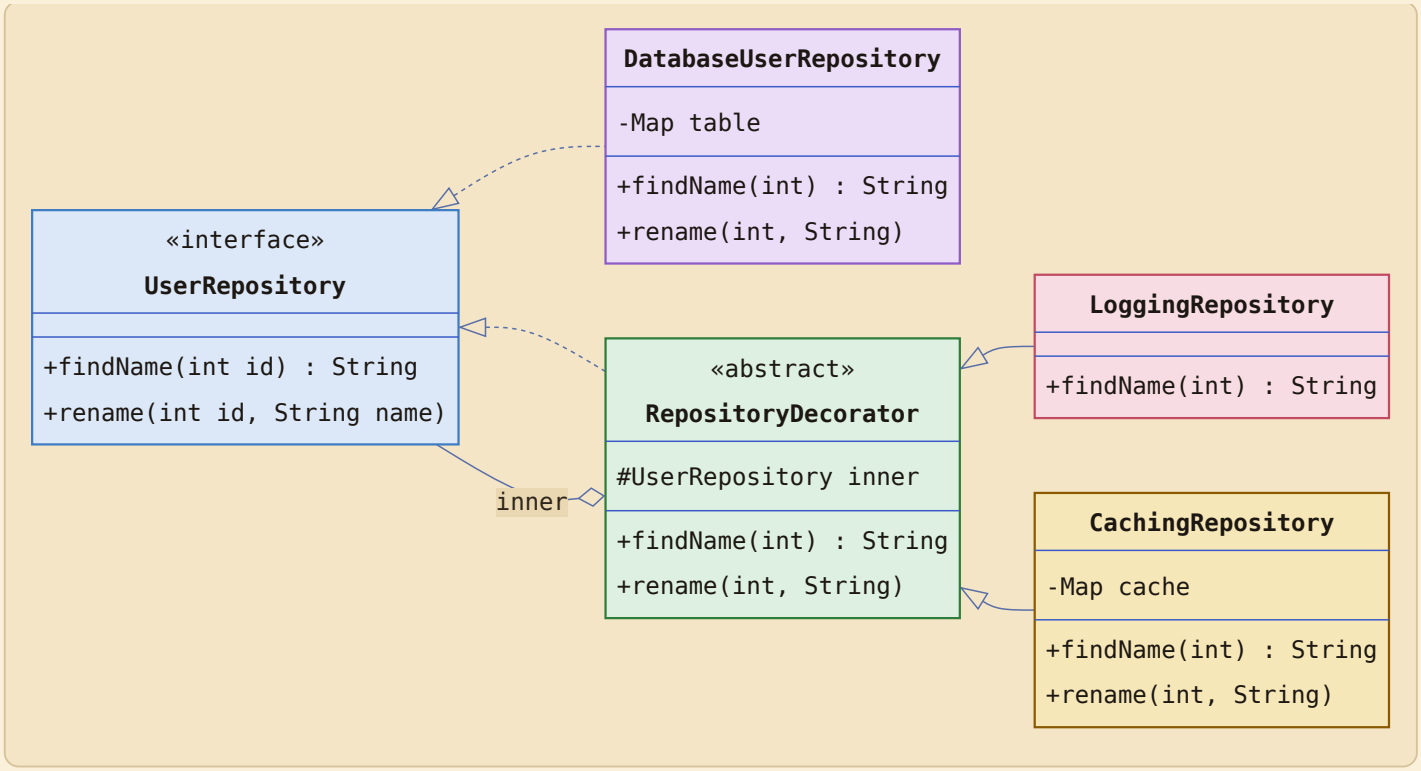
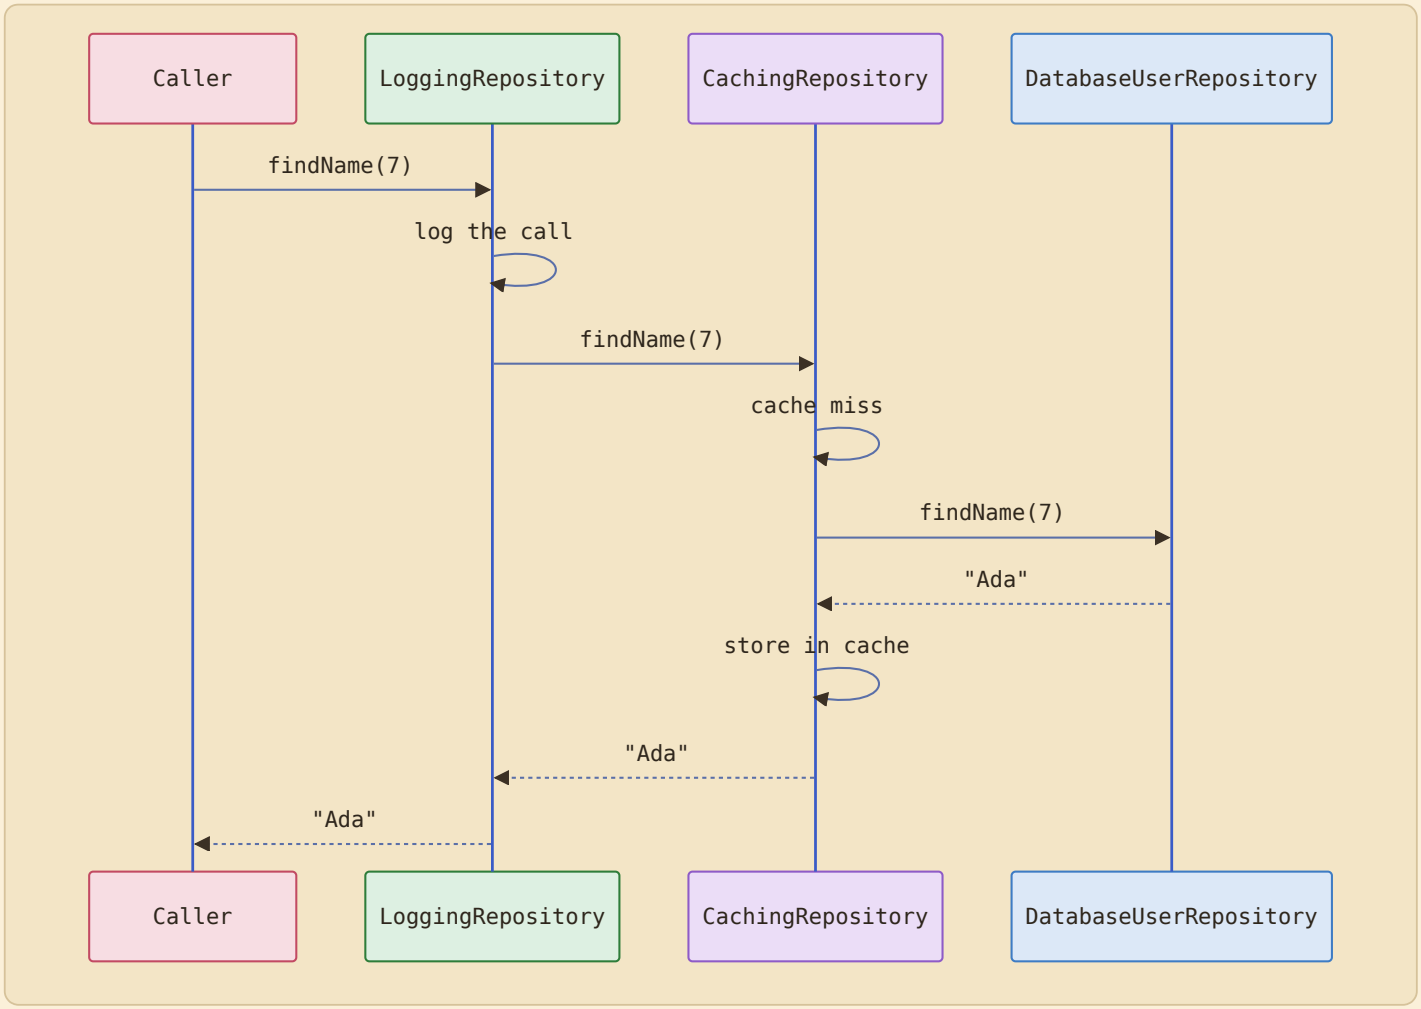
In the diagram above, every class implements `UserRepository` — the one property everything else depends on. `DatabaseUserRepository` always sits at the bottom and wraps nothing. Because each decorator's `inner` field is typed as the interface, decorators can wrap each other in any combination and any order.

The implementation detail that bites in practice is **delegation**: a decorator must forward every method it is not deliberately changing. One that overrides `findName` but silently swallows `rename` changes behaviour in a way that is very hard to spot. In Java the usual guard is an abstract base decorator that forwards everything by default (our `RepositoryDecorator`).



A decorated call, logging outside caching:



Java example

```java
// File: code/lld/ch09/decorator/UserRepository.java
package lld.ch09.decorator;

/** COMPONENT interface: every box in the stack implements it. */
interface UserRepository {
    String findName(int id);
    void rename(int id, String name);
}
```

```java
// File: code/lld/ch09/decorator/DatabaseUserRepository.java
package lld.ch09.decorator;

import java.util.HashMap;
import java.util.Map;

/** CONCRETE COMPONENT: the real work, always at the bottom of the stack. */
final class DatabaseUserRepository implements UserRepository {
    private final Map<Integer, String> table = new HashMap<>(Map.of(7, "Ada", 8, "Linus"));

    @Override
    public String findName(int id) {
        System.out.println("    [db]    query for user " + id);
        return table.get(id);
    }

    @Override
    public void rename(int id, String name) {
        System.out.println("    [db]    update user " + id);
        table.put(id, name);
    }
}
```

```java
// File: code/lld/ch09/decorator/RepositoryDecorator.java
package lld.ch09.decorator;

/**
 * BASE DECORATOR: holds the INTERFACE (not a concrete class) and forwards everything.
 * Subclasses override only what they change, so no method is ever forgotten.
 */
abstract class RepositoryDecorator implements UserRepository {
    protected final UserRepository inner;

    protected RepositoryDecorator(UserRepository inner) { this.inner = inner; }

    @Override public String findName(int id)          { return inner.findName(id); }
    @Override public void rename(int id, String name) { inner.rename(id, name); }
}
```

```java
// File: code/lld/ch09/decorator/LoggingRepository.java
package lld.ch09.decorator;

/** CONCRETE DECORATOR 1 */
final class LoggingRepository extends RepositoryDecorator {
    LoggingRepository(UserRepository inner) { super(inner); }

    @Override
    public String findName(int id) {
        System.out.println("    [log]   findName(" + id + ")");
        return super.findName(id);
    }
}
```

```java
// File: code/lld/ch09/decorator/CachingRepository.java
package lld.ch09.decorator;

import java.util.HashMap;
import java.util.Map;

/** CONCRETE DECORATOR 2 - note it must also invalidate on writes. */
final class CachingRepository extends RepositoryDecorator {
    private final Map<Integer, String> cache = new HashMap<>();

    CachingRepository(UserRepository inner) { super(inner); }

    @Override
    public String findName(int id) {
        if (cache.containsKey(id)) {
            System.out.println("    [cache] hit for " + id);
            return cache.get(id);
        }
        System.out.println("    [cache] miss for " + id);
        String name = super.findName(id);
        cache.put(id, name);
        return name;
    }

    @Override
    public void rename(int id, String name) {
        cache.remove(id);
        super.rename(id, name);
    }
}
```

```java
// File: code/lld/ch09/decorator/Beverage.java
package lld.ch09.decorator;

/** A second, classic decorator example: a coffee order priced by stacking add-ons.
 *  Prices are whole cents (int), so no floating-point money anywhere. */
interface Beverage {
    String description();
    int costCents();
}
```

```java
// File: code/lld/ch09/decorator/Espresso.java
package lld.ch09.decorator;

record Espresso() implements Beverage {
    public String description() { return "Espresso"; }
    public int costCents() { return 199; }
}
```

```java
// File: code/lld/ch09/decorator/HouseBlend.java
package lld.ch09.decorator;

record HouseBlend() implements Beverage {
    public String description() { return "House Blend"; }
    public int costCents() { return 89; }
}
```

```java
// File: code/lld/ch09/decorator/Milk.java
package lld.ch09.decorator;

/** Add-ons are decorators: they ARE a Beverage and HAVE a Beverage. */
record Milk(Beverage inner) implements Beverage {
    public String description() { return inner.description() + ", Milk"; }
    public int costCents() { return inner.costCents() + 10; }
}
```

```java
// File: code/lld/ch09/decorator/Mocha.java
package lld.ch09.decorator;

record Mocha(Beverage inner) implements Beverage {
    public String description() { return inner.description() + ", Mocha"; }
    public int costCents() { return inner.costCents() + 20; }
}
```

```java
// File: code/lld/ch09/decorator/Whip.java
package lld.ch09.decorator;

record Whip(Beverage inner) implements Beverage {
    public String description() { return inner.description() + ", Whip"; }
    public int costCents() { return inner.costCents() + 10; }
}
```

```java
// File: code/lld/ch09/decorator/UpperCaseInputStream.java
package lld.ch09.decorator;

import java.io.FilterInputStream;
import java.io.IOException;
import java.io.InputStream;

/**
 * Our own java.io decorator. FilterInputStream is the JDK's "base decorator":
 * it holds an InputStream and forwards every call to it.
 * Works byte-by-byte, so it is only correct for ASCII text.
 */
final class UpperCaseInputStream extends FilterInputStream {
    UpperCaseInputStream(InputStream in) { super(in); }

    @Override
    public int read() throws IOException {
        int b = super.read();
        return b == -1 ? -1 : Character.toUpperCase((char) b);
    }

    @Override
    public int read(byte[] buf, int off, int len) throws IOException {
        int n = super.read(buf, off, len);
        for (int i = off; i < off + Math.max(n, 0); i++) {
            buf[i] = (byte) Character.toUpperCase((char) buf[i]);
        }
        return n;
    }
}
```

```java
// File: code/lld/ch09/decorator/Main.java
package lld.ch09.decorator;

import java.io.BufferedInputStream;
import java.io.ByteArrayInputStream;
import java.io.IOException;
import java.io.InputStream;
import java.math.BigDecimal;
import java.nio.charset.StandardCharsets;

public class Main {

    static void lookUpTwice(String label, UserRepository repo) {
        System.out.println("  " + label);
        repo.findName(7);
        repo.findName(7);
    }

    public static void main(String[] args) throws IOException {
        System.out.println("== Same layers, different order ==");
        lookUpTwice("Logging outside caching (logs every caller request):",
                new LoggingRepository(new CachingRepository(new DatabaseUserRepository())));
        lookUpTwice("Caching outside logging (logs only what reaches the db):",
                new CachingRepository(new LoggingRepository(new DatabaseUserRepository())));

        System.out.println("== Write goes through every layer and invalidates the cache ==");
        UserRepository repo = new LoggingRepository(new CachingRepository(new DatabaseUserRepository()));
        repo.findName(8);
        repo.rename(8, "Linus T.");
        System.out.println("  now: " + repo.findName(8));

        System.out.println("== Coffee: stack add-ons at run time ==");
        Beverage order = new Whip(new Mocha(new Mocha(new Espresso())));
        System.out.println("  " + order.description() + " = $" + BigDecimal.valueOf(order.costCents(), 2));
        Beverage latte = new Milk(new HouseBlend());
        System.out.println("  " + latte.description() + " = $" + BigDecimal.valueOf(latte.costCents(), 2));

        System.out.println("== java.io is built from decorators ==");
        InputStream in = new UpperCaseInputStream(
                new BufferedInputStream(
                        new ByteArrayInputStream("decorators wrap streams".getBytes(StandardCharsets.US_ASCII))));
        try (in) {
            System.out.println("  " + new String(in.readAllBytes(), StandardCharsets.US_ASCII));
        }
    }
}
```

Output:

```
== Same layers, different order ==
  Logging outside caching (logs every caller request):
    [log]   findName(7)
    [cache] miss for 7
    [db]    query for user 7
    [log]   findName(7)
    [cache] hit for 7
  Caching outside logging (logs only what reaches the db):
    [cache] miss for 7
    [log]   findName(7)
    [db]    query for user 7
    [cache] hit for 7
== Write goes through every layer and invalidates the cache ==
    [log]   findName(8)
    [cache] miss for 8
    [db]    query for user 8
    [db]    update user 8
    [log]   findName(8)
    [cache] miss for 8
    [db]    query for user 8
  now: Linus T.
== Coffee: stack add-ons at run time ==
  Espresso, Mocha, Mocha, Whip = $2.49
  House Blend, Milk = $0.99
== java.io is built from decorators ==
  DECORATORS WRAP STREAMS
```

What each part does

- `RepositoryDecorator` — the **abstract base decorator**. It forwards *every* method, so a concrete decorator that only cares about `findName` cannot accidentally drop `rename`. This is the standard Java defence against forgotten delegation.
- `LoggingRepository` — prints, then delegates.
- `CachingRepository` — answers from its map on a hit (the value is already cached; a *miss* means it is not), otherwise delegates and stores. (More on caches in System Design Fundamentals.) It also overrides `rename` to **invalidate** (throw away the cached copy that is now out of date) — the third block of output shows the next read going to the database again.
- `Beverage` records — the classic coffee example (from *Head First Design Patterns*, rewritten): `new Whip(new Mocha(new Mocha(new Espresso())))` costs 1.99 + 0.20 + 0.20 + 0.10 = **$2.49**. Double mocha is just wrapping twice — impossible with one subclass per combination.
- `UpperCaseInputStream extends FilterInputStream` — our own `java.io` decorator. `FilterInputStream` is the JDK's base decorator: it holds an `InputStream` and forwards to it.

Layer order changes behaviour

Compare the two stacks in the output — they behave differently:

- **Logger on the outside, cache inside**: every request is logged, even those the cache serves → the log records *what callers requested*.
- **Cache on the outside, logger inside**: only cache misses are logged → the log records *what hit the database*, and the repeat request is absent.

Both are valid; they answer different questions. The mistake is picking one **without meaning to** and then reading the log as if it answered the other question. The same choice comes up wherever layers are stacked:

Pair	Outside	Inside
Retry vs cache	Repeats the entire lookup	Repeats only the database call, and a retry that succeeds populates the cache. Rule of thumb: put retry **next to the thing that fails**.
Metrics vs cache	Times what the caller experiences	Times the database alone — the number an on-call engineer (whoever is currently responsible for answering alerts) is paged on. Many teams record both.
Authorization (checking the caller is allowed) vs cache	**Correct** — every request is checked	**Security bug** — a cached answer is returned without the check ever running

The type checker accepts every ordering. **Record the reason for the order in a comment where the stack is built**, or the next person adding a layer will guess.

Two related traps

- **Stateful decorators that assume one wrap.** (Stateful means it keeps data between calls.) Apply a counting decorator twice to the same object and every call is counted twice.
- **Lost identity.** The wrapper is a different object from what it wraps, so `==` (same object?), `equals` (equal value?) and `instanceof` give answers callers don't expect. Code that digs through layers to "reach the real object" is working against the pattern.

Decorator vs inheritance

	Subclassing	Decorator
When behaviour is chosen	Compile time	Run time
How many at once	One subclass	Any number of layers, any order
Classes for N optional features	Up to 2^N	N
Works on `final` classes / classes you don't own	No	Yes (only needs the interface)
Can reach private state	Protected members, yes	No — only the public interface

Java I/O streams: the decorator you already use

`java.io` is built almost entirely from decorators:

```
new BufferedReader(new InputStreamReader(new FileInputStream("data.txt"), UTF_8))
```

- `FileInputStream` — concrete component (reads bytes from a file).
- `InputStreamReader` — strictly an **adapter** (bytes → characters), not a decorator.
- `BufferedReader` — a **decorator** on `Reader` (adds buffering — reading big chunks into memory to serve many small reads — and `readLine()`).

On the byte side, `FilterInputStream` is the abstract decorator, and `BufferedInputStream`, `DataInputStream`, `PushbackInputStream`, `java.util.zip.GZIPInputStream` (via `InflaterInputStream`) and `java.security.DigestInputStream` are concrete decorators. *Head First Design Patterns* notes the downside: the design produces many small classes, which can overwhelm newcomers until they see the pattern.

Trade-offs

Pros	Cons
Any mix without a class per mix — 4 concerns need 4 classes, not 16.	**Deeper stack traces** — the real work is buried under every layer.
Concerns tested in isolation — logging without a database, caching without a logger (Single Responsibility).	**Identity surprises** — `equals` / `instanceof` on the wrapper don't match the wrapped object.
Assembled at run time — different per caller, environment or feature flag (an on/off switch for a feature).	**Ordering matters for correctness**, and no compiler checks it.
The wrapped class is never edited (Open/Closed) — works even on classes you don't own.	**Over-layering** — eight wrappers deep, nobody knows which one changed a value.

When not to use it

- **Exactly one concern, forever.** Just put it in the class; a decorator for one behaviour is a whole class wrapped around a single `if`.
- **The concern needs private state.** A decorator can only use the public interface, so it is the wrong tool.
- **The framework already offers it** — middleware and interceptors (code a framework runs around every request or call), Spring AOP aspects (aspect-oriented programming: extra code applied automatically around chosen methods) are decorators with tooling. Don't hand-write ten wrappers beside them.

- **The stack would get deep.** Every extra layer is another frame in each stack trace, and with many layers "which one changed this value?" becomes a long debugging session.

Common mistakes

- Holding the **concrete class** instead of the interface (`private DatabaseUserRepository inner`) — then decorators cannot stack.
- **Forgetting to forward** some methods (use an abstract base decorator).
- A caching decorator that **doesn't invalidate on writes** (ours does in `rename`).
- Putting authorization **inside** a cache.
- Relying on `instanceof` of the outer object.

Real-world examples

- **`java.io` streams** — see above.
- **`java.util.Collections.unmodifiableList/synchronizedList/checkedList`** — each returns a wrapper with the same interface and one changed behaviour (read-only, synchronized, type-checked). Some authors call `unmodifiableList` a protection **proxy**; both labels are defensible.
- **`javax.servlet.http.HttpServletRequestWrapper`** (Jakarta: `jakarta.servlet...`) — a base decorator you subclass to change selected request methods in a filter (code that runs before and after each web request in a Java servlet — i.e. web — application).
- **HTTP middleware** (HTTP is the web's request/response protocol) — the web frameworks Express, Django, ASP.NET and Go's `http.Handler` wrap a handler in layers (logging, auth, compression, rate limiting — capping how many requests a client may make per time window). Middleware is this pattern with framework support.
- **Resilience4j (Java) and Polly (.NET)** — compose retry, circuit breaker (stops calling a failing service for a while), timeout and bulkhead (separate, limited resources so one slow dependency cannot use them all) as stacked wrappers, e.g. `Decorators.ofSupplier(...).withCircuitBreaker(...).withRetry(...).withBulkhead(...).decorate()`; both document the ordering carefully because it changes behaviour.
- **Python's `@functools.lru_cache`** (and `@retry` from libraries such as tenacity) — function decorators (LRU = least recently used: a full cache drops the entry that has gone unused longest): the same idea applied to functions, and the reason Python uses the name.

In modern languages

- **Java**: abstract forwarding base class (as here), or a dynamic proxy (a class generated at run time; see 9.7) that generates the forwarding.
- **Python**: function decorators (`@lru_cache` and friends) are this pattern with syntax; for objects, `__getattr__` forwarding (and `functools.wraps` for functions) avoids hand-writing every delegating method.
- **JavaScript / TypeScript**: a higher-order function (one that takes or returns functions) that returns a wrapped function; a `Proxy` object can forward every method automatically.
- **Go**: a struct (Go's plain record-like type) that embeds the interface value gets delegation for free — why Go middleware reads so cleanly.
- **C#**: `DelegatingHandler` in `HttpClient` is a framework-provided decorator chain.

In the interview

> **30-second answer:** "Decorator adds responsibilities to an object at run time by wrapping it in another object with the same interface. Without it, four optional concerns mean sixteen subclasses; with it, each concern — logging, caching, retries — is one class and I compose the stack I need. The decorator holds the interface, not the concrete class, which is what lets layers stack. And order matters: retry goes closest to what fails, and authorization must sit outside a cache or a cache hit skips the check."

Follow-ups

- *Q: Decorator vs Proxy?* — A: Same structure; different intent. Decorator **adds behaviour** and normally forwards the call; the client hands it the object to wrap and often stacks several. Proxy **controls access** — it may defer, cache or refuse — often creates or locates the real object itself, and is usually handed to a client that doesn't know it isn't the real thing. The boundary is genuinely fuzzy (a caching wrapper is fairly called either), and saying so is a better answer than pretending it is sharp.

- *Q: Decorator vs Adapter?* — A: Decorator keeps the interface and changes behaviour; Adapter changes the interface and keeps behaviour.
- *Q: Decorator vs Chain of Responsibility?* — A: Both are chains of objects. In Decorator every layer normally does its extra work and passes the call on to the core (a caching layer answering a hit is the usual exception). In Chain of Responsibility, typically one handler handles the request and the rest never see it.
- *Q: Decorator vs Composite?* — A: Decorator wraps exactly one child and adds behaviour; Composite holds many children and aggregates.
- *Q: Give a JDK example.* — A: `new BufferedInputStream(new FileInputStream(f))`; `FilterInputStream` is the base decorator.

Self-check

1. **Q:** How many classes for 5 optional features with decorators vs one subclass per combination? **A:** 5 vs up to 32.
2. **Q:** Why does `RepositoryDecorator` forward every method? **A:** So concrete decorators cannot silently drop methods they don't override.
3. **Q:** Why is "authorization inside cache" a bug? **A:** A cache hit returns data without ever running the authorization check.
4. **Q:** Is `InputStreamReader` a decorator? **A:** No — it changes the interface (bytes to chars), so it is an adapter. `BufferedReader` is the decorator.

TL;DR

> - **Wrap to add behaviour, keep the interface.** IS-A and HAS-A the same type.
> - N features = N classes, stacked at run time, in any order — and **order matters**.
> - Java I/O, `Collections.synchronizedList`, middleware, Resilience4j are all decorators. A decorator normally forwards every call; one that short-circuits (a cache hit) is drifting towards Proxy.

9.5 Facade Pattern

What it is

The **Facade** pattern gives a complicated subsystem **one simple front door**, so that most callers never deal with the machinery behind it. GoF's intent: *provide a unified interface to a set of interfaces in a subsystem; the facade defines a higher-level interface that makes the subsystem easier to use.*

Analogy: a hotel concierge. You say "book me dinner and a taxi"; the concierge calls the restaurant, the taxi company and the front desk in the right order. You can still phone the restaurant yourself if you want something unusual.

Term	Meaning	In our code
Facade	Knows which subsystem classes to call, in what order, and how to clean up	`OrderFacade`
Subsystem classes	Do the real work; unaware of the facade	`InventoryService`, `PaymentService`, `ShippingService`, `EmailService`
Client	Uses the facade instead of the subsystem	`Main` / a checkout page

The problem it solves

One useful action needs several objects, called in the right order. To place an order you must **reserve stock → charge the card → create a shipment → send a confirmation**. Every place in the code that places an order repeats those four calls — and each copy must also know what to do if the card is declined **after** the stock has been reserved.

That recovery step is where bugs live. Copying the success path is easy; copying the undo correctly is not. A caller that forgets to release the reservation leaves units locked for an order that was never placed.

Nothing is wrong with the subsystem itself — it is **flexible**, and flexibility means many knobs. The trouble is that nearly every caller wants the same standard sequence and writes it out yet again.

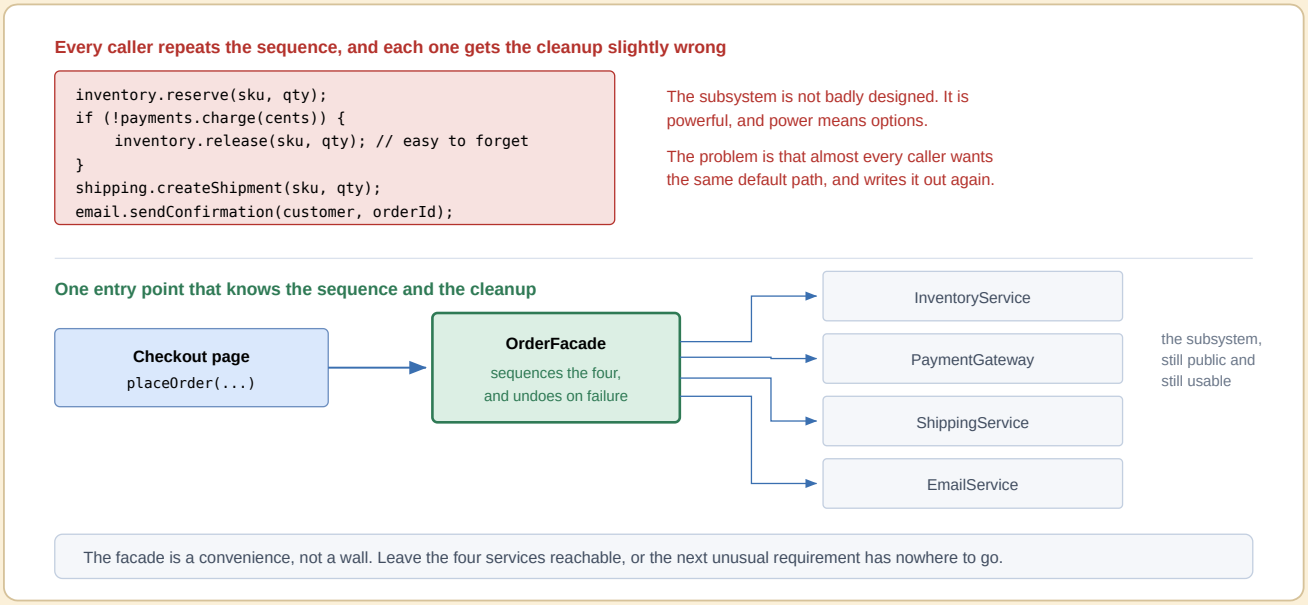


Figure — Top: each caller repeats the reserve/charge/release/ship/email sequence and may forget the release. Bottom: the checkout page calls `OrderFacade.placeOrder(...)`, which sequences the four services and undoes on failure; the services stay public (course diagram)

How it works

1. **Identify the common path** that many callers repeat.
2. **Create a facade class** that holds the subsystem objects.
3. **Expose one intention-revealing method** (`placeOrder`) that calls them in the correct order.
4. **Own the failure handling** — if payment fails, the facade releases the reservation (a *compensating action*).
5. **Keep the subsystem public**, so unusual callers can still reach past the facade.
6. **Add no business rules** — the facade *sequences*, it does not *decide*.

Structure

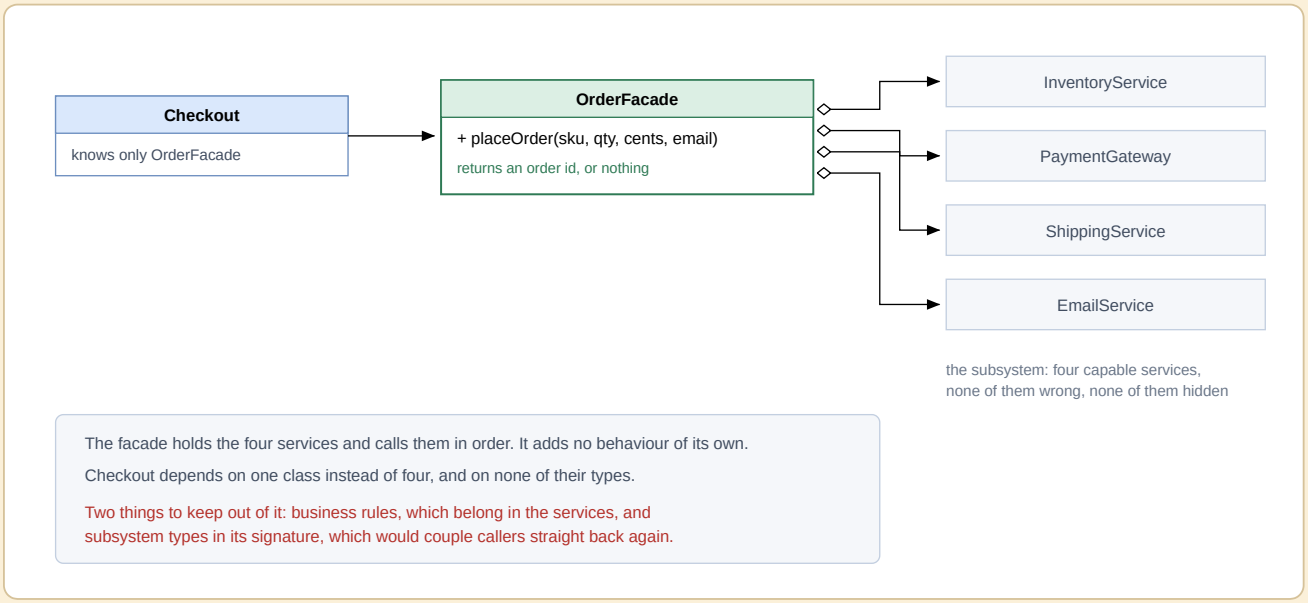

Figure — Facade class diagram: `Checkout` depends only on `OrderFacade`, which holds the four services (shown in grey) and exposes `placeOrder`. The figure labels the payment service `PaymentGateway` and shows a shorter `placeOrder` signature; our code calls it `PaymentService` and also passes customer and address (course diagram)

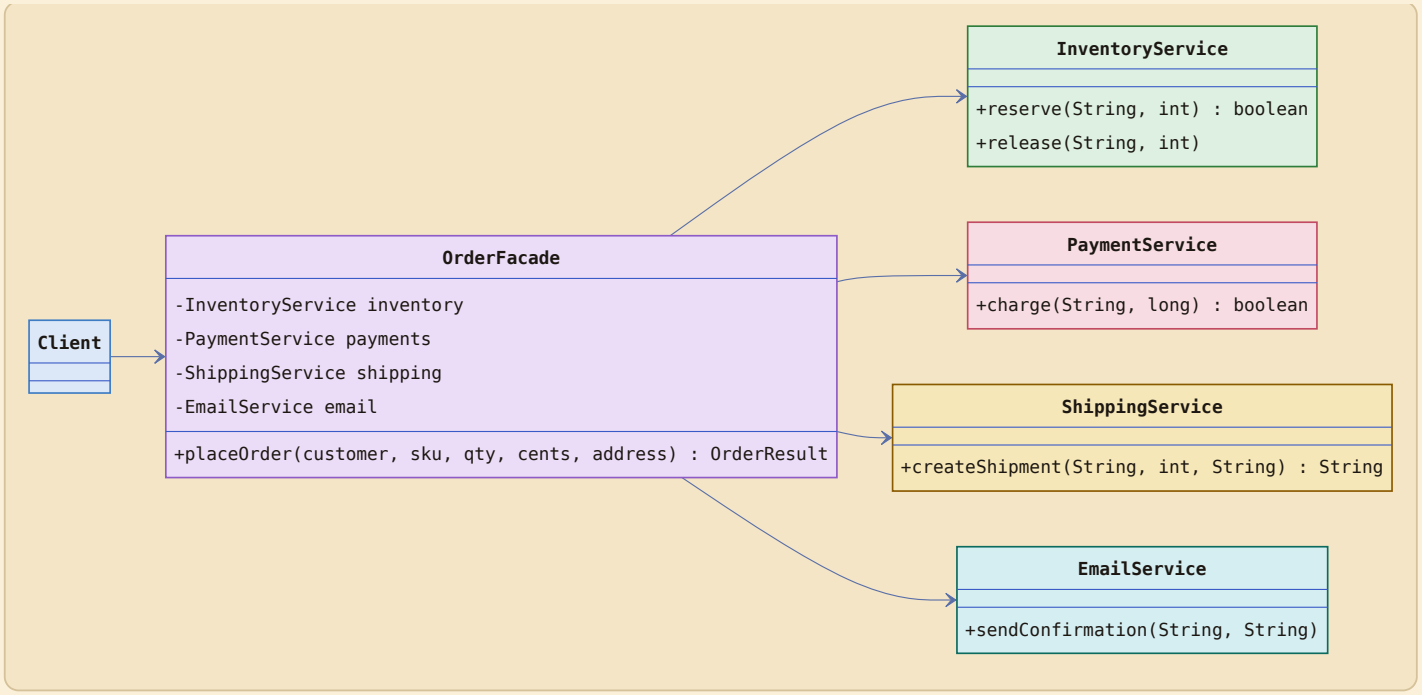
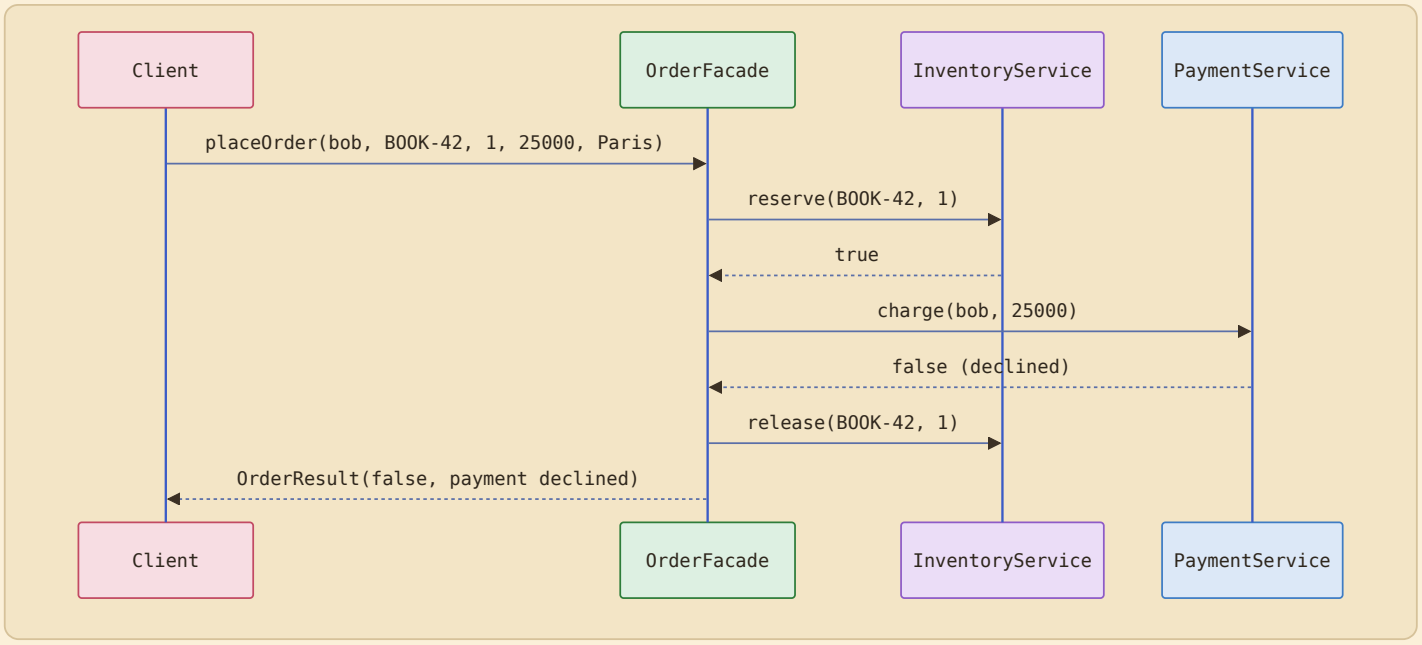
In the class diagram above, dependencies run in **one direction** only: none of the services knows the facade exists, so they remain usable on their own. Note also that there is no interface: a facade is normally a concrete convenience class, not an abstraction. Introduce an interface only if you plan to substitute the entire subsystem — which is a different job.



InventoryService
+reserve(String, int) : boolean
+release(String, int)
PaymentService
+charge(String, long) : boolean
Client
OrderFacade
-InventoryService inventory
-PaymentService payments
-ShippingService shipping
-EmailService email
+placeOrder(customer, sku, qty, cents, address) : OrderResult
ShippingService
+createShipment(String, int, String) : String
EmailService
+sendConfirmation(String, String)



Client
OrderFacade
InventoryService
PaymentService
placeOrder(bob, BOOK-42, 1, 25000, Paris)
reserve(BOOK-42, 1)
true
charge(bob, 25000)
false (declined)
release(BOOK-42, 1)
OrderResult(false, payment declined)
Client
OrderFacade
InventoryService
PaymentService

Java example

```java
// File: code/lld/ch09/facade/InventoryService.java
package lld.ch09.facade;

import java.util.HashMap;
import java.util.Map;

/*
 * SUBSYSTEM: four independent, still-public services.
 * None of them knows the facade exists.
 */

final class InventoryService {
    private final Map<String, Integer> stock = new HashMap<>(Map.of("BOOK-42", 5));

    boolean reserve(String sku, int qty) {
        int have = stock.getOrDefault(sku, 0);
        if (have < qty) return false;
        stock.put(sku, have - qty);
        System.out.println("  [inventory] reserved " + qty + " x " + sku + " (left " + (have - qty) + ")");
        return true;
    }

    void release(String sku, int qty) {
        stock.merge(sku, qty, Integer::sum);
        System.out.println("  [inventory] released " + qty + " x " + sku + " (left " + stock.get(sku) + ")");
    }
}
```

```java
// File: code/lld/ch09/facade/PaymentService.java
package lld.ch09.facade;

final class PaymentService {
    /** Declines anything over $100 so the demo can show the failure path. */
    boolean charge(String customer, long cents) {
        boolean ok = cents <= 10_000;
        System.out.println("  [payment]   charge " + customer + " " + cents + "c -> " + (ok ? "OK" : "DECLINED"));
        return ok;
    }
}
```

```java
// File: code/lld/ch09/facade/ShippingService.java
package lld.ch09.facade;

final class ShippingService {
    private int next = 1;

    String createShipment(String sku, int qty, String address) {
        String id = "SHP-" + next++;
        System.out.println("  [shipping]  " + id + ": " + qty + " x " + sku + " to " + address);
        return id;
    }
}
```

```java
// File: code/lld/ch09/facade/EmailService.java
package lld.ch09.facade;

final class EmailService {
    void sendConfirmation(String customer, String orderId) {
        System.out.println("  [email]     confirmation for " + orderId + " sent to " + customer);
    }
}
```

```java
// File: code/lld/ch09/facade/OrderResult.java
package lld.ch09.facade;

/** What callers get back: our own small result type. */
record OrderResult(boolean success, String orderId, String message) { }
```

```java
// File: code/lld/ch09/facade/OrderFacade.java
package lld.ch09.facade;

/**
 * FACADE: one method that knows the correct SEQUENCE and the CLEANUP.
 * It sequences; it does not decide business rules (no pricing, no fraud logic here).
 */
final class OrderFacade {
    private final InventoryService inventory;
    private final PaymentService payments;
    private final ShippingService shipping;
    private final EmailService email;
    private int orderSeq = 100;

    OrderFacade(InventoryService inventory, PaymentService payments,
                ShippingService shipping, EmailService email) {
        this.inventory = inventory;
        this.payments = payments;
        this.shipping = shipping;
        this.email = email;
    }

    OrderResult placeOrder(String customer, String sku, int qty, long cents, String address) {
        String orderId = "ORD-" + orderSeq++;
        if (!inventory.reserve(sku, qty)) {
            return new OrderResult(false, orderId, "out of stock");
        }
        if (!payments.charge(customer, cents)) {
            inventory.release(sku, qty);            // compensating step callers used to forget
            return new OrderResult(false, orderId, "payment declined");
        }
        String shipmentId = shipping.createShipment(sku, qty, address);
        email.sendConfirmation(customer, orderId);
        return new OrderResult(true, orderId, "shipped as " + shipmentId);
    }
}
```

```java
// File: code/lld/ch09/facade/Main.java
package lld.ch09.facade;

public class Main {
    public static void main(String[] args) {
        InventoryService inventory = new InventoryService();
        OrderFacade orders = new OrderFacade(inventory, new PaymentService(),
                new ShippingService(), new EmailService());

        System.out.println("== Happy path: one call instead of four ==");
        System.out.println("  -> " + orders.placeOrder("ada@x.com", "BOOK-42", 2, 5_000, "London"));

        System.out.println("== Declined card: the facade undoes the reservation ==");
        System.out.println("  -> " + orders.placeOrder("bob@x.com", "BOOK-42", 1, 25_000, "Paris"));

        System.out.println("== Out of stock ==");
        System.out.println("  -> " + orders.placeOrder("cy@x.com", "BOOK-42", 99, 1_000, "Rome"));

        System.out.println("== The subsystem is still reachable for unusual needs ==");
        inventory.reserve("BOOK-42", 1);   // e.g. a warehouse tool holding stock manually
    }
}
```

Output:

```
== Happy path: one call instead of four ==
  [inventory] reserved 2 x BOOK-42 (left 3)
  [payment]   charge ada@x.com 5000c -> OK
  [shipping]  SHP-1: 2 x BOOK-42 to London
  [email]     confirmation for ORD-100 sent to ada@x.com
  -> OrderResult[success=true, orderId=ORD-100, message=shipped as SHP-1]
== Declined card: the facade undoes the reservation ==
  [inventory] reserved 1 x BOOK-42 (left 2)
  [payment]   charge bob@x.com 25000c -> DECLINED
  [inventory] released 1 x BOOK-42 (left 3)
  -> OrderResult[success=false, orderId=ORD-101, message=payment declined]
== Out of stock ==
  -> OrderResult[success=false, orderId=ORD-102, message=out of stock]
== The subsystem is still reachable for unusual needs ==
  [inventory] reserved 1 x BOOK-42 (left 2)
```

What each part does

- The four services are ordinary classes with their own responsibilities; none mention `OrderFacade`.
- `OrderFacade.placeOrder` is the whole pattern: the correct **sequence** plus the **compensating step** (`inventory.release`) on a declined payment. Look at the second block of output — reserved, declined, released — without the caller writing any of it.
- `OrderResult` — a small result type so callers don't need subsystem types.
- The last line of `main` calls `inventory.reserve` directly: the facade is **a convenience, not a wall**.

Facade vs Adapter vs Mediator

	Facade	**Adapter**	**Proxy**	**Mediator (Ch. 10–11)**
Intent	Simplify a subsystem	Convert one interface to another	Control access to one object	Coordinate peers that would otherwise talk directly
Objects wrapped	**Several**	**One**	**One**	Several colleagues
Interface offered	New, smaller one	The client's (Target)	**Same** as the real object	Mediator's own
Who chose the interface	**You** — a simpler one over things you usually control	**Someone else** — you must fit it	Already fixed by the real object	You
Do the wrapped objects know about it?	**No** — one-way	No	No	**Yes** — colleagues talk *through* the mediator
Direction of communication	Client → facade → subsystem	Client → adapter → adaptee	Client → proxy → real subject	Colleague ↔ mediator ↔ colleague (both ways)
Example	`OrderFacade.placeOrder`	`StripeGateway.pay`	`LazyReport`	An air-traffic control tower; a chat room

The quickest way to spot a facade is the **"objects wrapped"** row: Adapter, Decorator and Proxy each stand in front of exactly one object; a Facade stands in front of **several**.

Another test: suppose the subsystem changed its API tomorrow to exactly what callers want. An **Adapter** would then be pointless; a **Facade** would still be useful, because its value was the *simplification*, not a translation.

Facade vs "service layer". (A service layer is the set of classes that expose the app's use cases — such as placing an order — to its UI or API.) Most of the time these are the same thing under two names. A service class that only *sequences* calls is a facade; once it holds business rules it has become something else (a domain/application service with logic of its own).

The failure mode to watch for

Facades **pull in features**. Day one it is four calls in order; then a discount rule lands in it ("orders are placed here, after all"), then a fraud check, and a year later it is the **god object** (one class that knows and does almost everything) everyone is afraid to edit. Keep one rule: **a facade orchestrates; it does not decide.** If it is making a business decision instead of calling the thing that makes it, that logic belongs elsewhere — and moving it out later is far harder than keeping it out now.

This connects to the **Principle of Least Knowledge** (Law of Demeter) that *Head First Design Patterns* pairs with Facade: "talk only to your immediate friends". Clients talk to the facade, not to a chain of subsystem objects, which reduces coupling.

Trade-offs

Pros	Cons
One call replaces a multi-step sequence, so the common path is no longer duplicated.	**One more class to maintain** as the subsystem evolves.
The order and the undo logic live in one place — exactly the part callers got wrong.	**Feature magnet** — grows into a god object unless someone pushes back.
One seam for swapping the subsystem later — only the facade changes.	**Opinionated** — some caller will need an option the facade left out.
Smaller public surface for the module; lower coupling.	**Can mask problems** — a neat front over a subsystem that still fails; everything funnels through it, so it can become a single point of failure (one part whose failure stops everything).

When not to use it

- **The subsystem is already simple** — wrapping two calls just adds a file to maintain.
- **Callers need the full range** — if every caller bypasses the facade for some option, its shape is wrong: widen it on purpose or remove it.
- **You are covering a mess instead of fixing it** — you get a neat front and the same failures behind it; sometimes the honest move is to repair the subsystem.
- **You want it to be the only entrance** — hiding the subsystem forces every unusual need into the facade, which is how god objects are born.

Common mistakes

- Putting business rules (pricing, fraud) in the facade.
- Making the subsystem inaccessible.
- Returning subsystem types from the facade so callers are still coupled to them.
- Forgetting the failure path — a facade that only does the happy path (the path where nothing goes wrong) misses its biggest value.
- Confusing it with Mediator (see table).

Real-world examples

- **Application service layers** — almost every `OrderService` or `RegistrationService` is a facade over repositories, gateways and notifiers (as long as it only sequences).
- **`java.net.URL`** — `url.openStream()` hides protocol handlers, connection setup and content handlers behind one call. (Since Java 20 the `URL` constructors are deprecated (officially discouraged and due for removal); create one with `URI.create(s).toURL()`. The facade idea is unchanged.)
- **SLF4J** **`LoggerFactory.getLogger(...)`** — hides configuration, appenders (log destinations such as files or the console) and formatters behind one call. (SLF4J literally calls itself a "Simple Logging Facade".)
- **`javax.faces.context.FacesContext`**, **jQuery** (historically the clearest example: one `$` function in front of DOM, events, animation and XHR (the browser's API for sending HTTP requests from JavaScript), each still usable directly), and Python's **`requests`**, which covers the common "just fetch this URL" cases on top of `urllib3`.
- **E-commerce checkout**: when you press "Place order" on Amazon or Flipkart, one backend (server-side) call orchestrates (coordinates) inventory, payment, shipping and notifications — a facade (often called an

orchestrator or backend-for-frontend — a server layer built for one particular UI).

In modern languages

- **Python / JavaScript**: a module exporting one function and keeping the rest private is a facade with no class at all.
- **Go**: a package's exported functions are the facade; lowercase identifiers stay internal.
- **Java**: a package with one public class (package-private subsystem), or a JPMS (Java Platform Module System) module that exports only the facade's package.
- **Any language**: a single well-named function is often the whole pattern — if `placeOrder` needs no state of its own, it does not have to be a class.

In the interview

> **30-second answer:** "A Facade gives one simple entry point to a complex subsystem. For order placement, `OrderFacade.placeOrder` reserves stock, charges, ships and emails in the right order, and if payment fails it releases the reservation — so no caller has to remember that cleanup. It wraps several objects, unlike Adapter, Decorator and Proxy which wrap one. I keep the subsystem public, because a facade is a convenience, not a wall, and I keep business rules out of it — the main risk is that it grows into a god object."

Follow-ups

- *Q: How is it different from Adapter?* — A: Adapter converts one interface because someone else chose it; Facade simplifies many objects behind a new interface you chose.
- *Q: And from Mediator?* — A: Subsystem classes don't know the facade exists; colleagues in a Mediator know it and communicate through it, in both directions.
- *Q: Risk?* — A: God object. A facade should sequence, not decide.
- *Q: Should the subsystem be hidden?* — A: Usually no; leave it reachable for unusual needs.
- *Q: Can a system have several facades?* — A: Yes — e.g. one per use case, or layered facades over sub-subsystems.

Self-check

1. **Q:** What is the fastest structural way to tell a Facade from Adapter/Decorator/Proxy? **A:** It wraps several objects; the others wrap one.
2. **Q:** In our code, what does the facade do when payment is declined? **A:** Releases the stock reservation and returns a failed `OrderResult`.
3. **Q:** A teammate adds a 10% discount rule inside `placeOrder`. Good idea? **A:** No — business rules belong in a service the facade calls; the facade only sequences.
4. **Q:** Which OO principle is closely related to Facade? **A:** Principle of Least Knowledge (Law of Demeter).

TL;DR

> - **One door into a complex subsystem.** Names the common path and owns the cleanup.
> - Wraps **several** objects; subsystem stays **public**; facade **sequences, never decides**.
> - Different from Adapter (translation of one) and Mediator (two-way coordination of peers).

9.6 Flyweight Pattern

What it is

The **Flyweight** pattern **shares** the portion of each object's state that is the same across many objects, so that huge numbers of them fit in memory. GoF's intent: *use sharing to support large numbers of fine-grained objects efficiently.*

Analogy: a printed book. Every letter "e" on every page uses the same metal type design (shared), placed at a different position (unique). You don't carve a new "e" for every occurrence.

Two terms carry the whole pattern:

Term	Meaning	In the map example
Intrinsic state	Part of the thing's own identity and **identical for every holder**. Lives inside the shared flyweight.	icon bitmap, colour, size
Extrinsic state	**Varies with the context** the object is used in; different for each holder. Stays outside and is **handed in** as method arguments.	latitude, longitude

The words are GoF's and interviewers use them, even though on their own they explain little — remember "intrinsic = inside the shared object", "extrinsic = supplied from outside".

Role	In our code
Flyweight (shared, immutable, intrinsic only)	`MarkerStyle`
Flyweight factory (owns the pool, returns existing or creates once)	`MarkerStyleFactory`
Context (one per logical object: extrinsic state + reference to a flyweight)	`Marker`
Client (asks the factory, supplies extrinsic state)	`Main`

GoF's own participant list is *Flyweight* (the interface that accepts extrinsic state), *ConcreteFlyweight* (the shared implementation — our `MarkerStyle` plays both roles since we need no interface), *UnsharedConcreteFlyweight* (objects of the same interface that are **not** shared, e.g. a row object holding its own children), *FlyweightFactory* and *Client*. "Context" is the name later sources (such as refactoring.guru) give to the object that stores the extrinsic state.

The problem it solves

Picture a map app showing **100,000 markers**. Every marker stores its latitude and longitude — plus an icon bitmap, a colour and a size. Positions are all different, but the icon is the same for thousands of markers, and the icon is by far the largest field. Keeping 100,000 copies of a 2 MB bitmap is not "a bit slow": it needs ~195 GB, so **the program simply runs out of memory.**

The same situation shows up in a game with a million trees that all use one mesh and texture (a 3D shape and the image painted onto it), in a text editor that would otherwise store font data for every character, and anywhere many objects **differ slightly but share a large common part**.

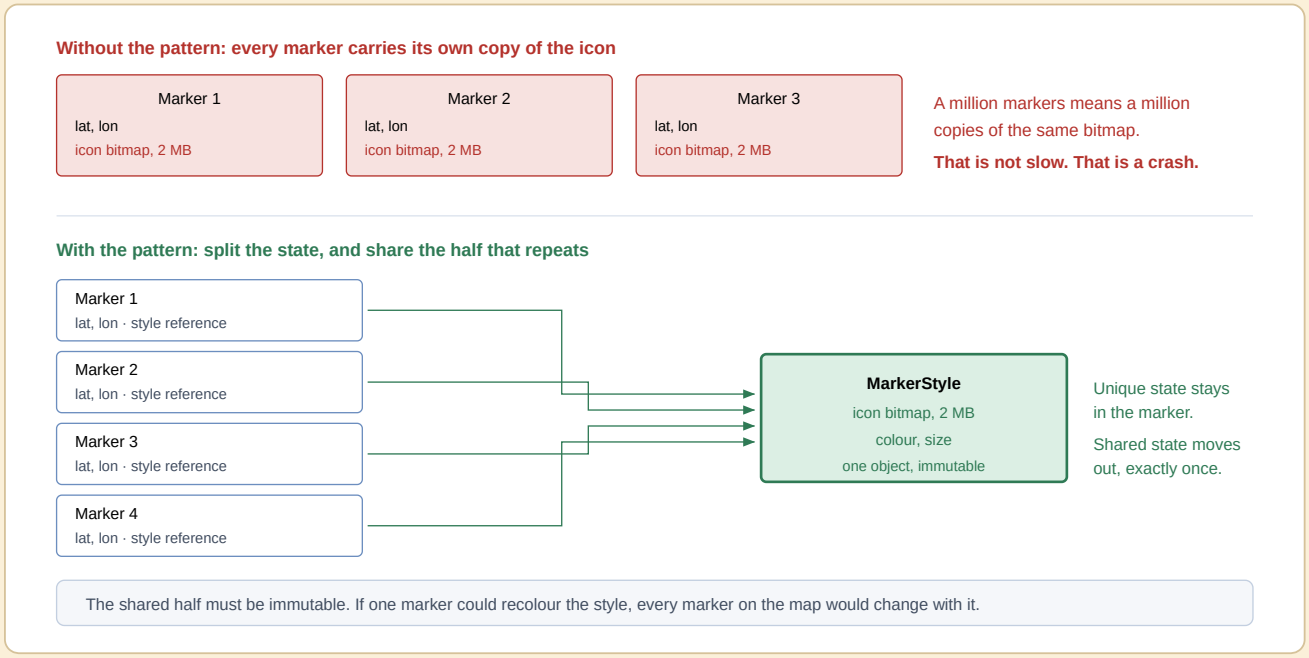


Figure — Top: every marker carries its own 2 MB icon. Bottom: each marker keeps only lat/lon and a style reference; one immutable `MarkerStyle` holds the icon, colour and size (course diagram)

How it works

1. **Split the state**: intrinsic (shared, invariant) vs extrinsic (per holder).
2. **Move intrinsic state into an immutable flyweight class** — all fields `final`, no setters.
3. **Pass extrinsic state as method arguments** (`draw(lat, lon)`) instead of storing it in the flyweight.

4. **Create a factory that owns the pool**, keyed by the intrinsic values. `get(...)` returns the existing object or creates it the first time.
5. **Clients must go through the factory**, never the constructor (enforce with package-private/private constructors).
6. **Context objects** keep only extrinsic state plus a **reference** (not a copy) to the flyweight.

> **Two rules — break either and the pattern silently stops working.**
>
> 1. **Flyweights never change.** Many holders point at the same object, so a modification made for one is seen by every other.
> 2. **Only the factory creates them.** If callers can use the constructor directly, identical copies appear and the memory saving is gone.

Structure

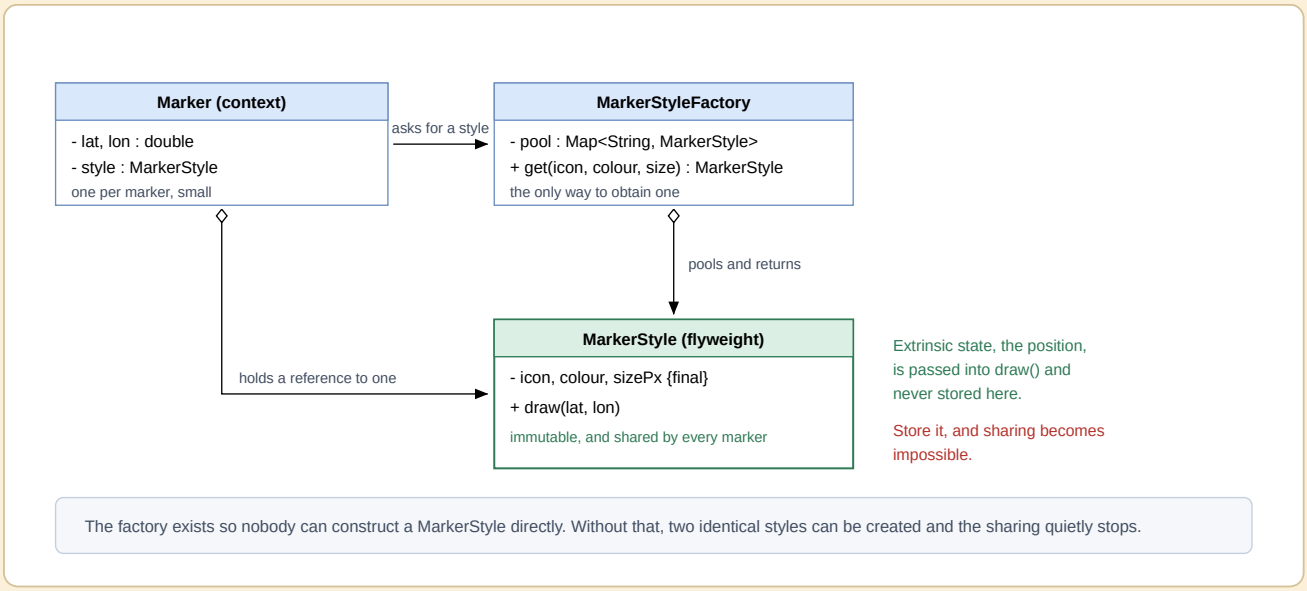

Figure — Flyweight class diagram: `MarkerStyle` (final fields, `draw(lat, lon)`), `MarkerStyleFactory` with a pool and `get()`, and `Marker` holding position plus a style reference (course diagram)

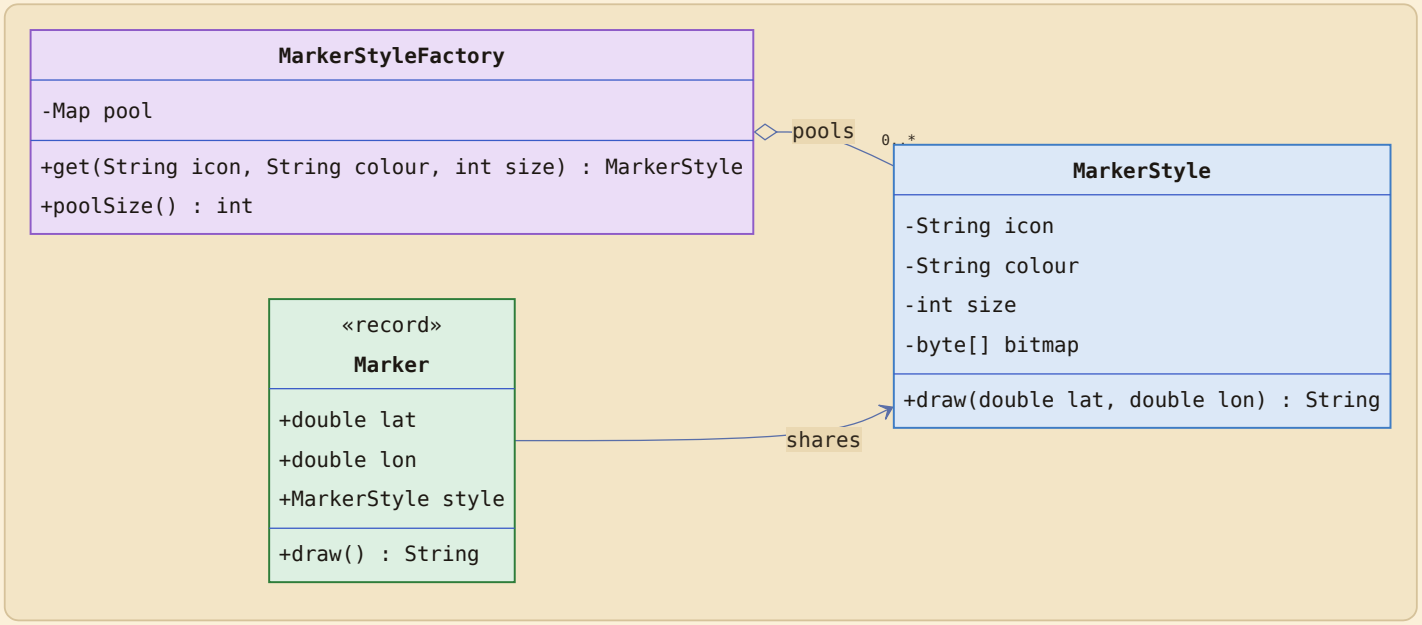
In the diagram above, `draw` receives the position as arguments rather than keeping it in a field, `Marker` holds a *reference* to a style rather than its own copy, and clients obtain styles from the factory, never from the constructor. That last rule has to be enforced — by a package-private (or private) constructor, or at least by convention and code review.



Java example

```java
// File: code/lld/ch09/flyweight/MarkerStyle.java
package lld.ch09.flyweight;

/**
 * FLYWEIGHT: holds only INTRINSIC state (same for every marker using this style).
 * Immutable: all fields final, no setters, and the bitmap array never leaves the object.
 * The constructor is package-private, so code outside this package cannot bypass the
 * factory. (Inside the package it is a convention: only MarkerStyleFactory calls it.)
 */
final class MarkerStyle {
    static final int ICON_BYTES = 2 * 1024 * 1024;   // pretend every icon bitmap is 2 MB

    private final String icon;
    private final String colour;
    private final int size;
    private final byte[] bitmap;   // the heavy part we want exactly one copy of

    MarkerStyle(String icon, String colour, int size) {
        System.out.println("  loading icon '" + icon + "' (" + colour + ", " + size + "px)");
        this.icon = icon;
        this.colour = colour;
        this.size = size;
        this.bitmap = new byte[ICON_BYTES];
    }

    /** EXTRINSIC state (the position) is passed in, never stored. */
    String draw(double lat, double lon) {
        return String.format("%s %s marker at (%.4f, %.4f)", colour, icon, lat, lon);
    }

    int bitmapBytes() { return bitmap.length; }
}
```

```java
// File: code/lld/ch09/flyweight/MarkerStyleFactory.java
package lld.ch09.flyweight;

import java.util.Map;
import java.util.concurrent.ConcurrentHashMap;

/** FLYWEIGHT FACTORY: owns the pool. Thread-safe via ConcurrentHashMap.computeIfAbsent. */
final class MarkerStyleFactory {
    /** The pool key is the combination of intrinsic values. */
    private record Key(String icon, String colour, int size) { }

    private final Map<Key, MarkerStyle> pool = new ConcurrentHashMap<>();

    MarkerStyle get(String icon, String colour, int size) {
        return pool.computeIfAbsent(new Key(icon, colour, size),
                k -> new MarkerStyle(k.icon(), k.colour(), k.size()));
    }

    int poolSize() { return pool.size(); }
}
```

```java
// File: code/lld/ch09/flyweight/Marker.java
package lld.ch09.flyweight;

/** CONTEXT: one per marker. Holds extrinsic state + a REFERENCE to a shared style. */
record Marker(double lat, double lon, MarkerStyle style) {
    String draw() { return style.draw(lat, lon); }
}
```

```java
// File: code/lld/ch09/flyweight/Main.java
package lld.ch09.flyweight;

import java.util.ArrayList;
import java.util.List;
import java.util.Random;

public class Main {
    public static void main(String[] args) {
        MarkerStyleFactory styles = new MarkerStyleFactory();

        System.out.println("== Five markers, three styles ==");
        List<Marker> few = List.of(
                new Marker(51.5074, -0.1278, styles.get("cafe", "brown", 24)),
                new Marker(48.8566, 2.3522, styles.get("cafe", "brown", 24)),
                new Marker(40.7128, -74.0060, styles.get("fuel", "green", 24)),
                new Marker(35.6762, 139.6503, styles.get("hospital", "red", 32)),
                new Marker(52.5200, 13.4050, styles.get("fuel", "green", 24)));
        few.forEach(m -> System.out.println("  " + m.draw()));
        System.out.println("  same shared object? " + (few.get(0).style() == few.get(1).style()));

        System.out.println("== Scale to 100,000 markers ==");
        String[] icons = {"cafe", "fuel", "hospital"};
        String[] colours = {"brown", "green", "red"};
        int[] sizes = {24, 24, 32};
        Random rnd = new Random(42);
        List<Marker> many = new ArrayList<>();
        for (int i = 0; i < 100_000; i++) {
            int t = rnd.nextInt(3);
            many.add(new Marker(rnd.nextDouble() * 180 - 90, rnd.nextDouble() * 360 - 180,
                    styles.get(icons[t], colours[t], sizes[t])));
        }
        long withoutMb = (long) many.size() * MarkerStyle.ICON_BYTES / (1024 * 1024);
        long withMb = (long) styles.poolSize() * MarkerStyle.ICON_BYTES / (1024 * 1024);
        System.out.println("  markers: " + many.size() + ", styles in pool: " + styles.poolSize());
        System.out.println("  icon memory without flyweight: ~" + withoutMb + " MB");
        System.out.println("  icon memory with flyweight:    ~" + withMb + " MB");

        System.out.println("== Flyweights already in the JDK ==");
        Integer a = 127, b = 127;          // autoboxing calls Integer.valueOf
        Integer c = 128, d = 128;
        System.out.println("  Integer 127 == 127 -> " + (a == b) + "  (cached -128..127)");
        System.out.println("  Integer 128 == 128 -> " + (c == d) + " (outside default cache)");
        System.out.println("  equals() is always right -> " + c.equals(d));
        System.out.println("  Boolean.valueOf(true) == Boolean.TRUE -> " + (Boolean.valueOf(true) ==
Boolean.TRUE));

        String lit = "hello";
        String built = new String("hello");
        System.out.println("  \"hello\" == \"hel\" + \"lo\" -> " + (lit == "hel" + "lo") + " (compile-time
constant, pooled)");
        System.out.println("  \"hello\" == new String(\"hello\") -> " + (lit == built));
        System.out.println("  \"hello\" == built.intern() -> " + (lit == built.intern()));
    }
}
```

Output:

```
== Five markers, three styles ==
  loading icon 'cafe' (brown, 24px)
  loading icon 'fuel' (green, 24px)
  loading icon 'hospital' (red, 32px)

  Boolean.valueOf(true) == Boolean.TRUE -> true
  "hello" == "hel" + "lo" -> true (compile-time constant, pooled)
  "hello" == new String("hello") -> false
  "hello" == built.intern() -> true
```

What each part does

- `MarkerStyle` — the flyweight. Final fields, no setters, package-private constructor, and `draw(lat, lon)` receives extrinsic state.
- `MarkerStyleFactory` — the pool. `ConcurrentHashMap.computeIfAbsent` makes "get or create once" **thread-safe and atomic** (correct when many threads — independent paths of execution running at once — use it, and done as one indivisible step), so two threads can't create two copies of the same style.
- `Key` record — the intrinsic values as a value object (an object defined only by its values); records give correct `equals`/`hashCode` (the methods a hash map uses to find a key) for free.
- `Marker` record — the context: two doubles plus one reference.
- Output: "loading icon" is printed **3 times for 5 markers**, and still only 3 styles for 100,000 markers — about 6 MB of icon data instead of ~200,000 MB (≈195 GB).
- JDK section: `Integer.valueOf` caching and the `String` pool (below).

Flyweights already in Java

- **`Integer.valueOf(int)`** (used by autoboxing — Java's automatic wrapping of an `int` into an `Integer` object) returns cached objects for **−128 to 127** — the Java Language Specification requires that range to be cached. That is why `Integer a = 127, b = 127; a == b` is `true` but the same with 128 is `false` on a default JVM (Java Virtual Machine, the program that runs Java code; the upper bound can be raised with `-XX:AutoBoxCacheMax`, so never rely on it). **Always compare boxed numbers with `equals`.** `Short`, `Byte`, `Long` (same range) and `Character` (0–127) have similar caches; `Boolean.valueOf` returns the two shared constants `Boolean.TRUE` / `Boolean.FALSE`.
- **The String pool**: string literals and compile-time constant expressions (`"hel" + "lo"`) are interned (stored once in a shared pool and reused), so equal literals share one object. `new String("hello")` always creates a new object; `intern()` returns the pooled one.
- **Enums**: exactly one instance per constant, shared everywhere.

Flyweight is not a cache

The two are mixed up all the time — even in code reviews — and the difference decides what you may do with the pool:

	Flyweight	Cache
Purpose	Make the data *fit in memory* at all	Make repeated work *quicker*
Contents	One copy of immutable state that many holders point to	Stored results of costly computations or lookups
May entries be removed?	Not while any holder still points to one	Yes, at any moment
Effect of removing one	Holders lose their shared object, or duplicates get created	None, apart from a slower next request

So an LRU cache in front of a database is not a flyweight, and a pool of shared marker styles is not a cache.

Two mistakes that undo the pattern

- **A flyweight that can change.** One caller updates a colour and every marker on the map changes with it — the classic failure, and hard to debug because the effect shows up far from the cause. Fix: `final` fields, no setters, no leaking of internal arrays.
- **An ever-growing pool keyed by open-ended input.** If users decide the keys, the pool never stops growing — a memory leak (memory that is never released) disguised as an optimisation. Flyweight is safe when the set of intrinsic values is **small and bounded** (3 styles, a few hundred glyphs). An open key space needs weak references (references the garbage collector is allowed to clear) and eviction (removing entries), and at that point you have built a cache — so call it a cache.

Measure first

Flyweight trades readability for memory, so using it without profiling (measuring where a program really spends time or memory) is textbook premature optimisation (optimising before you know it is needed). A thousand objects never need it; a million might. Answer two questions **with numbers** first: *how many of these objects will exist at once*, and *how much of each one is identical across all of them?* If you can't put numbers on both, it is too early; if most of each object is unique, there is nothing worth sharing.

Trade-offs

Pros	Cons
Memory use can fall by orders of magnitude — sometimes the difference between running and not running.	**State is split across two places**, which is harder to follow and change than one class.
Costly construction happens once per distinct value, not once per object.	**The pool keeps strong references (ordinary references, which stop the garbage collector from freeing an object)**, so it can leak memory itself.
Friendlier to CPU caches — the shared data stays hot (recently used, so fast to reach) instead of being scattered.	**Thread safety is on you** — the pool must be thread-safe and the flyweight immutable.
"Load once" logic gets one obvious home instead of being spread across callers.	**Tempting to apply too early**, and callers must pass extrinsic state on every call (some CPU cost).

When not to use it

- You **haven't measured**.
- The shared part **cannot be immutable**.
- The **counts are small**.
- The **unique state is most of the object**.
- The **key space is unbounded** (that's a cache).

Common mistakes

- Storing extrinsic state inside the flyweight (then it can't be shared).
- Public constructor so callers bypass the factory.
- Non-thread-safe pool (`HashMap` + check-then-put from many threads → duplicates or worse).
- Comparing boxed `Integer`s or `String`s with `==` because "it worked in the test" with small values or literals.

Other patterns it is confused with

Looks like	Actual difference
Cache	See table above.
Singleton	Singleton = exactly one instance of a class. Flyweight = one instance **per distinct intrinsic value** (3, or 300). A flyweight pool that happens to hold one entry only *looks* like a Singleton.
Object pool	An object pool **lends out mutable** objects and takes them back (e.g. DB connections). Flyweights are **immutable**, shared, never returned.
Prototype	Prototype makes many objects by copying; Flyweight avoids making them at all — opposite answers to the same "many similar objects" observation.

Real-world examples

- **`Integer.valueOf`**, **`Boolean.valueOf`**, **`String.intern()`**, **enums** — see above. (Python also interns small integers and many short strings automatically.)
- **Text rendering / word processors** — one glyph object per character in a font, shared by every occurrence on the page (the classic GoF example).
- **Game engines and map renderers** — meshes, textures and sprite atlases are loaded once and referenced by every entity (e.g. a forest of identical tree models, rendered with GPU *instancing* — the graphics card drawing one model many times in a single pass).
- **Map apps** — thousands of pins typically share a handful of icon styles (the example in this section).
- **`java.time.ZoneOffset`** caches offsets that are whole multiples of 15 minutes, so `ZoneOffset.ofHours(5)` returns a shared instance.

In modern languages

- **Java**: `Integer.valueOf`, `String.intern` and enums are built-in flyweights; a `record` is an immutable flyweight in one line, and a `Map` plus `computeIfAbsent` is the whole factory (as in our code).
- **Python**: small ints and many short strings are interned automatically; `functools.lru_cache` on a factory function gives a pool with a size bound built in.
- **JavaScript**: `Object.freeze` on the shared object plus a `Map` for the pool — freezing makes immutability enforced rather than a convention.
- **C++**: `std::shared_ptr<const Style>` expresses both the sharing and the immutability in the type.
- **Any language with value types**: an immutable value object plus a memoising (remembers results it already produced) factory is this pattern, usually unnamed.

In the interview

> **30-second answer:** "Flyweight saves memory when there are huge numbers of similar objects. I split state into intrinsic — shared and invariant, like an icon — and extrinsic — per object, like a position — which is passed in to methods. The intrinsic part lives in an immutable flyweight handed out by a factory that pools one instance per distinct value. `Integer.valueOf` and the String pool are JDK examples. I'd only do it after measuring."

Follow-ups

- *Q: Why must the flyweight be immutable?* — A: It is shared; mutating it changes every holder.
- *Q: How do you make the factory thread-safe?* — A: `ConcurrentHashMap.computeIfAbsent`, which runs the creation function at most once per key.
- *Q: Flyweight vs cache?* — A: A cache may evict anything and exists for speed; a flyweight exists because otherwise the program doesn't fit, and entries can't be dropped while referenced.
- *Q: Why is `Integer 128 == 128` false?* — A: Autoboxing uses `Integer.valueOf`, which only guarantees caching for −128..127; outside that range you get distinct objects on a default JVM. Use `equals`.
- *Q: Flyweight vs Singleton?* — A: One instance per distinct value vs one instance total.

Self-check

1. **Q:** In a chess game with a million saved positions, what is intrinsic and extrinsic for a piece? **A:** Intrinsic: type and colour (and image). Extrinsic: the square it is on.

2. **Q:** What goes wrong if `MarkerStyle` had `setColour`? **A:** Changing one marker's colour would change every marker sharing that style.
3. **Q:** Is `"a" + "b" == "ab"` true in Java? **A:** Yes — it is a compile-time constant expression, so it is interned. With a non-final variable in the expression, it would be a new object.
4. **Q:** When does a flyweight pool become a leak? **A:** When its key space is unbounded (e.g. keyed by user input) and it never evicts.

TL;DR

- **Share what repeats, pass in what varies.** Intrinsic inside, extrinsic outside.
- **Immutable** flyweight + **factory-owned** pool (thread-safe).
- JDK: `Integer.valueOf` (−128..127), String pool, enums. **Measure first**; not a cache.

9.7 Proxy Pattern

What it is

The **Proxy** pattern places a **stand-in with the identical interface** in front of a real object in order to control **who** may use it, **when** it gets created, or **how much** each use costs. GoF's intent: *provide a surrogate or placeholder for another object to control access to it.* (GoF also lists the name **Surrogate**.)

Analogy: a credit card is a proxy for your bank account. Shops accept it wherever cash is accepted (same "interface"), but it adds control — limits, fraud checks — and the money only moves when needed.

Term	Meaning	In our code
Subject	The interface shared by the proxy and the real object	`Report`, `RateService`, `Device`
Real Subject	The object that does the real work	`RealReport`, `LiveRateService`, `RealDevice`
Proxy	Holds (or creates) the real subject, same interface, decides what happens before/instead of/around the call	`LazyReport`, `AuditedReport`, `CachingRateProxy`, `RemoteRateProxy`, the `SharedDevice` handle

The problem it solves

There are times when callers should **not touch the real object directly — or not yet**:

- **Building it is costly and usually unnecessary.** Loading a 100 MB report during start-up is wasted work on the many runs that never display it — most screens only show its title.
- **Only some callers are permitted** to use it, and the permission logic has no business living inside the object.
- **It runs on a different machine**, and callers should not have to write networking code.
- **Each call must be logged or counted**, but the class belongs to someone else.

Since the proxy offers **the very same interface**, callers can't tell it apart from the real thing, so you can insert one **without editing any caller**. That is also its danger: a slow or remote call now **looks just like a cheap local one**.

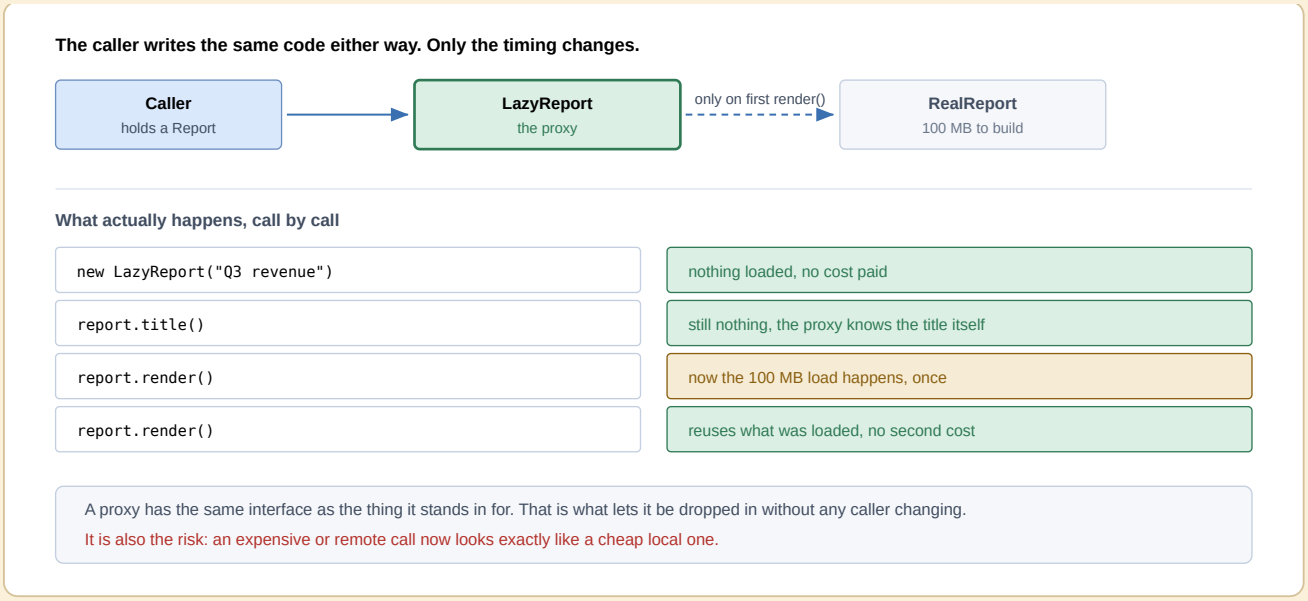

Figure — The caller holds a `Report`. Creating the `LazyReport` and calling `title()` cost nothing; the 100 MB load happens once on the first `render()`, and later renders reuse it (course diagram)

How it works

1. **Define (or reuse) the Subject interface** that callers already use.
2. **Write a proxy class implementing that interface** and holding a reference to the real subject — or the information needed to create it later.
3. In each method, **do the proxy's job first** — create lazily, check permission, look in a cache, marshal (convert into a message that can be sent) over a network, count references — then **delegate** (or refuse).
4. **Give callers the proxy** in place of the real object (often via a factory or DI container so they never see the difference).

Kinds of proxy

Kind	What it controls	Our code / real example
Virtual proxy	*When* the expensive object is created (lazy initialisation)	`LazyReport`; Hibernate (a Java ORM) lazy-loaded entities
Protection proxy	*Who* may call (access control)	`AuditedReport`; `Collections.unmodifiableList`
Remote proxy	*Where* the object lives — hides the network	`RemoteRateProxy` (stub) + `RateServer` (skeleton); RMI/gRPC (remote-call frameworks) stubs
Caching proxy	*Whether* the real call is needed — reuses results	`CachingRateProxy` (bounded LRU + TTL — time to live, how long an entry stays valid)
Logging / monitoring proxy	Records each call before/after forwarding	`LoggingHandler` (dynamic proxy)
Smart reference	Bookkeeping on access — reference counting, locking, loading on first use	`SharedDevice` handles close the device when the last one closes

GoF names four kinds — remote, virtual, protection and smart reference; they differ only in what the proxy does before delegating. Caching and logging proxies are widely used variants described by later sources such as refactoring.guru (GoF would file logging/counting under smart reference).

Structure

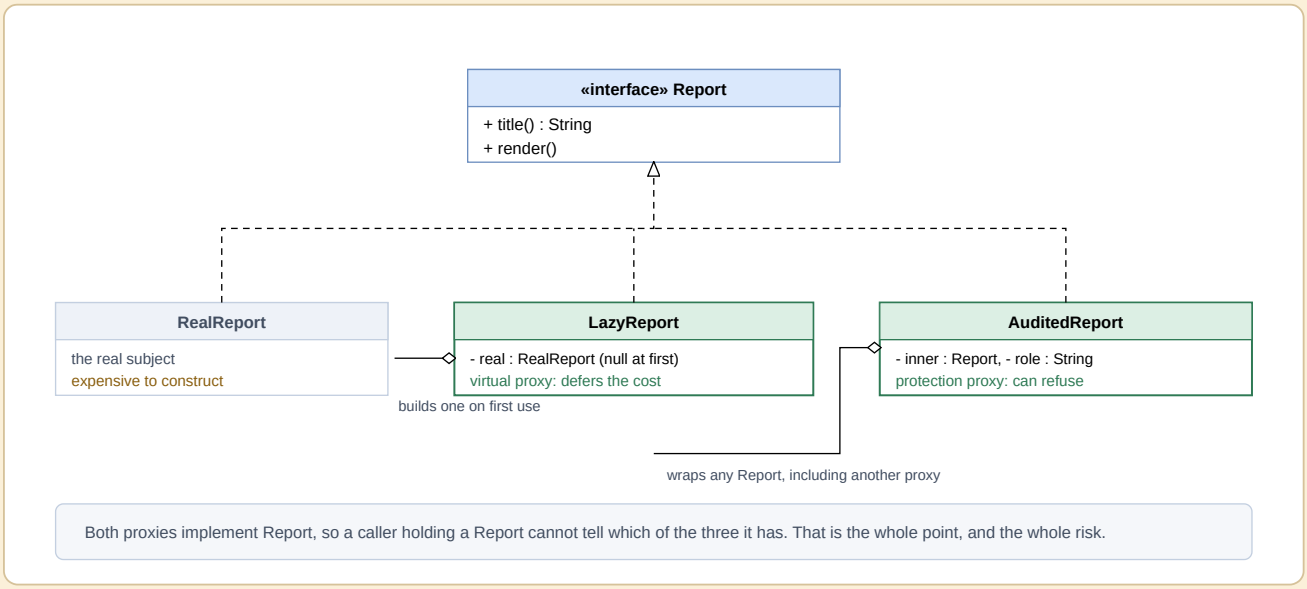

Figure — Proxy class diagram: `RealReport`, `LazyReport` (virtual proxy) and `AuditedReport` (protection proxy) all implement `Report`; `LazyReport` creates the `RealReport` itself, `AuditedReport` wraps any `Report` (course diagram)

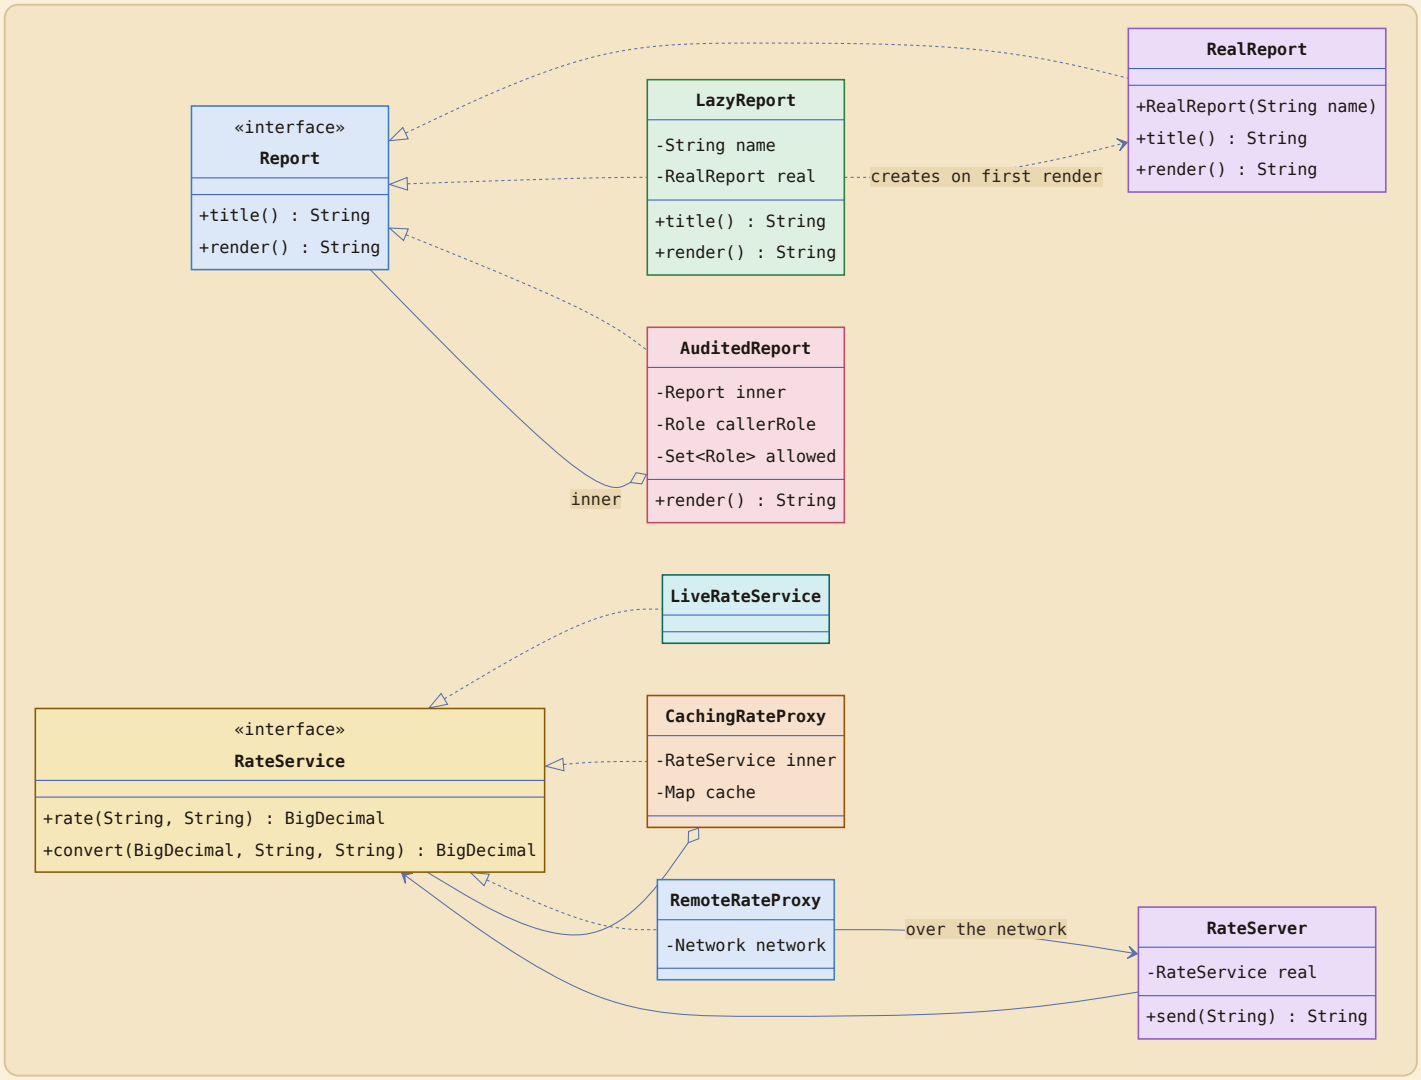
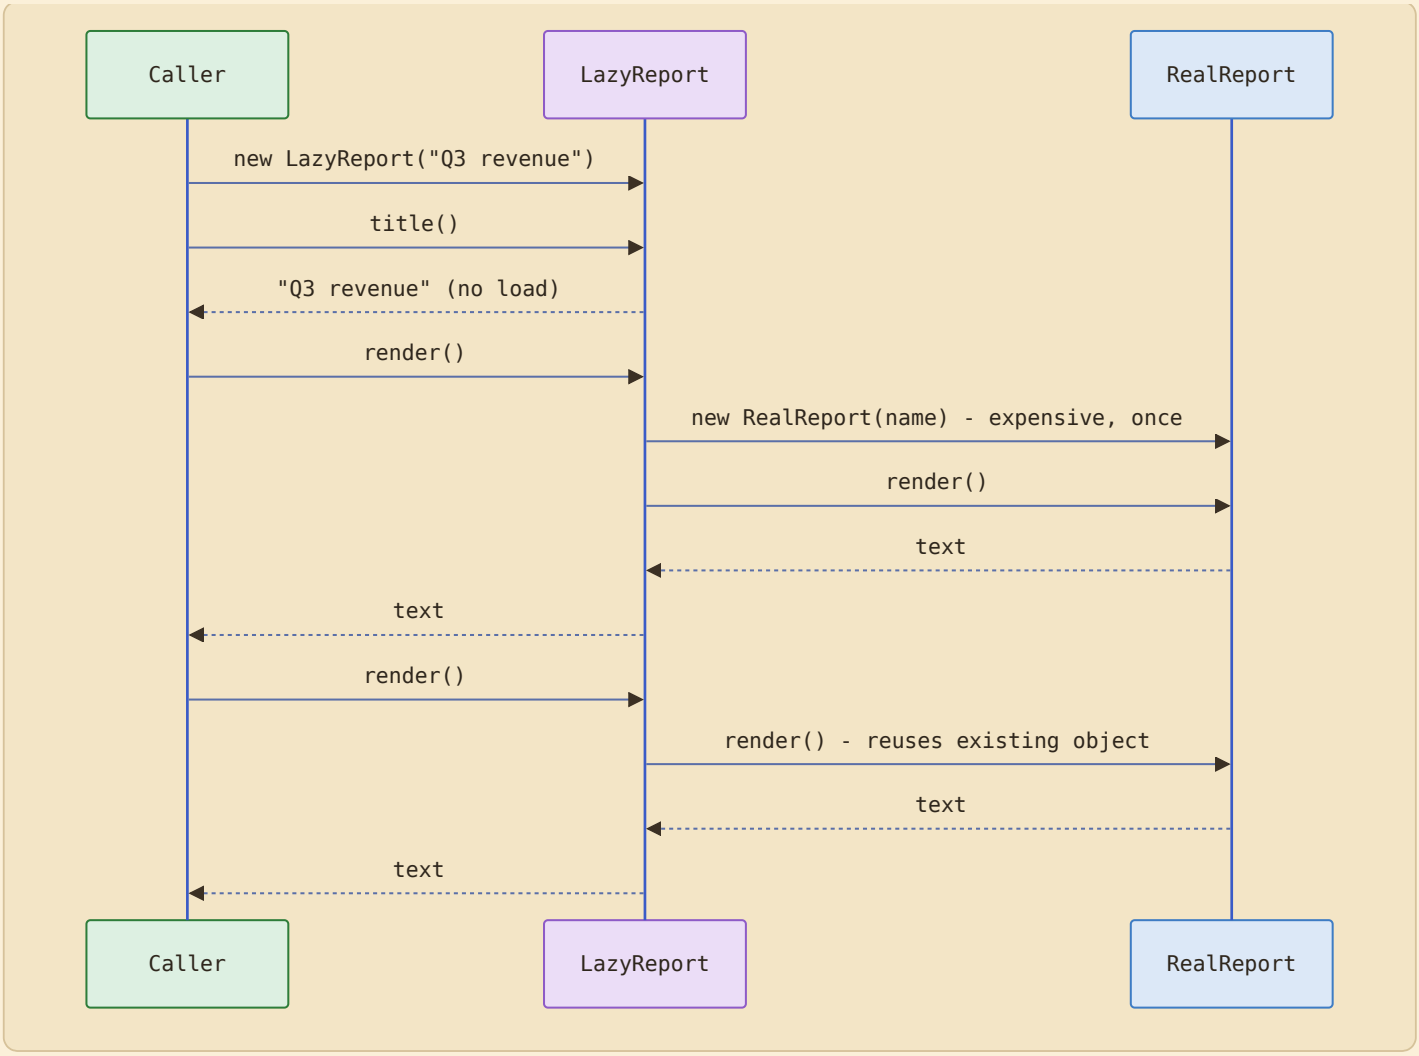
In the class diagram above, `RealReport` does the expensive work in its constructor; `LazyReport` keeps only the name, answers `title()` itself and constructs the `RealReport` the first time `render()` is called; `AuditedReport` checks a role before letting a call through. Because `AuditedReport` holds the **`interface`**, it can guard the real report, the lazy proxy or another protection proxy — our demo wraps the lazy one. Strip `LazyReport` down and only one line is special — the null check that triggers construction; the rest simply forwards calls.





Java example

```java
// File: code/lld/ch09/proxy/Report.java
package lld.ch09.proxy;

/** SUBJECT interface: callers only ever hold this type. */
interface Report {
    String title();
    String render();
}
```

```java
// File: code/lld/ch09/proxy/RealReport.java
package lld.ch09.proxy;

/** REAL SUBJECT: expensive constructor. */
final class RealReport implements Report {
    private final String name;
    private final int rows;

    RealReport(String name) {
        System.out.println("    [real] loading 100 MB of data for '" + name + "'...");
        this.name = name;
        this.rows = 1_000_000;
    }

    @Override public String title()  { return name; }
    @Override public String render() { return name + " (" + rows + " rows)"; }
}
```

```java
// File: code/lld/ch09/proxy/LazyReport.java
package lld.ch09.proxy;

/**
 * VIRTUAL PROXY: answers title() itself, builds the RealReport on first render().
 * Thread-safe lazy init with double-checked locking (field must be volatile).
 */
final class LazyReport implements Report {
    private final String name;
    private volatile RealReport real;      // created by the proxy itself, not handed in

    LazyReport(String name) { this.name = name; }

    @Override public String title() { return name; }   // no load needed

    @Override
    public String render() { return realReport().render(); }

    private RealReport realReport() {
        RealReport r = real;
        if (r == null) {
            synchronized (this) {
                r = real;
                if (r == null) real = r = new RealReport(name);
            }
        }
        return r;
    }
}
```

```java
// File: code/lld/ch09/proxy/Role.java
package lld.ch09.proxy;

enum Role { VIEWER, FINANCE, ADMIN }
```

```java
// File: code/lld/ch09/proxy/AuditedReport.java
package lld.ch09.proxy;

import java.util.Set;

/** PROTECTION PROXY: checks permission, may REFUSE the call. */
final class AuditedReport implements Report {
    private final Report inner;
    private final Role callerRole;
    private final Set<Role> allowed;

    AuditedReport(Report inner, Role callerRole, Set<Role> allowed) {
        this.inner = inner;
        this.callerRole = callerRole;
        this.allowed = Set.copyOf(allowed);
    }

    @Override public String title() { return inner.title(); }  // titles are public

    @Override
    public String render() {
        if (!allowed.contains(callerRole)) {
            throw new SecurityException(callerRole + " may not render " + inner.title());
        }
        return inner.render();
    }
}
```

```java
// File: code/lld/ch09/proxy/RateService.java
package lld.ch09.proxy;

import java.math.BigDecimal;
import java.math.RoundingMode;

/** Subject for the caching, remote and dynamic-proxy demos. Money and rates are BigDecimal, never double. */
interface RateService {
    BigDecimal rate(String from, String to);
    BigDecimal convert(BigDecimal amount, String from, String to);

    /** Shared rounding rule: amounts are returned to 2 decimal places. */
    static BigDecimal toMoney(BigDecimal value) { return value.setScale(2, RoundingMode.HALF_EVEN); }
}
```

```java
// File: code/lld/ch09/proxy/LiveRateService.java
package lld.ch09.proxy;

import java.math.BigDecimal;
import java.math.MathContext;
import java.util.Map;

/** Real subject: pretend each call is a slow lookup. */
class LiveRateService implements RateService {
    private static final Map<String, BigDecimal> PER_USD = Map.of(
            "USD", new BigDecimal("1"), "EUR", new BigDecimal("0.92"), "INR", new BigDecimal("83"));
    int lookups = 0;

    @Override
    public BigDecimal rate(String from, String to) {
        lookups++;
        return PER_USD.get(to).divide(PER_USD.get(from), MathContext.DECIMAL64);
    }

    @Override
    public BigDecimal convert(BigDecimal amount, String from, String to) {
        return RateService.toMoney(amount.multiply(rate(from, to)));   // self-call: goes to THIS object, not
through any proxy
    }
}
```

```java
// File: code/lld/ch09/proxy/CachingRateProxy.java
package lld.ch09.proxy;

import java.math.BigDecimal;
import java.util.LinkedHashMap;
import java.util.Map;

/** CACHING PROXY: bounded (LRU) and time-limited, because an unbounded cache is a leak. */
final class CachingRateProxy implements RateService {
    private record CachedRate(BigDecimal value, long expiresAt) { }

    private final RateService inner;
    private final long ttlMillis;
    private final Map<String, CachedRate> cache;

    CachingRateProxy(RateService inner, int maxEntries, long ttlMillis) {
        this.inner = inner;
        this.ttlMillis = ttlMillis;
        this.cache = new LinkedHashMap<>(16, 0.75f, true) {   // access order = LRU
            @Override
            protected boolean removeEldestEntry(Map.Entry<String, CachedRate> eldest) {
                return size() > maxEntries;
            }
        };
    }

    @Override
    public synchronized BigDecimal rate(String from, String to) {
        String key = from + "->" + to;
        CachedRate e = cache.get(key);
        long now = System.currentTimeMillis();
        if (e != null && e.expiresAt() > now) return e.value();
        BigDecimal v = inner.rate(from, to);
        cache.put(key, new CachedRate(v, now + ttlMillis));
        return v;
    }

    @Override
    public BigDecimal convert(BigDecimal amount, String from, String to) {
        return RateService.toMoney(amount.multiply(rate(from, to)));
    }
}
```

```java
// File: code/lld/ch09/proxy/Network.java
package lld.ch09.proxy;

/*
 * REMOTE PROXY: looks like a local RateService, but marshals each call into a
 * message and sends it across a "network". Here the network is simulated in-process.
 */
interface Network {
    String send(String request);
}
```

```java
// File: code/lld/ch09/proxy/RateServer.java
package lld.ch09.proxy;

import java.math.BigDecimal;

/** Server side "skeleton": unmarshals the request and calls the real object. */
final class RateServer implements Network {
    private final RateService real;

    RateServer(RateService real) { this.real = real; }

    @Override
    public String send(String request) {                  // format: "rate|FROM|TO"
        String[] p = request.split("\\|");
        return real.rate(p[1], p[2]).toPlainString();       // BigDecimal -> exact text on the wire
    }
}
```

```java
// File: code/lld/ch09/proxy/RemoteRateProxy.java
package lld.ch09.proxy;

import java.math.BigDecimal;

/** Client side "stub" = the remote proxy. */
final class RemoteRateProxy implements RateService {
    private final Network network;

    RemoteRateProxy(Network network) { this.network = network; }

    @Override
    public BigDecimal rate(String from, String to) {
        String request = "rate|" + from + "|" + to;
        System.out.println("    [stub] sending '" + request + "' over the wire");
        return new BigDecimal(network.send(request));
    }

    @Override
    public BigDecimal convert(BigDecimal amount, String from, String to) {
        return RateService.toMoney(amount.multiply(rate(from, to)));
    }
}
```

```java
// File: code/lld/ch09/proxy/Device.java
package lld.ch09.proxy;

/** A heavyweight resource, e.g. a connection to a device. */
interface Device extends AutoCloseable {
    String query(String command);
    @Override void close();
}
```

```java
// File: code/lld/ch09/proxy/RealDevice.java
package lld.ch09.proxy;

final class RealDevice implements Device {
    RealDevice() { System.out.println("    [device] opened (expensive)"); }
    @Override public String query(String command) { return "ok:" + command; }
    @Override public void close() { System.out.println("    [device] closed"); }
}
```

```java
// File: code/lld/ch09/proxy/SharedDevice.java
package lld.ch09.proxy;

/**
 * SMART REFERENCE PROXY: reference counting. Each client gets its own handle (a proxy).
 * The real device opens on the first handle and closes when the LAST handle closes.
 * Thread-safe: every read or write of 'refs', 'real' and a handle's 'closed' flag
 * happens while holding the SharedDevice's lock, so the count can never go wrong.
 */
final class SharedDevice {
    private int refs;              // guarded by 'this'
    private RealDevice real;       // guarded by 'this'

    synchronized Device acquire() {
        if (refs++ == 0) real = new RealDevice();
        System.out.println("    [ref] handle acquired, count=" + refs);
        return new Handle();
    }

    private final class Handle implements Device {
        private boolean closed;    // guarded by SharedDevice.this

        @Override
        public String query(String command) {

        System.out.println("  5 calls, real lookups = " + live.lookups);

        System.out.println("== Remote proxy (stub) ==");
        RateService remote = new RemoteRateProxy(new RateServer(new LiveRateService()));
        System.out.println("  100 USD = " + remote.convert(new BigDecimal("100"), "USD", "INR") + " INR");

        System.out.println("== Smart reference (reference counting) ==");
        SharedDevice printer = new SharedDevice();
        try (Device a = printer.acquire(); Device b = printer.acquire()) {
            System.out.println("  a -> " + a.query("status") + ", b -> " + b.query("print"));
        }

        System.out.println("== Dynamic proxy: one handler, any interface ==");
        Report loggedReport = LoggingHandler.wrap(new LazyReport("Q4 plan"), Report.class);
        loggedReport.title();
        loggedReport.render();
        RateService loggedRates = LoggingHandler.wrap(new LiveRateService(), RateService.class);
        loggedRates.convert(new BigDecimal("100"), "USD", "EUR");
        System.out.println("  ^ convert() called rate() on 'this', so the inner rate() call was NOT logged");
        System.out.println("  generated at run time: isProxyClass = "
                + Proxy.isProxyClass(loggedRates.getClass()));
    }
}
```

Output:

```
== Virtual proxy: pay only when needed ==
  created proxy; title = Q3 revenue
    [real] loading 100 MB of data for 'Q3 revenue'...
  render #1 -> Q3 revenue (1000000 rows)
  render #2 -> Q3 revenue (1000000 rows)
== Protection proxy wrapping the virtual proxy ==
    [real] loading 100 MB of data for 'Payroll'...
  finance -> Payroll (1000000 rows)
  viewer  -> refused: VIEWER may not render Payroll (nothing was loaded)
== Caching proxy (LRU, max 2 entries, 60 s TTL) ==
  5 calls, real lookups = 4
== Remote proxy (stub) ==
    [stub] sending 'rate|USD|INR' over the wire
  100 USD = 8300.00 INR
== Smart reference (reference counting) ==
    [device] opened (expensive)
    [ref] handle acquired, count=1
    [ref] handle acquired, count=2
  a -> ok:status, b -> ok:print
    [ref] handle released, count=1
    [ref] handle released, count=0
    [device] closed
== Dynamic proxy: one handler, any interface ==
    [proxy] -> title()
    [proxy] <- title() returned Q4 plan
    [proxy] -> render()
    [real] loading 100 MB of data for 'Q4 plan'...
    [proxy] <- render() returned Q4 plan (1000000 rows)
    [proxy] -> convert[100, USD, EUR]
    [proxy] <- convert[100, USD, EUR] returned 92.00
  ^ convert() called rate() on 'this', so the inner rate() call was NOT logged
  generated at run time: isProxyClass = true
```

What each part does

- `LazyReport` — **virtual proxy**. `title()` is answered locally; `render()` creates the `RealReport` on first use. The "loading" line appears **once**, only at the first render.
- **Thread-safe lazy init.** Without care, two threads calling `render()` at the same time both build the expensive object (harmless for a report, but a real bug if construction opens a connection or charges a card). We use **double-checked locking** (check without a lock, then lock and check again — see Chapter 8); the field **must be** `volatile` (a Java keyword that makes a write immediately visible to every thread) so a second thread never sees a half-constructed object.
- `AuditedReport` — **protection proxy**, wrapping a virtual proxy. The viewer is refused **before** anything is loaded — notice no second "loading 'Payroll'" line for the viewer.
- `RateService` works in `BigDecimal` (Java's exact decimal number type) — rates and money are never `double` — and `convert` rounds to 2 decimal places (`HALF_EVEN`, "banker's rounding": an exact half goes to the even digit).
- `CachingRateProxy` — **caching proxy**, **bounded** (LRU via `LinkedHashMap` in access order with `removeEldestEntry`) and **time-limited** (TTL). 5 calls → 4 real lookups: the second USD→EUR is a hit, the last one is a miss because it was evicted.
- `RemoteRateProxy` + `RateServer` — **remote proxy** (client "stub") and server "skeleton". The caller just calls `convert`; the stub turns it into a message and sends it over a (simulated) network.
- `SharedDevice` — **smart reference**. Each `acquire()` returns a lightweight handle proxy; the real device opens with the first handle and closes when the last handle closes. All bookkeeping (`refs`, `real`, each handle's `closed` flag) happens under the `SharedDevice` lock, and `close()` is idempotent (calling it twice has the same effect as calling it once), so concurrent or double closes can't corrupt the count.
- `LoggingHandler` — a **dynamic proxy** (next section).

Static vs dynamic proxies

	Static proxy	Dynamic proxy
How it's made	You hand-write a class per interface (`LazyReport`, `CachingRateProxy`)	Generated at **run time** from an interface list + a handler
Code per interface	One proxy class each; every method written out	One `InvocationHandler` for **any** interface
Type safety	Full; compiler checks each method	Calls arrive as `Method` + `Object[]` — reflective, less checked
Good for	Logic specific to one type (lazy load, access rules for a domain object)	**Cross-cutting concerns** (needs shared by many classes) on many types: logging, timing, transactions, security
JDK API	—	`java.lang.reflect.Proxy.newProxyInstance(loader, interfaces, handler)`
Limitation	Boilerplate	JDK proxies work **only for interfaces**; class-based proxies need bytecode (compiled JVM instructions) libraries (CGLIB, ByteBuddy)

How the JDK dynamic proxy works:

1. `Proxy.newProxyInstance(classLoader, new Class<?>[]{Report.class}, handler)` generates a class (named like `$Proxy0`) that implements `Report`.
2. **Every** method call on that object is routed to `handler.invoke(proxy, method, args)`.
3. The handler does its extra work and calls `method.invoke(target, args)` to forward.
4. If the target throws, reflection wraps it in `InvocationTargetException` — **unwrap it** (`e.getCause()`) so callers see the real exception.

The self-invocation trap (and Spring AOP)

Look at the last lines of the proxy output: we called `convert` through the logging proxy, and `convert` internally called `rate(...)` on `this` — the real object — so that inner call **bypassed the proxy** and was never logged.

This is exactly how **Spring AOP** behaves:

- Spring implements annotations (`@` tags on code that it reads) such as `@Transactional` (run this method inside a database transaction — all its changes succeed or fail together), `@Cacheable`, `@Async`, `@PreAuthorize` and custom `@Aspect` advice (the extra code AOP runs around a method) by wrapping your bean (an object the Spring container creates and manages) in a **proxy**. Callers get the proxy injected, not your object.
- Spring uses a **JDK dynamic proxy** when the target implements at least one interface, and a **CGLIB** subclass proxy otherwise (or when `proxyTargetClass = true`; Spring Boot 2.0+ defaults to CGLIB class-based proxies).
- **Self-invocation is not intercepted**: if `placeOrder()` calls `this.saveAudit()` which is `@Transactional(propagation = REQUIRES_NEW)`, the annotation is silently ignored because the call never leaves the object.
- With CGLIB proxies, `final` **classes cannot be proxied and** `final`/`private` **methods cannot be advised**.
- Fixes, in order of preference: move the method into another bean; inject the bean's own proxy (e.g. a lazily injected self-reference); or (discouraged) `AopContext.currentProxy()`, which also requires `exposeProxy = true`. AspectJ weaving (inserting the extra code directly into the compiled classes, at compile or load time) avoids the problem because it doesn't use proxies.

Proxy vs Decorator

This is the hardest pair in the catalogue to tell apart: both implement an interface, hold another object of that interface and forward calls to it. GoF itself says the implementations can be similar and that the difference is **purpose**: a decorator *adds responsibilities*, a proxy *controls access*.

	Proxy	Decorator
Purpose	**Controls access** to the object	**Adds behaviour** around the object
Does the call get through?	Not necessarily — may defer, cache or refuse	Normally yes — the added work runs around a forwarded call
Who creates / finds the real object?	**Often the proxy itself** (`LazyReport` builds `RealReport`; a remote proxy only knows an address)	**The caller**, who hands it in
Does the client know it has a wrapper?	Usually not — a factory/DI container hands it the proxy as if it were the real object	Usually yes — the client (or its configuration) builds the stack
How many layers?	Usually one	Often several, stacked recursively on purpose

The **creation test** is the most practical, because you can check it in the constructor: `LazyReport(String name)` builds its own subject; `LoggingRepository(UserRepository inner)` is given an existing one. A protection proxy such as `AuditedReport` *is* handed its subject, and is structurally identical to a decorator — there, only intent separates them. A caching wrapper genuinely sits on the line — both names are defensible — so the more useful question in review is whether its cache is bounded and invalidated.

Where proxies go wrong

- **Unsynchronised lazy creation** — two threads call `render()` together and both construct the expensive object: sometimes harmless, sometimes a duplicate connection or a double charge.
- **A caching proxy with no size limit or expiry** — a caching proxy *is* a cache, and every cache needs a bound and an invalidation story; without them it leaks memory and serves stale data. (Ours has both.)
- **Concealing a real cost** — a remote proxy that looks local tempts callers to use it inside loops. Network calls disguised as field access cause some of the nastiest distributed-system (many machines cooperating over a network) performance bugs; the cure is usually to make the cost visible again (batch APIs that fetch many items in one call, explicit `fetch...` names), not to tune the proxy.
- **ORM N+1 queries** (an ORM, or object-relational mapper, turns database rows into objects; N+1 means one query for the list plus one more per item) — iterating 100 orders and touching `order.getCustomer().getName()` fires one query per lazy proxy.

Trade-offs

Pros	Cons
Pay later — costly construction happens only if something needs it.	**Extra indirection**; stack traces show the proxy, not the real class.
No caller changes — the interface is identical (Open/Closed).	**Latency and failures are disguised** (latency = how long a call takes) as an ordinary method call.
Somewhere to put cross-cutting rules for a class you cannot edit.	**Lazy creation brings a thread-safety question** that is easy to get wrong.
Permission checks stay outside the object, which keeps to its own job.	**A cache with no eviction** leaks memory and returns stale data.

When not to use it

- **The real object is cheap** — making something small lazy only adds a null check to every call.
- **Callers need to see the cost** — sometimes the honest interface is a method literally named `fetchOverNetwork()`.
- **The framework already generates one** — ORMs, DI containers and service meshes (a layer of proxies placed next to every service to manage the traffic between them) create proxies; stacking a hand-written one on top of those just doubles the hidden behaviour.
- **You mean to add behaviour, not guard access** — that is a Decorator.

Common mistakes

- Non-`volatile` field in double-checked locking.
- Forgetting to unwrap `InvocationTargetException` in a dynamic proxy.
- Expecting Spring annotations to work on self-calls, `private` methods or `final` methods.

- Unbounded caching proxies.
- Using a remote proxy in a tight loop.

Real-world examples

- **ORM lazy loading** (Hibernate/JPA — JPA is Java's standard ORM API — also Entity Framework and Django) — `entityManager.getReference(...)` and lazy associations return proxy objects; the SQL (database query) runs the first time you touch a non-id field. The most widely used virtual proxy — and the source of the N+1 problem and, in Hibernate, `LazyInitializationException` when the session (Hibernate's open unit of work with the database) is already closed.
- **Spring AOP** — `@Transactional`, `@Cacheable`, `@Async`, method security: all proxies. Spring's `@Configuration` classes are also CGLIB-enhanced subclasses so that calling one `@Bean` method from another returns the container's singleton (unless `proxyBeanMethods = false`).
- **Remote stubs** — Java RMI stubs, gRPC and Thrift generated clients, SOAP clients: a network call behind an ordinary method.
- **`java.lang.reflect.Proxy`** — JDK support for dynamic proxies (used by many frameworks, e.g. Spring Data repositories and MyBatis mappers are interfaces whose implementations are generated proxies).
- **`Collections.unmodifiableList`** — a protection proxy that refuses mutation (also seen as a decorator).
- **Service meshes / sidecars** (Envoy in Istio) — intercept traffic for retries, mTLS (mutual TLS: both sides prove their identity and the traffic is encrypted) and telemetry (metrics and traces sent for monitoring): the proxy idea at infrastructure level. **Reverse proxies / CDNs** (Nginx, Cloudflare) cache and protect origin servers (your own servers holding the original content). A reverse proxy is a server that sits in front of yours and receives requests on their behalf; a CDN (content delivery network) caches content on servers close to users — see System Design Fundamentals.
- **C++ `shared_ptr`** — a smart-reference proxy doing reference counting.

In modern languages

- **Java**: `java.lang.reflect.Proxy`, plus bytecode generation (CGLIB, ByteBuddy) for classes.
- **JavaScript/TypeScript**: built-in `Proxy` intercepts property access and calls.
- **Python**: `__getattr__` forwards anything not defined locally, so a proxy only writes the methods it intercepts; `functools.cached_property` is a virtual proxy for one field.
- **C#**: `DispatchProxy`, and `Lazy<T>` — a virtual proxy for one value.
- **C++**: `std::shared_ptr` and other smart pointers are smart-reference proxies that count references behind `operator->`.

Other patterns it is confused with

Looks like	Actual difference
Decorator	Same structure; see the table above. Decorator adds behaviour to an object it is handed; Proxy controls access and often creates or locates the real object itself.
Adapter	An Adapter has a **different** interface on purpose — it exists to translate. A Proxy has the **same** interface — it exists to substitute.
Facade	A Facade offers a new, simpler interface over **several** objects. A Proxy offers the same interface over **one**.
A cache	A caching proxy is a cache with a proxy's shape. Calling it a proxy does not remove the need to design its size bound and eviction.

In the interview

30-second answer: "A Proxy is a stand-in with the same interface as the real object that controls access to it. I'd name the kind: a virtual proxy defers expensive creation, a protection proxy checks permissions, a remote proxy hides the network, a caching proxy reuses results, and a smart reference does bookkeeping like reference counting. Because the interface is identical, callers don't change — which is also the danger, since an expensive call looks cheap. Lazy creation needs thread safety, and ORM lazy-loading proxies are the classic source of N+1 queries. In Java I'd use `java.lang.reflect.Proxy` for cross-cutting concerns; that's how Spring AOP implements `@Transactional`."

Follow-ups

- *Q: Proxy vs Decorator?* — A: Proxy controls access and often creates the real object; Decorator adds behaviour to an object handed to it and normally forwards every call. Check the constructor.
- *Q: Make the virtual proxy thread-safe.* — A: Double-checked locking with a `volatile` field (as in `LazyReport`), or simply make the getter `synchronized` if contention (threads waiting on each other for the lock) is low. (The static holder-class idiom only works for a *static* lazy field, so it does not fit a per-instance proxy.)
- *Q: Why doesn't `@Transactional` work when I call the method from the same class?* — A: Spring's proxy only intercepts calls that come through the proxy; `this.method()` goes straight to the target.
- *Q: JDK proxy vs CGLIB?* — A: JDK proxies implement interfaces only; CGLIB creates a subclass, so it works without interfaces but can't handle `final` classes/methods.
- *Q: How does lazy loading cause N+1?* — A: Loading N parents and then touching each parent's lazy child proxy triggers N extra queries; fix with fetch joins / entity graphs / batch fetching (ways to load the children together with their parents).

Self-check

1. **Q:** Which proxy kind is `LazyReport`? `AuditedReport`? **A:** Virtual; protection.
2. **Q:** Why is the field in `LazyReport` `volatile`? **A:** So double-checked locking is safe — other threads see a fully constructed object.
3. **Q:** In the dynamic proxy demo, why wasn't the inner `rate()` call logged? **A:** `convert()` called `rate()` on `this` (the real object), bypassing the proxy — the self-invocation trap.
4. **Q:** Can `java.lang.reflect.Proxy` proxy a class with no interface? **A:** No; it needs interfaces. Use CGLIB/ByteBuddy for classes.
5. **Q:** What two properties must a caching proxy have? **A:** A size bound (eviction) and an invalidation/expiry policy.

TL;DR

- **Same interface, controlled access.** Virtual, protection, remote, caching, logging, smart reference.
- **Static** = hand-written per interface; **dynamic** = `java.lang.reflect.Proxy` + `InvocationHandler` for any interface.
- Spring AOP = proxies → beware self-invocation, `final`, `private`. Watch thread safety and hidden costs.

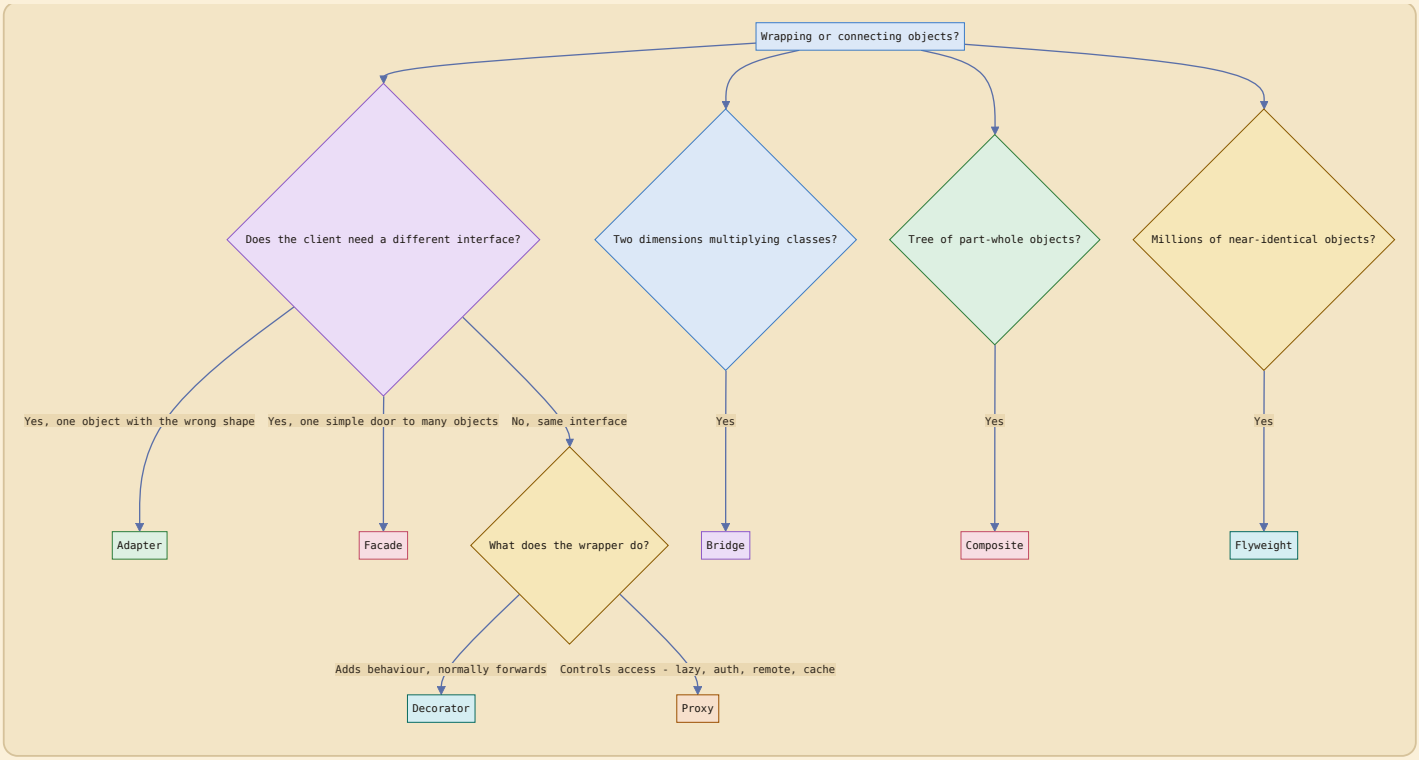
9.8 Putting it all together — comparison

Summary of all seven structural patterns

Pattern	Distinctive feature	Use it when	Example	Pros	Cons
Adapter	Bridges incompatible interfaces	You must use an existing class whose interface doesn't fit your code	Travel plug adapter; `StripeGateway`	Interoperability; reuse of existing code	Extra class and complexity
Bridge	Separates abstraction from implementation	Two dimensions vary independently; avoid permanent binding	UI shapes × platform renderers; notifications × channels	Both sides vary independently; scales by addition	More concepts up front; indirection
Composite	Part-whole tree with one interface	Treat single objects and groups uniformly	Drawing editor with shapes and groups; file system	Simpler client code; easy to add node types	Interface can become over-general
Decorator	Adds responsibilities dynamically	Extend an object's behaviour at run time, in combinations	Adding scrolling/border to a text view; Java I/O	More flexible than subclassing; no feature-bloated classes	Many small objects; hard to debug; order matters
Facade	Simple interface to a complex subsystem	Most callers need one common path through many classes	Home-theatre "watch movie" button; `OrderFacade`	Simplifies use; fewer dependencies	Can become a god object or single point of failure
Flyweight	Shares common state among many objects	Huge numbers of similar objects with little variation	Characters in a word processor; map markers	Big memory savings	Complexity; managing shared immutable state
Proxy	Placeholder that controls access	Lazy loading, access control, remote, caching, logging, smart reference	Internet proxy server; Hibernate lazy entity	Controls access; defers costly work	Indirection; hidden latency

Adapter vs Decorator vs Proxy vs Facade vs Bridge

	Adapter	Decorator	Proxy	Facade	Bridge
Intent	Convert an interface to the one the client expects	Add behaviour without changing the interface	Control access to an object	Simplify a complex subsystem	Let abstraction and implementation vary independently
Interface seen by client	**Different** from the wrapped object's (it's yours)	**Same** as wrapped	**Same** as real subject	**New, simpler** interface	Abstraction's own interface
Behaviour	Unchanged (translated)	**Extended**	Unchanged but **controlled** (may defer/cache/refuse)	Unchanged (fewer calls)	Delegated to implementor
Objects wrapped	One	One (stackable)	One	**Several**	One implementor (by reference)
Who creates the wrapped object	Usually passed in	Passed in by client	**Often the proxy itself**	Passed in / owned	Passed in at construction
Structure	Implements Target, holds Adaptee	IS-A and HAS-A Component	IS-A Subject, HAS-A Real Subject	HAS-A many subsystem objects	Abstraction HAS-A Implementor; two hierarchies
When introduced	**After the fact**, to make existing things fit	Any time a concern is added	Any time access needs controlling	When callers repeat a multi-step sequence	**Up front**, before the class explosion
Typical trigger	"The vendor API doesn't match ours"	"Sometimes we need logging, sometimes caching, sometimes both"	"It's expensive / remote / restricted"	"Every caller copies these 5 steps"	"Class names with two nouns"
JDK / framework example	`Arrays.asList`, `InputStreamReader`	`BufferedInputStream`, `Collections.synchronizedList`	`java.lang.reflect.Proxy`, Spring `@Transactional`, Hibernate lazy load	SLF4J `LoggerFactory`, service layers	JDBC `Connection` + drivers, AWT peers



Memory hooks

- **Adapter** — *"make it fit"* (changes the interface).
- **Decorator** — *"add to it"* (same interface, more behaviour, stackable).
- **Proxy** — *"guard it"* (same interface, controlled access).
- **Facade** — *"simplify it"* (one door, many rooms).
- **Bridge** — *"split it"* (two hierarchies, add instead of multiply).
- **Composite** — *"nest it"* (one interface for leaf and tree).
- **Flyweight** — *"share it"* (intrinsic shared, extrinsic passed in).

Chapter self-check

1. **Q:** Which of these patterns wrap exactly one object? **A:** Adapter, Decorator, Proxy (Bridge also holds one implementor, but by design rather than as a wrapper). Facade wraps several; Composite holds many children.
2. **Q:** Which two have identical code shape but differ in intent and timing? **A:** Adapter and Bridge (after-the-fact vs up-front); also Bridge and Strategy; also Decorator and Proxy.
3. **Q:** A wrapper returns cached results with the same interface. Decorator or Proxy? **A:** Either is defensible; the important question is whether the cache is bounded and invalidated.
4. **Q:** You have `WindowsButton`, `MacButton`, `WindowsCheckbox`, `MacCheckbox`… and a Linux port is coming. Which pattern? **A:** Bridge (widget abstraction × platform implementor) — often combined with Abstract Factory to pick the implementor.
5. **Q:** Which pattern explains why `Integer.valueOf(100) == Integer.valueOf(100)` is true? **A:** Flyweight (Integer cache).

Chapter TL;DR

- Structural patterns **compose objects into bigger structures** while keeping them flexible.
- **Adapter / Decorator / Proxy / Facade** share a shape; tell them apart by **what changes as the call passes through** and **how many objects are wrapped**.
- **Bridge** prevents class explosion across two dimensions; **Composite** makes trees uniform; **Flyweight** shares immutable state to save memory.
- In interviews: name the pattern, state the **constraint** that justifies it, name its **trap** (vendor leaks, wrong split, cycles, decorator order, god facade, mutable flyweight, self-invocation), and give a **real JDK/Spring example**.

Chapter 10 — Behavioral Design Patterns (Part 1)

> **What you will learn.** What behavioral patterns are, and six of them in depth: **Chain of Responsibility, Command, Iterator, Mediator, Memento** and **Interpreter**. For each one you get a plain definition, the problem it fixes, the class diagram, Java 21 code that compiles and runs, real products and JDK (Java Development Kit — Java's compiler, tools and standard library) classes that use it, and interview questions with answers. Chapter 11 covers the other five GoF behavioral patterns (Observer, State, Strategy, Template Method, Visitor) and some important patterns that are not in the GoF book.

How to run the code in this chapter

```
cd chapters/10-patterns-behavioral-1/code
javac --release 21 -d /tmp/lld_10 $(find . -name '*.java')
java -cp /tmp/lld_10 lld.ch10.chain.Main        # also: command, iterator, mediator, memento, interpreter
```

10.0 Behavioral patterns: the big picture

What it is

Creational patterns (Chapter 8) are about **how objects are made**. Structural patterns (Chapter 9) are about **how objects are put together**. **Behavioral patterns** are about **how objects share work and talk to each other**: who is responsible for what, and who calls whom.

Everyday analogy: a restaurant kitchen. The structural question is "which stations exist?" The behavioral question is "when an order comes in, who hears about it first, who passes it on, who decides the order of the dishes, and who can cancel it?"

Behavioral patterns help you to:

- let objects work together in a flexible, efficient way;
- cut tight coupling (classes depending heavily on each other's internal details) between classes, so each class is easier to change and test;
- turn tangled communication between many objects into something simple to follow;
- change behaviour **while the program runs** (at run time), not only when you compile it.

The eleven GoF behavioral patterns

The "Gang of Four" (GoF) book, *Design Patterns* (Gamma, Helm, Johnson, Vlissides, 1994), lists eleven behavioral patterns. This chapter covers the first six; Chapter 11 covers the rest.

Pattern	One-line intent	Chapter
Chain of Responsibility	Hand a request down a row of handler objects; each may deal with it, stop it, or forward it.	10
Command	Wrap a request in an object, which can then be stored, queued, logged or reversed.	10
Interpreter	Represent the grammar of a small language as classes, and evaluate sentences in it.	10
Iterator	Walk through a collection one element at a time without seeing how it is stored.	10
Mediator	Route communication between many objects through one coordinator.	10
Memento	Let an object save a snapshot of its own state and later return to it, while keeping that state private.	10
Observer	When one object changes, notify all the objects that depend on it.	11
State	Let an object change its behaviour when its internal state changes.	11
Strategy	Choose one of several interchangeable algorithms at run time.	11
Template Method	Fix the skeleton of an algorithm in a base class; let subclasses fill in some steps.	11
Visitor	Add a new operation to a set of classes without changing those classes.	11

Class scope vs object scope. GoF splits behavioral patterns into two kinds. *Class* behavioral patterns use **inheritance** to share behaviour: only **Template Method** and **Interpreter**. All the others are *object* behavioral patterns: they use **composition** (objects holding references to other objects) and can therefore be rewired at run time.

One idea runs through all of them: take a piece of behaviour that is hidden inside a big method (a chain of `if`s, a hard-coded call, a loop) and turn it into an **object** you can name, pass around, swap, store and test on its own.

10.1 Chain of Responsibility

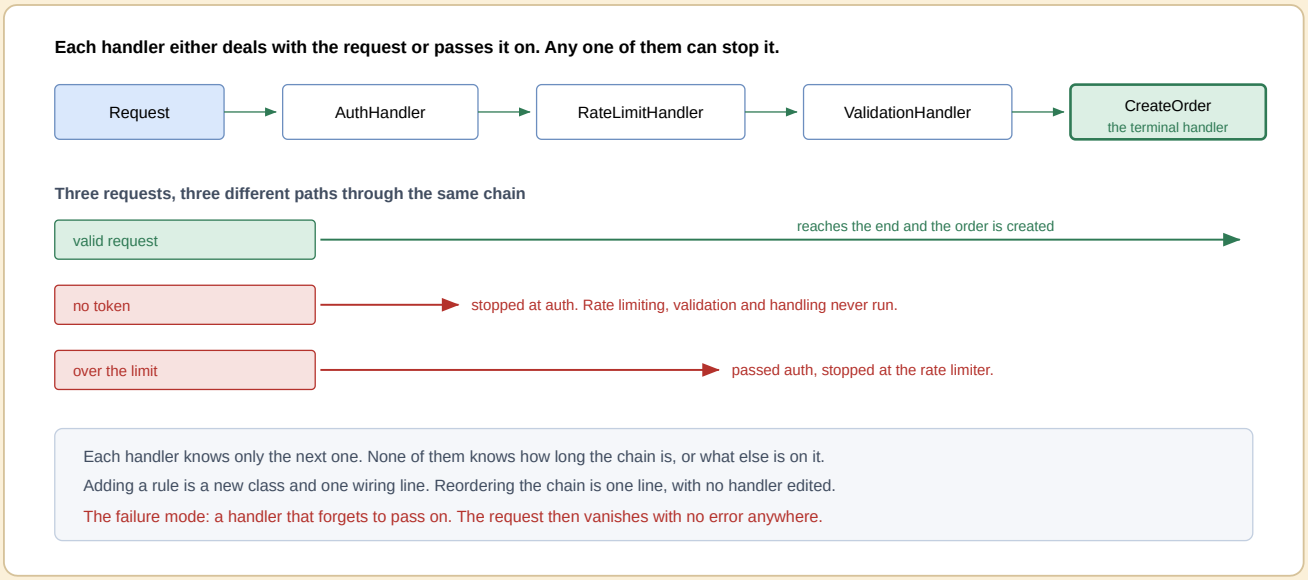


Figure — Three requests go into the same chain of handlers and each stops at a different place (course diagram)

What it is

Chain of Responsibility (CoR) sends a request through a row of **handler** objects. Every handler makes one of three choices: deal with the request, reject it (so nobody later sees it), or forward it to its successor (the next handler in the row). The sender talks only to the first handler and never learns which one finally took care of the request.

GoF intent, in plain words: *avoid tying the sender of a request to one particular receiver by giving several objects a chance to handle it; link those objects and forward the request until one handles it.* GoF

participants: **Handler** (declares the handling method, optionally holds the successor link), **ConcreteHandler** (handles what it is responsible for, otherwise forwards), and **Client** (starts the request at a handler in the chain).

Everyday analogy: a customer-support phone line. Level-1 support tries first. If they cannot help, they pass you to level 2, then to an engineer. You only ever dialled one number.

In the figure above, one chain (auth → rate limit → validation → create order) receives three requests. A valid request reaches the end. A request with no token stops at auth. A request over the limit passes auth but stops at the rate limiter. Each handler knows only the next one.

The problem it solves

Before an order is created, a request must survive several gates: who is calling (authentication), are they calling too often (rate limit), and is the body (the data sent with the request) well-formed (validation). Written directly, one method does all of them:

- The method grows every time a rule is added.
- The **order of the checks is hidden inside the method body**, yet it matters: authenticating before rate limiting is a different system from rate limiting before authenticating.
- Some routes (the URL paths a server handles, such as `/orders`) need only two of the checks. Soon there are boolean flags, then a second copy of the method that someone forgets to update.

CoR makes **each check its own small object**, and links them into a line. No handler knows how long the line is or what else is on it, so **the line itself is configuration, not logic**: a new rule costs one new class plus one wiring line; changing the order touches only the wiring; each route can be given its own line, assembled when the application starts.

How it works

1. Define a **Handler** type with a method such as `handle(request)` and a reference to the **next** handler.
2. Write one **concrete handler** per check. Each one does its own check, then either **stops** (returns a result) or **passes on** (`next.handle(request)`).
3. Put a **terminal handler** at the end that does the real work (or reports "nobody handled this").
4. **Wire** the chain once, at start-up: `auth.setNext(rateLimit).setNext(validate).setNext(createOrder)`.
5. The client calls only the **first** handler. It never knows how long the chain is.

Structure (UML)

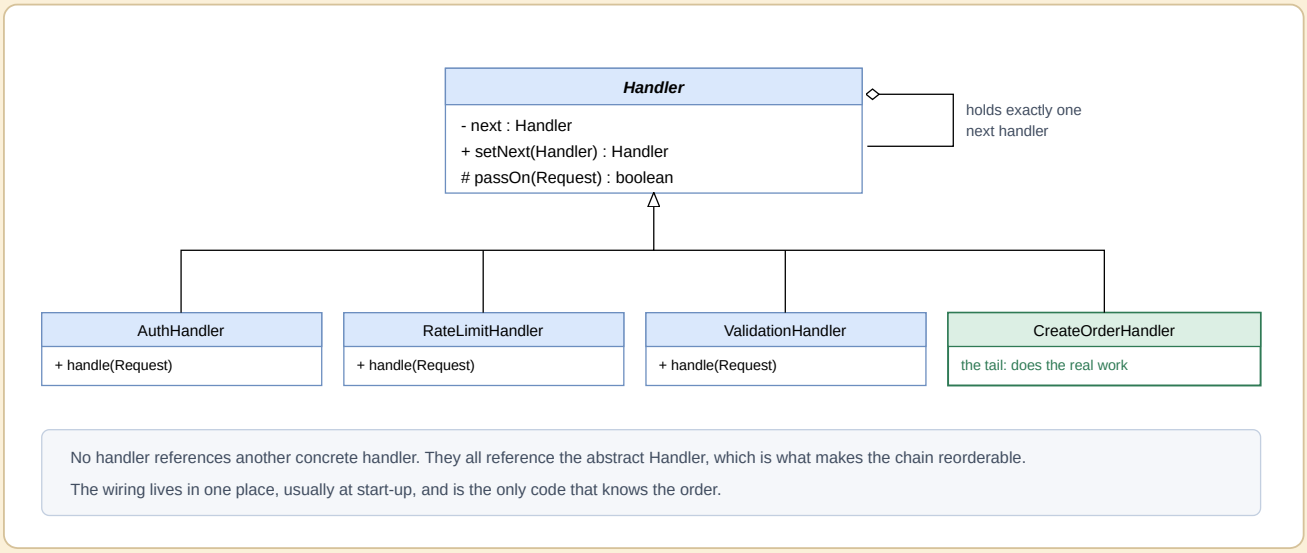

Figure — Class diagram: an abstract Handler holds `next`; concrete handlers extend it; CreateOrderHandler is the tail (course diagram)

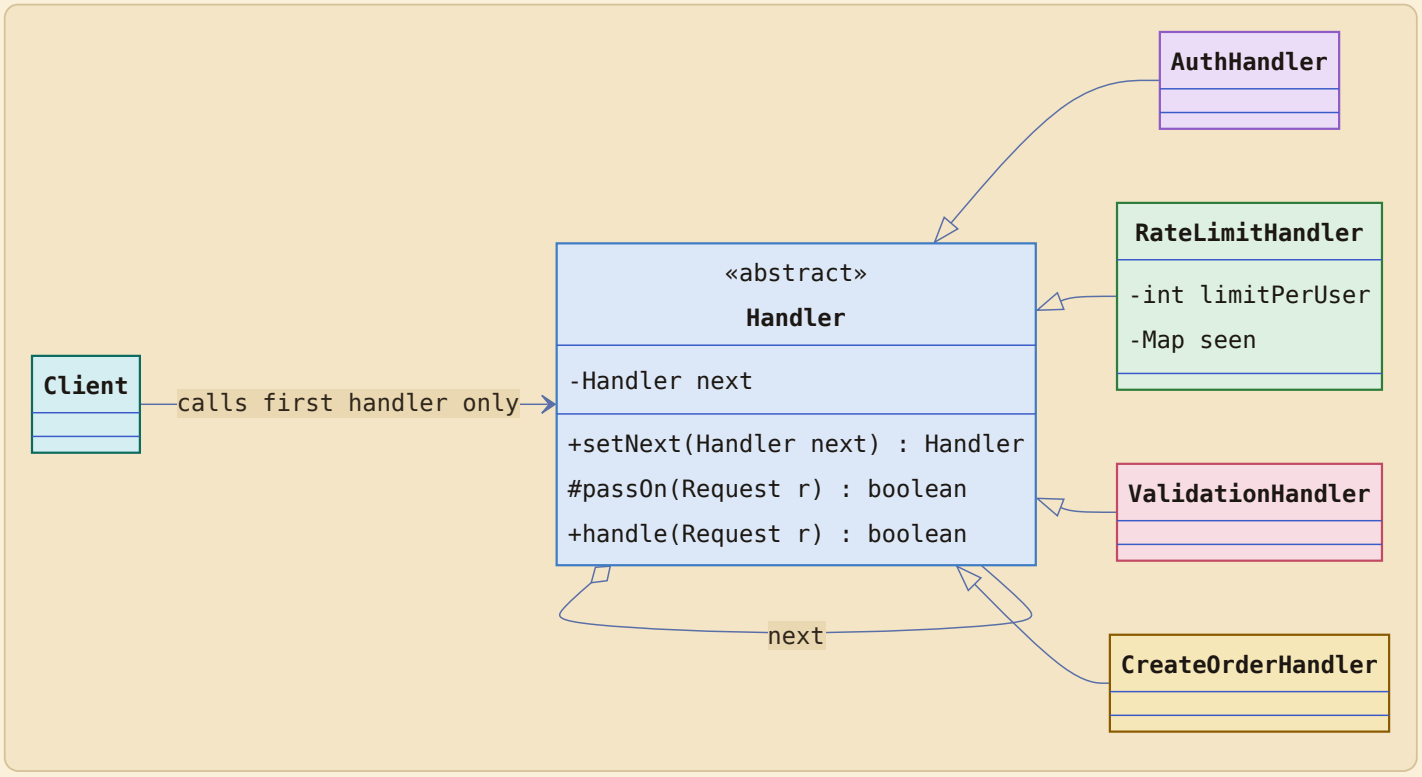
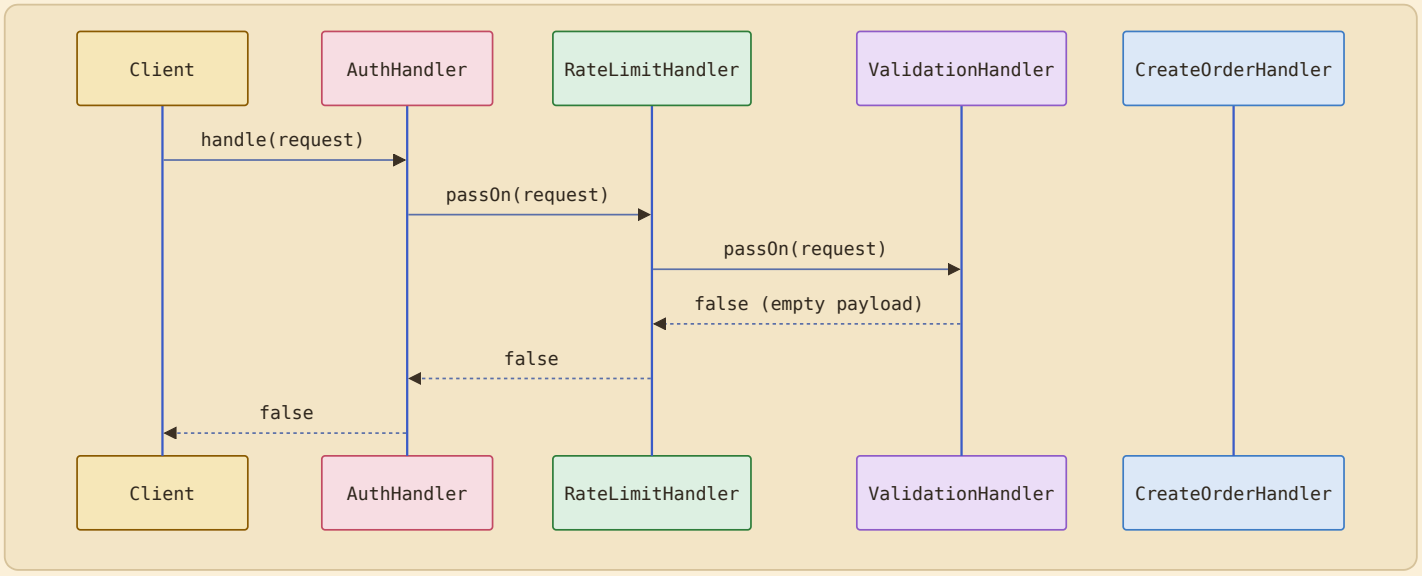
In the class diagram above (a UML — Unified Modeling Language — diagram, the standard notation for classes and their links), notice what is **missing**: no handler refers to another *concrete* handler. Every link is typed as the abstract `Handler`, and that is why the stages can be shuffled freely. `setNext` hands back its argument, which lets the wiring be written as one fluent expression (calls chained with dots, each returning the object for the next call).

> **Our code vs the course pseudocode.** In the course version, `passOn` returns `true` ("success") when there is no next handler. Our `passOn` **throws** instead, because silently reporting success when the chain simply ran out is exactly the kind of invisible failure this pattern is prone to. Either choice is legal; just make it deliberate.

Our Java design:





Java example

The package `lld.ch10.chain` shows **four flavours** of the pattern:

1. **Classic linked handlers** (`Handler`, `AuthHandler`, `RateLimitHandler`, `ValidationHandler`, `CreateOrderHandler`). Each handler returns an *explicit* outcome: `false` = rejected, `passOn(...)` = continue. `passOn` **throws** if there is no next handler, so a chain without a terminal handler fails loudly instead of silently "succeeding".
2. **Approval chain** (`Approver`, `Expense`). A pure CoR: the *first* approver whose limit is high enough approves, and nobody after it sees the request. Note that there is only **one** class — the chain is just data (role + limit). Amounts and limits are `BigDecimal` (Java's exact decimal number type) compared with `compareTo` — never `double` for money.

3. **Servlet-style filters** (`Filter`, `FilterChain`, `Endpoint`, `HttpRequest`). This is how `jakarta.servlet.Filter` (part of the servlet API, Java's standard way to handle web requests) works: the "next" step is passed **in as an argument** (`chain.doFilter(...)`). A filter can act before *and after* the rest of the chain (see the timing filter), or stop the chain by not calling it (the auth filter).
4. **Logging levels** (`LogHandler`, `ConsoleLog`, `FileLog`, `PagerLog`, `Level`). A common *variant*: each handler acts if the message is severe enough and then **always** passes it on. Several handlers may act. Strictly, when nothing can stop the flow it is closer to a *pipeline* (a fixed series of steps that every item passes through), but textbooks often show logging this way, and it is worth knowing the difference.

```java
// File: code/lld/ch10/chain/Handler.java
package lld.ch10.chain;

/** Classic Chain of Responsibility base: each handler knows only "the next one". */
public abstract class Handler {
    private Handler next;

    /** Links the next handler and returns it, so wiring reads as one chained expression. */
    public Handler setNext(Handler next) {
        this.next = next;
        return next;
    }

    /** Forwards the request. Falling off the end means the chain has no terminal handler: a wiring bug. */
    protected boolean passOn(Request request) {
        if (next == null) {
            throw new IllegalStateException(
                getClass().getSimpleName() + " tried to pass on, but the chain has no terminal handler");
        }
        return next.handle(request);
    }

    /** @return true if the request was fully handled, false if some handler rejected it. */
    public abstract boolean handle(Request request);
}
```

```java
// File: code/lld/ch10/chain/Request.java
package lld.ch10.chain;

/** The request that travels down the API pipeline. */
public record Request(String user, String token, String payload) {}
```

```java
// File: code/lld/ch10/chain/AuthHandler.java
package lld.ch10.chain;

/** Stage 1: reject requests with no token. */
final class AuthHandler extends Handler {
    @Override
    public boolean handle(Request r) {
        if (r.token() == null || r.token().isBlank()) {
            System.out.println("  [auth] rejected: missing token");
            return false;                    // explicit outcome: the chain stops here
        }
        System.out.println("  [auth] ok for " + r.user());
        return passOn(r);                    // explicit outcome: continue
    }
}
```

```java
// File: code/lld/ch10/chain/RateLimitHandler.java
package lld.ch10.chain;

import java.util.HashMap;
import java.util.Map;

/** Stage 2: at most N requests per user (keyed by user because auth ran first). */
final class RateLimitHandler extends Handler {
    private final int limitPerUser;
    private final Map<String, Integer> seen = new HashMap<>();

    RateLimitHandler(int limitPerUser) { this.limitPerUser = limitPerUser; }

    @Override
    public boolean handle(Request r) {
        int count = seen.merge(r.user(), 1, Integer::sum);
        if (count > limitPerUser) {
            System.out.println("  [ratelimit] rejected: " + r.user() + " made " + count + " requests, limit " +
limitPerUser);
            return false;
        }
        System.out.println("  [ratelimit] ok (" + count + "/" + limitPerUser + ")");
        return passOn(r);
    }
}
```

```java
// File: code/lld/ch10/chain/ValidationHandler.java
package lld.ch10.chain;

/** Stage 3: the payload must not be empty. */
final class ValidationHandler extends Handler {
    @Override
    public boolean handle(Request r) {
        if (r.payload() == null || r.payload().isBlank()) {
            System.out.println("  [validate] rejected: empty payload");
            return false;
        }
        System.out.println("  [validate] ok");
        return passOn(r);
    }
}
```

```java
// File: code/lld/ch10/chain/CreateOrderHandler.java
package lld.ch10.chain;

/** Terminal handler: does the real work and never passes on. */
final class CreateOrderHandler extends Handler {
    @Override
    public boolean handle(Request r) {
        System.out.println("  [order] created order for " + r.user() + ": " + r.payload());
        return true;
    }
}
```

```java
// File: code/lld/ch10/chain/Expense.java
package lld.ch10.chain;

import java.math.BigDecimal;

/** An expense claim that needs someone with enough authority to approve it. Money is BigDecimal, never double. */
record Expense(String id, BigDecimal amountUsd) {}
```

```java
// File: code/lld/ch10/chain/Approver.java
package lld.ch10.chain;

import java.math.BigDecimal;

/**
 * Approval chain. Pure Chain of Responsibility: the FIRST handler able to deal
 * with the request handles it, and nobody after it sees the request.
 * Note there is only one class: the chain is data (name + limit), not code.
 */
final class Approver {
    private final String role;
    private final BigDecimal limitUsd;
    private Approver next;

    Approver(String role, BigDecimal limitUsd) {
        this.role = role;
        this.limitUsd = limitUsd;
    }

    Approver then(Approver next) {
        this.next = next;
        return next;
    }

    String approve(Expense e) {
        if (e.amountUsd().compareTo(limitUsd) <= 0) {   // compareTo, not equals: 300 and 300.00 are the same
amount
            return role + " approved " + e.id() + " ($" + e.amountUsd() + ")";
        }
        if (next == null) {   // explicit terminal outcome instead of a silent "nothing happened"
            return "REJECTED " + e.id() + " ($" + e.amountUsd() + "): above every approver's limit";
        }
        System.out.println("    " + role + " (limit $" + limitUsd + ") escalates " + e.id());
        return next.approve(e);
    }
}
```

```java
// File: code/lld/ch10/chain/HttpRequest.java
package lld.ch10.chain;

import java.util.Map;

/** Minimal HTTP request for the servlet-style demo. */
record HttpRequest(String path, Map<String, String> headers) {}
```

```java
// File: code/lld/ch10/chain/Filter.java
package lld.ch10.chain;

/** Same shape as jakarta.servlet.Filter: "next" is an explicit argument, so forgetting it is visible. */
@FunctionalInterface
interface Filter {
    void doFilter(HttpRequest request, StringBuilder response, FilterChain chain);
}
```

```java
// File: code/lld/ch10/chain/Endpoint.java
package lld.ch10.chain;

/** The endpoint at the end of the chain (like a Servlet). */
@FunctionalInterface
interface Endpoint {
    void service(HttpRequest request, StringBuilder response);
}
```

            System.out.println("request from " + r.user() + ":");
            System.out.println("  => handled = " + pipeline.handle(r));
        }

        System.out.println("\n=== 2. Expense approval chain (first capable handler wins) ===");
        Approver chain = new Approver("TeamLead", new BigDecimal("1000"));
        chain.then(new Approver("Manager", new BigDecimal("10000")))
             .then(new Approver("Director", new BigDecimal("50000")));
        for (Expense e : List.of(new Expense("EXP-1", new BigDecimal("300")),
                                 new Expense("EXP-2", new BigDecimal("7500")),
                                 new Expense("EXP-3", new BigDecimal("120000")))) {
            System.out.println("  " + chain.approve(e));
        }

        System.out.println("\n=== 3. Servlet-style filters (next is an explicit argument) ===");
        Filter timing = (req, res, next) -> {
            System.out.println("  [timing] start " + req.path());
            next.doFilter(req, res);                        // filters can act before AND after
            System.out.println("  [timing] end   " + req.path() + " -> " + res);
        };
        Filter auth = (req, res, next) -> {
            if (!req.headers().containsKey("Authorization")) {
                res.append("401 Unauthorized");             // does not call next: chain stops
                return;
            }
            next.doFilter(req, res);
        };
        Endpoint ordersEndpoint = (req, res) -> res.append("200 OK orders list");

        for (HttpRequest req : List.of(
                new HttpRequest("/orders", Map.of("Authorization", "Bearer abc")),
                new HttpRequest("/orders", Map.of()))) {
            new FilterChain(List.of(timing, auth), ordersEndpoint).doFilter(req, new StringBuilder());
        }

        System.out.println("\n=== 4. Logging levels (variant: every handler may act) ===");
        LogHandler logger = new ConsoleLog();
        logger.setNext(new FileLog()).setNext(new PagerLog());
        System.out.println("  log DEBUG:");
        logger.log(Level.DEBUG, "cache miss for key=42");
        System.out.println("  log ERROR:");
        logger.log(Level.ERROR, "payment service down");
    }
}
```

Output:

```
=== 1. API request pipeline (classic linked handlers) ===
request from alice:
  [auth] ok for alice
  [ratelimit] ok (1/2)
  [validate] ok
  [order] created order for alice: 2 x widget
  => handled = true
request from bob:
  [auth] rejected: missing token
  => handled = false
request from alice:
  [auth] ok for alice
  [ratelimit] ok (2/2)
  [validate] rejected: empty payload
  => handled = false
request from alice:
  [auth] ok for alice
  [ratelimit] rejected: alice made 3 requests, limit 2
  => handled = false

=== 2. Expense approval chain (first capable handler wins) ===
  TeamLead approved EXP-1 ($300)
    TeamLead (limit $1000) escalates EXP-2
  Manager approved EXP-2 ($7500)
    TeamLead (limit $1000) escalates EXP-3
    Manager (limit $10000) escalates EXP-3
  REJECTED EXP-3 ($120000): above every approver's limit

=== 3. Servlet-style filters (next is an explicit argument) ===
  [timing] start /orders
  [timing] end   /orders -> 200 OK orders list
  [timing] start /orders
  [timing] end   /orders -> 401 Unauthorized

=== 4. Logging levels (variant: every handler may act) ===
  log DEBUG:
    console <- DEBUG cache miss for key=42
  log ERROR:
    console <- ERROR payment service down
    app.log <- ERROR payment service down
    PAGER   <- ERROR payment service down
```

Walk through the output:

- Request 1 travels the full chain. Request 2 stops at auth — the rate limiter, validator and order code never run. Request 3 passes auth and the limiter (2 of 2) and stops at validation. Request 4 is the third request from alice, so the limiter stops it.
- `EXP-2` is escalated once and approved by the Manager. `EXP-3` is above every limit, so the chain gives an explicit "REJECTED" outcome rather than disappearing.
- The timing filter prints both before and after the rest of the chain. For the unauthenticated request, the auth filter wrote `401` (the HTTP status code for "not authenticated") and did not call `next`, so the endpoint never ran.
- A `DEBUG` message only reaches the console; an `ERROR` goes to all three.

Trade-offs

Pros	Cons
A new stage costs one class and one wiring line; no working class is edited (Open/Closed — open for extension, closed for modification).	To see the route a request takes you must read the wiring plus several files.
Every stage can be unit-tested (tested in isolation) on its own against a stub (a minimal stand-in) successor.	When a request is refused, you may have to step through several handlers to learn which one refused it.
Each route or environment can get its own chain, assembled at start-up.	No compiler or framework verifies that the chain is complete or correctly ordered.
The sender does not know which object will end up handling its request.	A handler that neither handles nor forwards makes the request vanish without any error.
	Each extra stage adds a call; rarely matters, but can on very hot paths (code that runs extremely often) with long chains.

The order of the stages is a design decision that no tool verifies. Auth before rate limiting means the limiter can count per *user*, and requests without valid credentials are turned away before they can use up a real user's quota (allowed number of requests). Rate limiting before auth means the limiter can only key on something like the IP address (the network address of the calling machine) — but it shields the (possibly expensive) auth step from floods (huge bursts of requests). Both are reasonable; they behave differently. **Put a comment with the reason beside the wiring** (see `Main`): the order is written down nowhere else.

When not to use it

- **Every request always goes through every stage in a fixed order.** Four calls in one method are clearer and have no wiring to get wrong.
- **Handlers need each other's results.** Then the stages are not independent: what you really have is a *pipeline* in which each step reshapes a value for the next. Call the steps one after another and pass an accumulating context object between them instead.
- **No terminal handler exists.** If the end of the chain can be reached with nothing done, failures become silent. Add an explicit terminal handler first.
- **The chain is long and on a very hot path**, where every extra call is measurable.

Common mistakes

1. **The swallowing bug.** A handler does its check and then just `return`s instead of calling `passOn`. No exception, no log; orders "sometimes don't appear". Fixes: give every path an explicit outcome (handled / rejected with reason / passed on); prefer the style where `next` is an explicit parameter (servlet filters, Express, Go `http.Handler`) so forgetting it is visible; unit-test each handler against a stub successor that remembers whether it got the request.
2. **No terminal handler.** Reaching the end should be an error or a clear "not handled" result — never a shrug.
3. **Wrong order, undocumented.** See the trade-offs above.
4. **Handlers that know about each other** (`new RateLimitHandler()` inside `AuthHandler`). The chain is then fixed in code again.
5. **Sharing a stateful chain object between requests.** The servlet-style `FilterChain` keeps a position, so it must be **one per request** (our `Main` creates a new one for each).

Real-world examples

- **Servlet filters**: `jakarta.servlet.Filter.doFilter(request, response, chain)` — calling `chain.doFilter(...)` *is* "pass on". **Spring Security** (Spring's authentication and authorisation library) is a chain of such filters (`SecurityFilterChain`).
- **Spring MVC** `HandlerInterceptor`: `preHandle` returns `false` to stop the request.
- **HTTP middleware** (code a web framework runs around every request; HTTP is the web's request/response protocol) in Express (`next()`), Django, Ruby's Rack, ASP.NET Core, Go (`func(http.Handler) http.Handler`, the usual way to structure a Go web service). **OkHttp** interceptors call `chain.proceed(request)`. **Netty**'s `ChannelPipeline` passes events from handler to handler.

- **In languages with first-class functions** (functions that can be stored and passed around like values) the chain is usually a list of `(request, next) => ...` functions rather than classes; JavaScript frameworks often build it by folding (combining a list into one value step by step) the list with `Array.reduce`, and in Python several decorators (`@` wrappers around a function) stacked on one view function (the function that handles a web request) form a chain written as syntax. Passing `next` explicitly removes the "forgot to pass on" bug by design.
- **`java.util.logging`**: a `LogRecord` is published to the logger's handlers and then, by default, to its parent logger's handlers; `setUseParentHandlers(false)` stops that. This is why setting a level or handler on a parent logger affects its children.
- **Exception handling**: each stack frame (one method call in progress) either catches the exception or lets it travel up — the language's own chain.
- **DOM event bubbling** (the DOM — Document Object Model — is the browser's tree of page elements): a click event climbs from the clicked element through its parent elements; any listener can call `stopPropagation()` to end the climb.
- **Approval workflows** (expenses, leave requests, loan approvals) where authority is based on amount or role, and **customer-support escalation** tiers.

In the interview

> **30-second answer:** "Chain of Responsibility splits a series of checks into separate handler objects, each linked only to its successor. The request moves down the line until some handler completes it or refuses it. Because only the wiring knows the order, adding, removing or reordering a rule is cheap. Servlet filters and HTTP middleware are the everyday examples. The classic bug is a handler that forgets to pass on and swallows the request, so I give every path an explicit outcome and put a terminal handler at the end."

Follow-ups:

- *How is it different from Decorator?* Both link objects that share one interface. With a **Decorator**, all wrappers run and the call is always delivered to the inner object; the point is to *add* behaviour. With **CoR**, a handler may **end** the request, and handlers further down never see it.
- *How is it different from Observer?* Observer tells **every** subscriber, and no subscriber can block the rest. CoR ends at the **first** handler that accepts the job.
- *How is it different from a pipeline?* A pipeline pushes a value through **all** of its steps and produces a transformed result. A chain *routes* a request to whichever handler takes it. Rule of thumb: if no stage can stop the flow, you have a pipeline.
- *Combine it with Command?* Yes — the request moving through the handlers is frequently itself a Command object (e.g. a job checked by validation and authorisation handlers before a worker runs it).
- *What if no handler can handle the request?* Put an explicit terminal handler (e.g. `NoHandlerFound`) that returns an error or logs, so failures are never silent.
- *How do you test it?* Test each handler with a fake next handler that records whether it was called and with what; then one integration test (a test of several parts working together) for the wiring order.
- *Where should rate limiting go, before or after auth?* Explain the trade-off above and say you would document the reason next to the wiring.

Self-check

1. **Q:** What does each handler hold a reference to? **A:** Only the next handler (through the abstract `Handler` type).
2. **Q:** Name the most common CoR bug. **A:** A handler that neither handles nor passes on — the request silently disappears.
3. **Q:** Why do modern frameworks pass `next` as a parameter? **A:** Because a missing `next(...)` call is then easy to spot in the handler's own body, and because the handler can do work both before and after the rest of the chain runs.
4. **Q:** Is a logging chain where every handler always passes on a "pure" CoR? **A:** Not strictly; since no handler can stop the flow it behaves like a pipeline. It is a common variant.
5. **Q:** When should you *not* use CoR? **A:** When every stage always runs in a fixed order, when stages depend on each other's results, or when there is no terminal handler.

TL;DR

A request walks a line of handlers; each handles, rejects, or passes on. The chain is data, so it is easy to change — but **order matters**, **always have a terminal handler**, and **never swallow a request**.

10.2 Command

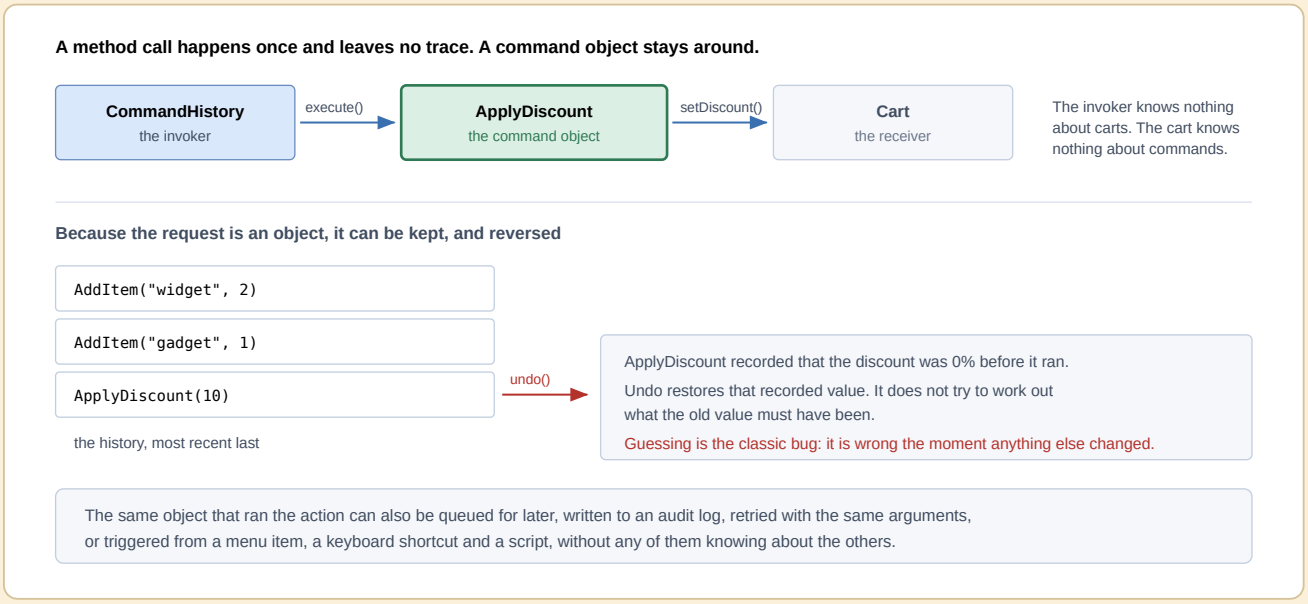

Figure — The invoker (CommandHistory) runs command objects against the receiver (Cart) and keeps them so they can be undone (course diagram). The figure assumes the discount was 0% before; our code deliberately starts at 5% to prove undo restores the recorded value.

What it is

Command packages a request ("add 2 widgets to the cart") as an **object** containing everything required to perform it later. Once the request is a value you can hold, you can **keep it in a list, put it on a queue (a first-in, first-out waiting line), write it to an audit log (a permanent record of who did what), run it again, hand it to a worker thread (a background thread — an independent path of execution — that takes jobs and runs them)** — and, when it also knows its own inverse, **reverse it**.

GoF intent, in plain words: *wrap a request in an object, so clients can be given different requests, requests can be queued or logged, and operations can be undone.*

Everyday analogy: a restaurant order slip. The waiter (invoker) does not cook; they write the order on a slip (command) and put it on the queue. The cook (receiver) acts on it later. The slip can be queued, prioritised, or cancelled.

The problem it solves

A plain method call such as `cart.setDiscount(10)` runs immediately and is forgotten the moment it returns. That is not enough once you need any of these:

- **Undo** — "reverse my last two changes".
- **A queue** — run the work later, on a worker thread, not in the request thread (the thread serving the user's request).
- **A log of intent** — an auditor asks which operations were *requested*, not just what state the data ended up in.
- **Retry** — run a failed action again with the same arguments.
- **One action, many triggers** — a menu item, a hot-key (keyboard shortcut) and an automation script should all fire the same "apply discount".

Command gives the request a body that outlives the call.

How it works

Interviewers usually want **three roles** named — **invoker**, **command**, **receiver** — plus the **client** that creates commands. GoF lists five participants in total: **Command** (the interface), **ConcreteCommand** (binds a receiver to an action), **Client**, **Invoker** and **Receiver**:

Role	Job	In our code
Command	Interface with `execute()` (and optionally `undo()`).	`Command`, `UndoableCommand`
Concrete command	Stores its receiver and arguments; can perform (and reverse) exactly one operation.	`AddItemCommand`, `ApplyDiscountCommand`, `MacroCommand`
Receiver	The object whose state is really modified. Has no idea commands exist.	`Cart`
Invoker	Triggers commands and keeps a record of them. Has no idea carts exist.	`CommandHistory`, `ExecutorService`
Client	Builds a concrete command and gives it its receiver.	`Main`

Steps:

1. The client creates a concrete command, passing the **receiver** and the **arguments**.
2. It hands the command to the **invoker**.
3. The invoker calls `execute()` and, if the command is undoable, pushes it on an **undo stack** (a stack is a last-in, first-out pile: you add and remove only at the top).
4. **Undo** = pop the last command and call `undo()`; push it on a **redo stack**.
5. **Redo** = pop from redo, `execute()` again, push back on undo. **Running a fresh command empties the redo stack**: the branch of history you might have re-applied has been replaced.

Structure (UML)

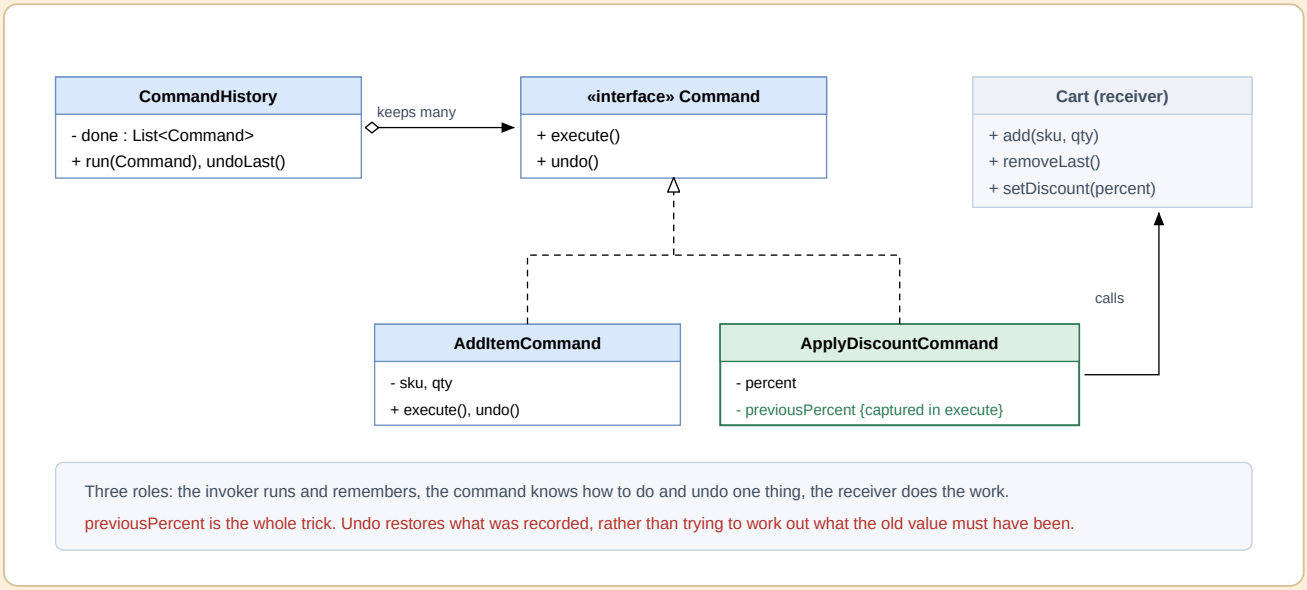

Figure — Class diagram: Command interface with execute/undo, two concrete commands, Cart as receiver, CommandHistory as invoker (course diagram; its `undoLast`/`removeLast` are named `undo`/`remove` in our code)

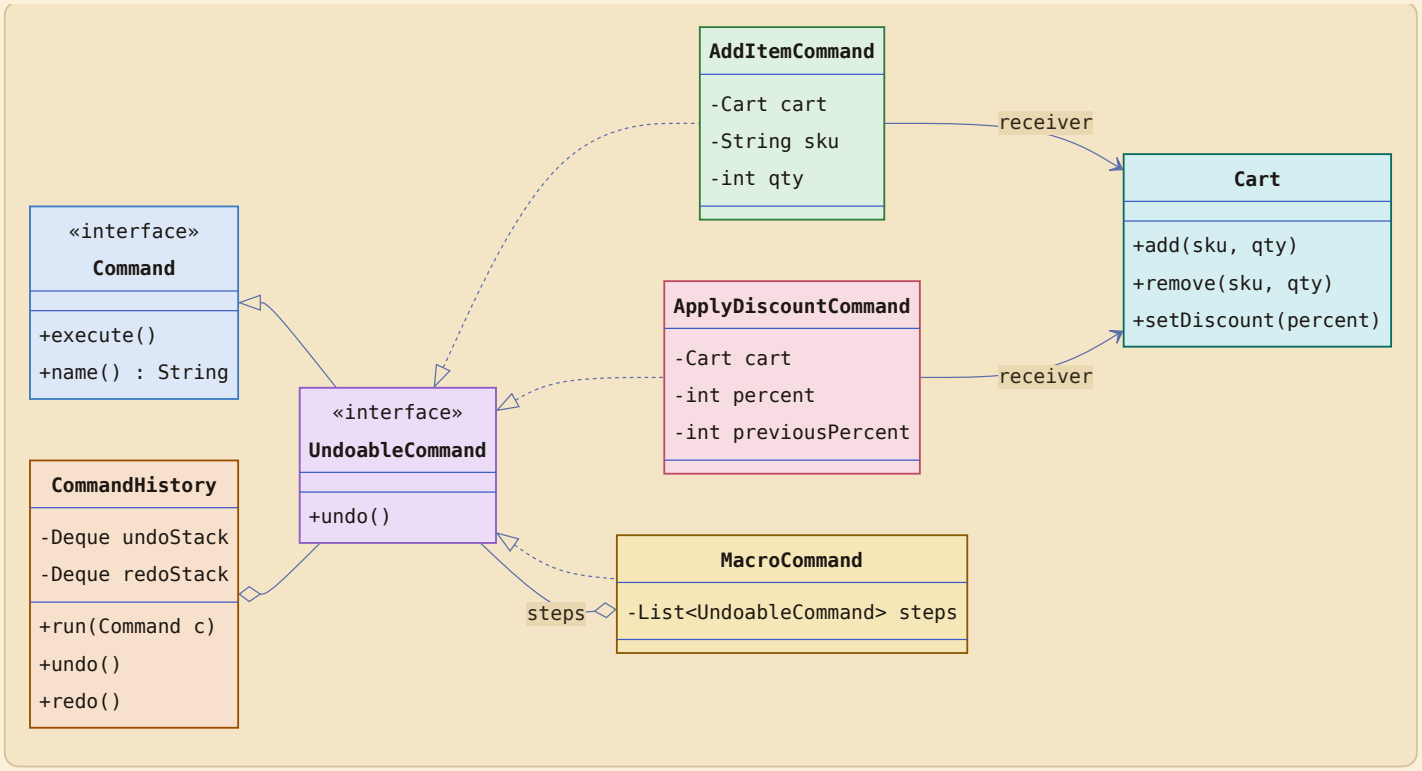
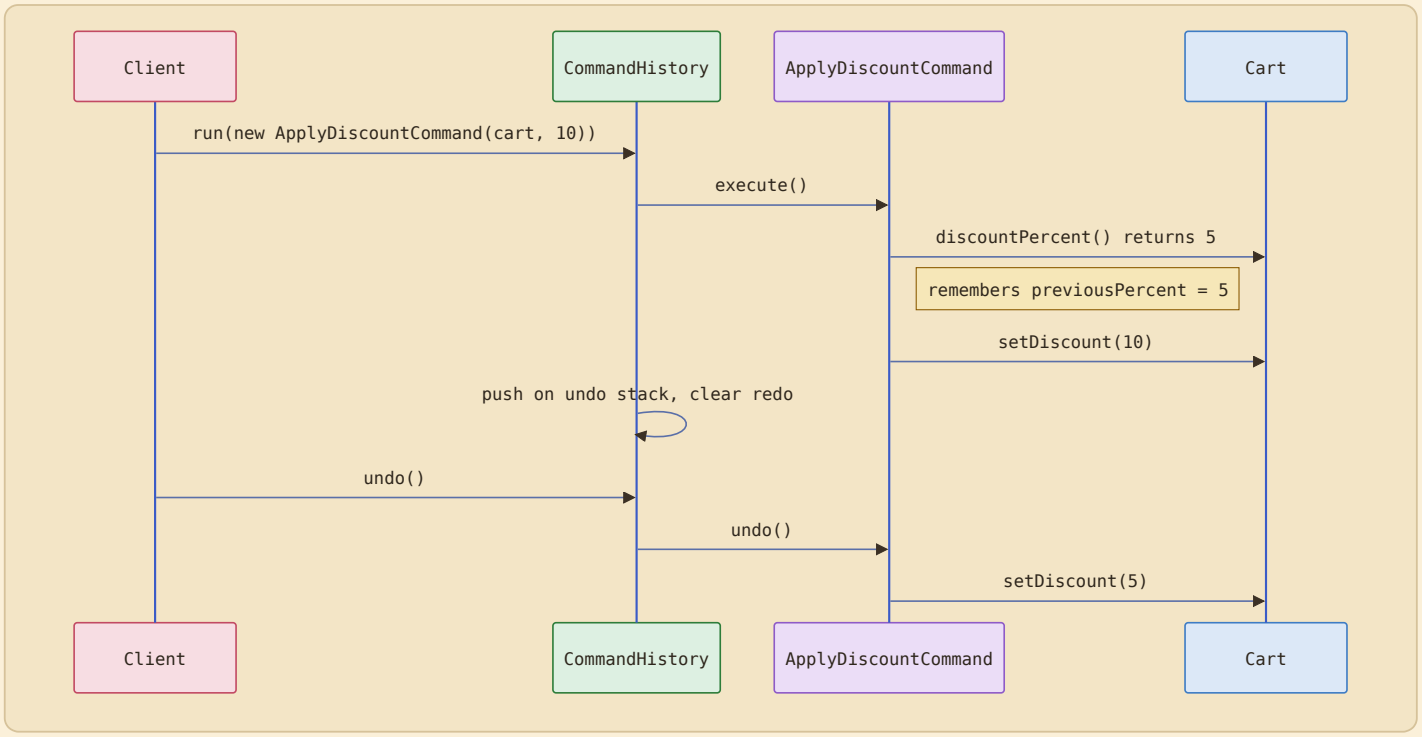
In the diagram above, each command keeps its own reference to the `Cart`. It has to: when it finally runs, the code that created it may have finished long ago, so the target object must travel inside the command along with the arguments. Also note `ApplyDiscountCommand.previousPercent` — the single field that makes its undo correct. And note that `CommandHistory` never mentions `Cart`; hand it any other commands and it still works, which is why one history can serve a whole application.

Our Java design:





Java example

Key design points in `lld.ch10.command`:

- `Command` has **one abstract method**, so any lambda (a short unnamed function) or `Runnable`-like block (`Runnable` is Java's built-in "code to run" interface) can be a command. Only commands that can *honestly* be reversed implement `UndoableCommand`. `CommandHistory` keeps irreversible commands out of the undo stack.
- `ApplyDiscountCommand` **captures the old value in** `execute()` and restores exactly that in `undo()`. The cart deliberately starts at 5%, to show that "undo = set to 0" would be wrong.
- `MacroCommand` is a command made of commands (a **Composite** of commands): it executes steps in order and undoes them in **reverse** order.
- Section 4 of `Main` shows the JDK's own version: `Runnable` is the command interface and an `ExecutorService` (Java's thread-pool service for running tasks) is the invoker that runs commands on a worker thread.

```java
// File: code/lld/ch10/command/Command.java
package lld.ch10.command;

/** A request turned into an object. One abstract method, so a lambda is a Command. */
@FunctionalInterface
public interface Command {
    void execute();

    default String name() { return getClass().getSimpleName(); }
}
```

```java
// File: code/lld/ch10/command/UndoableCommand.java
package lld.ch10.command;

/** Only commands that can honestly be reversed implement this. */
public interface UndoableCommand extends Command {
    void undo();
}
```

```java
// File: code/lld/ch10/command/Cart.java
package lld.ch10.command;

import java.util.ArrayList;
import java.util.List;

/** The RECEIVER: knows how to change itself and nothing about commands. */
public final class Cart {
    public record Line(String sku, int qty) {}

    private final List<Line> lines = new ArrayList<>();
    private int discountPercent = 0;

    public void add(String sku, int qty) { lines.add(new Line(sku, qty)); }

    /** Removes the most recent line matching sku and qty. */
    public void remove(String sku, int qty) {
        for (int i = lines.size() - 1; i >= 0; i--) {
            if (lines.get(i).equals(new Line(sku, qty))) {
                lines.remove(i);
                return;
            }
        }
    }

    public int discountPercent() { return discountPercent; }
    public void setDiscount(int percent) { this.discountPercent = percent; }

    @Override
    public String toString() {
        StringBuilder sb = new StringBuilder("Cart[");
        for (int i = 0; i < lines.size(); i++) {
            if (i > 0) sb.append(", ");
            sb.append(lines.get(i).sku()).append(" x").append(lines.get(i).qty());
        }
        return sb.append("] discount=").append(discountPercent).append('%').toString();
    }
}
```

```java
// File: code/lld/ch10/command/AddItemCommand.java
package lld.ch10.command;

/** Adds a line; undo removes exactly that line. */
final class AddItemCommand implements UndoableCommand {
    private final Cart cart;      // the command carries its receiver...
    private final String sku;     // ...and all the arguments it needs to run later
    private final int qty;

    AddItemCommand(Cart cart, String sku, int qty) {
        this.cart = cart;
        this.sku = sku;
        this.qty = qty;
    }

    @Override public void execute() { cart.add(sku, qty); }
    @Override public void undo()    { cart.remove(sku, qty); }
    @Override public String name()  { return "AddItem(" + sku + ", " + qty + ")"; }
}
```

```java
// File: code/lld/ch10/command/ApplyDiscountCommand.java
package lld.ch10.command;

/** Sets a discount; captures the previous value during execute so undo RESTORES, never guesses. */
final class ApplyDiscountCommand implements UndoableCommand {
    private final Cart cart;
    private final int percent;
    private int previousPercent;          // filled in by execute()

    ApplyDiscountCommand(Cart cart, int percent) {
        this.cart = cart;
        this.percent = percent;
    }

    @Override
    public void execute() {
        previousPercent = cart.discountPercent();   // capture BEFORE changing
        cart.setDiscount(percent);
    }

    @Override public void undo()   { cart.setDiscount(previousPercent); }
    @Override public String name() { return "ApplyDiscount(" + percent + "%)"; }
}
```

```java
// File: code/lld/ch10/command/MacroCommand.java
package lld.ch10.command;

import java.util.List;

/** A command made of commands. Runs in order; undoes in REVERSE order. */
final class MacroCommand implements UndoableCommand {
    private final String label;
    private final List<UndoableCommand> steps;

    MacroCommand(String label, List<UndoableCommand> steps) {
        this.label = label;
        this.steps = List.copyOf(steps);
    }

    @Override public void execute() { steps.forEach(Command::execute); }

    @Override
    public void undo() {
        for (int i = steps.size() - 1; i >= 0; i--) steps.get(i).undo();
    }

    @Override public String name() { return "Macro:" + label; }
}
```

```java
// File: code/lld/ch10/command/CommandHistory.java
package lld.ch10.command;

import java.util.ArrayDeque;
import java.util.Deque;

/** The INVOKER: runs commands and remembers them. Knows nothing about carts. */
public final class CommandHistory {
    private final Deque<UndoableCommand> undoStack = new ArrayDeque<>();
    private final Deque<UndoableCommand> redoStack = new ArrayDeque<>();

    public void run(Command command) {
        command.execute();
        if (command instanceof UndoableCommand u) {
            undoStack.push(u);
            redoStack.clear();     // a new action destroys the "future" you could have redone
            System.out.println("  ran  " + command.name());
        } else {
            System.out.println("  ran  " + command.name() + " (irreversible: kept out of history)");
        }
    }

    public void undo() {
        if (undoStack.isEmpty()) { System.out.println("  nothing to undo"); return; }
        UndoableCommand c = undoStack.pop();
        c.undo();
        redoStack.push(c);
        System.out.println("  undo " + c.name());
    }

    public void redo() {
        if (redoStack.isEmpty()) { System.out.println("  nothing to redo"); return; }
        UndoableCommand c = redoStack.pop();
        c.execute();
        undoStack.push(c);
        System.out.println("  redo " + c.name());
    }
}
```

```java
// File: code/lld/ch10/command/Main.java
package lld.ch10.command;

import java.util.List;
import java.util.concurrent.ExecutorService;
import java.util.concurrent.Executors;
import java.util.concurrent.TimeUnit;

public class Main {
    public static void main(String[] args) throws InterruptedException {
        Cart cart = new Cart();
        CommandHistory history = new CommandHistory();

        System.out.println("=== 1. Undo / redo ===");
        cart.setDiscount(5);   // the cart does NOT start at 0%: a guessing undo would be wrong
        history.run(new AddItemCommand(cart, "widget", 2));
        history.run(new AddItemCommand(cart, "gadget", 1));
        history.run(new ApplyDiscountCommand(cart, 10));
        System.out.println("  " + cart);
        history.undo();
        history.undo();
        System.out.println("  " + cart + "   <- discount restored to the recorded 5%, not 0%");
        history.redo();
        System.out.println("  " + cart);
        history.run(new AddItemCommand(cart, "cable", 3));   // clears the redo stack
        history.redo();

        System.out.println("\n=== 2. Macro command ===");
        UndoableCommand starterKit = new MacroCommand("starter-kit", List.of(
            new AddItemCommand(cart, "keyboard", 1),
            new AddItemCommand(cart, "mouse", 1),
            new ApplyDiscountCommand(cart, 15)));
        history.run(starterKit);
        System.out.println("  " + cart);
        history.undo();                                      // one undo reverses all three steps
        System.out.println("  " + cart);

        System.out.println("\n=== 3. Irreversible command (no undo offered) ===");
        Command sendReceipt = new Command() {
            @Override public void execute() { System.out.println("  [email] receipt sent for " + cart); }
            @Override public String name()  { return "SendReceipt"; }
        };
        history.run(sendReceipt);

        System.out.println("\n=== 4. Commands on a queue: Runnable + ExecutorService (the invoker) ===");
        List<Runnable> jobs = List.of(
            () -> System.out.println("  [worker] resize image 1"),
            () -> System.out.println("  [worker] resize image 2"),
            () -> System.out.println("  [worker] send newsletter"));
        System.out.println("  queued " + jobs.size() + " jobs");
        ExecutorService worker = Executors.newSingleThreadExecutor();   // one thread => FIFO order
        jobs.forEach(worker::submit);
        worker.shutdown();
        worker.awaitTermination(5, TimeUnit.SECONDS);
        System.out.println("  all jobs done");
    }
}
```

Output:

```
=== 1. Undo / redo ===
  ran  AddItem(widget, 2)
  ran  AddItem(gadget, 1)
  ran  ApplyDiscount(10%)
  Cart[widget x2, gadget x1] discount=10%
  undo ApplyDiscount(10%)
  undo AddItem(gadget, 1)
  Cart[widget x2] discount=5%   <- discount restored to the recorded 5%, not 0%
  redo AddItem(gadget, 1)
  Cart[widget x2, gadget x1] discount=5%
  ran  AddItem(cable, 3)
  nothing to redo

=== 2. Macro command ===
  ran  Macro:starter-kit
  Cart[widget x2, gadget x1, cable x3, keyboard x1, mouse x1] discount=15%
  undo Macro:starter-kit
  Cart[widget x2, gadget x1, cable x3] discount=5%

=== 3. Irreversible command (no undo offered) ===
  [email] receipt sent for Cart[widget x2, gadget x1, cable x3] discount=5%
  ran  SendReceipt (irreversible: kept out of history)

=== 4. Commands on a queue: Runnable + ExecutorService (the invoker) ===
  queued 3 jobs
  [worker] resize image 1
  [worker] resize image 2
  [worker] send newsletter
  all jobs done
```

Undo must restore, not recompute

It is tempting to write a discount undo as "reset to 0" or "calculate what the old value probably was". Both are **guesses**. If the cart began at 5%, or some other command touched the discount meanwhile, the user ends up with a value that never existed. The rule: `execute` **must record whatever** `undo` **will need** — normally just the fields it is about to overwrite, not a copy of the whole object.

Undo history is strictly last-in, first-out. Commands are reversed newest first: the sequence `AddItem, AddItem, ApplyDiscount` is undone as `ApplyDiscount`, then the second `AddItem`, then the first. Reversing them in any other order can produce states that never existed, hence a stack, never a list you can index into at random.

When undo is a lie. Some effects escape your system: an email that was sent, a card that was charged, a call made to a partner's API (the interface a service exposes for other programs to call). An `undo()` on those promises something impossible, which is worse than having no undo at all. Two honest options: keep them out of the history (our `SendReceipt`), or use **compensation** — a *new* action that produces a similar end state, like a **refund** for a charge. A refund is not an undo: both events stay in the record.

Trade-offs

Pros	Cons
Since the request lives on after the call, undo/redo, queues, audit logs, retries and scheduling all become possible.	Every action needs its own class, so the number of classes tracks the number of actions.
The invoker has no knowledge of what it runs, so a single history works for all commands.	Each command has to record enough to run later and to reverse itself; subtle mistakes are easy.
One action object can back a menu entry, a hot-key, a script and an API endpoint.	Extra hop when reading code: to learn what a button does you first find the command it builds.
Commands can be grouped into macro commands.	A single faulty `undo` corrupts the whole history.

When not to use it

- **The call is simple and immediate.** A `SaveCommand` class that nobody ever undoes, queues or logs is extra code with no benefit.
- **Undo is not really possible.** Use compensation and call it that.

- **You only need deferral.** A lambda (`Runnable`) already is a one-method command. Promote it to a class once you need `undo`, a readable name in logs, or serialization (turning it into bytes or text so it can be stored or sent).
- **Commands must outlive the process.** They then have to be serialized, which drags in format versioning; a durable queue (one that survives restarts — see System Design Fundamentals) or an event log (Kafka — a durable, distributed message log — or a jobs table) handles that better than hand-rolled command classes.

Common mistakes

1. **Recomputing in `undo`** instead of restoring captured state.
2. **Forgetting to clear the redo stack** when a new command runs.
3. **Putting business logic in the invoker** (`if (cmd instanceof AddItem) ...` — `instanceof` checks an object's concrete type). The invoker should only run and remember.
4. **Commands that capture a mutable object by reference** (mutable = changeable after creation) and then read it later, when it has changed. Capture values.
5. **Unbounded history** — cap the depth, as editors do.

Real-world examples

- **Undo in editors**: word processors, IDEs (integrated development environments — code editors such as IntelliJ), Photoshop. The JDK has `javax.swing.undo.UndoManager` with `UndoableEdit` objects that have `undo()`/`redo()`.
- **`Runnable` / `Callable`** are the JDK's command interfaces; `ExecutorService`, `ScheduledExecutorService` and `Thread` are invokers.
- **GUI actions** (GUI = graphical user interface): Swing's (Java's desktop UI toolkit) `javax.swing.Action` lets one action back a menu item, a toolbar button and a shortcut; WPF's `ICommand` in .NET plays the same role.
- **Event sourcing** (Chapter 11; storing every change as an event and rebuilding state by replaying them): recording the *requested changes* instead of only the resulting state is the command idea applied to a whole system.
- **Job queues**: a Sidekiq/Celery (background-job libraries for Ruby and Python) job, a Spring `@Async` task, a message on a Kafka/RabbitMQ (message brokers) queue that asks a worker to "send invoice #42" — a serialized command.
- **Database migrations** (versioned scripts that change a database's structure) with `up`/`down` (e.g. Liquibase changesets with rollback) mirror `execute`/`undo`.
- **Redux** (a JavaScript state-management library) actions are command objects: the store dispatches them (invoker role) and reducers apply them to state (receiver role); Redux DevTools' time travel replays them.
- **In other languages**: in Python, a callable object (one defining `__call__`) with an extra `undo` method works well, and `functools.partial` can bind the arguments; in C#, UI frameworks ship an `ICommand` interface, and a `record` gives you an immutable (unchangeable after creation) command in a single line.
- **Transactional outbox / task tables** (the job is written to a database table in the same transaction — the same all-or-nothing database update — as the data change, so it cannot be lost) in food-delivery or e-commerce back ends store "commands" (send SMS, notify restaurant) to be run reliably by workers.

In the interview

> **30-second answer:** "Command wraps a request, together with its receiver and arguments, in an object — so the request can be kept, queued, logged, retried or reversed. Three roles matter: the invoker triggers and records commands without knowing what they touch, each command can perform and reverse a single operation, and the receiver holds the state that actually changes. For undo, `execute` must capture the old value and `undo` restores it; history is a stack, and a new command clears redo. Irreversible actions like charging a card get compensation, not undo. In Java, `Runnable` plus an `ExecutorService` is the everyday form."

Follow-ups:

- *Command vs Strategy?* Each puts behaviour inside an object. A **Strategy** answers *how* a job is done and is picked and replaced by the caller. A **Command** captures *which* job to do, arguments included, and is held on to so it can run later or be reversed.
- *Command vs a plain lambda?* A one-method closure (a function that remembers variables from where it was created) already is a command. Write a class only when you also need `undo`, a readable log name, or to serialize it.

- *Command vs Memento for undo?* Command stores the **action** plus a small piece of state; undo runs the inverse. Memento stores the **whole state**; undo puts a snapshot back. Command is cheaper per step; Memento is always correct. Real systems combine them (snapshot occasionally, replay commands in between).
- *How do you implement redo?* A second stack; undo moves a command to it; redo moves it back after re-executing; a new command clears it.
- *How do you make a command queue thread-safe (correct when many threads use it at once)?* Use a `BlockingQueue` (a queue whose `take()` waits until an item arrives) or an `ExecutorService`; make commands immutable apart from captured undo state.
- *How would you persist commands?* Serialize them (JSON — a common text format for structured data — with a type field and a version), store in a durable queue or table, make them **idempotent** (running one twice has the same effect as running it once — see System Design Fundamentals) so a retry is safe.

Self-check

1. **Q:** What must a command carry? **A:** Its receiver and all arguments needed to run later (and any state needed for undo).
2. **Q:** Why does `ApplyDiscountCommand` store `previousPercent`? **A:** So undo restores the real previous value instead of guessing.
3. **Q:** What happens to the redo stack when a new command runs? **A:** It is cleared.
4. **Q:** How do you "undo" a card charge? **A:** You don't; you issue a compensating action (a refund) and keep both in the record.
5. **Q:** Which JDK interface is a command? **A:** `Runnable` (and `Callable`).

TL;DR

Make the request an object: **invoker** runs it, **command** knows do/undo, **receiver** changes. Undo **restores captured state**, history is a **stack**, and irreversible actions get **compensation**. A lambda is a command when you only need deferral.

10.3 Iterator

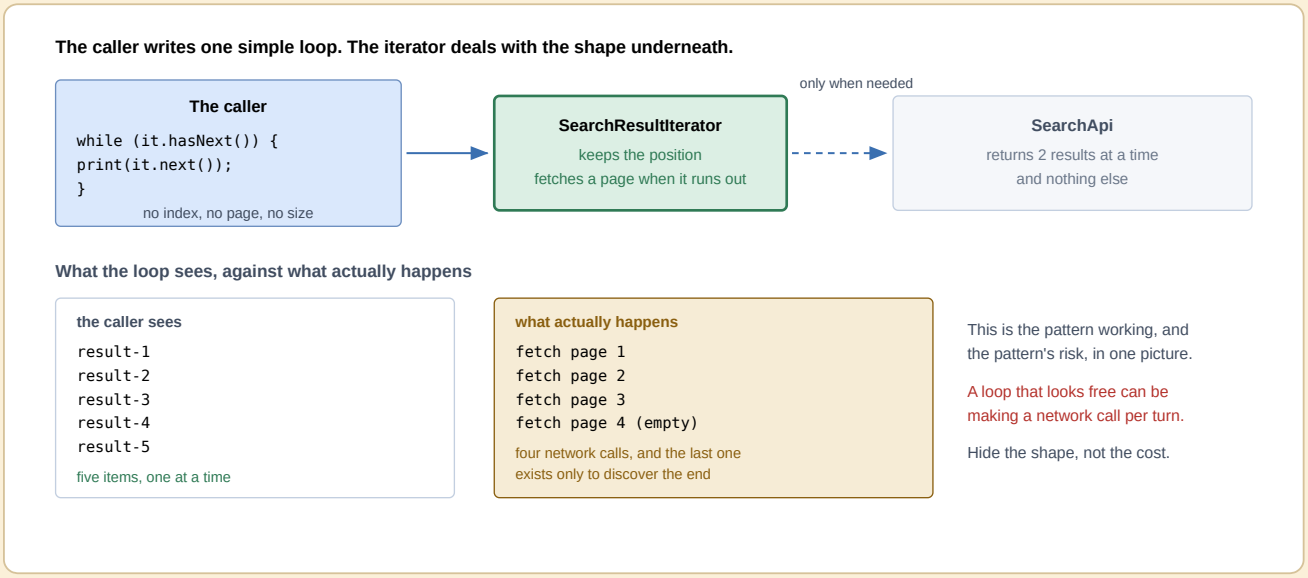


Figure — The caller writes one simple loop; the iterator fetches pages from the API only when needed (course diagram)

What it is

Iterator lets you visit the elements of a collection **one at a time, in order, without knowing how the collection stores them** — array, linked list (elements chained together by references), tree, or a remote API that returns two results per page.

GoF intent, in plain words: *give sequential access to the elements of an aggregate (GoF's word for a collection) without exposing its internal representation.* GoF participants: **Iterator** (interface for accessing and

traversing), **ConcreteIterator** (implements it and tracks the current position), **Aggregate** (interface for creating an iterator) and **ConcreteAggregate** (returns the right ConcreteIterator).

Everyday analogy: a TV remote's "next channel" button. You do not need to know how the channels are stored in the TV; you just press *next* until there are no more.

The problem it solves

- Code that loops with `get(i)` quietly assumes the data sits in an array. Move the data into a linked list, a tree or a paginated (returns results one page at a time) remote service, and each of those loops must be rewritten.
- Many sources **cannot be indexed at all**: a tree has several valid visiting orders (depth-first — follow one branch all the way down before the next; breadth-first — level by level); a graph (nodes joined by edges, possibly with loops) must remember which nodes were already seen; a search API hands out pages. When each caller writes its own traversal, each caller also re-implements paging — and some implement it wrongly.

Iterator moves the walking logic **into a separate object** that answers two questions: *are any elements left?* (`hasNext`) and *hand me the following element* (`next`).

Key detail: the current position is stored inside the iterator object, never in the collection. So two traversals of one collection can be in progress together without disturbing each other, and every call to `iterator()` must build a **new** iterator instead of rewinding a shared cursor (a marker of the current position).

How it works

1. The **aggregate** (the collection) has a method `iterator()` that creates a new iterator. In Java it implements `Iterable<T>`.
2. The **iterator** implements `Iterator<T>`: `hasNext()` and `next()` (and optionally `remove()`).
3. The iterator keeps its own **cursor** (index, stack of tree nodes, current page...).
4. The client loops: `while (it.hasNext()) use(it.next());` — or just `for (T x : collection)`, which the Java compiler turns into exactly that.

Structure (UML)

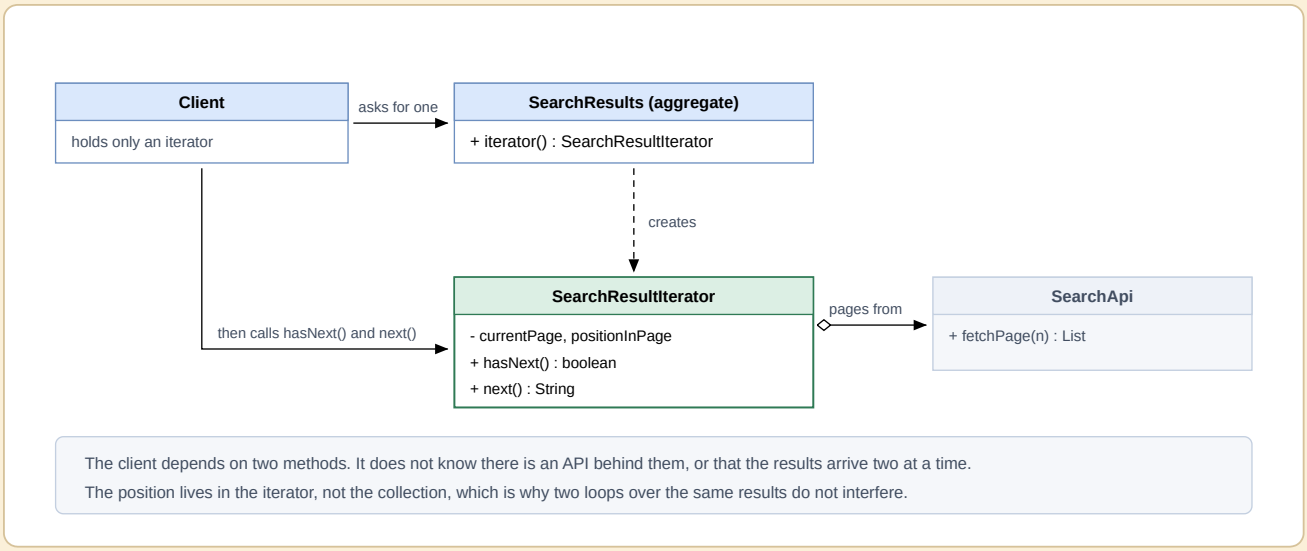

Figure — Class diagram: SearchResults (aggregate) hands out a SearchResultIterator, which calls SearchApi page by page; the client only calls hasNext/next (course diagram)

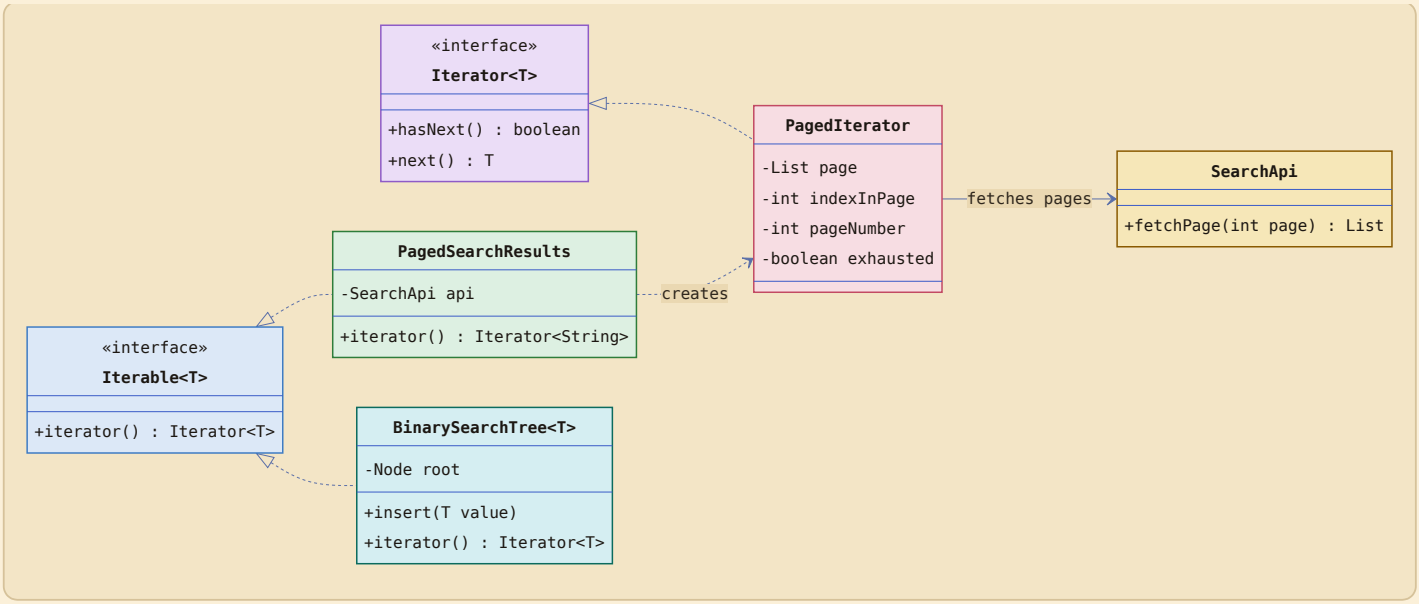
In the diagram above, `hasNext` does real work: once the buffered page runs out, it asks the API for another page. A *lazy* iterator (one that produces elements only on demand) commonly behaves like this — so never assume `hasNext` is cheap or has no side effects (effects beyond returning a value, such as a network call).

Our Java design:



Java example

`lld.ch10.iterator` shows:

1. **A paged remote source behind a plain for-each.** `PagedSearchResults implements Iterable<String>`, so `for (String r : results)` just works. The inner `PagedIterator` fetches a page only when the current one is used up, and follows the `Iterator` contract (the documented rules every implementation must obey) (`next()` throws `NoSuchElementException` when empty).
2. **A tree iterator.** `BinarySearchTree` hides an in-order walk (left subtree, then the node, then the right subtree — which yields sorted order) behind `hasNext/next` using an explicit stack; two iterators over the same tree run independently.
3. **External vs internal iteration.** *External*: the **client** drives (`hasNext/next`) and can stop early with `break`. *Internal*: the **collection** drives and calls your code for each element (`forEach(lambda)`, streams — Java's pipeline API for processing collections).
4. **Fail-fast vs fail-safe.** Structurally changing an `ArrayList` (adding or removing) while a for-each loop is walking it *usually* makes the next `next()` throw `ConcurrentModificationException`. It is only **best-effort**: the demo also removes the second-to-last element, after which `hasNext()` simply returns `false` — no exception, and the last element is silently never visited. The safe way is `Iterator.remove()` (or `removeIf`). `CopyOnWriteArrayList` iterates over a **snapshot**, so it never throws — but the loop does not see the new elements. ("Fail-safe" is an informal name; the Javadoc (Java's official API documentation) talks about *snapshot* and *weakly consistent* iterators.)
5. `Spliterator` (Java 8): an iterator that can **split** itself (`trySplit`) so parallel streams can process parts on different threads. It reports **characteristics** such as `SIZED` and `ORDERED`.

```java
// File: code/lld/ch10/iterator/SearchApi.java
package lld.ch10.iterator;

import java.util.List;

/** A remote source that returns two results per page and knows nothing about iteration. */
final class SearchApi {
    private static final List<String> ALL = List.of("result-1", "result-2", "result-3", "result-4", "result-5");
    private static final int PAGE_SIZE = 2;
    private int calls = 0;

    List<String> fetchPage(int page) {          // pages are 1-based
        calls++;
        System.out.println("    [api] fetching page " + page);
        int from = (page - 1) * PAGE_SIZE;
        if (from >= ALL.size()) return List.of();
        return ALL.subList(from, Math.min(from + PAGE_SIZE, ALL.size()));
    }

    int calls() { return calls; }
}
```

```java
// File: code/lld/ch10/iterator/PagedSearchResults.java
package lld.ch10.iterator;

import java.util.Iterator;
import java.util.List;
import java.util.NoSuchElementException;

/**
 * The AGGREGATE. Implements Iterable, so the enhanced for-loop works on it.
 * Its only job is to hand out a FRESH iterator each time.
 */
final class PagedSearchResults implements Iterable<String> {
    private final SearchApi api;

    PagedSearchResults(SearchApi api) { this.api = api; }

    @Override
    public Iterator<String> iterator() { return new PagedIterator(); }

    /** The ITERATOR. The position lives here, not in the collection. */
    private final class PagedIterator implements Iterator<String> {
        private List<String> page = List.of();
        private int indexInPage = 0;
        private int pageNumber = 0;
        private boolean exhausted = false;

        @Override
        public boolean hasNext() {                // NOT a passive question: may hit the network
            if (indexInPage < page.size()) return true;
            if (exhausted) return false;

  SIZED=true ORDERED=true
  left half:  1 2 3 4
  right half: 5 6 7 8
  parallel stream sum = 36
```

Hide the shape, not the cost

Look at section 1 of the output: five results, **four** network calls. The last call comes back empty; its only purpose is to find out that the data has ended, because this API reports neither a total nor a "next page" token. That is genuine behaviour, not a bug in the demo. The takeaway: **a tidy loop conceals how much each step costs.** The **N+1 query problem** in ORMs (object-relational mappers: libraries that turn database rows into objects) has the same shape (one query for the list, then one more query *per element* as you iterate). Ways to keep the cost visible:

- **Name the type honestly** (`PagedResults`, `LazySearchResults`, not `List`).
- **Offer a batch API** for callers who want everything, with bigger pages.
- **Return the total or a next-page cursor** when the source knows it, so the extra call is not needed.
- **Log or count the fetches**, so a growing request count gets noticed.

Java's iterator family (quick reference)

Type	What it adds
`Iterable<T>`	`iterator()`; lets a type be used in the enhanced for-loop. Also `forEach` (internal iteration) and `spliterator()`.
`Iterator<T>`	`hasNext()`, `next()`, optional `remove()`, `forEachRemaining()`.
`ListIterator<T>`	Bidirectional: `hasPrevious()`, `previous()`, indexes, `set()`, `add()`.
`Spliterator<T>`	`tryAdvance`, `forEachRemaining`, `trySplit` for parallelism, `characteristics()` like `ORDERED`, `SIZED`, `DISTINCT`, `IMMUTABLE`.
`Enumeration<E>`	The old (Java 1.0) version: `hasMoreElements()`, `nextElement()`. Prefer `Iterator`.

Fail-fast, weakly consistent, snapshot. Iterators of `ArrayList`, `HashMap` and friends are **fail-fast**: they detect a structural change made behind their back and throw `ConcurrentModificationException`. The Javadoc says this is done on a **best-effort** basis — never write code that relies on the exception (section 4 of the demo shows a removal that goes unnoticed). Despite its name, the exception is most often caused by **one thread** changing a collection inside its own loop, not by concurrency (several threads running at the same time). `ConcurrentHashMap` iterators are **weakly consistent** (never throw, may or may not show concurrent changes). `CopyOnWriteArrayList` iterators work on a **snapshot** (and their `remove()` throws `UnsupportedOperationException`).

Trade-offs

Pros	Cons
Client code no longer cares whether data lives in an array, in a tree or behind an API.	One more object is created per traversal (only noticeable in extremely hot loops).
One structure can offer several named, reusable visiting orders.	Changing the collection mid-loop is a bug unless you use the iterator's own `remove` or a concurrent collection.
Elements can be produced lazily, so even huge or endless sequences work.	If a lazy iterator owns a file or DB cursor and the loop breaks early, the resource leaks unless it is closed.
Paging, buffering and prefetching (loading the next data before it is asked for) disappear behind an ordinary loop.	Per-step cost becomes invisible — the root of N+1 problems.

When not to use it

- **The data is already an in-memory list.** Hand out the list (or its own iterator); writing a custom iterator around an array adds code and no value.
- **Callers jump around** ("I need element 4,000"). Iterators only move forward step by step; offer indexed access instead.
- **All elements are in memory and always consumed in full.** An ordinary loop over the list is simpler and faster.
- **A step has side effects the caller must decide on.** Silently loading another page is acceptable; silently charging a customer is not.

Common mistakes

1. **Modifying the collection while iterating** (other than through `Iterator.remove`). Collect changes and apply them after the loop, or use `removeIf`.
2. **Leaking a resource** from a lazy iterator on early `break`. Use try-with-resources (Java's `try (...)` form that closes resources automatically) (`Files.lines`, `DirectoryStream` and JDBC (Java's standard database API) `ResultSet` are all closeable).
3. **Reusing a one-shot iterator** or stream a second time: it is already exhausted. A Java `Stream` at least throws `IllegalStateException`; a Python generator (a function that produces values one at a time with `yield`) just yields nothing the second time, so the bug shows up as missing data. That is why `iterator()` must return a *new* object.
4. **`next()` without `hasNext()`**, or a `next()` that returns `null` at the end instead of throwing `NoSuchElementException`.
5. **Storing the cursor in the collection** — then two loops interfere.

6. **Assuming every language fails loudly.** Java's fail-fast iterators usually throw `ConcurrentModificationException` when you modify a list mid-loop; Python may simply skip elements and finish with a wrong result. Record the intended changes while looping and make them once the loop has finished.

Real-world examples

- **Every for-each loop** in Java, Python, C#, JavaScript (`for...of`).
- **JDBC** `ResultSet` moves through rows that need not all be loaded at once; `Scanner` implements `Iterator<String>`; `Files.newDirectoryStream` returns an `Iterable` over directory entries.
- **Paginated SDKs** (software development kits — a provider's ready-made client libraries): the AWS (Amazon Web Services) SDK for Java v2 "paginators" and Stripe's auto-pagination give you an iterable that fetches pages behind the scenes — exactly section 1.
- **Java** `Stream`**s** are built on `Spliterator`s; that is how parallel streams split work. C#'s LINQ (built-in query syntax for collections) is likewise a lazy layer over iteration, which is why both can work on endless sequences.
- **Generators**: Python's `yield`, JavaScript's `function*` and C#'s `yield return` let you write an iterator as a *function*; the language remembers the position for you. A generator is the same pattern with less code.
- **Kafka consumer** `poll()` **loops**, and **infinite feeds** (Instagram/Twitter timelines) that load the next page as you scroll.

In the interview

> **30-second answer:** "Iterator pulls traversal out into a separate object with `hasNext` and `next`, so a caller can walk data without caring whether the data is an array, a tree or a paginated API. Each iterator keeps its own position, so two loops over the same data are independent. Rather than a home-made interface I'd implement the language's protocol — `Iterable<T>` in Java — so the native for-each works. My example would be the lazy paged case, not an array, and I'd flag the risk: when every step can hit the network, the loop hides its cost — that is how N+1 problems start."

Follow-ups:

- *Internal vs external iterator?* External: the client controls stepping (`hasNext/next`) and can stop, pause or interleave two iterators. Internal: the collection controls the loop and calls your function (`forEach`, streams); simpler, easier to parallelise, but harder to stop early or to walk two collections in lock-step (one element from each at a time).
- *What is fail-fast?* The iterator checks a modification counter and throws `ConcurrentModificationException` if the collection was structurally changed outside the iterator. Best-effort only.
- *How do you remove while iterating?* `Iterator.remove()` or `Collection.removeIf(predicate)` (a predicate is a function that returns true or false).
- *What is a Spliterator?* A splittable iterator used by streams; `trySplit` hands off part of the elements so another thread can process them; characteristics tell the stream framework what it can optimise.
- *Iterator vs Visitor?* Iterator decides **how you move** through a structure; Visitor decides **what you do** at each element. They are often used together.
- *Iterator vs Composite?* Composite makes leaves and branches of a tree look alike; an iterator supplies a way to visit them. The two are often used together.
- *Iterator vs generator?* A generator (Python `yield`, JS `function*`) is the same pattern with the class replaced by a function that `yield`s.
- *Iterator vs stream?* Streams sit on top of iteration and add operations such as `map` and `filter`. When you need to transform data, not merely visit it, reach for streams.
- *How is Iterator expressed in other languages?* Python: `__iter__`/`__next__` or a generator. JavaScript/TypeScript: `[Symbol.iterator]` or `function*`, which makes `for...of` and spread work. C#: `IEnumerable<T>` with `yield return`. C++: `begin()`/`end()` for range-based for and the standard algorithms. Go: traditionally a `Next() bool` plus a value accessor (`sql.Rows`, `bufio.Scanner`), and since Go 1.23 range-over-function iterators.

Self-check

1. **Q:** Where does the cursor live? **A:** In the iterator object.
2. **Q:** What does the enhanced for-loop need from a class? **A:** That it implements `Iterable<T>`.

3. **Q:** Why did five results take four API calls? **A:** Without a total or cursor, the iterator can only discover the end by asking for one more page.
4. **Q:** Does `CopyOnWriteArrayList`'s iterator throw on concurrent modification? **A:** No; it iterates over a snapshot taken when the iterator was created.
5. **Q:** What should `next()` do when there are no more elements? **A:** Throw `NoSuchElementException`.

TL;DR

A separate object walks the collection with `hasNext/next`; the **position lives in the iterator**. Implement `Iterable` in Java. Know **fail-fast** vs snapshot iterators, **internal vs external** iteration, and don't let a lazy loop **hide its cost**.

10.4 Mediator

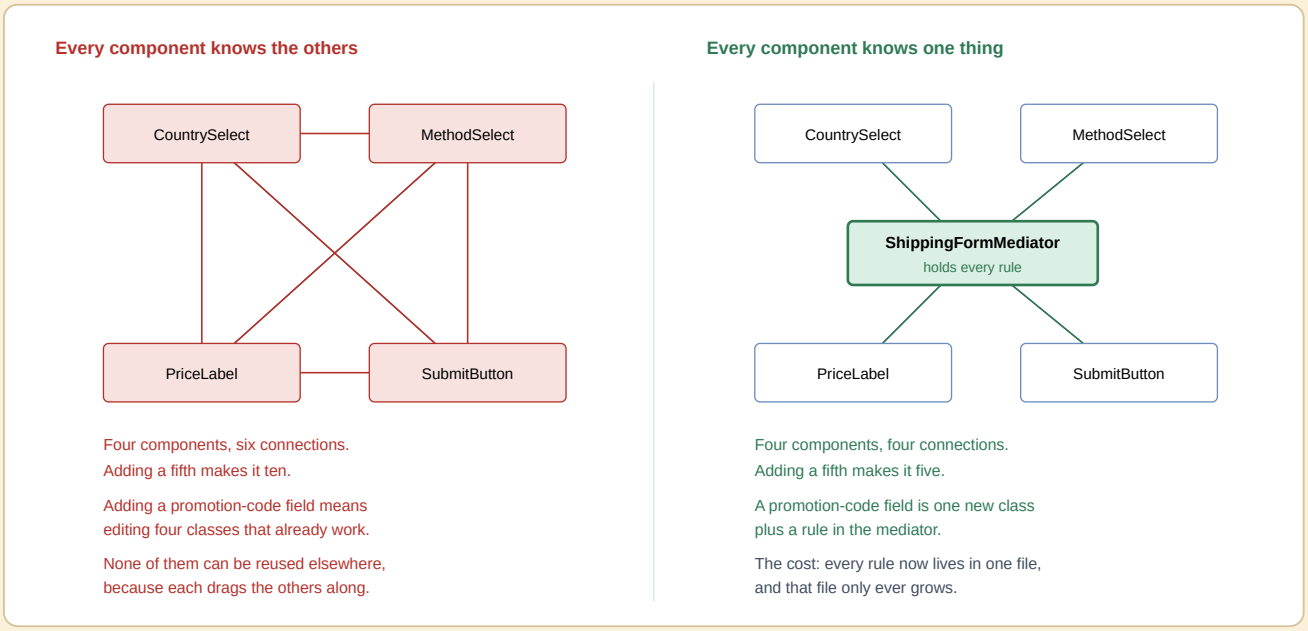

Figure — Left: four form components all know each other (six links). Right: each knows only the mediator (four links) (course diagram)

What it is

Mediator makes a group of objects talk through **a single coordinator** instead of holding references to one another. Each object only reports "this just happened" to the mediator, and the mediator works out how the rest should respond.

GoF intent, in plain words: *define an object that encapsulates how a set of objects interact, so they stop referring to each other explicitly and their interaction can be varied independently.* GoF participants: **Mediator** (interface for talking to colleagues), **ConcreteMediator** (knows the colleagues and implements the coordination), and **Colleague** classes (each knows its mediator and talks to it instead of to other colleagues). Some literature simply calls the mediator a *controller*.

Everyday analogy: **air traffic control**. Planes do not radio each other to agree who lands first. Each plane talks only to the tower, and the tower holds the rules about spacing and order.

The problem it solves

Picture a checkout form with four widgets: a **country** picker, a **delivery-method** picker, a **price** label and a **submit** button. Picking a country refreshes the list of delivery methods; the new method changes the price; the price situation decides whether submit is clickable. For some destinations no delivery is offered at all.

If each widget talks to the others directly:

- every widget holds references to three others — four widgets need **six** connections, five need **ten** (n(n−1)/2, growing roughly with the square);
- a new "promo code" field forces changes to four classes that were already tested and working;

- no widget can be reused on another screen: if `CountrySelect` calls `methodSelect.reload()`, it cannot be used anywhere without bringing `MethodSelect` too.

With a mediator, each widget has **one** reference (to the mediator): four widgets, four links; a fifth makes five. `CountrySelect` is now unaware that any price label exists, so another screen can reuse it with its own mediator and its own rules. Each widget also has no idea how many other widgets exist.

The honest trade: the dependencies are not removed — **they are relocated** into the mediator, a class that tends to keep getting bigger.

How it works

1. Define a **Mediator** interface, e.g. `notify(sender, event)`.
2. Each **component** (colleague) holds a reference to the mediator — and nothing else.
3. When something happens, a component calls `mediator.notify(this, event)`.
4. The **concrete mediator** holds all components and all the rules: "when the country changes, reload methods, then show the price, then enable or disable submit".
5. The mediator calls back **down** into specific components. Traffic is **two-way** through one object.

Structure (UML)

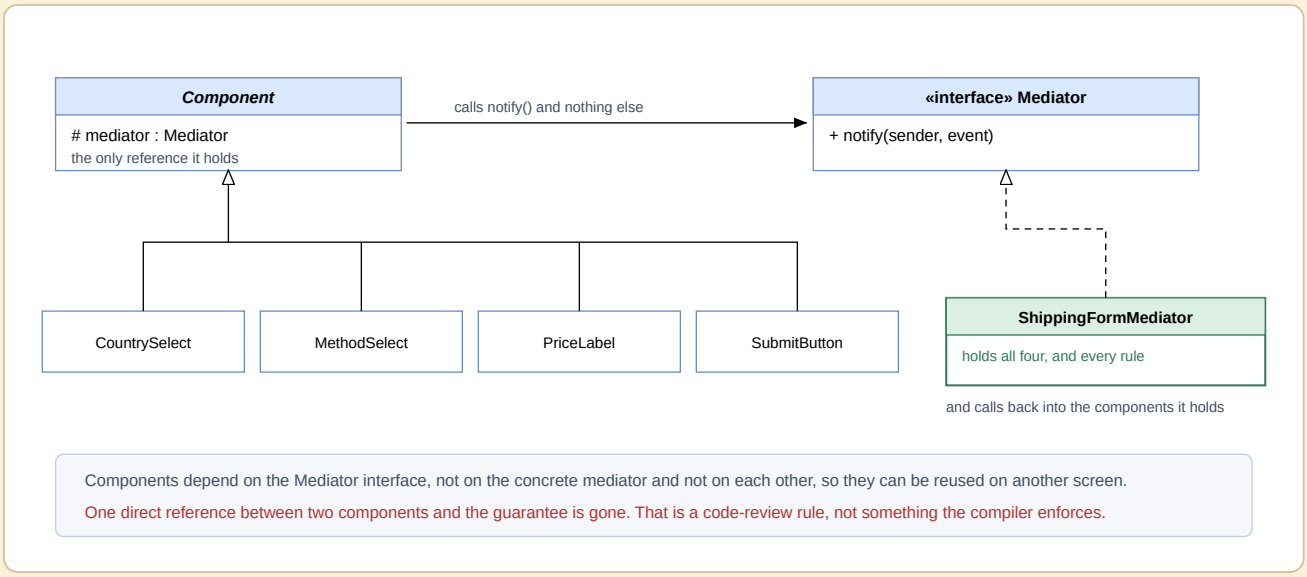

Figure — Class diagram: components extend Component (which holds a Mediator); ShippingFormMediator implements Mediator and holds all four components (course diagram)

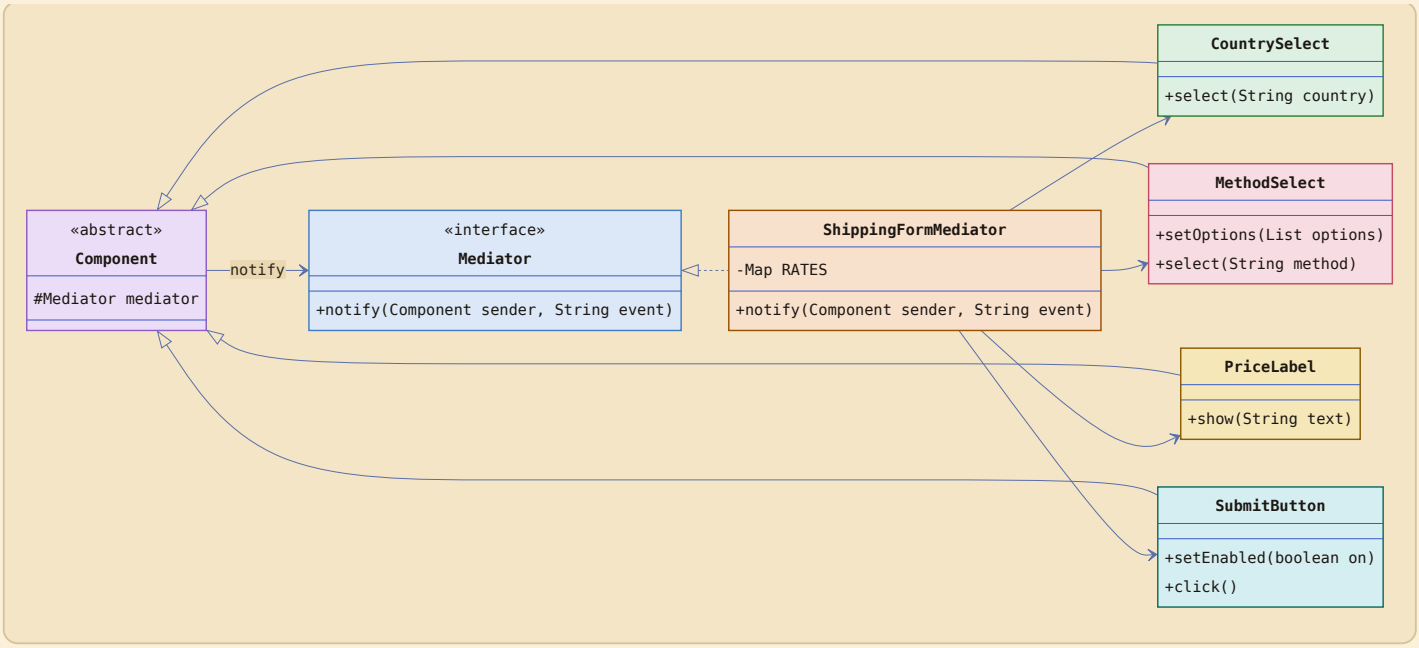
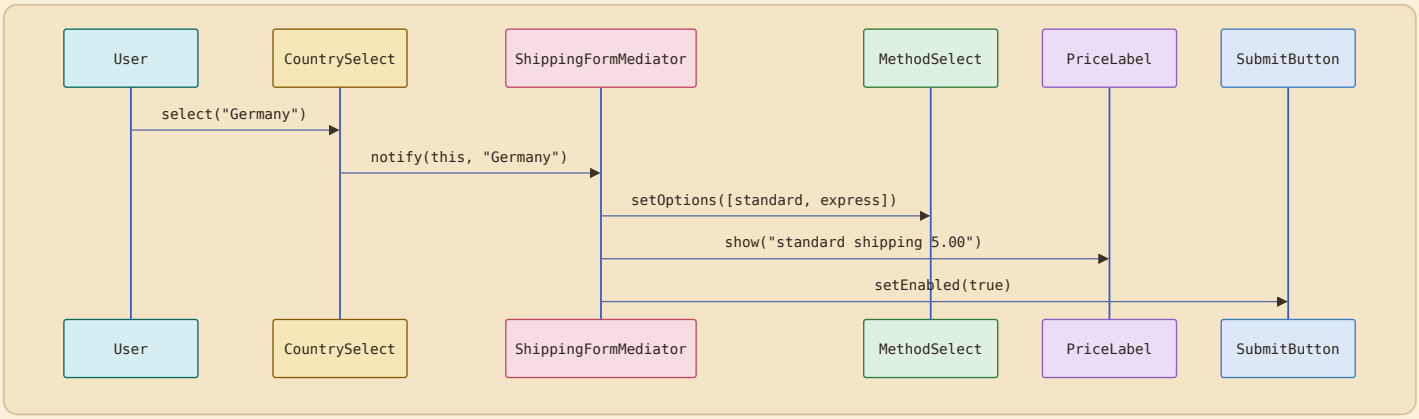
In the diagram above, follow the arrows: widgets report **upward** by calling `notify`, and the mediator issues instructions **downward** to the widgets it owns. Traffic in both directions passing through one hub is what separates a mediator from an observer.

Our Java design:





Java example

`lld.ch10.mediator` has three mediators:

1. **Shipping form** (`ShippingFormMediator` + four components). No code except `notify` knows that choosing a country influences the price. Components identify themselves by reference (`sender == country`), not by strings. Shipping rates are `BigDecimal` — money is never stored as `double`.
2. **Chat room** (`ChatRoom`, `ChatUser`). Users never hold references to each other. The room routes broadcasts and private messages and applies **moderation** (filtering or blocking unwanted messages) rules — rules live in the mediator, not in the users.
3. **Air traffic control** (`ControlTower`, `Flight`). Flights only request landing and report "vacated"; the tower owns the runway and the holding queue.

```java
// File: code/lld/ch10/mediator/Mediator.java
package lld.ch10.mediator;

/** Components report "something happened" here. They depend on this interface only. */
public interface Mediator {
    void notify(Component sender, String event);
}
```

```java
// File: code/lld/ch10/mediator/Component.java
package lld.ch10.mediator;

/** Base for every form widget: its ONLY reference is the mediator. */
public abstract class Component {
    protected Mediator mediator;

    void setMediator(Mediator mediator) { this.mediator = mediator; }
}
```

```java
// File: code/lld/ch10/mediator/CountrySelect.java
package lld.ch10.mediator;

final class CountrySelect extends Component {
    private String selected;

    void select(String country) {
        selected = country;
        System.out.println("  [country] user picked " + country);
        mediator.notify(this, country);          // report up; never call a sibling
    }

    String selected() { return selected; }
}
```

```java
// File: code/lld/ch10/mediator/MethodSelect.java
package lld.ch10.mediator;

import java.util.List;

final class MethodSelect extends Component {
    private List<String> options = List.of();
    private String selected;

    void setOptions(List<String> options) {
        this.options = options;
        this.selected = options.isEmpty() ? null : options.get(0);
        System.out.println("  [methods] reloaded: " + options + (selected == null ? "" : ", default " + selected));
    }

    void select(String method) {
        if (!options.contains(method)) throw new IllegalArgumentException(method + " not offered");
        selected = method;
        System.out.println("  [methods] user picked " + method);
        mediator.notify(this, method);
    }

    String selected() { return selected; }
}
```

```java
// File: code/lld/ch10/mediator/PriceLabel.java
package lld.ch10.mediator;

final class PriceLabel extends Component {
    void show(String text) { System.out.println("  [price] " + text); }
}
```

```java
// File: code/lld/ch10/mediator/SubmitButton.java
package lld.ch10.mediator;

final class SubmitButton extends Component {
    private boolean enabled;

    void setEnabled(boolean enabled) {
        this.enabled = enabled;
        System.out.println("  [submit] " + (enabled ? "enabled" : "disabled"));
    }

    void click() {
        if (enabled) mediator.notify(this, "click");
        else System.out.println("  [submit] click ignored: button is disabled");
    }
}
```

```java
// File: code/lld/ch10/mediator/ShippingFormMediator.java
package lld.ch10.mediator;

import java.math.BigDecimal;
import java.util.ArrayList;
import java.util.LinkedHashMap;
import java.util.Map;

/** The ONLY place that knows how a country change affects methods, price and submit. */
final class ShippingFormMediator implements Mediator {
    private static final Map<String, Map<String, BigDecimal>> RATES = Map.of(
        "Germany", ordered("standard", "5.00", "express", "15.00"),
        "USA", ordered("standard", "8.00", "express", "20.00"),
        "Antarctica", Map.of());

    private final CountrySelect country;
    private final MethodSelect methods;
    private final PriceLabel price;
    private final SubmitButton submit;

    ShippingFormMediator(CountrySelect c, MethodSelect m, PriceLabel p, SubmitButton s) {
        this.country = c; this.methods = m; this.price = p; this.submit = s;
        for (Component comp : new Component[] {c, m, p, s}) comp.setMediator(this);
        submit.setEnabled(false);
    }

    @Override

  [tower] BA22 vacated the runway
  [tower] LH7: cleared to land
```

One user action ("picked Germany") updated three components — and **no component called another**.

Mediator or Observer?

Both decouple objects. The difference is **what happens to the news**.

	Mediator	**Observer**
What travels	An event **and** the decision on what should follow	Only the event
Where reaction logic sits	In one place: the mediator	Spread across the observers, each deciding alone
Do the parties know each other?	No — not even how many peers exist	No; the subject only knows it has a list of subscribers
Flow	Both ways: colleagues report in, the mediator calls out to them	One way: the subject publishes, observers respond
Order of reactions	Written explicitly in the mediator — a reason to choose it	Not part of the contract; observers should not depend on each other's order

Practical test: does something need to be coordinated? "The country changed; anyone interested, update yourself" is Observer, and it is the lighter choice. "The country changed: refresh the methods, *after that* price the new default method, *after that* decide about submit" is sequenced coordination — Mediator territory. Short version: **with Observer the listeners decide; with Mediator the hub decides and gives orders.** (A mediator is often *implemented* using observer-style notifications from the components.)

Trade-offs

Pros	Cons
Every widget depends on exactly one thing, so links grow linearly instead of quadratically.	Every new rule lands in the mediator, so it keeps growing.
All interaction rules sit in one class you can read and unit-test.	Anyone changing the screen changes that same file, so merge conflicts (clashing edits to the same lines) pile up there.
Widgets are reusable because they no longer pull their neighbours with them.	To learn why a widget changed you read the mediator, not the widget.
A new widget costs one class plus one rule.	It can quietly become a **god object** (a class that knows and does too much).

Keeping the mediator from becoming a god object:

- **Split by area** — one mediator per screen section or workflow, not one per application. Two 80-line mediators are much easier to live with than one 160-line one.
- **Keep it to coordination.** Tax and pricing calculations belong in their own classes; the mediator decides *what to call*, not *how to compute* (a Facade has to respect the same boundary).
- **Reject shortcuts in code review.** A single widget-to-widget reference breaks the whole guarantee, and the compiler will not catch it.
- **Dispatch by table, not by `if`-chain.** In languages with first-class functions the mediator can keep a map from event (or sender) to handler function — e.g. a Python `dict` of `{event: method}` — so each rule is easy to find.

When not to use it

- **Only two objects interact.** Let them call each other; a coordinator for a single relationship adds a layer that does nothing.
- **The interactions are few and stable.** The pattern swaps many small, scattered links for one bigger central class; that only pays off once the tangle is large.
- **Nothing needs coordinating** — components react independently. Use Observer.
- **The mediator is already a 400-line god object.** More rules will not help; break it into smaller mediators first.

Common mistakes

1. **Components calling each other "just this once".**
2. **Computation inside the mediator** (tax, pricing), turning it into a god object.
3. **Confusing it with Facade.** A Facade is placed *in front of* a subsystem, and the subsystem's classes are unaware of it; calls flow one way. A Mediator is placed *among* peers that all know it and report to it; calls flow both ways.
4. **String-typed events everywhere** (`"country"`, `"method"`) that silently break on a typo. Use the sender reference, an enum, or typed events.

Real-world examples

- **UI controllers / view-models** coordinating several widgets (MVC — Model–View–Controller — controllers, MVVM — Model–View–ViewModel — view-models, Android `ViewModel` wiring). GoF's own example is a dialog box coordinating its widgets.
- **Chat servers** (Slack, WhatsApp): clients send messages to the server, which routes them to rooms and people and applies moderation.
- **Air traffic control** — the classic analogy.
- **Workflow / saga orchestrators** (a saga is a multi-step process spread across services, each step with its own undo; e.g. Temporal, Camunda, AWS Step Functions): a checkout orchestrator invokes payment, stock reservation and shipping in sequence and holds the recovery plan for each failure. Ride-hailing dispatch (matching riders and drivers through a central service rather than drivers talking to riders directly) has the same shape.
- **Redux store** at application scale (components dispatch actions instead of calling each other; reducers hold the rules); **MediatR** in .NET popularised the name on the server side, using it to dispatch each request to its handler.

- **Message brokers / event buses** (servers that receive messages and deliver them to the right consumers) at system scale: a service hands messages to the broker rather than calling other services; the broker's routing configuration is the mediator logic — and it can become a god object too.
- `java.util.Timer` and `Executor`/`ExecutorService` are often listed (including by the course) as JDK mediators: they stand between submitted tasks and the threads that run them, so neither side knows the other. Treat this as a *loose* fit — they do not coordinate peer colleagues the way the GoF dialog example does, so in an interview lead with UI controllers or orchestrators.

In the interview

> **30-second answer:** "Mediator swaps peer-to-peer references for a single hub. Widgets just report events to it; the hub owns the rules and instructs particular widgets. Four widgets go from six links to four, and a fifth gives five instead of ten. The dependencies aren't gone — they're concentrated in one class that I can read and test. The risk is a god object, so I split mediators per screen area or workflow and push computation into its own classes."

Follow-ups:

- *Mediator vs Observer?* With Observer each listener decides for itself; with Mediator the hub decides and instructs. When the sequence of reactions matters, pick Mediator.
- *Mediator vs Facade?* Facade simplifies a subsystem for outside callers (one-way, subsystem unaware). Mediator coordinates peers that know it (two-way).
- *How does it relate to Command?* A mediator often creates and dispatches commands.
- *How do you test a mediator?* Give it fake components and assert which calls it made for each event.
- *What about in microservices (a system split into many small, separately deployed services)?* Orchestration (a central saga orchestrator) is mediator-style; choreography (services react to each other's events) is observer-style.

Self-check

1. **Q:** How many links do 5 fully connected components need, and how many with a mediator? **A:** 10 vs 5.
2. **Q:** Does a mediator remove coupling? **A:** No, it moves it into one class.
3. **Q:** What is the main failure mode? **A:** The mediator grows into a god object.
4. **Q:** Which way does traffic flow in a Mediator vs an Observer? **A:** Mediator two-way; Observer one-way.
5. **Q:** What should *not* go into a mediator? **A:** Business calculations — only coordination.

TL;DR

Peers talk through **one coordinator** that holds the interaction rules. Links become linear and components reusable, but the coupling **moves** into the mediator — keep it small and split it before it becomes a god object.

10.5 Memento

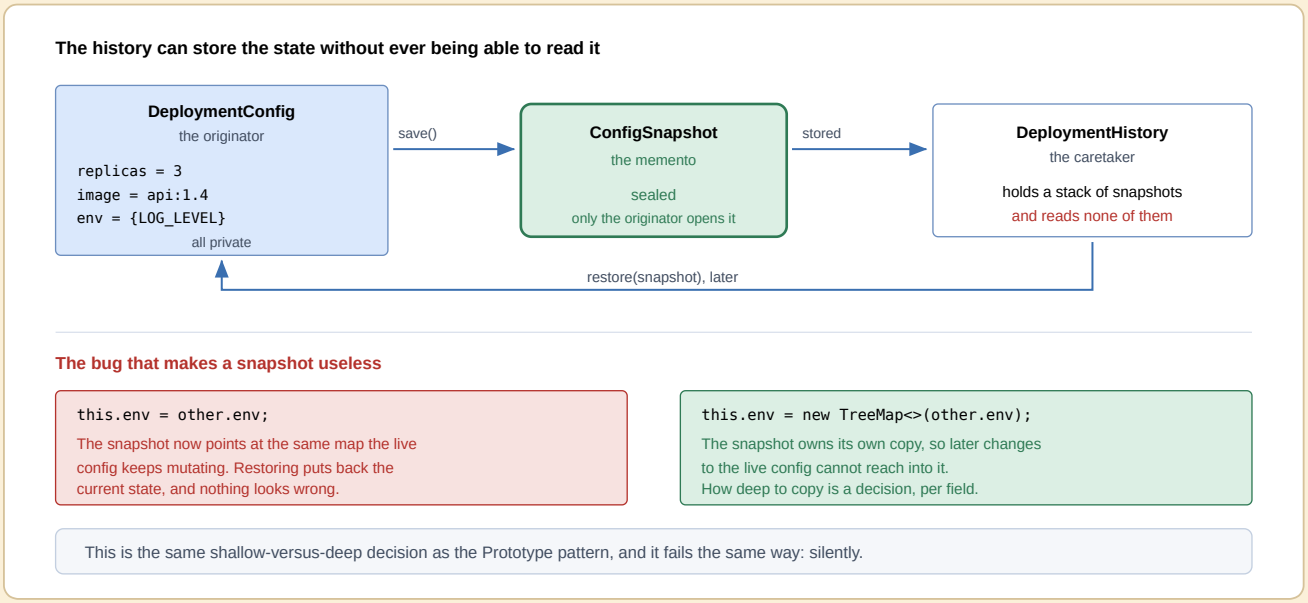

Figure — The originator (DeploymentConfig) saves a sealed snapshot; the caretaker (DeploymentHistory) stores it without being able to read it; below, the shared-map bug that makes a snapshot useless (course diagram)

What it is

Memento lets an object record its internal state in a **snapshot** and later **return** to that state — while nobody else gets to **see** what the snapshot contains.

GoF intent, in plain words: *without breaking encapsulation, capture and externalize an object's internal state so the object can be put back into that state later.* GoF participants: **Memento** (stores the state; offers a narrow interface to the caretaker and a wide one to the originator), **Originator** (creates a memento of its current state and uses one to restore itself) and **Caretaker** (keeps mementos safe but never operates on or examines their contents).

Everyday analogy: a **save game**. The game writes a save file; the menu lists the saves by name and date and lets you load one. The menu never needs to understand what is inside the file.

The problem it solves

You need a **rollback** (a return to the previous working version): record the deployment configuration just before a risky change, and if the rollout (the release of a change to the running servers) misbehaves, bring the recorded version back.

The obvious way — something *outside* reads every field and stores them — breaks two things:

1. **Encapsulation.** The history class must now understand replicas (copies of the service running side by side), image names (which packaged build to run) and environment variables (named settings passed to a program). Every new config field forces a change in the history class, and details that were private are now exposed.
2. **Atomicity.** Atomicity means all-or-nothing; a restore done one field at a time can stop half-way. If three fields are written and an exception hits before the fourth, the config holds a combination that was never real.

With Memento the object **takes its own snapshot** and hands it out as a sealed token that **only it can open**. Restoring becomes **one call into the originator**, which is in full control of the restore and can make it all-or-nothing (our `restore` validates the token first, then assigns every field; nothing in between can fail half-way).

How it works

Three roles, with standard names interviewers use:

Role	Job	In our code
Originator	Owns the state; produces snapshots (`save`) and returns to them (`restore`). No other class can look inside a snapshot.	`DeploymentConfig`
Memento	Carries the state; opaque to everyone else.	`DeploymentConfig.Snapshot` (narrow) / private `State` record (wide)
Caretaker	Decides **when** to save and restore; never looks **inside**.	`DeploymentHistory`

Steps:

1. Caretaker asks the originator: `snapshot = config.save(label)`.
2. Caretaker stores the snapshot (usually on a stack).
3. Later, caretaker calls `config.restore(snapshot)`.
4. The originator copies the state back in one step.

How opacity is enforced in Java. GoF describes a **narrow interface** (what the caretaker sees) and a **wide interface** (what the originator sees). Our design does this with types: the public interface `Snapshot` exposes only `label()`; the real data is in a **private nested record** `State` that only `DeploymentConfig` can see. `restore` checks `instanceof State`, so even a forged `Snapshot` (see section 4 of the output) is refused. (Strictly, reflection — Java's ability to inspect and call even private members at run time — or a debugger can still peek; Java access control protects against honest code, not a hostile JVM, the Java Virtual Machine that runs the program.) Other options by language: package-private accessors in Java; the originator declared a `friend` in C++; a private nested class in C#; Python and JavaScript offer no true enforcement, so it is a naming convention (leading underscore) plus code review — although a JavaScript closure *can* hide the contents in a way a class field cannot.

Structure (UML)

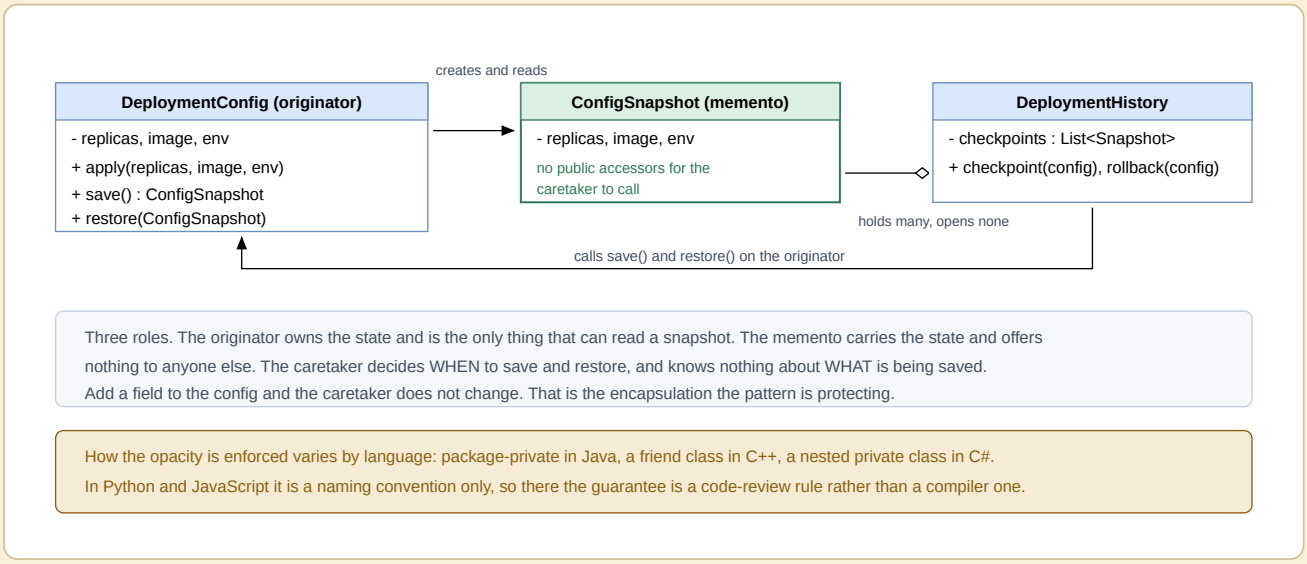

Figure — Class diagram: DeploymentConfig creates and restores ConfigSnapshot; DeploymentHistory holds a list of snapshots (course diagram)

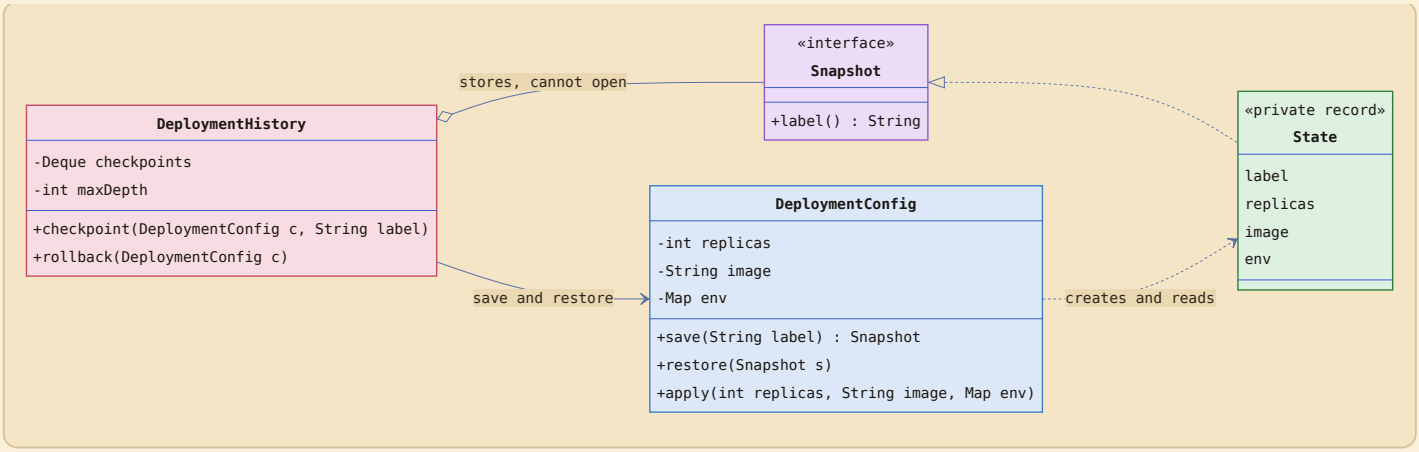
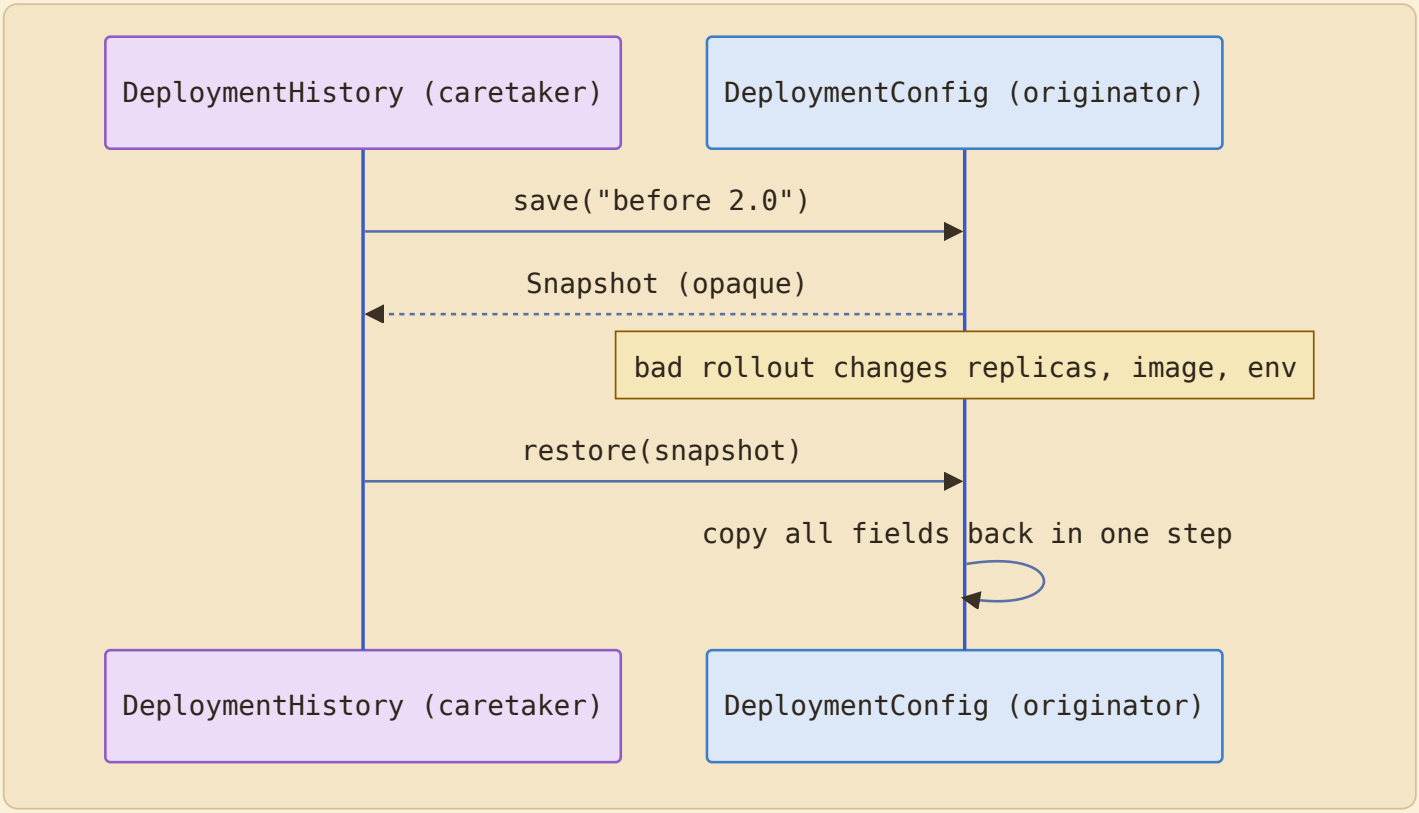
In the diagram above, `DeploymentHistory` never refers to a single configuration field. That is the quick check for a real Memento: if the caretaker names the fields, you have only relocated them.

Our Java design:





Java example

Points to notice in `lld.ch10.memento`:

- The `State` record's (a record is Java's short syntax for an immutable data class) compact constructor (a constructor with no parameter list that runs on every creation) does `env = Map.copyOf(env)`, so the snapshot **owns its own copy**. In section 1 the live map is changed *after* saving (`FEATURE_X`), and the rollback still restores the original.
- `DeploymentHistory` is **bounded** (`maxDepth`) and drops the oldest checkpoint when full.
- Section 3 shows the **shallow-copy bug** in isolation.

```java
// File: code/lld/ch10/memento/DeploymentConfig.java
package lld.ch10.memento;

import java.util.Map;
import java.util.TreeMap;

/** The ORIGINATOR: owns the state, and is the only class that can read a snapshot. */
public final class DeploymentConfig {

    /**
     * The NARROW interface the caretaker sees: a label, nothing else.
     * (GoF: caretaker gets a narrow interface, originator a wide one.)
     */
    public interface Snapshot {
        String label();
    }

    /** The WIDE interface: private, so only DeploymentConfig can open it. Immutable record. */
    private record State(String label, int replicas, String image, Map<String, String> env)
            implements Snapshot {
        State {
            env = Map.copyOf(env);   // DEEP enough: the snapshot owns its own copy, not the live map
        }
    }

    private int replicas;
    private String image;
    private final Map<String, String> env = new TreeMap<>();

    public DeploymentConfig(int replicas, String image, Map<String, String> env) {
        apply(replicas, image, env);
    }

    public void apply(int replicas, String image, Map<String, String> env) {
        this.replicas = replicas;
        this.image = image;
        this.env.clear();
        this.env.putAll(env);
    }

    public void setEnv(String key, String value) { env.put(key, value); }

    public Snapshot save(String label) {
        return new State(label, replicas, image, env);
    }

    /** One call restores everything: all-or-nothing. */
    public void restore(Snapshot snapshot) {
        if (!(snapshot instanceof State s)) {
            throw new IllegalArgumentException("not a snapshot produced by DeploymentConfig");
        }
        apply(s.replicas(), s.image(), s.env());
    }

    @Override
    public String toString() {
        return "replicas=" + replicas + " image=" + image + " env=" + env;
    }
}
```

```java
// File: code/lld/ch10/memento/DeploymentHistory.java
package lld.ch10.memento;

import java.util.ArrayDeque;
import java.util.Deque;

/** The CARETAKER: decides WHEN to save/restore, never WHAT is inside. Bounded to avoid leaks. */
public final class DeploymentHistory {
    private final Deque<DeploymentConfig.Snapshot> checkpoints = new ArrayDeque<>();
    private final int maxDepth;

    public DeploymentHistory(int maxDepth) { this.maxDepth = maxDepth; }

    public void checkpoint(DeploymentConfig config, String label) {
        if (checkpoints.size() == maxDepth) {
            DeploymentConfig.Snapshot dropped = checkpoints.removeLast();   // oldest
            System.out.println("  [history] full, dropped oldest checkpoint '" + dropped.label() + "'");
        }
        checkpoints.push(config.save(label));
        System.out.println("  [history] checkpoint '" + label + "' taken");
    }

    public void rollback(DeploymentConfig config) {
        if (checkpoints.isEmpty()) { System.out.println("  [history] nothing to roll back to"); return; }
        DeploymentConfig.Snapshot s = checkpoints.pop();
        config.restore(s);
        System.out.println("  [history] rolled back to '" + s.label() + "'");
    }
}
```

```java
// File: code/lld/ch10/memento/Main.java
package lld.ch10.memento;

import java.util.HashMap;
import java.util.Map;

public class Main {
    public static void main(String[] args) {
        System.out.println("=== 1. Checkpoint, bad rollout, rollback ===");
        DeploymentConfig config = new DeploymentConfig(3, "api:1.4", Map.of("LOG_LEVEL", "info"));
        DeploymentHistory history = new DeploymentHistory(2);
        System.out.println("  live: " + config);

        history.checkpoint(config, "before 2.0");
        config.apply(10, "api:2.0", Map.of("LOG_LEVEL", "debug"));   // the risky rollout
        config.setEnv("FEATURE_X", "on");                             // mutates the live map after saving
        System.out.println("  live: " + config);
        history.rollback(config);
        System.out.println("  live: " + config + "   <- snapshot was a real copy");

        System.out.println("\n=== 2. Bounded history ===");
        history.checkpoint(config, "v1");
        history.checkpoint(config, "v2");
        history.checkpoint(config, "v3");      // drops v1
        history.rollback(config);
        history.rollback(config);
        history.rollback(config);

        System.out.println("\n=== 3. The shallow-copy bug, shown in isolation ===");
        Map<String, String> liveEnv = new HashMap<>(Map.of("LOG_LEVEL", "info"));
        Map<String, String> badSnapshot = liveEnv;                  // shares the live map
        Map<String, String> goodSnapshot = new HashMap<>(liveEnv);  // owns a copy
        liveEnv.put("LOG_LEVEL", "debug");
        System.out.println("  bad snapshot  = " + badSnapshot + "  <- changed with the live object");
        System.out.println("  good snapshot = " + goodSnapshot);

        System.out.println("\n=== 4. The caretaker cannot open a snapshot ===");
        DeploymentConfig.Snapshot s = config.save("peek");
        System.out.println("  caretaker can read only: label=" + s.label());
        try {
            config.restore(() -> "forged");                         // a Snapshot not made by the originator
        } catch (IllegalArgumentException e) {
            System.out.println("  forged snapshot refused: " + e.getMessage());
        }
    }
}
```

Output:

```
=== 1. Checkpoint, bad rollout, rollback ===
  live: replicas=3 image=api:1.4 env={LOG_LEVEL=info}
  [history] checkpoint 'before 2.0' taken
  live: replicas=10 image=api:2.0 env={FEATURE_X=on, LOG_LEVEL=debug}
  [history] rolled back to 'before 2.0'
  live: replicas=3 image=api:1.4 env={LOG_LEVEL=info}   <- snapshot was a real copy

=== 2. Bounded history ===
  [history] checkpoint 'v1' taken
  [history] checkpoint 'v2' taken
  [history] full, dropped oldest checkpoint 'v1'
  [history] checkpoint 'v3' taken
  [history] rolled back to 'v3'
  [history] rolled back to 'v2'
  [history] nothing to roll back to

=== 3. The shallow-copy bug, shown in isolation ===
  bad snapshot  = {LOG_LEVEL=debug}  <- changed with the live object
  good snapshot = {LOG_LEVEL=info}

=== 4. The caretaker cannot open a snapshot ===
  caretaker can read only: label=peek
  forged snapshot refused: not a snapshot produced by DeploymentConfig
```

The bug that makes a snapshot useless

If the memento keeps a **pointer to the very map (or list) the originator goes on mutating**, you have not taken a snapshot: the "saved" copy drifts along with the live object, and a restore just re-applies today's state. Nothing throws and nothing looks wrong — until somebody notices the rollback had no effect. Always copy mutable parts (`Map.copyOf`, `new TreeMap<>(...)`, deep copies — copies that also duplicate the objects inside — of nested objects). It is the same shallow-vs-deep copy decision as the Prototype pattern (Chapter 8).

Two more things to bound: history depth — keep a cap and evict the oldest entry, because a short undo list is useful while an endless one is just a memory leak (memory that keeps growing and is never released) — and **state that cannot be captured** (live sockets — open network connections — open files, data owned by another system). A snapshot that claims to cover those will fail, usually long after the mistake was made.

Memento or Command undo?

	Memento	Command undo
Saved per step	A full copy of the state at that moment	The operation plus the little bit of state its reversal needs
How undo happens	Re-install an earlier copy	Execute the opposite operation
Memory cost per step	Proportional to the state size	Proportional to one operation
Correctness risk	Low — the copy was a genuine state	Every reverse operation must be written correctly
Prefer it when	Reversal is tricky or the state is small	Reversal is simple or the state is big

A drawing app that snapshots the whole canvas on every brush stroke runs out of memory — use Command ("stroke added, here are its points"). A wizard (a multi-step form) where step 3 changes six interacting fields is the opposite — six correct inverses are hard, one snapshot is easy. **Real systems combine them:** take a snapshot occasionally, log commands in between; to go back, restore the nearest snapshot and replay commands forward. Databases and event-sourced systems (Chapter 11) do exactly this.

Trade-offs

Pros	Cons
Rollback is possible while the internals stay private.	Memory use rises with every stored snapshot, quickly for large state.
New fields in the originator need no change in the caretaker.	Mutable parts must be deep-copied, or snapshots share live data.
The originator controls the restore, so it can be all-or-nothing, and it returns a state that really existed.	Some languages cannot truly hide the snapshot, only by convention.
Checkpoints, wizards, save games, transactions: one mechanism.	Some state (sockets, external systems) cannot be captured at all.

When not to use it

- **Large state that changes often** — use Command undo or periodic snapshots + replay.
- **State you cannot capture** (sockets, file handles, remote systems).
- **The object is immutable.** An old instance already *is* a perfect snapshot; holding a reference to it is enough (which is why functional code rarely names this pattern).
- **Each operation has an easy exact inverse** — per-step Command undo costs less memory.

Common mistakes

1. Storing references to mutable internals (the shallow-copy bug).
2. Letting the caretaker read or edit the snapshot's fields (encapsulation lost).
3. Restoring field by field from outside (not atomic).
4. Unbounded history.
5. Snapshotting things that cannot really be restored (connections, locks).

Real-world examples

- **Database transactions** (groups of changes that succeed or fail together): `BEGIN` ... `ROLLBACK`. The DB keeps enough information (undo logs) to put things back; your code never sees it.
- **Version control** (tools that record the history of files): a Git commit is a snapshot of the tree; `git checkout` restores it, and the history (the caretaker) does not need to understand file contents to do its job.
- **Kubernetes Deployments** (Kubernetes runs and manages containers across many machines) keep old ReplicaSets (the group of identical running copies for each version) as revision history (bounded by `revisionHistoryLimit`, default 10), and `kubectl rollout undo` restores a previous pod template — a bounded caretaker, just like ours.
- **VM / container snapshots** (VM = virtual machine, a whole computer simulated in software; a container is a lighter, isolated, packaged process) and infrastructure state files that make `rollback` possible.
- **Game saves and checkpoints**; **form wizards** with a "back" button; **editor undo** for small documents.
- In Java, `Serializable` or a JSON mapper is often *how* a memento is stored when it must outlive the process; a `record` gives an immutable memento in one line.
- **Other languages**: in Python, `copy.deepcopy(self.__dict__)` is a quick memento and `dataclasses.replace` covers immutable objects; in JavaScript, `structuredClone(state)` deep-copies plain data.

In the interview

30-second answer: "With Memento an object packs its state into a token that only the object itself can unpack. The originator produces and consumes snapshots, the memento holds the data, and the caretaker chooses when to save or roll back without ever inspecting the contents. Restoring is a single call the originator controls, so it can be all-or-nothing, and a new field in the object never touches the history code. I'd make sure the snapshot deep-copies mutable parts, bound the history, and compare it with Command undo: Memento stores state, Command stores actions; real systems combine periodic snapshots with a command log."

Follow-ups:

- *How do you enforce that the caretaker can't read the memento in Java?* A narrow public interface (e.g. only a label) implemented by a private nested record; or package-private accessors.
- *Memento vs Prototype?* Each copies state. A prototype clone becomes a live object you keep working with. A memento does nothing on its own; its sole purpose is to be given back to the originator.
- *Memento vs a backup?* A backup targets disaster recovery (getting systems back after a major failure) and lives outside the process (disk, another region — a separate data-centre location). A memento is usually an in-memory checkpoint for undo. Same idea, very different lifetime and cost.
- *How would you implement undo for a large document?* Command undo for each edit, plus periodic snapshots so undo far back doesn't replay thousands of commands.
- *How does it relate to serialization?* Serialization is one common *storage format* for a memento; the pattern itself is about *access* — only the originator may look inside.

Self-check

1. **Q:** Name the three roles. **A:** Originator, memento, caretaker.
2. **Q:** Who may read the memento's contents? **A:** Only the originator.
3. **Q:** Why copy the `env` map in the snapshot? **A:** Otherwise the snapshot shares the live map and changes with it.
4. **Q:** When is Command undo better than Memento? **A:** When state is large and each action has an easy inverse.
5. **Q:** What does Kubernetes' `revisionHistoryLimit` correspond to? **A:** A bounded caretaker history.

TL;DR

The object **snapshots itself**; the caretaker **stores but cannot read**; restore is **one call the originator controls**. **Deep-copy** mutable parts, **bound** the history, and choose Memento (store state) vs Command (store actions) by which is smaller.

10.6 Interpreter

(Not covered by a lesson in the course beyond its one-line entry in the behavioral-patterns table; this section is from the GoF book and standard practice.)

What it is

Interpreter represents the **grammar** of a small language as a set of classes — **one class per grammar rule** — and evaluates a sentence of that language by building a **tree** of those objects and asking the root to `interpret` itself.

Everyday analogy: a calculator. `2 + 3 * 4` is a sentence in a tiny language. The calculator understands that `*` binds tighter than `+`, builds the structure `2 + (3 * 4)` in its head, and works it out from the inside.

Key terms:

- **Grammar** — the rules saying which sentences are valid, e.g. "an expression is terms joined by `+` or `-`".
- **DSL (domain-specific language)** — a small language for one job: search filters, pricing rules, feature-flag conditions, cron schedules (a compact text format for repeating times, such as "every weekday at 9").
- **AST (abstract syntax tree)** — the tree form of a sentence, with operators as inner nodes and numbers/variables as leaves.
- **Terminal expression** — a leaf rule (a number, a variable).
- **Nonterminal expression** — a rule made of other expressions (addition, multiplication).
- **Context** — outside information the evaluation needs, e.g. the current values of variables.

The problem it solves

Some problems keep coming back as *sentences*: "price * qty − discount", "age > 18 AND country = IN", "every weekday at 9:00". Hard-coding each rule in Java means a redeploy (building and releasing the application again) for every new rule. Letting business users write rules in a tiny language, and interpreting them, turns rules into **data**. Interpreter is the simplest object-oriented way to evaluate such a language when the grammar is **small**.

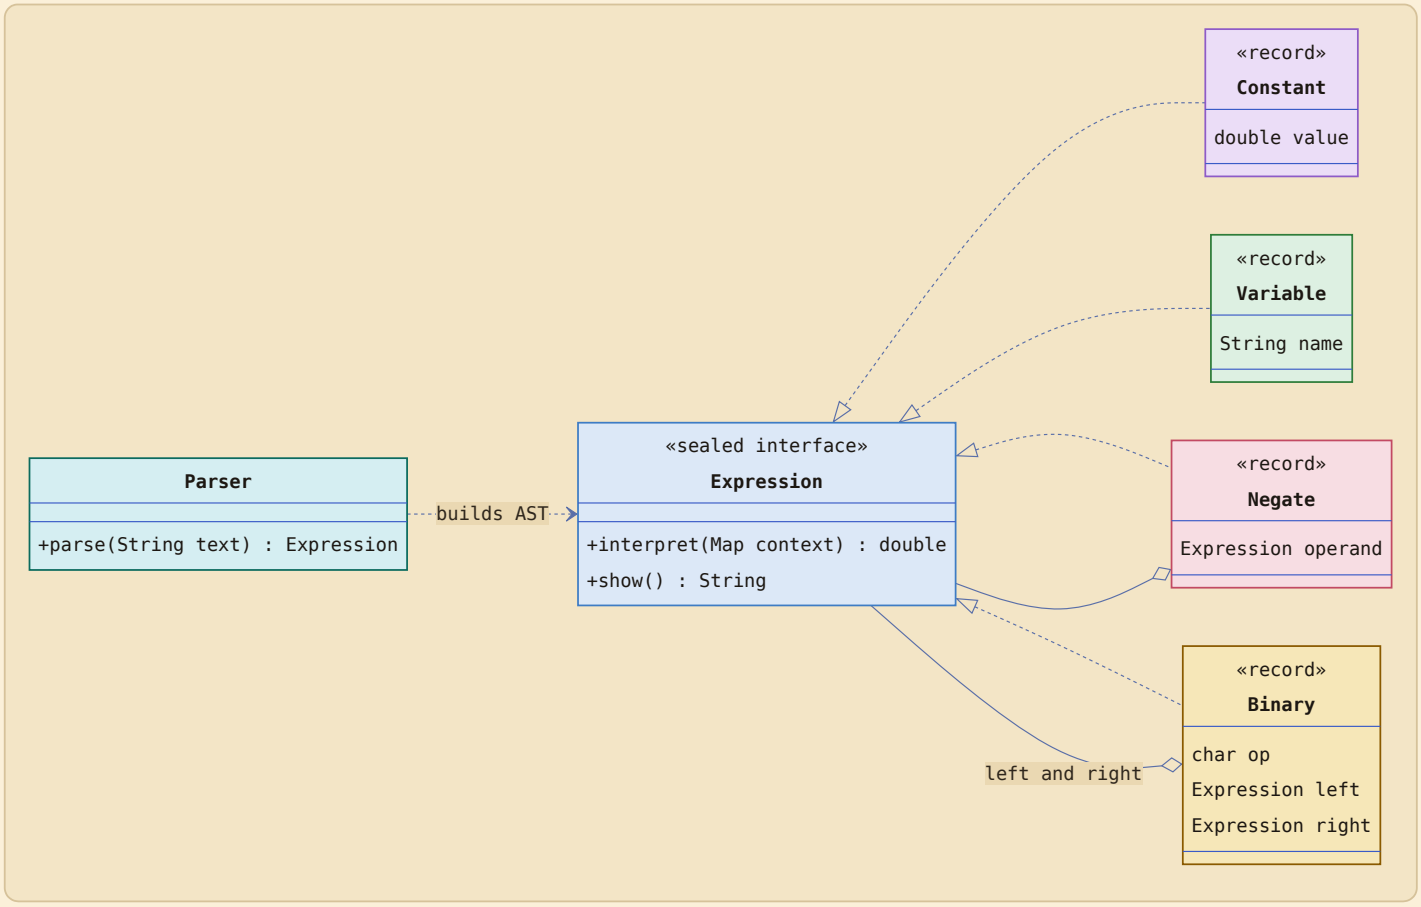
How it works

1. **Write the grammar** (here in EBNF, a standard notation):

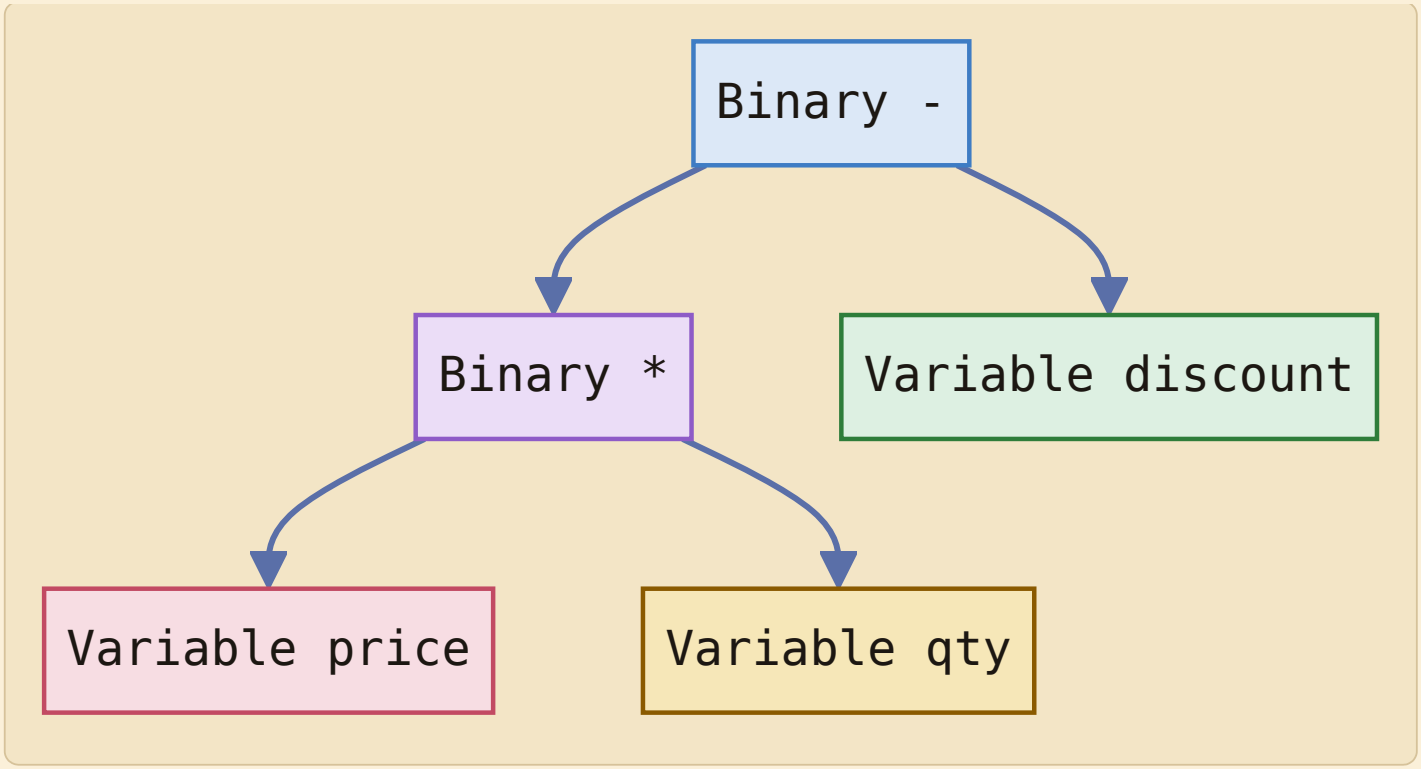
```
expr   := term   (('+' | '-') term)*
term   := factor (('*' | '/') factor)*
factor := NUMBER | NAME | '(' expr ')' | '-' factor
```

2. **One class per rule**: `Constant` and `Variable` (terminals), `Negate` and `Binary` (nonterminals), all implementing `Expression.interpret(context)`.
3. **Build the AST.** GoF deliberately leaves **parsing** (reading text and building a structure such as the AST from it) out of the pattern; any parser will do. We use a small *recursive-descent* parser: one method per grammar rule, which calls the others.
4. **Interpret**: the root calls `interpret` on its children and combines their results (a *recursive* evaluation).
5. **Reuse the tree**: parse once, interpret many times with different contexts.

Structure (UML)



The AST for `price * qty - discount`:



Notice the structure is a **Composite** (Chapter 9): leaves and inner nodes share one interface. Interpreter is essentially "Composite + an `interpret` operation".

Java example

`lld.ch10.interpreter`: `Expression` is a **sealed interface** (only the four listed records may implement it), each record is one grammar rule, and `Parser` is a recursive-descent parser whose methods `expr`, `term` and `factor` mirror the grammar lines. Errors (unknown variable, division by zero, bad syntax) are reported with clear messages.

> **Why `double` here?** This is a general-purpose arithmetic calculator used to teach the pattern, and variable names like `price` are only sample data. A real pricing or promotion DSL must evaluate money with `BigDecimal` (and an explicit `RoundingMode` for division), exactly as the domain code elsewhere in this chapter does — `double` cannot represent values like 0.10 exactly.

```java
// File: code/lld/ch10/interpreter/Expression.java
package lld.ch10.interpreter;

import java.util.Map;

/**
 * AbstractExpression. One class per grammar rule; each knows how to interpret itself.
 * Grammar (EBNF):
 *   expr   := term   (('+' | '-') term)*
 *   term   := factor (('*' | '/') factor)*
 *   factor := NUMBER | NAME | '(' expr ')' | '-' factor
 */
public sealed interface Expression
        permits Expression.Constant, Expression.Variable, Expression.Negate, Expression.Binary {

    /** Evaluate against a context (variable name -> value). */
    double interpret(Map<String, Double> context);

    /** Print the tree back as fully-parenthesised text. */
    String show();

    /** TerminalExpression: a literal number. */
    record Constant(double value) implements Expression {
        public double interpret(Map<String, Double> ctx) { return value; }
        public String show() { return value == Math.rint(value) ? String.valueOf((long) value) :
String.valueOf(value); }
    }

    /** TerminalExpression: a variable looked up in the context. */
    record Variable(String name) implements Expression {
        public double interpret(Map<String, Double> ctx) {
            Double v = ctx.get(name);
            if (v == null) throw new IllegalArgumentException("unknown variable '" + name + "'");
            return v;
        }
        public String show() { return name; }
    }

    /** NonterminalExpression: unary minus. */
    record Negate(Expression operand) implements Expression {
        public double interpret(Map<String, Double> ctx) { return -operand.interpret(ctx); }
        public String show() { return "(-" + operand.show() + ")"; }
    }

    /** NonterminalExpression: + - * / . Interprets its children, then combines. */
    record Binary(char op, Expression left, Expression right) implements Expression {
        public double interpret(Map<String, Double> ctx) {
            double l = left.interpret(ctx), r = right.interpret(ctx);
            return switch (op) {
                case '+' -> l + r;
                case '-' -> l - r;
                case '*' -> l * r;
                case '/' -> {
                    if (r == 0) throw new ArithmeticException("division by zero in " + show());
                    yield l / r;
                }
                default -> throw new IllegalStateException("unknown operator " + op);
            };
        }
        public String show() { return "(" + left.show() + " " + op + " " + right.show() + ")"; }
    }
}
```

```java
// File: code/lld/ch10/interpreter/Parser.java
package lld.ch10.interpreter;

/**
 * Recursive-descent parser: turns text into an Abstract Syntax Tree (AST).
 * Parsing is NOT part of the GoF Interpreter pattern; the pattern starts once the tree exists.
 * One method per grammar rule, mirroring the grammar in Expression.
 */
public final class Parser {
    private final String src;
    private int pos = 0;

    private Parser(String src) { this.src = src; }

    public static Expression parse(String text) {
        Parser p = new Parser(text);
        Expression e = p.expr();
        p.skipSpaces();

        skipSpaces();
        return pos < src.length() && src.charAt(pos) == expected;
    }
```

```
    private void skipSpaces() {
        while (pos < src.length() && Character.isWhitespace(src.charAt(pos))) pos++;
    }

    private IllegalArgumentException error(String msg) {
        return new IllegalArgumentException(msg + " at position " + pos + " in \"" + src + "\"");
    }
}
```

```
// File: code/lld/ch10/interpreter/Main.java
package lld.ch10.interpreter;

import java.util.List;
import java.util.Map;

public class Main {
    public static void main(String[] args) {
        Map<String, Double> context = Map.of("price", 250.0, "qty", 3.0, "discount", 50.0, "a", 7.0, "b", 3.0);
        System.out.println("context: " + new java.util.TreeMap<>(context));

        List<String> inputs = List.of(
            "price * qty - discount",
            "2 + 3 * 4",
            "(2 + 3) * 4",
            "(a + b) * (a - b)",
            "-a + 10 / 4",
            "price / (qty - 3)",
            "price * tax",
            "2 + * 3");

        for (String text : inputs) {
            try {
                Expression ast = Parser.parse(text);          // build the tree once...
                double value = ast.interpret(context);        // ...interpret it (could be many times)
                System.out.printf("  %-24s AST %-32s = %s%n", text, ast.show(), value);
            } catch (IllegalArgumentException | ArithmeticException e) {
                System.out.printf("  %-24s ERROR: %s%n", text, e.getMessage());
            }
        }

        System.out.println("\nSame tree, different contexts (parse once, evaluate many):");
        Expression total = Parser.parse("price * qty - discount");
        for (double q : new double[] {1, 2, 4}) {
            System.out.println("  qty=" + (int) q + " -> " + total.interpret(Map.of("price", 250.0, "qty", q,
"discount", 50.0)));
        }
    }
}
```

Output:

```
context: {a=7.0, b=3.0, discount=50.0, price=250.0, qty=3.0}
  price * qty - discount   AST ((price * qty) - discount)       = 700.0
  2 + 3 * 4                AST (2 + (3 * 4))                    = 14.0
  (2 + 3) * 4              AST ((2 + 3) * 4)                    = 20.0
  (a + b) * (a - b)        AST ((a + b) * (a - b))              = 40.0
  -a + 10 / 4              AST ((-a) + (10 / 4))                = -4.5
  price / (qty - 3)        ERROR: division by zero in (price / (qty - 3))
  price * tax              ERROR: unknown variable 'tax'
  2 + * 3                  ERROR: unexpected '*' at position 4 in "2 + * 3"

Same tree, different contexts (parse once, evaluate many):
  qty=1 -> 200.0
  qty=2 -> 450.0
  qty=4 -> 950.0
```

Notice operator precedence (which operator binds first) (`2 + 3 * 4` = 14, but `(2 + 3) * 4` = 20) comes from the **grammar**: `term` handles `*` and `/` below `expr`, so they bind tighter.

Trade-offs

Pros	Cons
Easy to change and extend the grammar: a new rule is a new class.	One class per rule: large grammars become a jungle of classes.
Each rule's evaluation is small and testable.	Tree-walking is slow compared with compiling to bytecode (compiled JVM instructions).
Rules become data (stored in a DB, edited by users).	Adding a new *operation* (pretty-print, type-check, optimise) means touching every class — that is where **Visitor** (Chapter 11) comes in.
Parse once, evaluate many times.	You still need a parser, which the pattern does not give you.

When not to use it

- **The grammar is large or complex** (a real programming language, SQL). Use a parser generator (a tool that writes a parser from a grammar file) such as **ANTLR** and a compiler/visitor design.
- **Performance matters** and expressions run millions of times — compile to bytecode or use an existing engine.
- **An existing language fits.** Regular expressions (patterns for matching text), SpEL (Spring's expression language), JSONPath (queries into JSON data), CEL (Google's Common Expression Language), or a scripting engine (an embedded interpreter for a full language such as JavaScript) may already do the job.
- **Security matters.** Never let users run a *general-purpose* script engine on your server; a small, restricted DSL is safer precisely because it can do only what its grammar allows.

Common mistakes

1. **Mixing parsing and evaluation** in one pass, so each evaluation re-parses the text.
2. **Ignoring precedence and associativity** (associativity decides how operators of equal precedence group: `8 - 3 - 2` must be `(8 - 3) - 2`; our `expr` loop builds left-associative trees).
3. **Poor error messages** — always report the position.
4. **Adding many operations to every node** instead of switching to Visitor or pattern matching (a `switch` that branches on an object's type and unpacks its fields).
5. **Growing a "tiny" DSL** until it is an accidental programming language.

Real-world examples

- `java.util.regex.Pattern`: compiling a regex builds an internal tree of node objects, and a `Matcher` walks it — a classic interpreter.
- **Spring Expression Language (SpEL)**: `SpelExpressionParser` parses text like `#user.age > 18` into an AST of `SpelNode`s, and `getValue()` evaluates it against a context. Jakarta Expression Language (EL) is similar.
- **SQL engines** evaluate `WHERE` clauses as expression trees; **spreadsheet formulas** (`=SUM(A1:A3)*2`) are a DSL.
- **Rule and pricing engines**: e-commerce promotions ("10% off if cart > 999 and category = electronics"), feature-flag targeting rules, and Google's **CEL** (Common Expression Language) used in Kubernetes validation rules and IAM (identity and access management — who may do what) conditions.
- **Cron expressions** (`0 9 * * MON-FRI`), e.g. Quartz's (a Java job-scheduling library) `CronExpression`.

In the interview

> **30-second answer:** "Interpreter models a small language's grammar as classes, one per rule — terminals like numbers and variables, nonterminals like addition. A sentence is parsed into an AST made of those objects and evaluated by calling `interpret` on the root with a context. It's really Composite plus an evaluate operation. It's great for small DSLs like pricing rules or filters; for big grammars I'd use a parser generator like ANTLR, and when I need many operations over the tree I'd switch to Visitor or sealed types with pattern matching."

Follow-ups:

- *Is parsing part of the pattern?* No. GoF assumes the tree already exists; parsing is a separate concern (hand-written recursive descent, or ANTLR).
- *Interpreter vs Visitor?* Interpreter puts evaluation **inside** the node classes. Visitor takes operations **out** into separate classes. A real interpreter usually starts as the first and becomes the second when a second pass (type-check, optimise, pretty-print) arrives.
- *Interpreter vs Composite?* Composite is the structure; Interpreter uses that structure to evaluate a language.
- *How would you make it faster?* Cache parsed trees; constant-fold (pre-compute parts with no variables); or compile to bytecode/lambdas once.
- *How do you design a rule engine for promotions?* A small grammar (comparisons, AND/OR/NOT, fields from the cart), rules stored as text, parsed once into trees and cached, evaluated per cart.

Self-check

1. **Q:** What is the difference between terminal and nonterminal expressions? **A:** Terminals are leaves (numbers, variables); nonterminals combine other expressions (operators).
2. **Q:** What is the "context"? **A:** External information needed for evaluation, such as variable values.
3. **Q:** Why does `2 + 3 * 4` give 14? **A:** The grammar puts `*` in `term`, below `expr`, so it binds tighter.
4. **Q:** Name a JDK class that is an interpreter. **A:** `java.util.regex.Pattern`.
5. **Q:** When should you not use it? **A:** Large grammars, performance-critical evaluation, or when an existing language fits.

TL;DR

One class per grammar rule; parse a sentence into an **AST**; evaluate by calling `interpret` recursively with a **context**. Perfect for **tiny DSLs**; for big grammars use a parser generator and Visitor.

10.7 Chapter recap: the six patterns side by side

Pattern	The object you create	The question it answers	Classic JDK / real example	Often confused with
Chain of Responsibility	A handler per check	*Who* should handle this request?	Servlet filters, logging handlers	Decorator (all layers run)
Command	An object per request	How do I store, queue or undo *this request*?	`Runnable`, `UndoManager`	Strategy (how vs what)
Iterator	A cursor object	How do I walk this without knowing its shape?	`Iterator`, `Spliterator`, `ResultSet`	Visitor (what to do at each node)
Mediator	One coordinator	How do many objects cooperate without knowing each other?	UI controllers, chat servers, saga orchestrators	Observer (broadcast only), Facade
Memento	A sealed snapshot	How do I go back to an earlier state safely?	DB rollback, Git, `kubectl rollout undo`	Command undo, Prototype
Interpreter	A node per grammar rule	How do I evaluate sentences of a small language?	`Pattern`, SpEL	Composite, Visitor

Interview combo facts to remember:

- The request flowing through a **Chain of Responsibility** is frequently a **Command** object.
- A **Mediator** often creates and dispatches **Commands**.
- **Memento + Command** together give scalable undo (snapshots + replay).
- **Iterator + Composite** walk trees; **Interpreter = Composite + evaluate**; when operations multiply, move to **Visitor** (Chapter 11).

Self-check (whole chapter)

1. **Q:** Which two GoF behavioral patterns are class-scoped (inheritance-based)? **A:** Template Method and Interpreter.
2. **Q:** A request must pass auth, then a rate limit, then validation, and any step can reject it. Which pattern? **A:** Chain of Responsibility.

3. **Q:** You need undo/redo for a text editor. Which patterns? **A:** Command (per edit), optionally Memento for periodic snapshots.
4. **Q:** Five form widgets depend on each other's values. Which pattern? **A:** Mediator.
5. **Q:** Your team needs business users to write discount rules. Which pattern? **A:** Interpreter (a small DSL), possibly with Specification (Chapter 11).

> **TL;DR**

Behavioral patterns turn **hidden control flow** into **named objects**: handlers (CoR), requests (Command), cursors (Iterator), coordinators (Mediator), snapshots (Memento) and grammar nodes (Interpreter). Each one buys flexibility with indirection — use it when the flexibility is a real requirement, not "just in case".

Chapter 11 — Behavioral Design Patterns (Part 2) & Beyond GoF

> **What you will learn.** The remaining five **GoF** ("Gang of Four" — the four authors of the 1994 book *Design Patterns*, which catalogued 23 classic patterns) behavioral patterns — **Observer, State, Strategy, Template Method, Visitor** — including the three that share one class diagram (Strategy, State, Bridge) and how to tell them apart. Then six widely used patterns that are *not* in the GoF book but come up constantly in interviews and real code: **Null Object, Dependency Injection, Repository, Specification, MVC** (the Head First "compound pattern") and **Event Sourcing (lite)**. The chapter ends with a "which behavioral pattern do I need?" decision table.

How to run the code in this chapter

```
cd chapters/11-patterns-behavioral-2/code
javac --release 21 -Xlint:all -d /tmp/lld_11 $(find . -name '*.java')   # compiles with 0 warnings
java -cp /tmp/lld_11 lld.ch11.observer.Main
# also: state, strategy, templatemethod, visitor, nullobject, di, repository, specification, mvc, eventsourcing
```

Chapter 10 introduced behavioral patterns: patterns about **how objects share work and talk to each other**. Keep one idea in mind for this chapter: most of these patterns take a conditional (`if` / `switch`) or a hard-coded call and turn it into an **object** that can be swapped, subscribed, or visited.

11.1 Observer

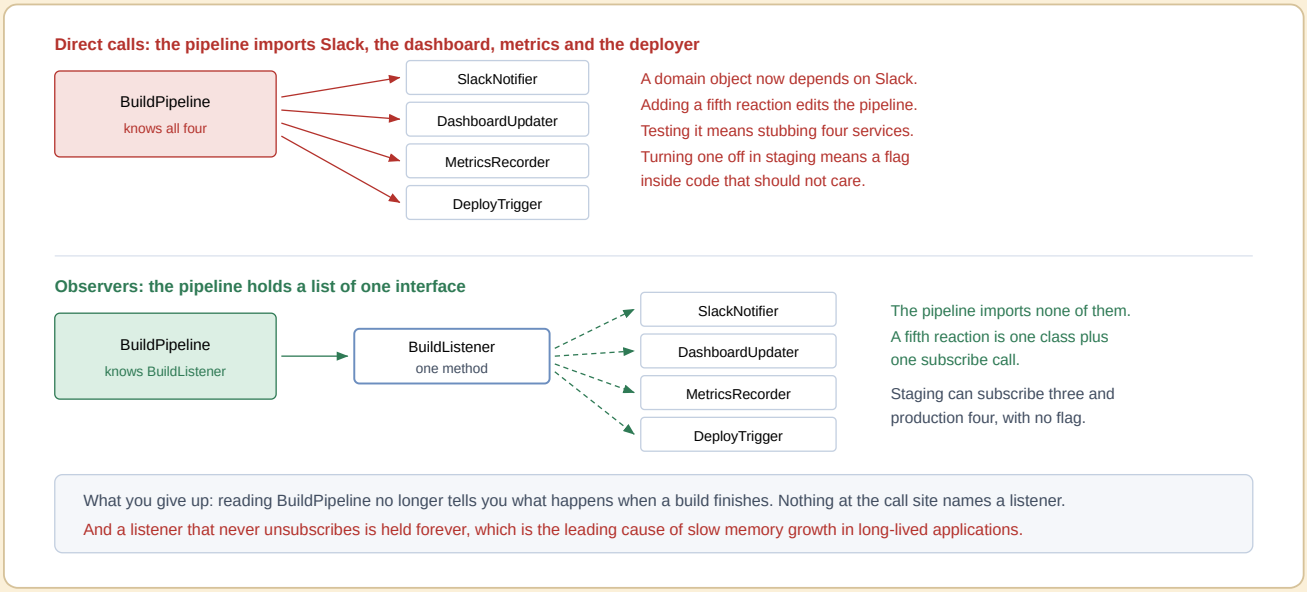

Figure — Top: the build pipeline calls Slack, dashboard, metrics and deployer directly. Bottom: it holds one list of BuildListener and imports none of them (course diagram)

What it is

Observer lets one object (the **subject**, also called *publisher* or *observable*) notify many dependent objects (the **observers**, *subscribers* or *listeners*) when something happens — **without knowing who they are or what they do**.

Everyday analogy: a YouTube channel. You subscribe; when a new video is published, every subscriber is notified. The channel does not know or care what each subscriber does with the notification, and you can unsubscribe at any time.

GoF intent (paraphrased): set up a one-to-many dependency, so that when one object's state changes, every object that depends on it is told and can update itself automatically.

GoF participants (and who plays them in our code):

Participant	Role	In `lld.ch11.observer`
Subject	Knows its observers (any number) and offers attach/detach operations	`BuildPipeline` (`addListener` + the returned unsubscribe handle)
Observer	The update interface that subjects call	`BuildListener`
ConcreteSubject	Holds the state observers care about; notifies them when it changes	`BuildPipeline` (GoF split Subject into an abstract class and a concrete one; in modern Java one class usually plays both)
ConcreteObserver	Implements the update interface; may keep its own state in step with the subject	`SlackNotifier`, `DashboardUpdater`, `MetricsRecorder`, `DeployTrigger`

The problem it solves

Suppose four reactions must follow every finished build: a Slack message, a dashboard refresh, a metrics record and a deployment. The naive version calls all four itself:

```
void finish(int buildNumber, String result) {
    slack.post(buildNumber, result);
    dashboard.update(result);
    metrics.record(buildNumber);
    deployer.start();
}
```

This costs more than it looks: the build pipeline now **depends on a chat service**; a fifth reaction means editing the pipeline; a **unit test** (an automated test that checks one class on its own) must fake four services; and disabling deployment in **staging** (the pre-production copy of the system used for final checks) needs an environment flag inside a class that ought to know nothing about environments.

Observer replaces the four references with **one list of one interface**. Anything that cares subscribes. **The source only announces; every listener chooses its own reaction.** No one orchestrates them, and listeners are unaware of one another.

How it works

1. Define an **observer interface** with one method, e.g. `onBuildFinished(buildNumber, result)`.
2. The **subject** keeps a list of observers and offers subscribe and unsubscribe operations (classically `addListener` / `removeListener`; our `addListener` instead returns a handle that unsubscribes).
3. When its state changes, the subject **first finishes changing its state**, then loops over the list and calls each observer.
4. Observers can be added and removed at run time (e.g. staging subscribes three listeners, production four).

Push vs pull — two ways to deliver the data:

	Push model	Pull model
What the observer receives	All the data about the change (e.g. a `Reading` record)	Just "I changed" plus a reference to the subject
How the observer gets data	It is in the call	It calls getters on the subject for what it needs
Pros	Simple; observers don't depend on the subject's getters	Each observer takes only what it needs; the interface doesn't change when new data is added
Cons	Sends data some observers don't need; adding data changes the interface	Observers depend on the subject; they must work out *what* changed

`java.util.Observer.update(Observable o, Object arg)` supported both: `o` for pull, `arg` for push. *Head First Design Patterns* shows the same trade-off with its weather-station example.

Structure (UML)

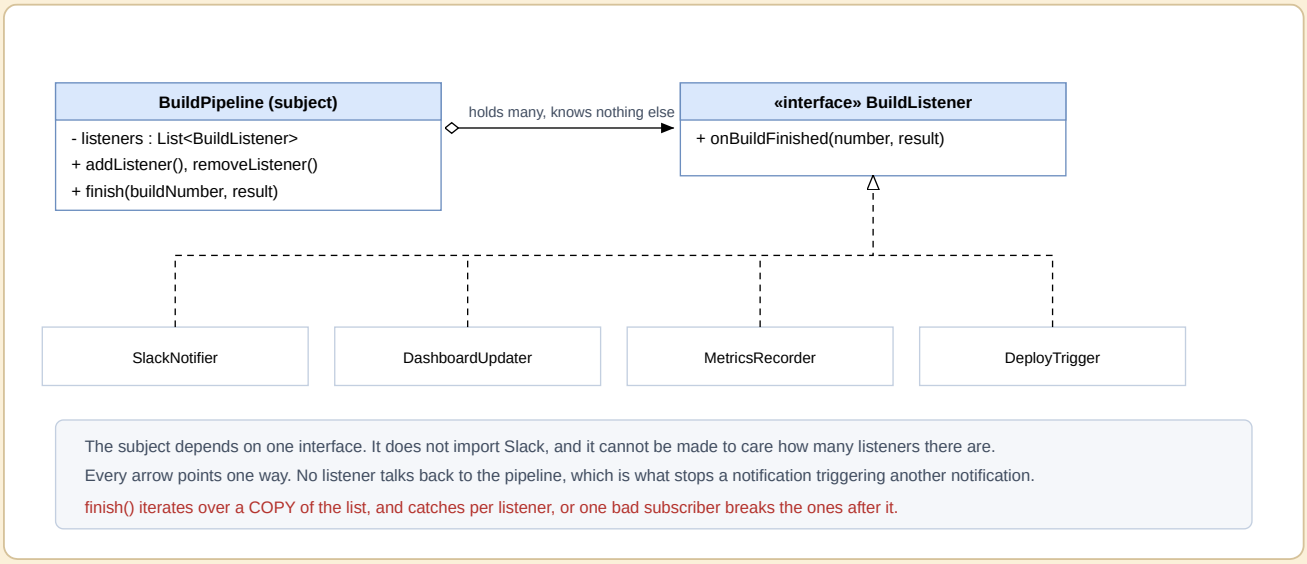

Figure — Class diagram: BuildPipeline holds a list of BuildListener; SlackNotifier, DashboardUpdater, MetricsRecorder and DeployTrigger implement it (course diagram)

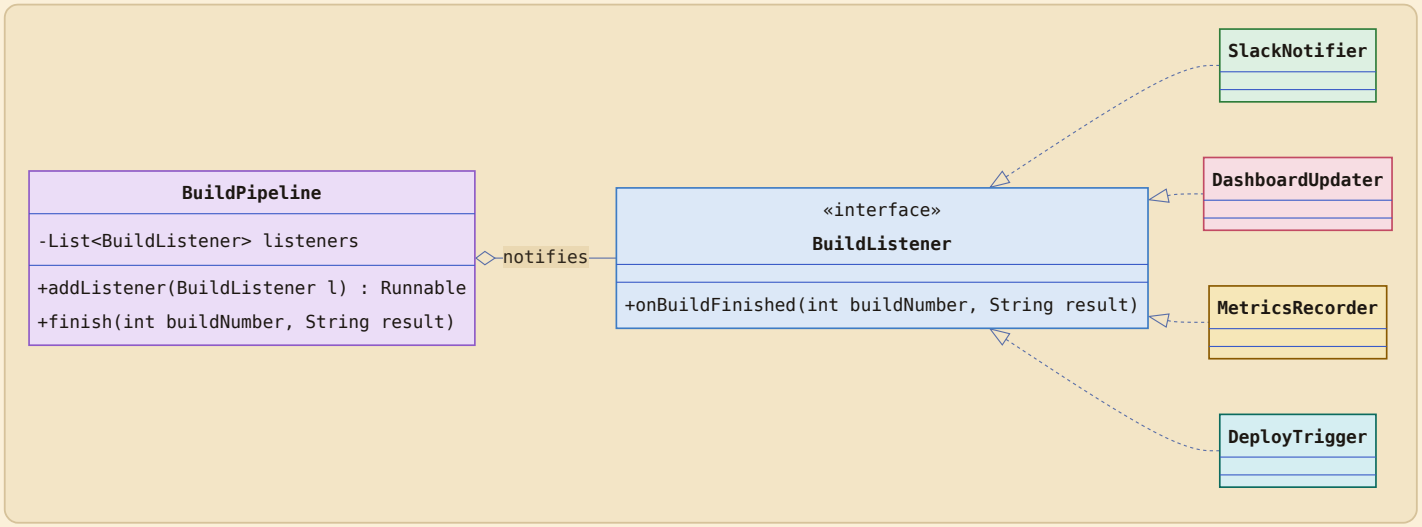
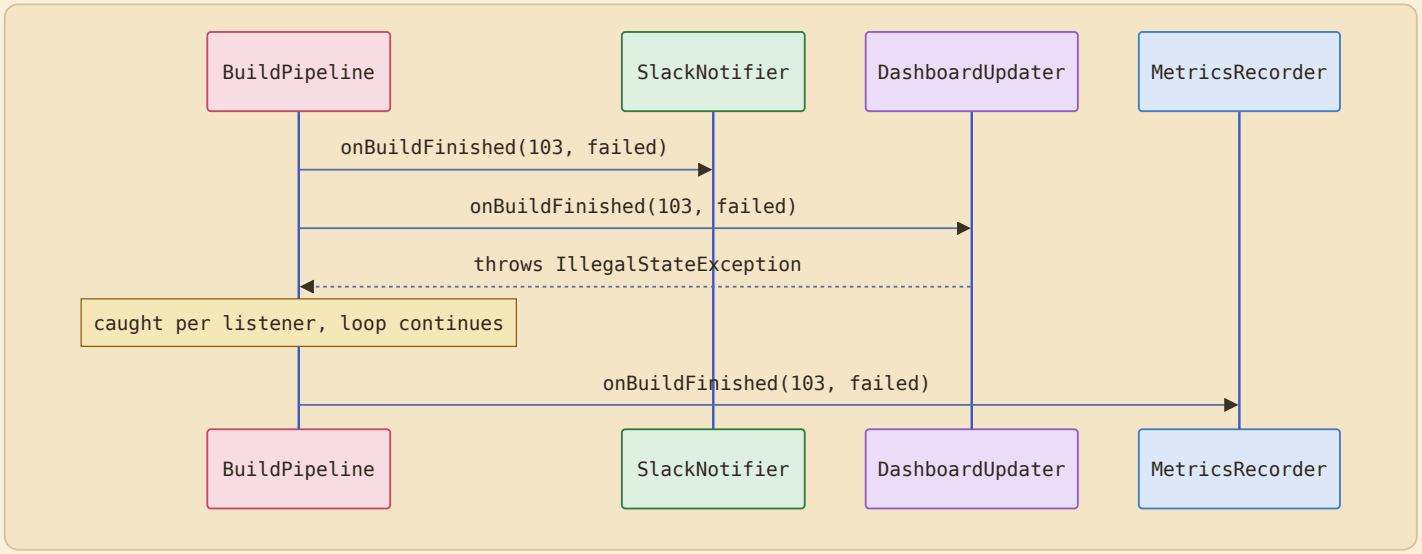
In the diagram above (a **UML** class diagram — UML, the Unified Modeling Language, is the standard box-and-arrow notation for classes and how they relate) all dependencies run in a single direction. Listeners never call the pipeline back, so one notification cannot set off another.

Our Java design:





Java example

`lld.ch11.observer` shows four things:

1. **Build pipeline.** Listeners live in a `CopyOnWriteArrayList` (a JDK list that copies its internal array on every write, so readers never see it change under them), whose iterator works on a **snapshot** — so a listener that unsubscribes during notification cannot break the loop, and the list is **thread-safe** (safe to use from several *threads* — independent paths of execution running at the same time — at once). `finish` **catches exceptions per listener**, so a broken dashboard does not stop metrics. `addListener` returns a `Runnable` (Java's built-in interface for "a piece of code to run later", with one method `run()`) that unsubscribes: whoever subscribes owns the matching unsubscribe.
2. **Push vs pull** (`WeatherStation`): one display receives the whole `Reading`; the other receives the station and pulls only the temperature.
3. **A tiny event bus** (`EventBus`): subscribers register for an event *type* (a class); publishers just publish objects. The returned `Subscription` is the unsubscribe handle. `Main` closes it in a `finally` block, so the refunds handler is removed even if publishing throws. (`Subscription` is also `AutoCloseable` — an interface whose `close()` method is called automatically when a *try-with-resources* block ends — so `try (var s = bus.subscribe(...)) { ... }` works too. But if the body never uses `s`, `javac -Xlint` warns that the resource is never referenced. Java 22+ lets you write `try (var _ = ...)` to say "unused on purpose". On Java 21, `try`/`finally` is the warning-free form.) The bus's handler list is a `CopyOnWriteArrayList`, so subscribing and publishing from different threads is safe. Delivery is still **synchronous on the publisher's thread** (the publisher waits while each handler runs, one after another) and nothing is stored, so it is not a **queue** (a waiting line that stores items and hands them out later, in order).
4. `java.beans.PropertyChangeSupport` (the price is whole cents in an `int` — exact, never `double`), which the `Observable` **Javadoc** (the official API documentation generated from comments in Java source code) itself points to (the `java.beans` package) as the richer event model. Note it does **not** fire when the old and new values are both non-null and equal. (Since Java 9, `java.beans` lives in the `java.desktop` module; on the class path (the list of folders and JAR files where Java looks for classes) this needs nothing extra, but a modular app (one that declares its dependencies in a `module-info.java` file) must `requires java.desktop`.)

```java
// File: code/lld/ch11/observer/BuildListener.java
package lld.ch11.observer;

/** The OBSERVER interface: one method. A lambda can implement it. */
@FunctionalInterface
public interface BuildListener {
    void onBuildFinished(int buildNumber, String result);
}
```

```java
// File: code/lld/ch11/observer/BuildPipeline.java
package lld.ch11.observer;

import java.util.List;
import java.util.concurrent.CopyOnWriteArrayList;

/** The SUBJECT: holds a list of one interface and imports none of the concrete reactions. */
public final class BuildPipeline {
    // CopyOnWriteArrayList iterates over a snapshot: a listener that unsubscribes
    // itself mid-notification cannot break the loop, and it is safe across threads.
    private final List<BuildListener> listeners = new CopyOnWriteArrayList<>();

    /** Returns a handle: whoever subscribes owns the matching unsubscribe (prevents leaks). */
    public Runnable addListener(BuildListener listener) {
        listeners.add(listener);
        return () -> listeners.remove(listener);
    }

    public void finish(int buildNumber, String result) {
        System.out.println("Build " + buildNumber + " finished: " + result);
        for (BuildListener l : listeners) {
            try {
                l.onBuildFinished(buildNumber, result);
            } catch (RuntimeException e) {          // one bad listener must not starve the rest
                System.out.println("  [pipeline] a listener failed: " + e.getMessage());
            }
        }
    }
}
```

```java
// File: code/lld/ch11/observer/SlackNotifier.java
package lld.ch11.observer;

final class SlackNotifier implements BuildListener {
    @Override
    public void onBuildFinished(int n, String result) {
        System.out.println("  [slack] #builds: build " + n + " " + result);
    }
}
```

```java
// File: code/lld/ch11/observer/DashboardUpdater.java
package lld.ch11.observer;

final class DashboardUpdater implements BuildListener {
    boolean offline = false;

    @Override
    public void onBuildFinished(int n, String result) {
        if (offline) throw new IllegalStateException("dashboard is offline");
        System.out.println("  [dashboard] status tile -> " + result);
    }
}
```

```java
// File: code/lld/ch11/observer/MetricsRecorder.java
package lld.ch11.observer;

final class MetricsRecorder implements BuildListener {
    private int recorded = 0;

    @Override
    public void onBuildFinished(int n, String result) {
        recorded++;
        System.out.println("  [metrics] recorded build " + n + " (total " + recorded + ")");
    }
}
```

```java
// File: code/lld/ch11/observer/DeployTrigger.java
package lld.ch11.observer;

final class DeployTrigger implements BuildListener {
    @Override
    public void onBuildFinished(int n, String result) {
        if (result.equals("success")) System.out.println("  [deploy] deploying build " + n);
    }
}
```

```java
// File: code/lld/ch11/observer/WeatherStation.java
package lld.ch11.observer;

import java.util.ArrayList;
import java.util.List;
import java.util.function.Consumer;

/** A subject that supports both notification styles, to compare PUSH and PULL. */
public final class WeatherStation {

" C"));
        station.measure(new WeatherStation.Reading(31.5, 0.62, 1008));

        System.out.println("\n=== 3. Event bus (typed topics, scoped unsubscribe) ===");
        EventBus bus = new EventBus();
        bus.subscribe(OrderPlaced.class, e -> System.out.println("  [email] confirmation for " + e.orderId()));
        bus.subscribe(Object.class, e -> System.out.println("  [audit] " + e));
        EventBus.Subscription refunds = bus.subscribe(OrderCancelled.class,
                e -> System.out.println("  [refunds] start refund for " + e.orderId()));
        try {
            bus.publish(new OrderPlaced("A-1", new BigDecimal("499.00")));
            bus.publish(new OrderCancelled("A-1"));
        } finally {
            refunds.close();                                    // refunds handler removed here, even on error
        }
        bus.publish(new OrderCancelled("A-2"));                 // only audit sees this one

        System.out.println("\n=== 4. JDK: PropertyChangeSupport (replacement for deprecated Observable) ===");
        PricedItem phone = new PricedItem("phone", 49_900);
        phone.addPropertyChangeListener(evt -> System.out.println(
            "  [price watcher] " + phone.name() + " " + evt.getPropertyName() + ": "
            + evt.getOldValue() + " -> " + evt.getNewValue()));
        phone.setPriceCents(44_900);
        phone.setPriceCents(44_900);    // same value: no event fired
        phone.setPriceCents(39_900);
    }
}
```

Output:

```
=== 1. Build pipeline: subscribe, unsubscribe, failing listener ===
Build 101 finished: success
  [slack] #builds: build 101 success
  [dashboard] status tile -> success
  [metrics] recorded build 101 (total 1)
  [deploy] deploying build 101
Build 102 finished: success
  [slack] #builds: build 102 success
  [dashboard] status tile -> success
  [metrics] recorded build 102 (total 2)
Build 103 finished: failed
  [slack] #builds: build 103 failed
  [pipeline] a listener failed: dashboard is offline
  [metrics] recorded build 103 (total 3)

=== 2. Push vs pull ===
  [push display] got everything: Reading[tempC=31.5, humidity=0.62, pressureHpa=1008.0]
  [pull display] asked only for temp: 31.5 C

=== 3. Event bus (typed topics, scoped unsubscribe) ===
  [email] confirmation for A-1
  [audit] OrderPlaced[orderId=A-1, amount=499.00]
  [audit] OrderCancelled[orderId=A-1]
  [refunds] start refund for A-1
  [audit] OrderCancelled[orderId=A-2]

=== 4. JDK: PropertyChangeSupport (replacement for deprecated Observable) ===
  [price watcher] phone priceCents: 49900 -> 44900
  [price watcher] phone priceCents: 44900 -> 39900
```

Why `java.util.Observer` / `Observable` were deprecated

Since **Java 9**, `java.util.Observer` and `java.util.Observable` are **deprecated** (officially marked "don't use in new code; may be removed one day") but not removed. The official reasons (Javadoc): the event model is **quite limited**, the **order of notifications is unspecified**, and **state changes are not one-for-one with notifications**. Other well-known problems:

- `Observable` is a **class**, not an interface — your subject must *extend* it, using up Java's **single inheritance** (a Java class can extend only one parent class).
- `setChanged()` is **protected**, so you cannot use `Observable` by composition (holding one as a field) without subclassing.
- The `update(Observable, Object)` signature is untyped (`Object arg`), so observers must cast.
- Its thread safety is only partial: its methods are `synchronized` (only one thread at a time may run them, because each call first takes the object's **lock** — a token only one thread can hold), but `notifyObservers` calls observers outside the lock on a snapshot, so (as a comment in the **JDK** — Java Development Kit: the compiler, runtime and standard library — source admits) a newly added observer may miss a notification and a just-removed one may still get it.

What to use instead (the Javadoc names the first, third and fourth): `java.beans.PropertyChangeSupport`/`PropertyChangeListener` for bean properties; your own typed listener interface (as in `BuildPipeline`); `java.util.concurrent` data structures (queues) for reliable, ordered hand-off between threads; the `java.util.concurrent.Flow` API (Java 9) for **reactive streams** (asynchronous streams of data items flowing from a producer to consumers) with **back-pressure** (the consumer tells the producer to slow down when it cannot keep up).

Trade-offs

Pros	Cons
The source no longer depends on its reactions (a build pipeline no longer imports Slack).	Harder to trace: the call site gives no hint of which code will execute.
Reactions are added/removed at run time; environments differ without flags.	**Memory leaks** (memory that is never freed) if an observer is never removed (the subject holds them forever).
Each reaction is testable alone.	Stack traces start inside a loop over a list; debugging is harder.
A new reaction = one class + one subscribe call (Open/Closed: open to extension, closed to modification).	**No ordering or delivery guarantee**; a crash loses the reactions not yet called.
	With synchronous observers, the subject takes as long as all its listeners combined.

Observer vs Mediator, Chain of Responsibility, callbacks

Looks like	The actual difference
Mediator	Observer carries only "this changed"; each observer decides for itself, one way, and no order between reactions can be expressed. A mediator receives the change **and decides what happens next**, calling specific components back (two-way), and explicit ordering is its reason to exist.
Publish-subscribe with a broker (a server that stores and forwards messages)	Same idea, but the broker contributes persistence, redelivery, ordering guarantees and a network hop — none of which in-process observers offer.
Chain of Responsibility	Observer informs **all** listeners, and no listener can prevent the rest from running. A chain ends as soon as one handler accepts the request.
A callback	One callback is one observer. It becomes the Observer pattern when the number of listeners varies and they subscribe and unsubscribe at run time.

Observer outside Java. With **first-class functions** (functions that can be stored in variables and passed around like any other value) a listener is just a **lambda** (a short anonymous function, written `x -> ...` in Java) — keep the handle, or you cannot unsubscribe. JavaScript has `EventTarget` / `EventEmitter`, and `AbortController` can unsubscribe by signal. Python often uses a plain list of callables, and `weakref.WeakSet` avoids the leak. C# has `event`, `IObservable<T>`, and `IDisposable` subscriptions. In every language, **weak references** (references that do not keep their target alive, so the garbage collector may still free it) fix the leak, at the cost of a listener disappearing when nothing else holds it.

When not to use it

- **One listener, forever.** Call it directly.
- **You need ordering or guaranteed delivery.** Use a queue or message broker (Kafka, RabbitMQ, SQS — popular broker products): same idea plus persistence, retries and a network — and very different failure modes.
- **Reactions are slow.** Either notify **asynchronously** (hand the work to another thread and return at once — e.g. via an *executor*, a pool of worker threads, or a queue) or don't use in-process observers.
- **The whole flow must be auditable/traceable.** Explicit calls are kinder to readers.

Common mistakes (the four classic ways observers go wrong, plus one)

1. **No unsubscribe → memory leak.** The subject keeps a **strong reference** (an ordinary reference, which keeps the object alive in memory) to the listener and everything it points to. In long-running apps this is a top cause of slow memory growth. Every `add` needs an owner for the matching `remove`. (Weak references are one fix, at the cost of listeners vanishing when nothing else holds them.)
2. **A throwing listener kills the loop.** Without a per-listener try/catch, listener 3 fails and 4 and 5 never run.
3. **Changing the list during notification** → `ConcurrentModificationException` (the error Java throws when a collection is changed while it is being looped over) (or silently skipped listeners in some languages). Iterate over a copy, or use `CopyOnWriteArrayList`.

4. **Listeners calling back into the subject** → cycles or endless recursion. Finish updating state before notifying, and never let a notification synchronously cause another one.
5. **Notifying before the state is updated**, so pull-style observers read stale data.
6. **Relying on notification order.** Listeners are called in the order they happened to subscribe, which is a side effect of start-up code rather than a decision anyone made. If "update the dashboard, then decide whether to deploy" matters, that is coordination, and it belongs in a Mediator.

Real-world examples

- **Every UI event handler**: Swing `ActionListener`, Android `OnClickListener`, DOM `addEventListener`.
- **JDK**: `PropertyChangeListener`, `java.util.concurrent.Flow` (`Publisher`/`Subscriber`), servlet listeners such as `HttpSessionListener`.
- **Spring** (the most widely used Java application framework): `ApplicationEventPublisher` + `@EventListener` (in-process events, optionally `@Async` or `@TransactionalEventListener`).
- **Guava** `EventBus`, **RxJava / Project Reactor / RxJS**, Kotlin `Flow`, and signals in front-end frameworks — observers with composable operators (map, filter, debounce — wait until events pause, then pass on only the latest) layered on top.
- **Model–view separation**: a view registers with its model, which then updates freely with no idea that any screen is attached (see MVC in §11.7.5).
- **Distributed publish–subscribe**: Kafka topics, Google Pub/Sub, AWS SNS. When an order is placed on an e-commerce site, the order service publishes one event and email, inventory, analytics and recommendation services each consume it independently — Observer at system scale, with durability added.
- **Database triggers and change data capture** (CDC: streaming every row change out of a database's internal log; Debezium is a popular tool) — observers at the storage layer.

In the interview

> **30-second answer:** "Observer swaps a handful of hard-coded calls for a list of objects that share one listener interface. The subject just says "this happened" and every observer picks its own response, so each reaction can be plugged in, unplugged and unit-tested on its own, and the subject no longer depends on any of them. In production I iterate over a copy of the listener list, catch exceptions per listener, and make sure every subscribe has a matching unsubscribe to avoid leaks. When I need durability, retries or ordering I use a message broker instead."

Follow-ups:

- *Push or pull?* Push sends the data (simple, but the interface grows with the data); pull sends a reference and observers ask for what they need (flexible, but couples observers to the subject's getters).
- *Why was `java.util.Observable` deprecated?* Limited event model, unspecified notification order, notifications not one-for-one with changes; plus it's a class (uses up inheritance) with protected `setChanged`. Use `PropertyChangeSupport`, custom listeners, or `Flow`.
- *Observer vs Pub/Sub?* In Observer the subject holds its observers directly. In publish–subscribe a **broker/event bus** sits in between, so publishers and subscribers don't know each other at all; brokers add durability, retries and ordering.
- *Observer vs Mediator?* With Observer, the news is broadcast and every listener makes its own call; with Mediator, one central object makes the decision and tells particular components what to do. When the sequence of reactions matters, pick a mediator.
- *How do you make it thread-safe?* `CopyOnWriteArrayList` for listeners (reads far outnumber writes), no locks held while calling listeners, and dispatch to an executor if listeners are slow.
- *How do you avoid leaks?* Return a subscription handle, tie it to a lifecycle (try-with-resources, `onDestroy`, `@PreDestroy`), or use weak references.

Self-check

1. **Q:** What does the subject know about its observers? **A:** Only that they implement the observer interface.
2. **Q:** Why iterate over a copy of the listener list? **A:** So a listener that (un)subscribes during notification can't break the loop.
3. **Q:** What is the classic Observer memory leak? **A:** Listeners that are never removed stay strongly referenced by the subject.

4. **Q:** What should replace `java.util.Observable`? **A:** `PropertyChangeSupport`, a custom typed listener interface, or the `Flow` API.
5. **Q:** When is a message broker better than in-process observers? **A:** When you need durability, retries, ordering, or slow/remote consumers.

TL;DR

One subject, a list of listeners, one-way notification. **Iterate over a copy, catch per listener, always unsubscribe.** Push vs pull is a trade-off; `Observable` is deprecated; use a broker when you need guarantees.

11.2 State

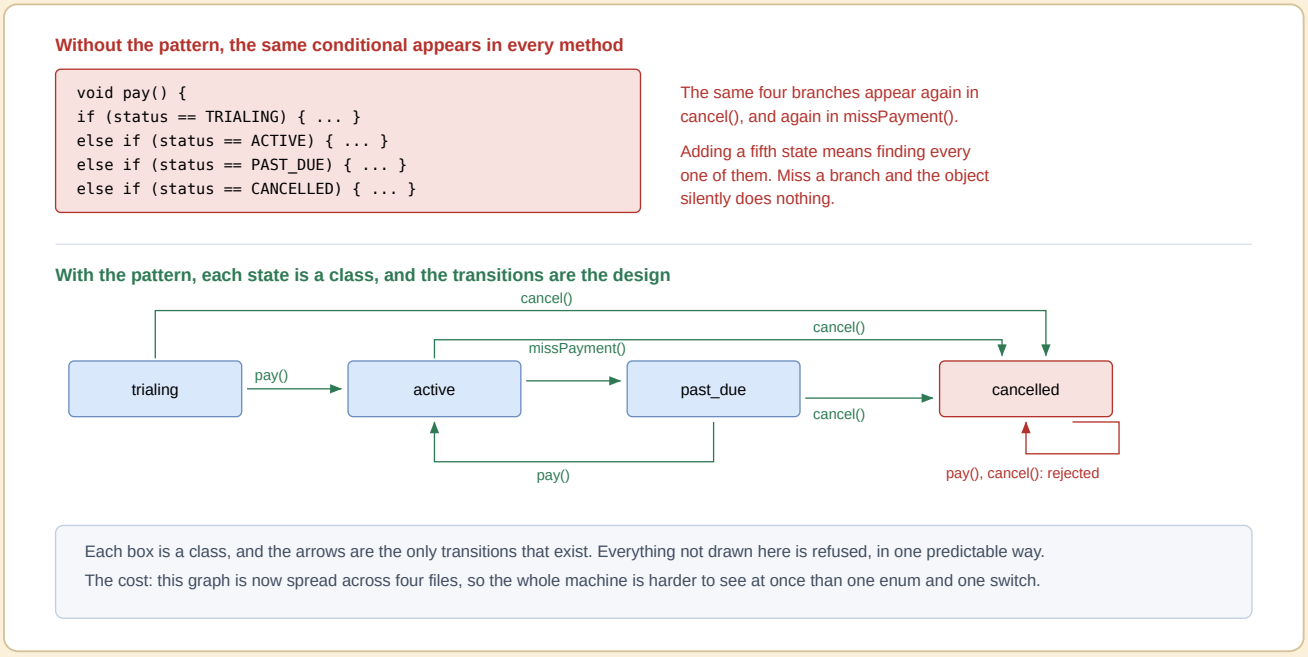

Figure — Top: the same four-branch status check repeated in every method. Bottom: each state is a class and the transitions form a graph (course diagram)

What it is

State (GoF intent, paraphrased): when an object's internal condition changes, **its behaviour changes with it**, so from the outside it looks as if the object had switched to a different class. Rather than every method testing a status field, the object hands each action to a **state object**, and replaces that object whenever the condition changes.

GoF participants (and who plays them in our code):

Participant	Role	In `lld.ch11.state`
Context	The object clients use; holds the current state object and forwards requests to it	`Subscription`, `VendingMachine`
State	Interface declaring one method per request the context forwards	`SubscriptionState`, `VendingState`
ConcreteState	One class per state, implementing the behaviour for that state	`Trialing`, `Active`, `PastDue`, `Cancelled`; `Idle`, `HasMoney`, `SoldOut`

GoF leaves open *who* performs the transitions: the context (with a fixed table) or the states themselves. Letting the states choose their successor, as here, is more flexible but makes the states know about each other.

Everyday analogy: a phone's ringer switch. Pressing "call received" does something different in *ring*, *vibrate* and *silent* mode — the phone is the same, its mode decides the behaviour.

The problem it solves

Take a subscription whose life runs **trialing → active → past due → cancelled**. Written naively, each public method opens with an identical four-way branch:

```
public void pay() {
    if (status == TRIALING)       { /* charge the card, switch to ACTIVE */ }
    else if (status == ACTIVE)    { /* renew */ }
    else if (status == PAST_DUE)  { /* settle arrears, back to ACTIVE */ }
    else if (status == CANCELLED) { /* reject */ }
}
```

`cancel()` and `missPayment()` repeat those four branches. A fifth state forces you to hunt down every copy. Everything that defines one state is spread over all the methods. Worst of all, a **forgotten branch** quietly does nothing, and the bug surfaces weeks later as a vague "subscriptions randomly stop working".

With the State pattern, **each state is a class**. The conditional vanishes (each context method shrinks to a single line), and everything about one state is gathered in one file — exactly what a reviewer or auditor wants to read.

How it works

1. Define a **State interface** with one method per action (`pay`, `missPayment`, `cancel`). Each state has to respond to each action, even when the response is "not allowed".
2. Write one **concrete state** class per state.
3. The **context** (`Subscription`) holds the current state and delegates each action: `state.pay(this)`.
4. A state rules on whether the action is **legal** and which state comes **after** it, and advances the machine by calling `context.setState(new Active())`.
5. Terminal states refuse everything, loudly, in one place.

The objects choose their own successors — the machine advances itself. That is the key difference from Strategy.

Structure (UML)

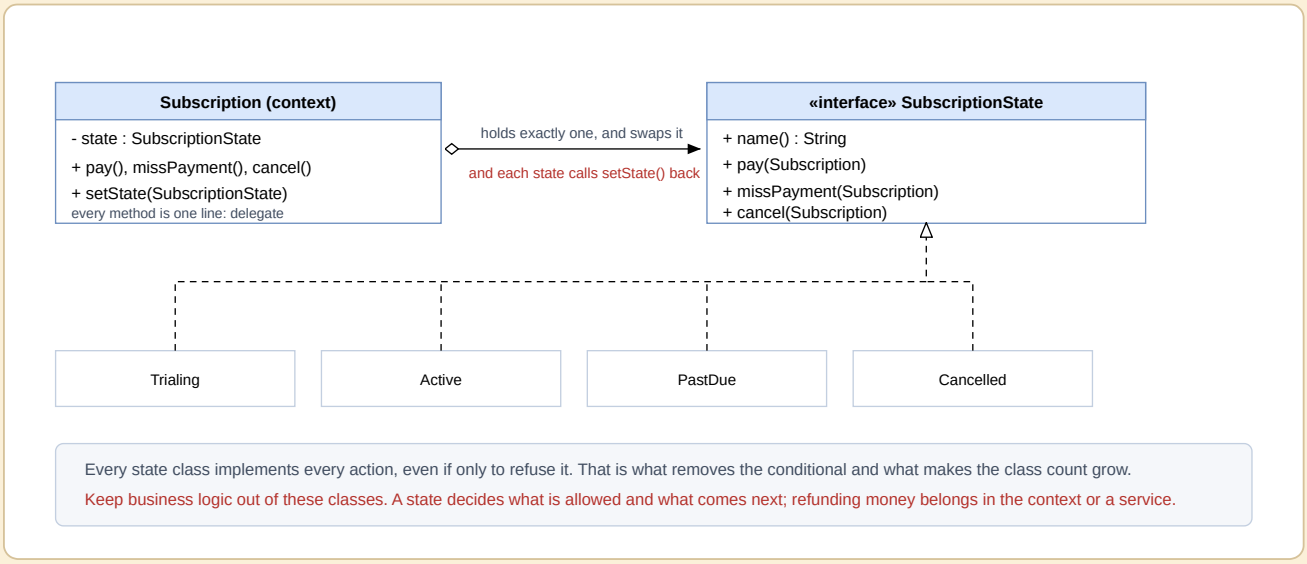

Figure — Class diagram: Subscription (context) holds a SubscriptionState; Trialing, Active, PastDue and Cancelled implement it and call setState on the context (course diagram)

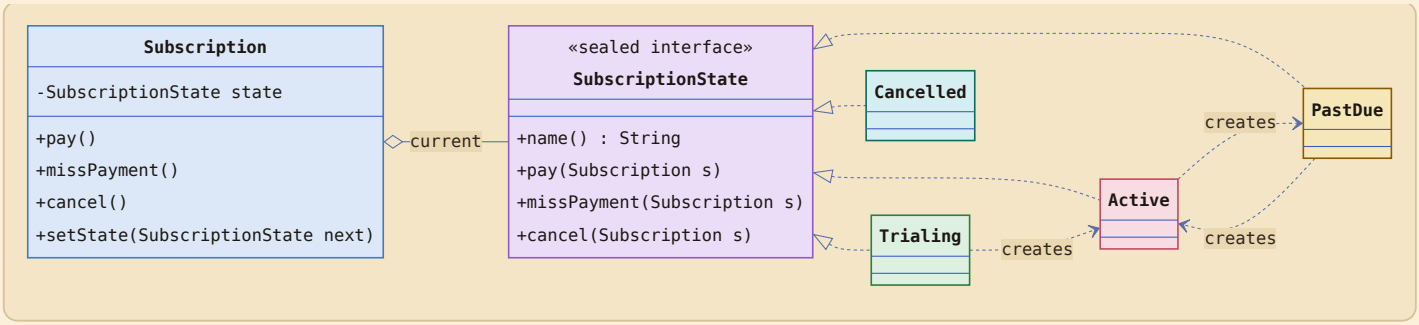
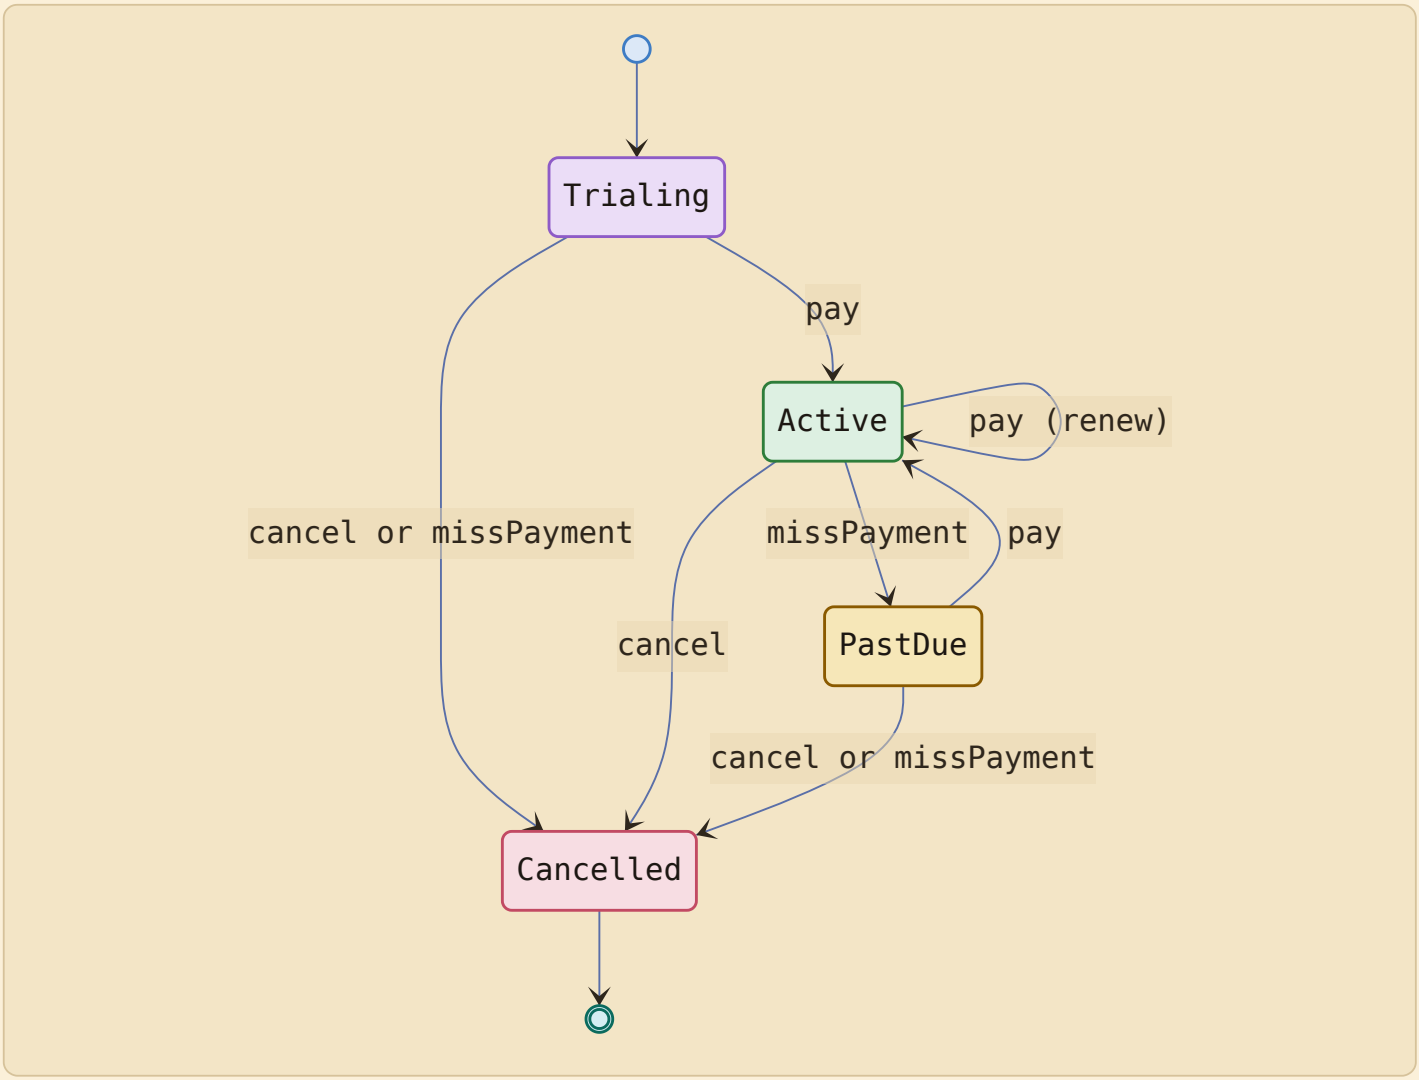
In the diagram above the states reach **back** into the context to replace themselves, and the state classes know each other (Trialing creates an Active).

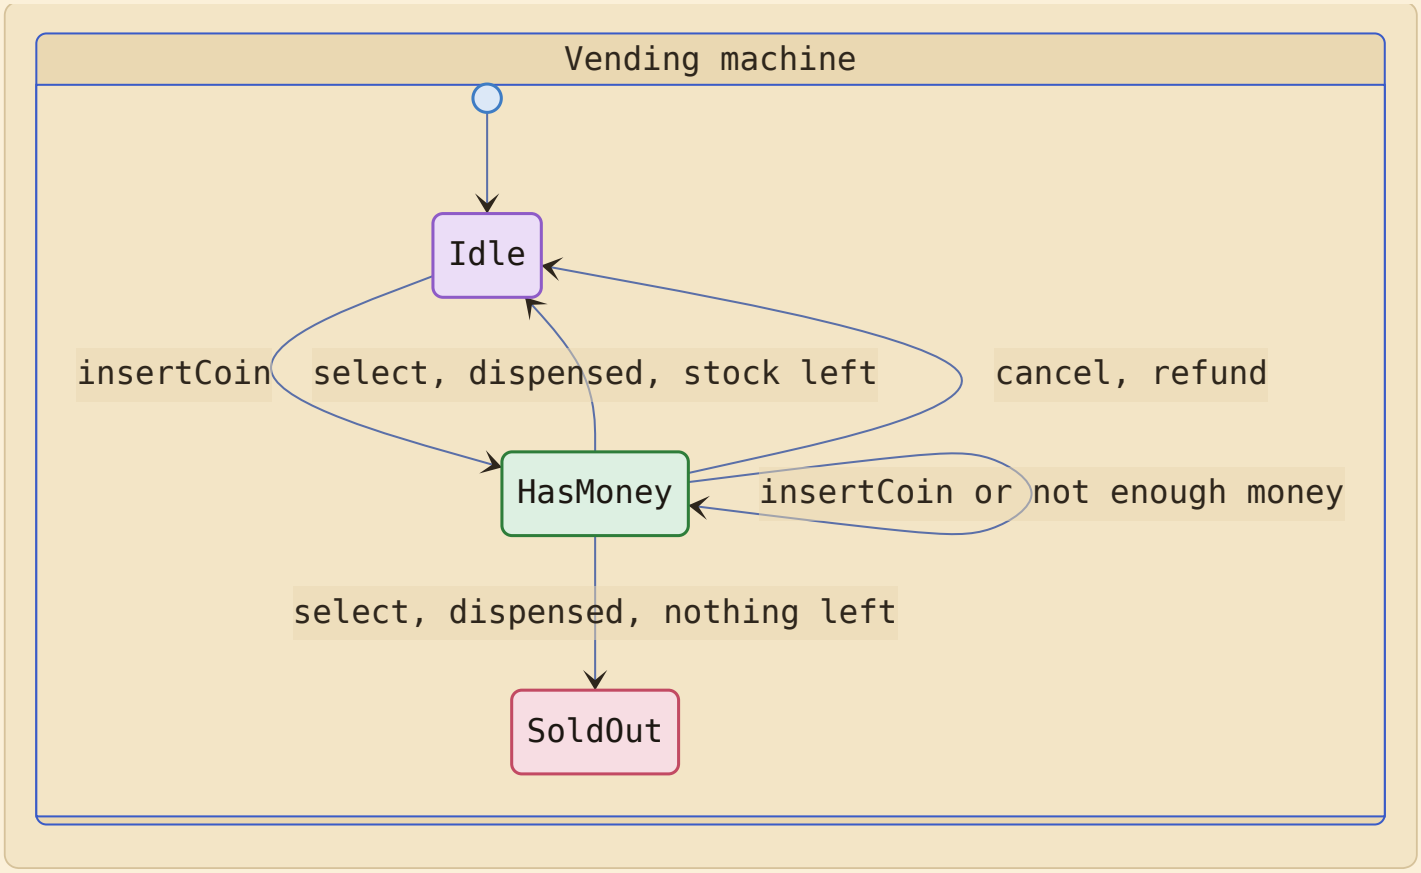
Our Java design (class-per-state version):



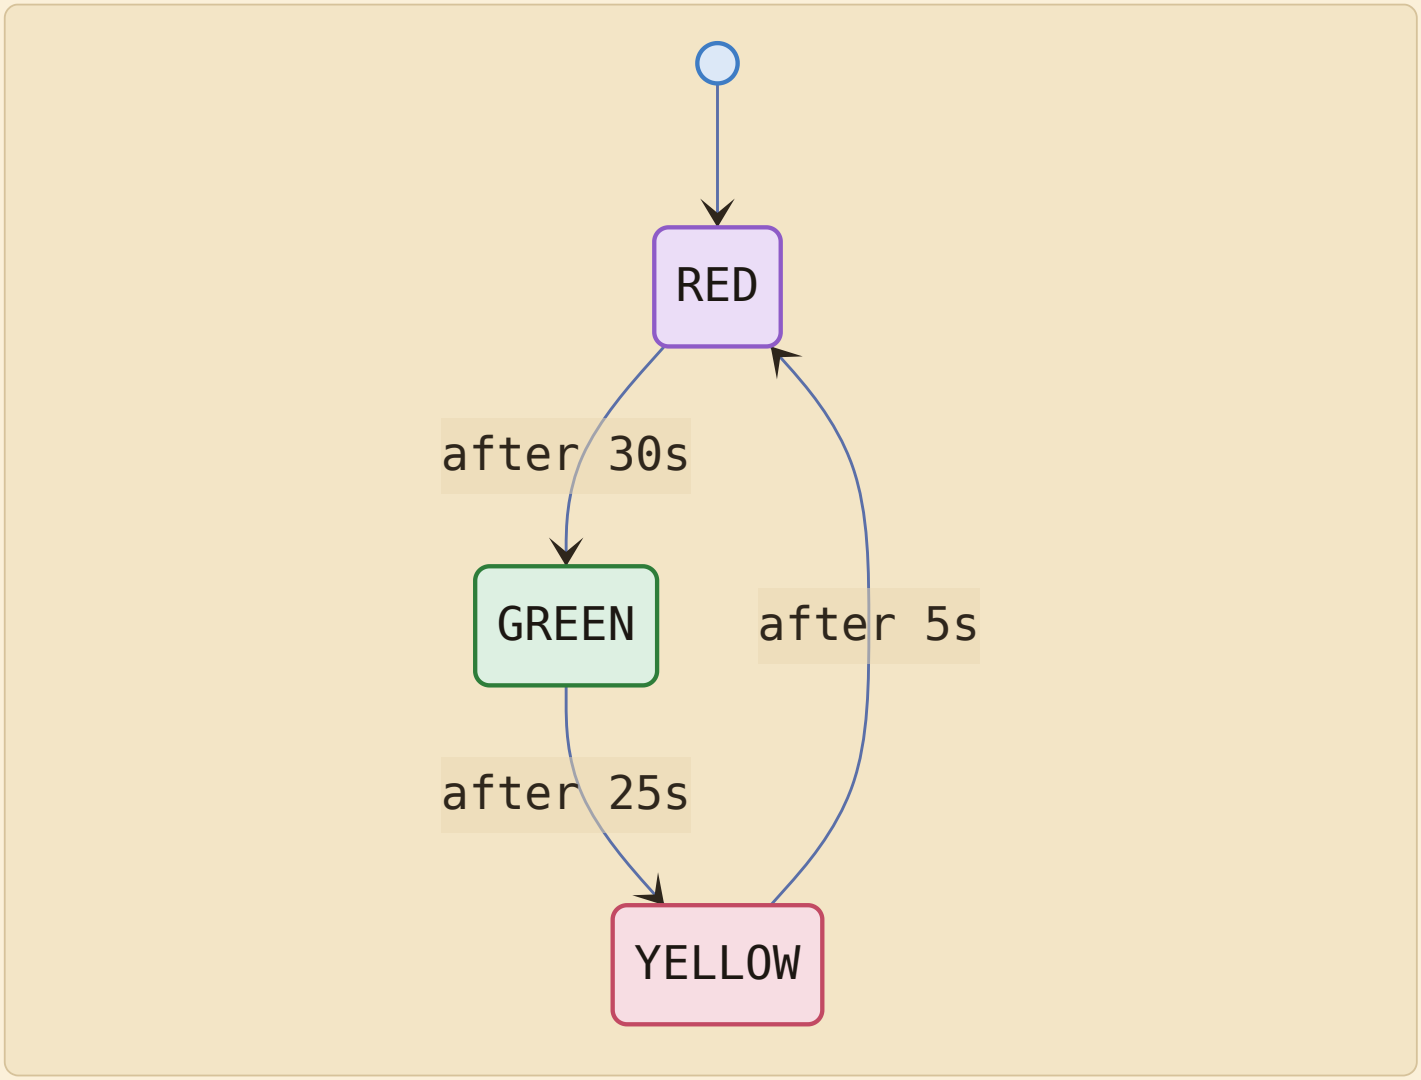
The state machine itself:



Vending machine and traffic light:



Vending machine
Idle
insertCoin
select, dispensed, stock left
cancel, refund
HasMoney
insertCoin or not enough money
select, dispensed, nothing left
SoldOut



RED
after 30s
GREEN
after 5s
after 25s
YELLOW

Java example

`lld.ch11.state` shows three styles:

1. **Class per state** (`Subscription` + four `record` states). `SubscriptionState` is a **sealed** interface (one that lists exactly which types may implement it): the compiler knows the complete set of states. The states have no fields, so **records** (Java's compact data classes whose fields are fixed at creation) with no components are a neat, **immutable** (cannot change after creation) choice.
2. **Enum-based state machine** (`TrafficLight`). Each enum constant overrides `next()`; shared behaviour is a **default method** (an interface method with a body, inherited by implementers unless they override it). The **whole machine is readable in one file** — the idiomatic Java answer for simple machines.
3. **Vending machine** (`VendingMachine` + `Idle`, `HasMoney`, `SoldOut`). The state interface uses **default methods that refuse**, so each state overrides only the actions it allows (`SoldOut` overrides nothing). Business actions (dispensing, returning change) live in the **context**; states only rule on whether an action is legal and which state follows. Money is kept as whole **cents in an `int`**, which is exact (unlike `double`); a real machine would use a `Money`/`BigDecimal` type (`BigDecimal` is Java's exact decimal-number class), as the Strategy and Visitor examples do.

```java
// File: code/lld/ch11/state/SubscriptionState.java
package lld.ch11.state;

/**
 * STATE interface. Each state implements all actions, including ones it only turns down.
 * Sealed: the compiler knows the full set of states.
 */
public sealed interface SubscriptionState permits Trialing, Active, PastDue, Cancelled {
    String name();
    void pay(Subscription s);
    void missPayment(Subscription s);
    void cancel(Subscription s);
}
```

```java
// File: code/lld/ch11/state/Trialing.java
package lld.ch11.state;

public record Trialing() implements SubscriptionState {
    public String name() { return "trialing"; }
    public void pay(Subscription s) {
        System.out.println("  [trialing] first payment taken");
        s.setState(new Active());                    // the state chooses its successor
    }
    public void missPayment(Subscription s) {
        System.out.println("  [trialing] trial ended unpaid");
        s.setState(new Cancelled());
    }
    public void cancel(Subscription s) { s.setState(new Cancelled()); }
}
```

```java
// File: code/lld/ch11/state/Active.java
package lld.ch11.state;

public record Active() implements SubscriptionState {
    public String name() { return "active"; }
    public void pay(Subscription s) { System.out.println("  [active] renewed for another period"); }
    public void missPayment(Subscription s) {
        System.out.println("  [active] payment failed, grace period started");
        s.setState(new PastDue());
    }
    public void cancel(Subscription s) { s.setState(new Cancelled()); }
}
```

```java
// File: code/lld/ch11/state/PastDue.java
package lld.ch11.state;

public record PastDue() implements SubscriptionState {
    public String name() { return "past_due"; }
    public void pay(Subscription s) {
        System.out.println("  [past_due] arrears paid");
        s.setState(new Active());
    }
    public void missPayment(Subscription s) {
        System.out.println("  [past_due] grace period over");
        s.setState(new Cancelled());
    }
    public void cancel(Subscription s) { s.setState(new Cancelled()); }
}
```

```java
// File: code/lld/ch11/state/Cancelled.java
package lld.ch11.state;

/** Terminal state: refuses everything, loudly, in one place. */
public record Cancelled() implements SubscriptionState {
    public String name() { return "cancelled"; }
    public void pay(Subscription s) { System.out.println("  [cancelled] refused: no payments after cancellation");
}
    public void missPayment(Subscription s) { System.out.println("  [cancelled] ignored: nothing is billed"); }
    public void cancel(Subscription s) { System.out.println("  [cancelled] rejected: already cancelled"); }
}
```

```java
// File: code/lld/ch11/state/Subscription.java
package lld.ch11.state;

/** The CONTEXT: every public action is one line of delegation. No status switch anywhere. */
public final class Subscription {
    private SubscriptionState state = new Trialing();

    void setState(SubscriptionState next) {
        System.out.println("    " + state.name() + " -> " + next.name());
        state = next;
    }

    public String status() { return state.name(); }

    public void pay()         { state.pay(this); }
    public void missPayment() { state.missPayment(this); }
    public void cancel()      { state.cancel(this); }
}
```

```java
// File: code/lld/ch11/state/TrafficLight.java
package lld.ch11.state;

/**
 * State pattern the idiomatic-Java way: an enum whose constants override behaviour.
 * The whole machine is readable in one file.
 */
public enum TrafficLight {
    RED(30) {
        TrafficLight next() { return GREEN; }
        boolean pedestriansMayCross() { return true; }
    },
    GREEN(25) {
        TrafficLight next() { return YELLOW; }
    },
    YELLOW(5) {
        TrafficLight next() { return RED; }
    };

    private final int seconds;

    TrafficLight(int seconds) { this.seconds = seconds; }

    int seconds() { return seconds; }
    abstract TrafficLight next();
    boolean pedestriansMayCross() { return false; }    // default for most states
}
```

```java
// File: code/lld/ch11/state/VendingState.java
package lld.ch11.state;

/** Vending machine states. Default methods = "refuse", so each state overrides only what it allows. */
interface VendingState {
    String name();

    default void insertCoin(VendingMachine m, int cents) {
        System.out.println("  [" + name() + "] coin rejected, returned " + cents);
    }

    default void select(VendingMachine m, String code) {
        System.out.println("  [" + name() + "] selection ignored");
    }

    default void cancel(VendingMachine m) {
        System.out.println("  [" + name() + "] nothing to cancel");
    }
}
```

```java
// File: code/lld/ch11/state/Idle.java
package lld.ch11.state;

final class Idle implements VendingState {
    public String name() { return "idle"; }

    @Override
    public void insertCoin(VendingMachine m, int cents) {
        m.addBalance(cents);
        m.setState(new HasMoney());
    }
}
```

```java
// File: code/lld/ch11/state/HasMoney.java
package lld.ch11.state;

final class HasMoney implements VendingState {
    public String name() { return "has_money"; }

    @Override
    public void insertCoin(VendingMachine m, int cents) { m.addBalance(cents); }

    @Override
    public void select(VendingMachine m, String code) {
        if (!m.inStock(code)) { System.out.println("  [has_money] " + code + " is empty, choose another"); return;
}
        int price = m.priceOf(code);
        if (m.balance() < price) {
            System.out.println("  [has_money] " + code + " costs " + price + ", balance " + m.balance());
            return;
        }
        m.dispense(code);                                  // business action lives in the context
        m.returnChange();
        m.setState(m.anythingInStock() ? new Idle() : new SoldOut());
    }

    @Override
    public void cancel(VendingMachine m) {
        m.returnChange();
        m.setState(new Idle());
    }
}
```

```java
// File: code/lld/ch11/state/SoldOut.java
package lld.ch11.state;

final class SoldOut implements VendingState {
    public String name() { return "sold_out"; }        // every action uses the refusing defaults
}
```

```java
// File: code/lld/ch11/state/VendingMachine.java
package lld.ch11.state;

import java.util.LinkedHashMap;
import java.util.Map;

/** CONTEXT: owns inventory and money; states rule on legality and pick the next state. */
final class VendingMachine {
    private record Slot(String product, int priceCents, int count) {}

    private final Map<String, Slot> slots = new LinkedHashMap<>();
    private VendingState state = new Idle();
    private int balance = 0;

    void load(String code, String product, int price, int count) { slots.put(code, new Slot(product, price,
count)); }

    // actions: delegate to the current state
    void insertCoin(int cents) { System.out.println("insert " + cents); state.insertCoin(this, cents); }
    void select(String code)   { System.out.println("select " + code); state.select(this, code); }
    void cancel()              { System.out.println("cancel"); state.cancel(this); }

    // helpers the states call
    void setState(VendingState next) {
        System.out.println("    " + state.name() + " -> " + next.name());
        state = next;
    }
    void addBalance(int cents) { balance += cents; System.out.println("  balance " + balance); }
    int balance() { return balance; }
    boolean inStock(String code) { return slots.containsKey(code) && slots.get(code).count() > 0; }
    boolean anythingInStock() { return slots.values().stream().anyMatch(s -> s.count() > 0); }
    int priceOf(String code) { return slots.get(code).priceCents(); }

    void dispense(String code) {
        Slot s = slots.get(code);
        slots.put(code, new Slot(s.product(), s.priceCents(), s.count() - 1));
        balance -= s.priceCents();
        System.out.println("  >> dispensed " + s.product());
    }

    void returnChange() {
        if (balance > 0) System.out.println("  >> change returned " + balance);
        balance = 0;
    }
}
```

```java
// File: code/lld/ch11/state/Main.java
package lld.ch11.state;

public class Main {
    public static void main(String[] args) {
        System.out.println("=== 1. Subscription lifecycle (class per state) ===");
        Subscription sub = new Subscription();
        sub.pay();           // trialing -> active
        sub.missPayment();   // active -> past_due
        sub.pay();           // past_due -> active
        sub.cancel();        // active -> cancelled
        sub.pay();           // rejected, stays cancelled
        System.out.println("  final status: " + sub.status());

        System.out.println("\n=== 2. Traffic light (enum-based state machine) ===");
        TrafficLight light = TrafficLight.RED;
        for (int i = 0; i < 4; i++) {
            System.out.printf("  %-6s for %2ds, pedestrians may cross: %s%n",
                light, light.seconds(), light.pedestriansMayCross());
            light = light.next();
        }

        System.out.println("\n=== 3. Vending machine ===");
        VendingMachine vm = new VendingMachine();
        vm.load("A1", "cola", 150, 1);
        vm.load("B2", "chips", 100, 0);
        vm.select("A1");        // idle: ignored
        vm.insertCoin(100);     // idle -> has_money
        vm.select("A1");        // not enough
        vm.select("B2");        // empty slot
        vm.insertCoin(100);
        vm.select("A1");        // dispense, change 50, -> sold_out (nothing left)
        vm.insertCoin(25);      // sold_out: rejected
    }
}
```

Output:

```
=== 1. Subscription lifecycle (class per state) ===
  [trialing] first payment taken
    trialing -> active
  [active] payment failed, grace period started
    active -> past_due
  [past_due] arrears paid
    past_due -> active
    active -> cancelled
  [cancelled] refused: no payments after cancellation
  final status: cancelled

=== 2. Traffic light (enum-based state machine) ===
  RED    for 30s, pedestrians may cross: true
  GREEN  for 25s, pedestrians may cross: false
  YELLOW for  5s, pedestrians may cross: false
  RED    for 30s, pedestrians may cross: true

=== 3. Vending machine ===
select A1
  [idle] selection ignored
insert 100
  balance 100
    idle -> has_money
select A1
  [has_money] A1 costs 150, balance 100
select B2
  [has_money] B2 is empty, choose another
insert 100
  balance 200
select A1
  >> dispensed cola
  >> change returned 50
    has_money -> sold_out
insert 25
  [sold_out] coin rejected, returned 25
```

The final subscription line shows the payoff: an **illegal action** is refused the same way every time, by code in a single file.

State vs Strategy (and Bridge) — same diagram, different reasons

These patterns draw **the same class diagram** (an object keeps a reference to an interface and forwards work to it). It is one of the most common interview questions, and the diagram cannot answer it:

	State	Strategy	Bridge
Who chooses the object	The **states**, which replace themselves via the context	The **caller**, from outside	Chosen once at construction, usually by configuration
How often it changes	Repeatedly — that is the point	Set once, sometimes per call	Effectively never after wiring
Do the alternatives reference one another?	**Yes** (`Trialing` builds an `Active`)	**No** — never	No
What varies	The object's current *condition*, and therefore its allowed actions	*How* one job gets done	A whole dimension of the design
Why it exists	To model a lifecycle	To make one algorithm replaceable	To stop two class hierarchies multiplying

The reliable test: do the alternatives name each other? If yes, it is a State machine. If no, it is Strategy (or Bridge — then ask how often the choice changes).

Two more things State gets confused with:

Looks like	The actual difference
An enum plus one `switch`	Frequently the better answer, and easy to defend in an interview. Class-per-state starts to win only once the same status switch is repeated in three or more methods.
A state-machine library (Spring Statemachine, XState)	The same idea expressed as data (states, events, guards, actions) rather than classes. Once a machine grows past roughly a dozen states, the declarative form is easier to read and to draw.

Trade-offs

Pros	Cons
Everything about one state sits in a single file.	One class per state; small classes multiply.
The repeated conditional disappears; no branch can be missed.	The transitions live in several files, so no single place shows the whole machine.
Illegal actions are rejected consistently.	Each state class must implement all actions, even if only to say no.
A new state = a new class; the compiler lists what it must implement.	Persisting needs a name↔class mapping — keep it in exactly one place.

When not to use it

- **Only two states and a handful of methods** — a boolean flag with an `if` reads better.
- **Behaviour doesn't change, only data does** — store the differing value in a field; a class per state adds nothing.
- **A big, formal machine** (more than about a dozen states with guards) — use a **transition table** (`Map<(state, event), handler>`) or a state-machine library (e.g. **Spring Statemachine**), where the diagram can be the source of truth.
- **Rule of thumb from the course:** the pattern pays off once **three or more methods repeat the same status switch**. Below that, an enum with a switch is a perfectly defensible answer.
- **A signal you have outgrown it:** you keep sketching the machine on paper just to follow your own code. At that point make the sketch (a transition table or state chart) the real source of truth, instead of classes that only approximate it.

Common mistakes

1. **Successors hard-coded everywhere.** Fine at 4 states, painful at 12. Past that, let the context or a transition table own the transitions.
2. **Business logic inside state classes.** A state's job is to rule on *legality* and pick the *successor*; charging cards and sending emails belong in the context or a service it calls. Otherwise the state classes become a dumping ground.
3. **Forgetting to make illegal actions explicit** (silently doing nothing).
4. **Storing state objects in the DB** — store a name/enum and map it back to a state in exactly one place.
5. **Sharing stateful state objects** between contexts. Stateless states (like ours) can be shared safely; stateful ones cannot.

State in other languages

- **Java:** an `enum` whose constants override behaviour (like `TrafficLight`) keeps the whole graph in one file. A `sealed` interface plus exhaustive pattern-matching `switch` gives compiler-checked coverage of every state.
- **Kotlin / Scala:** `sealed` hierarchies with exhaustive `when` / `match`.
- **Rust:** enums with data, matched exhaustively. With the **typestate** pattern each state is a separate *type*, so calling an action that is illegal in that state is a compile error.
- **Python:** a dict mapping `(state, action)` to a handler is a compact transition table that shows every transition in one place.
- **TypeScript:** a **discriminated union** (a set of object types that each carry a fixed tag field saying which kind they are) plus a `switch` over its tag field, which the compiler can check for missing cases.

Real-world examples

- **Order lifecycles** in food-delivery and e-commerce apps: placed → accepted → preparing → out for delivery → delivered (or cancelled); which actions are legal depends on the status (you can cancel while "placed" but usually not once "out for delivery").
- **Payment and subscription lifecycles** (Stripe subscription statuses such as `trialing`, `active`, `past_due`, `canceled`).
- **TCP connections** (TCP is the protocol under most internet traffic, giving ordered, reliable delivery; see System Design Fundamentals) — GoF's own example: `LISTEN`, `ESTABLISHED`, `CLOSED`, each responding differently to the same call.
- **Workflow/approval engines** (draft → in review → approved/rejected), **document editors' modes**, **game characters** (idle, running, jumping).
- **Lexers/parsers** (programs that split text into tokens, then build a structure from them), **vending machines, ATMs, elevators, traffic lights** — favourite **machine-coding** questions (an interview round where you write working code for a small system in an hour or two) (see the case-study chapters).
- **Libraries**: Spring Statemachine; in the JDK, `Thread.State` is an *enum of states* (the data), not the pattern itself.

In the interview

> **30-second answer:** "State swaps a status field, and the switch statements repeated around it, for one class per state. The context forwards each action to whichever state object it currently holds, and that object decides whether the action is legal and which state follows. Each state's rules sit together in one file, and an illegal action is refused the same way every time. It draws exactly like Strategy, but states name one another and move the machine forward on their own, while strategies are picked from outside and never reference each other. In Java, for small machines, I'd use an enum with per-constant behaviour or a sealed interface."

Follow-ups:

- *State vs Strategy?* Use the naming test and the "who chooses" test (table above).
- *Where should transitions live?* In the states for small machines; in the context or a transition table when the machine grows, so the whole graph is visible in one place.
- *How do you persist it?* Store the state's name (enum) in the DB (database); rebuild the state object through one factory/mapping.
- *How do you handle concurrency?* Two requests (e.g. "cancel" and "deliver") can **race** (run at the same moment and interfere, so the result depends on timing): guard transitions with a lock or, in a DB, an **optimistic** (no lock held; the write simply fails if someone changed the row first) `UPDATE ... WHERE status = 'PLACED'` and check the affected row count.
- *Design a vending machine.* States Idle, HasMoney, SoldOut (maybe Dispensing, Maintenance); context owns inventory and balance; states allow or refuse actions (as in our code).

Self-check

1. **Q:** Who changes the current state in the State pattern? **A:** The state objects (via the context's `setState`).
2. **Q:** What is the "naming test"? **A:** If the alternatives reference each other, it's State; if never, it's Strategy/Bridge.
3. **Q:** When is an `enum` better than class-per-state? **A:** When the machine is small; the whole machine is visible in one file.
4. **Q:** What belongs in the context, not the state? **A:** Business actions and data (dispensing, charging, inventory).
5. **Q:** What does a sealed state interface give you? **A:** The compiler knows every state, so `switch`es over states can be checked for exhaustiveness.

TL;DR

A class for each state; the context forwards every action; each state picks what follows it. Same diagram as Strategy, but states **know each other**. Use enums for small machines, tables/libraries for big ones.

11.3 Strategy

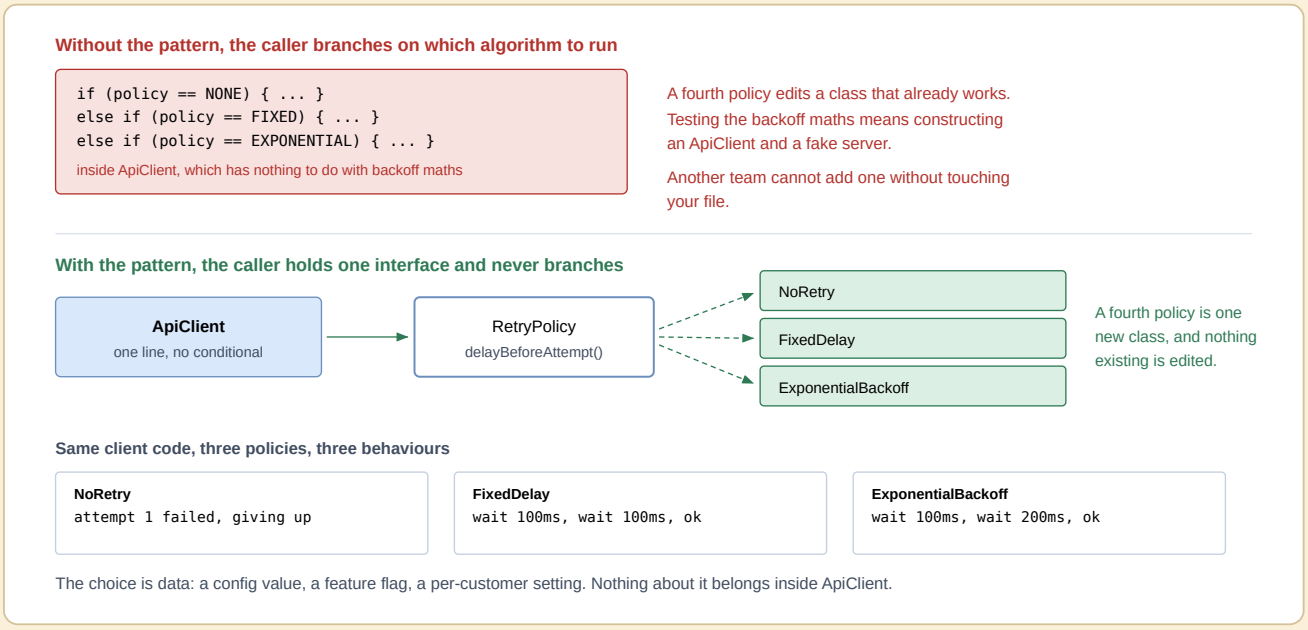


Figure — Top: ApiClient branches on which retry policy to use. Bottom: ApiClient holds one RetryPolicy interface and never branches (course diagram)

What it is

Strategy (GoF intent, paraphrased): group related algorithms into a **family**, wrap each one in its own class behind a **common interface**, and make them interchangeable, so the algorithm can change without touching the code that calls it; the choice can be made at run time. The object using it (the **context**) does not branch on which algorithm it has.

GoF participants (and who plays them in our code):

Participant	Role	In `lld.ch11.strategy`
Strategy	Interface shared by all the algorithms; the context calls only this	`RetryPolicy` (also `Comparator` in part 2)
ConcreteStrategy	One implementation per algorithm	`FixedDelay`, `ExponentialBackoff`, the `RetryPolicy.none()` lambda (the course diagram names it `NoRetry`)
Context	Is configured with a strategy object and delegates to it; may pass it the data it needs	`ApiClient`

Everyday analogy: getting to the airport. Car, train or taxi — same goal, different algorithm. You pick based on time, money and weather; the trip itself ("get to the airport") doesn't change.

The problem it solves

Retrying a failed request can mean: no retry, a fixed delay, or **exponential backoff** (doubling the wait after each failure — e.g. 100 ms, 200 ms, 400 ms). Written directly, the branch sits inside `ApiClient`:

```
if (policy == NONE)             { /* give up */ }
else if (policy == FIXED)       { /* wait 100ms, try again */ }
else if (policy == EXPONENTIAL) { /* double the wait after each failure */ }
```

`ApiClient` now contains backoff arithmetic that has nothing to do with calling an API. A fourth policy means editing a working class; you cannot test the backoff maths without building a client and faking a server; and a different team has to edit your class just to contribute a policy.

Strategy gives every algorithm a class of its own. `ApiClient` asks its `RetryPolicy` "how long before the next attempt?" and **never checks what kind of policy it holds**. The choice is made **outside** the client — from

configuration, a **feature toggle** (a setting that switches behaviour on or off without redeploying), or a customer-specific setting.

How it works

1. Define a **strategy interface** — small, ideally one question (`delayBeforeAttempt(attempt)`).
2. Write one **concrete strategy** per algorithm; each holds only its own parameters.
3. The **context** receives a strategy (constructor, setter or method parameter) and calls it.
4. A **factory, configuration or DI container** (a library that creates objects and hands them their dependencies — see §11.7.2) decides which strategy to use — not every call site.

Structure (UML)

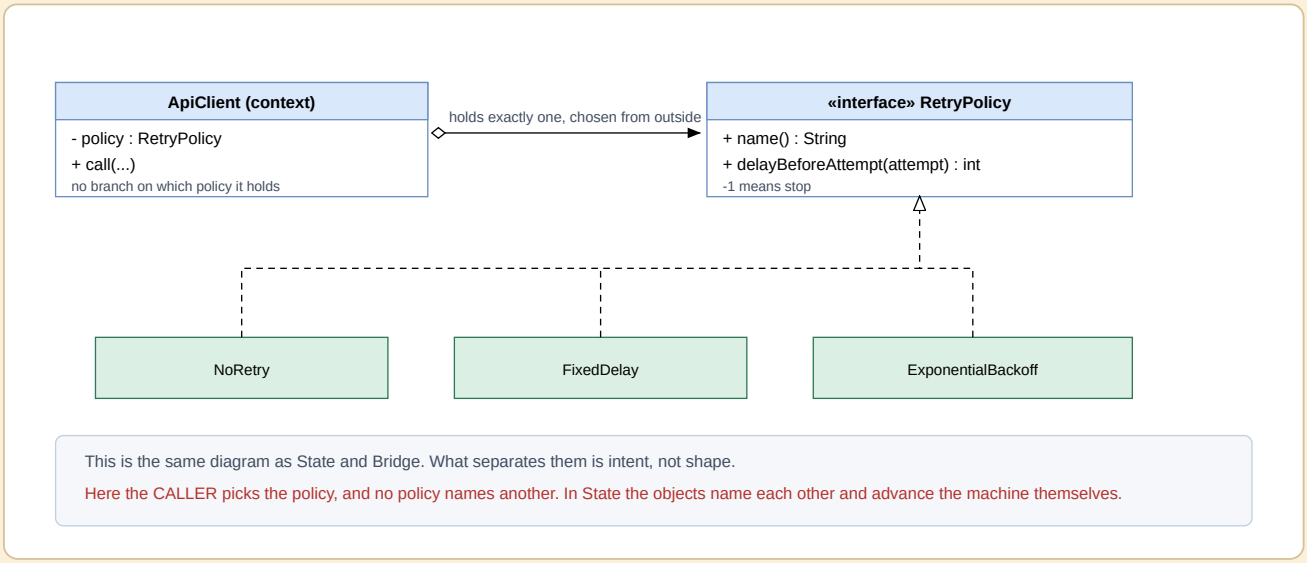

Figure — Class diagram: ApiClient holds a RetryPolicy; NoRetry, FixedDelay and ExponentialBackoff implement it (course diagram)

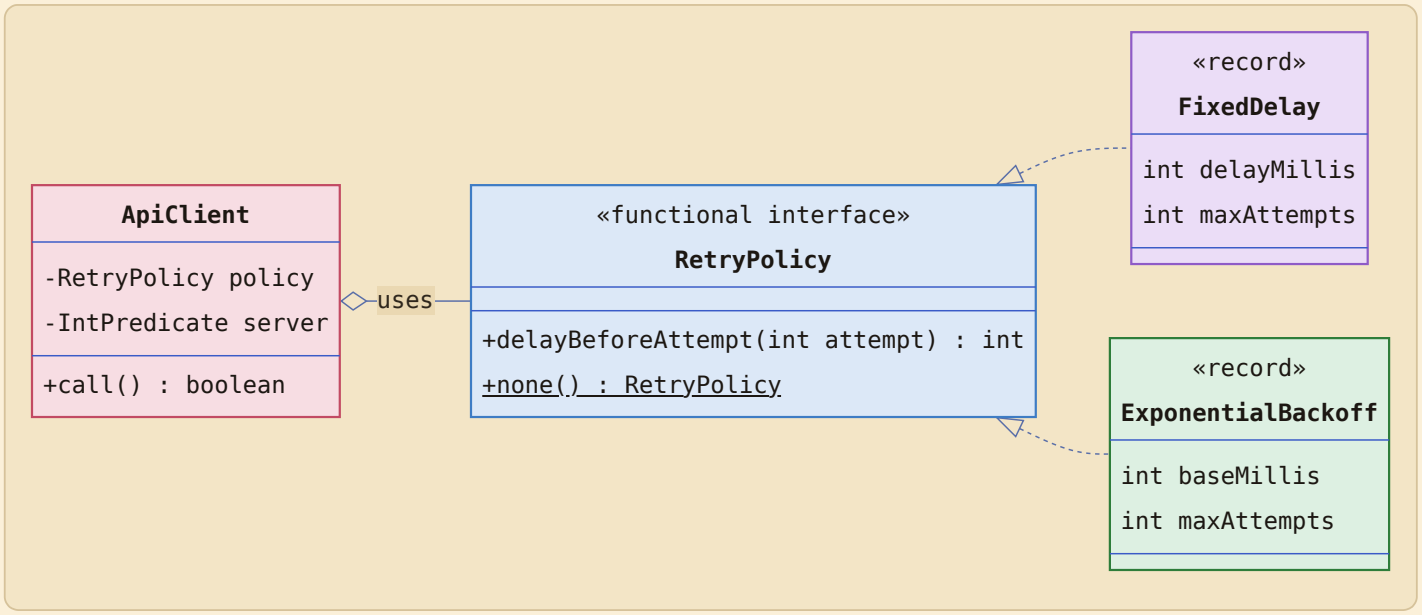
In the diagram above, **no strategy references another** — `ExponentialBackoff` has never heard of `FixedDelay`. That absence is how you tell Strategy from State.

Our Java design:



Java example

`lld.ch11.strategy`:

1. **Retry policies.** `RetryPolicy` has one abstract method, so `RetryPolicy.none()` is just a **lambda**. Strategies with configuration (`FixedDelay`, `ExponentialBackoff`) are **records**. `ApiClient.call()` is identical for all runs; only the injected policy differs. (Delays are printed, not slept, to keep the demo fast.)

2. `Comparator` — the JDK's everyday strategy. `List.sort(comparator)` keeps the sorting algorithm fixed and lets you plug in the comparison. `Comparator.comparing(...).reversed().thenComparing(...)` composes strategies.
3. **Strategy registry.** A `Map<String, LongUnaryOperator>` of lambdas picked by a configuration key — short and readable when each strategy is one line.

```java
// File: code/lld/ch11/strategy/RetryPolicy.java
package lld.ch11.strategy;

/**
 * STRATEGY interface: one small question. Returns the delay in ms before the given
 * attempt (attempt >= 2), or STOP. One abstract method, so a lambda can be a policy.
 */
@FunctionalInterface
public interface RetryPolicy {
    int STOP = -1;

    int delayBeforeAttempt(int attempt);

    static RetryPolicy none() { return attempt -> STOP; }
}
```

```java
// File: code/lld/ch11/strategy/FixedDelay.java
package lld.ch11.strategy;

/** Strategies with configuration earn a real type (a record here). */
public record FixedDelay(int delayMillis, int maxAttempts) implements RetryPolicy {
    public int delayBeforeAttempt(int attempt) {
        return attempt > maxAttempts ? STOP : delayMillis;
    }
}
```

```java
// File: code/lld/ch11/strategy/ExponentialBackoff.java
package lld.ch11.strategy;

/** 100, 200, 400, ... ms. Knows nothing about FixedDelay: strategies never name each other. */
public record ExponentialBackoff(int baseMillis, int maxAttempts) implements RetryPolicy {
    public int delayBeforeAttempt(int attempt) {
        return attempt > maxAttempts ? STOP : baseMillis << (attempt - 2);
    }
}
```

```java
// File: code/lld/ch11/strategy/ApiClient.java
package lld.ch11.strategy;

import java.util.function.IntPredicate;

/** CONTEXT: holds a policy and never asks WHICH policy it has. */
public final class ApiClient {
    private final RetryPolicy policy;
    private final IntPredicate server;     // fake server: attempt number -> success?

    public ApiClient(RetryPolicy policy, IntPredicate server) {
        this.policy = policy;
        this.server = server;
    }

    public boolean call() {
        for (int attempt = 1; ; attempt++) {
            if (server.test(attempt)) {
                System.out.println("  attempt " + attempt + ": ok");
                return true;
            }
            int delay = policy.delayBeforeAttempt(attempt + 1);
            if (delay == RetryPolicy.STOP) {
                System.out.println("  attempt " + attempt + ": failed, giving up");
                return false;
            }
            System.out.println("  attempt " + attempt + ": failed, waiting " + delay + "ms");  // simulated, no
sleep
        }
    }
}
```

```java
// File: code/lld/ch11/strategy/Main.java
package lld.ch11.strategy;

import java.math.BigDecimal;
import java.math.RoundingMode;
import java.util.ArrayList;
import java.util.Comparator;
import java.util.List;
import java.util.Map;
import java.util.function.IntPredicate;
import java.util.function.UnaryOperator;

public class Main {
    record Product(String name, long priceCents, double rating) {}

    public static void main(String[] args) {
        System.out.println("=== 1. Retry policies: same ApiClient code, three strategies ===");
        IntPredicate succeedsOnThirdTry = attempt -> attempt >= 3;
        List<Map.Entry<String, RetryPolicy>> policies = List.of(
            Map.entry("none (a lambda)", RetryPolicy.none()),
            Map.entry("FixedDelay(100, 4)", new FixedDelay(100, 4)),
            Map.entry("ExponentialBackoff(100, 4)", new ExponentialBackoff(100, 4)));
        for (Map.Entry<String, RetryPolicy> e : policies) {
            System.out.println(e.getKey() + ":");
            new ApiClient(e.getValue(), succeedsOnThirdTry).call();
        }
        System.out.println("ExponentialBackoff(100, 4) against a server that is always down:");
        new ApiClient(new ExponentialBackoff(100, 4), attempt -> false).call();

        System.out.println("\n=== 2. Comparator: the JDK's everyday strategy ===");
        List<Product> products = new ArrayList<>(List.of(
            new Product("mouse", 1_999, 4.5), new Product("keyboard", 4_999, 4.7),
            new Product("cable", 499, 4.5), new Product("monitor", 19_999, 4.2)));
        Comparator<Product> byPrice = Comparator.comparingLong(Product::priceCents);
        Comparator<Product> byRatingThenName =
            Comparator.comparingDouble(Product::rating).reversed().thenComparing(Product::name);
        products.sort(byPrice);
        System.out.println("  by price:          " + products.stream().map(Product::name).toList());
        products.sort(byRatingThenName);
        System.out.println("  by rating, name:   " + products.stream().map(Product::name).toList());

        System.out.println("\n=== 3. Strategy registry: lambdas chosen by configuration ===");
        Map<String, UnaryOperator<BigDecimal>> pricing = Map.of(
            "regular", p -> p,
            "member", p -> p.multiply(new BigDecimal("0.90")).setScale(2, RoundingMode.HALF_EVEN),  // 10% off
            "flash-sale", p -> p.subtract(new BigDecimal("20.00")).max(BigDecimal.ZERO));          // flat 20.00
off
        BigDecimal keyboardPrice = new BigDecimal("49.99");
        for (String tier : List.of("regular", "member", "flash-sale")) {   // e.g. read from config
            UnaryOperator<BigDecimal> strategy = pricing.get(tier);
            System.out.printf("  %-10s keyboard costs %s%n", tier, strategy.apply(keyboardPrice));
        }
    }
}
```

Extending it is cheap: a policy that adds random **jitter** to the delay, or one that honours a server's `Retry-After` header (an **HTTP** response header in which the server says how long to wait; HTTP is the request/response protocol of the web), is one more class (or lambda) plus one line where the policy is chosen. `ApiClient` does not change.

Output:

```
=== 1. Retry policies: same ApiClient code, three strategies ===
none (a lambda):
  attempt 1: failed, giving up
FixedDelay(100, 4):
  attempt 1: failed, waiting 100ms
  attempt 2: failed, waiting 100ms
  attempt 3: ok
ExponentialBackoff(100, 4):
  attempt 1: failed, waiting 100ms
  attempt 2: failed, waiting 200ms
  attempt 3: ok
ExponentialBackoff(100, 4) against a server that is always down:
  attempt 1: failed, waiting 100ms
  attempt 2: failed, waiting 200ms
  attempt 3: failed, waiting 400ms
  attempt 4: failed, giving up

=== 2. Comparator: the JDK's everyday strategy ===
  by price:          [cable, mouse, keyboard, monitor]
  by rating, name:   [keyboard, cable, mouse, monitor]

=== 3. Strategy registry: lambdas chosen by configuration ===
  regular    keyboard costs 49.99
  member     keyboard costs 44.99
  flash-sale keyboard costs 29.99
```

Lambdas as strategies

Of all the patterns, Strategy is the one a plain function replaces most often, and recognising that is part of understanding it. Since Java 8, any interface with a **single abstract method** (a *functional interface*) can be implemented by a lambda or method reference. So many strategies need **no class at all**: `Comparator<T>`, `Function`, `Predicate`, `Supplier`, or your own `RetryPolicy`. Keep a named class (or record) when the strategy has **configuration or state** (`FixedDelay(100, 4)`), needs a **name for logging**, or must be **discovered/registered** (e.g. Spring beans — objects the Spring container creates and manages — or `ServiceLoader`, the JDK's built-in plug-in discovery mechanism).

Other languages: Python passes a function (or `functools.partial` to bind its parameters), and a dict from name to function is a one-line registry. JavaScript/TypeScript pass a function argument, or an object whose properties are functions. Kotlin/Scala take a function-typed constructor parameter, often with a default. Go uses a one-method interface (satisfied implicitly) or a `func` field.

The registry in part 3 of the demo uses `BigDecimal` for prices. Money in domain code should never be `double`, because binary floating point cannot represent most cent values exactly.

Trade-offs

Pros	Cons
New variants without editing working code — even by other teams (Open/Closed).	One class per variant (unless lambdas), one more file to open.
Each algorithm is testable alone.	Someone must choose — ideally a factory or container, not every caller.
Behaviour is configurable at run time (flag, setting, header).	The interface must fit every variant, including future ones.
The context keeps to its real responsibility (no backoff maths in an API client).	Tempting to overuse: three strategies of one line each means three classes for three lines.

When not to use it

- **Just two branches, with no third in sight** — an `if` reads better. Introduce the pattern when a third variant actually shows up.
- **One-line branches** — a `Map` from key to lambda is shorter than a class for each.

- **Variants need different inputs** (one needs the customer, another the warehouse) — the shared interface is forced; rethink the split.
- **The choice is fixed for the life of the program** — decide it when wiring the program (or use Bridge) instead.

Common mistakes

1. **Making every call site choose** — the branch moved instead of disappearing. Let a factory/config/DI container choose.
2. **A bloated interface** with parameters half the implementations ignore — a sign the variants do different jobs and should not share one abstraction.
3. **Strategies that know about each other** — then you have State.
4. **Stateful strategies shared between threads** — keep strategies immutable (records help).

Real-world examples

- `Comparator` with `Collections.sort` / `List.sort` / `TreeMap` — the textbook example.
- `ThreadPoolExecutor`**'s** (the JDK's configurable thread pool) `RejectedExecutionHandler`: `AbortPolicy`, `CallerRunsPolicy`, `DiscardPolicy`, `DiscardOldestPolicy` — pick what happens when the pool is full.
- **Spring Security** `PasswordEncoder` (`BCryptPasswordEncoder`, `Argon2PasswordEncoder`, ...) chosen by configuration, so upgrading the **hash** (a one-way scrambling of the password, so the stored value can't be turned back into it) does not touch login code.
- **Resilience4j** (a Java fault-tolerance library) retry `IntervalFunction` (fixed, exponential, randomized backoff) and **Polly** in .NET — exactly this lesson's retry policies.
- **AWT/Swing** `LayoutManager` (`FlowLayout`, `BorderLayout`, `GridLayout`) — a container delegates layout to a strategy.
- **Payment method at checkout** (card, UPI [India's instant bank-to-bank payment system], wallet, cash on delivery), **pricing/discount rules by customer tier**, **route planning modes** (drive, walk, transit) in map apps, **compression/serialization formats** (serialization = turning objects into bytes or text for storage or sending) chosen by a content-type header.

In the interview

> **30-second answer:** "Strategy gives every variant of one job its own class behind a common interface, and something outside — usually a factory or configuration — picks the variant at run time. The context stops branching: my API client asks its retry policy how long to wait and never asks which policy it is. Each algorithm is testable alone and new ones don't touch working code. In Java a lambda is often enough, like a `Comparator`; I keep a class when the strategy has configuration. It shares its diagram with State, but strategies never reference each other."

Follow-ups:

- *Strategy vs State?* Strategies are picked from outside and don't know each other; states pick their successors.
- *Strategy vs Template Method?* Template Method swaps **one step** of an algorithm whose order is fixed, through **inheritance** (fixed once the object is created, by the subclass you instantiate). Strategy swaps **the complete algorithm** through **composition** (holding another object in a field and delegating to it) (chosen at run time, can vary several axes at once). Prefer Strategy when both fit.
- *Strategy vs Bridge?* Same diagram again. Bridge splits off a dimension of the design that is fixed when the program is assembled; Strategy is a decision that is meant to change, even from one call to the next. If a reviewer cannot tell which you meant, little is lost — the code is identical. What matters more is not using any of the three for two branches that will never become three.
- *Strategy vs Command?* Strategy is *how* to do something; Command is *what* to do, with its arguments, kept to run later or undo.
- *How is the strategy selected?* Config + factory (`Map<String, Strategy>`), DI container (Spring can inject a `Map<String, PaymentStrategy>` of all beans), or per-request (header, customer tier).
- *Relation to Open/Closed and DIP?* The context depends on an abstraction (DIP) and new strategies extend behaviour without modifying it (OCP).

Self-check

1. **Q:** Who chooses the strategy? **A:** Someone outside the context — ideally a factory/config/DI container.

2. **Q:** Why can `RetryPolicy.none()` be a lambda? **A:** `RetryPolicy` is a functional interface (one abstract method).
3. **Q:** Name two JDK strategies. **A:** `Comparator`; `RejectedExecutionHandler` (also `LayoutManager`).
4. **Q:** When is a map of lambdas better than classes? **A:** When each strategy is one line and needs no configuration.
5. **Q:** How do you tell Strategy from State in code? **A:** Strategies never reference each other.

TL;DR

Interchangeable algorithms behind one interface, chosen from outside. The context stops branching. Use lambdas for one-liners, records/classes when configured. Don't confuse with State (states know each other) or Template Method (inheritance, one step).

11.4 Template Method

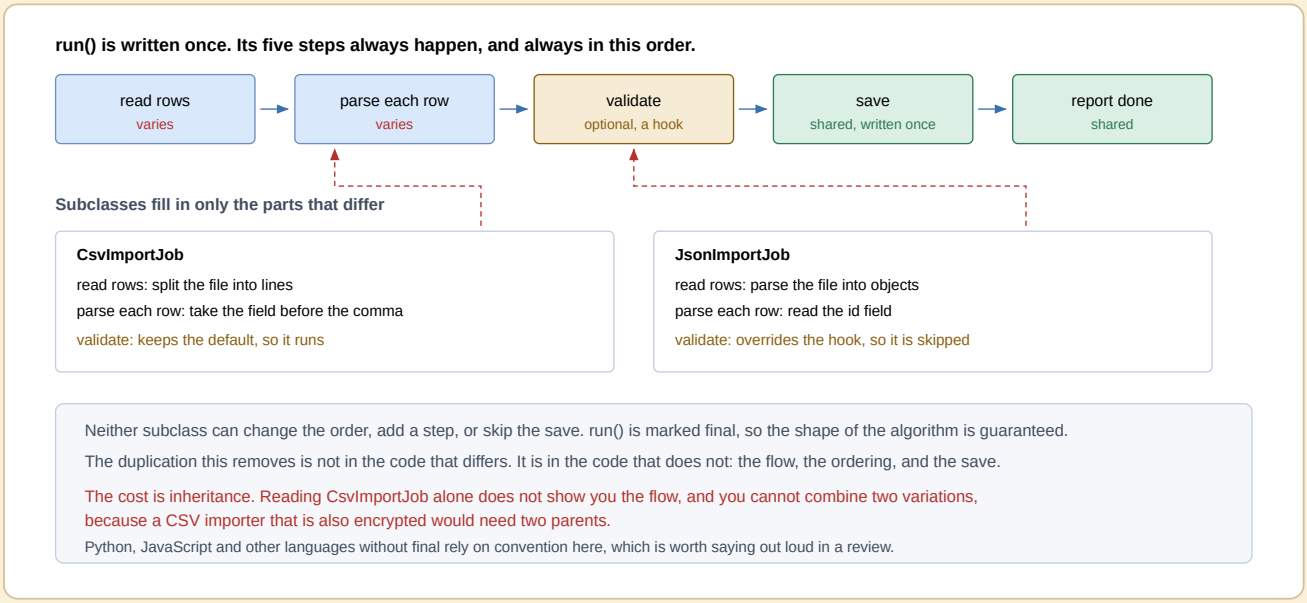


Figure — run() always performs five steps in the same order; subclasses fill in only reading and parsing, and one optional hook (course diagram)

What it is

Template Method (GoF intent, paraphrased): put the **outline of an algorithm** into one base-class operation (the *template method*) and leave certain steps for **subclasses** to fill in; subclasses may redefine those steps but cannot alter the overall sequence.

GoF participants (and who plays them in our code):

Participant	Role	In `lld.ch11.templatemethod`
AbstractClass	Declares the primitive steps (abstract or with a default) and implements the template method that calls them in order	`ImportJob`, `CaffeineBeverage`
ConcreteClass	Implements the primitive steps that differ for its variant	`CsvImportJob`, `JsonImportJob`, `Tea`, `Coffee`

Everyday analogy: a recipe card with blanks. "Boil water → brew ___ → pour into cup → add ___ (if wanted)." Tea and coffee fill the blanks differently; the order never changes.

The problem it solves

A data import job always: reads rows, parses each one, validates, saves, reports "done". Only reading and parsing differ between CSV and JSON. Written as separate classes, the **shared flow** (order, validation, saving, reporting) is copied into each. When saving must also write an audit record, three files change — and the missed one is the bug.

Template Method writes the flow once, in a method subclasses **cannot override** (`final`). The varying steps become methods the subclasses must supply.

How it works

1. Write the **template method** in an abstract class and mark it `final` so the order is guaranteed.
2. Inside it, call the steps in order. Steps come in three kinds:
   - **Required (abstract) steps** — every subclass must implement them; the compiler enforces it.
   - **Hooks** — steps with a **default** (often empty or `true`) that a subclass *may* override, e.g. `shouldValidate()`.
   - **Shared steps** — `private`, written once, not changeable.
3. Each subclass implements only what differs.

The Hollywood Principle — "Don't call us, we'll call you." (*Head First Design Patterns*.) The base class (high-level component) decides **when** the subclass's methods run; the subclass never calls the base class's flow itself. That **inversion of control** is the backbone of most **frameworks** (libraries that own the program's flow and call your code at set points): **the framework runs the sequence, and your class supplies only your own pieces.**

Structure (UML)

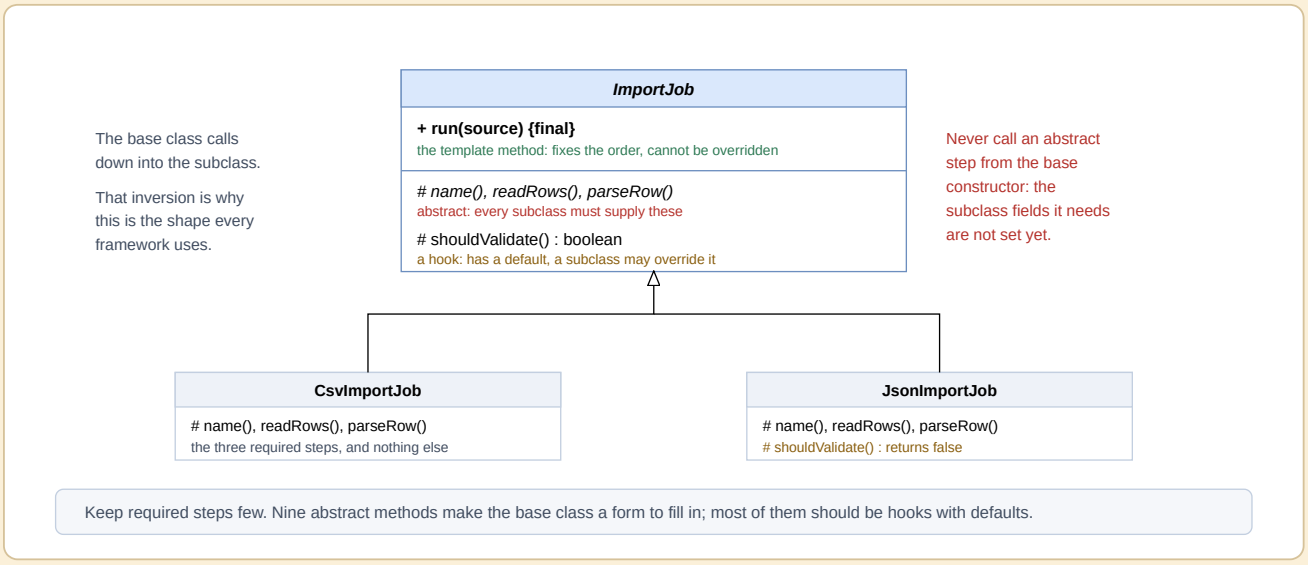

Figure — Class diagram: ImportJob with final run(), abstract steps name/readRows/parseRow, hook shouldValidate and private save; CsvImportJob and JsonImportJob override only what differs (course diagram)

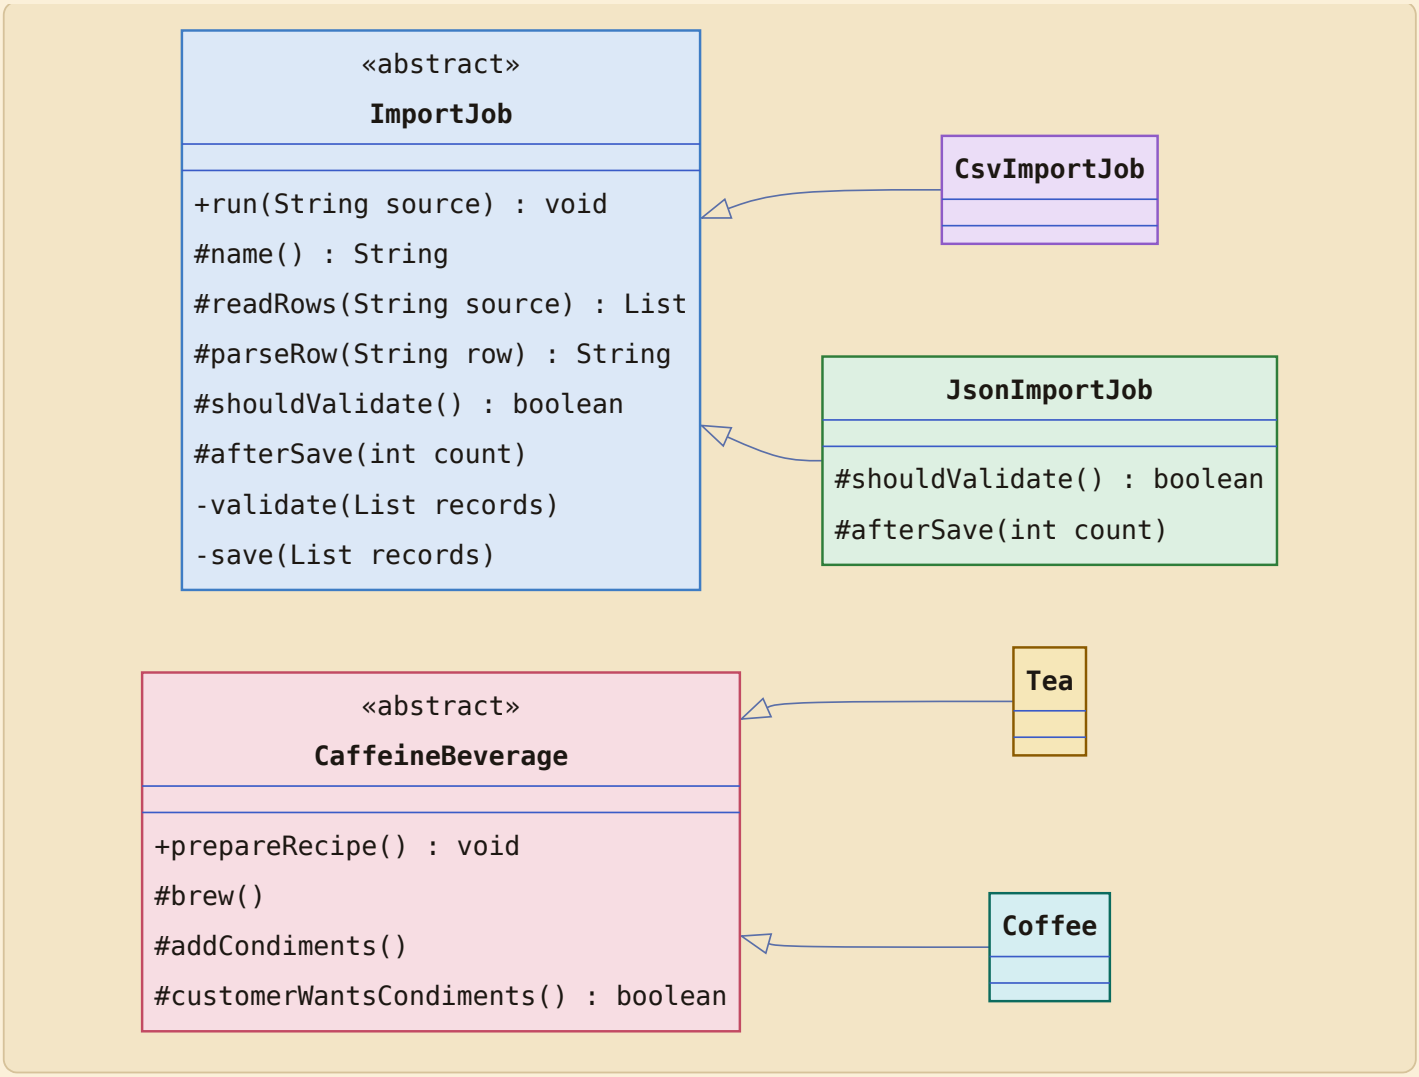
In the diagram above, the subclasses are tiny — but `CsvImportJob` on its own does not reveal the sequence it will follow at run time; only the parent shows that. That is the trade-off.

Our Java design:



`run()` and `prepareRecipe()` are `final` in the code (Mermaid has no marker for `final`).

Java example

`lld.ch11.templatemethod`:

1. **Import jobs.** `ImportJob.run` is `final`. `name`, `readRows`, `parseRow` are **abstract** (required). `shouldValidate` and `afterSave` are **hooks** (defaults `true` and "do nothing"). `validate` and `save` are **private** shared steps. `JsonImportJob` overrides both hooks.
2. **Beverages** (the *Head First* example). `customerWantsCondiments()` is a hook: `Coffee(black = true)` turns off the optional step.

```java
// File: code/lld/ch11/templatemethod/ImportJob.java
package lld.ch11.templatemethod;

import java.util.ArrayList;
import java.util.List;

/** ABSTRACT CLASS holding the TEMPLATE METHOD. */
public abstract class ImportJob {

    /** Template method. Marked final: subclasses cannot change the order, drop a step or insert one. */
    public final void run(String source) {
        System.out.println("Running the " + name() + " import:");
        List<String> rows = readRows(source);                // required step
        List<String> records = new ArrayList<>();
        for (String row : rows) records.add(parseRow(row));   // required step
        System.out.println("  parsed " + records.size() + " records: " + records);
        if (shouldValidate()) {                              // hook
            validate(records);
        } else {
            System.out.println("  skipping validation, source is validated upstream");
        }
        save(records);                                       // shared, fixed
        afterSave(records.size());                           // hook with an empty default
        System.out.println("  done");
    }

    // Required steps: the compiler forces every subclass to supply them.
    protected abstract String name();
    protected abstract List<String> readRows(String source);
    protected abstract String parseRow(String row);

    // Hooks: sensible defaults, overriding is optional.
    protected boolean shouldValidate() { return true; }
    protected void afterSave(int count) { }

    // Shared steps: written once, private, cannot be changed by subclasses.
    private void validate(List<String> records) {
        long blank = records.stream().filter(String::isBlank).count();
        System.out.println("  validated " + records.size() + " records, " + blank + " blank");
    }

    private void save(List<String> records) {
        System.out.println("  saved " + records.size() + " records (+ audit entry)");
    }
}
```

```java
// File: code/lld/ch11/templatemethod/CsvImportJob.java
package lld.ch11.templatemethod;

import java.util.Arrays;
import java.util.List;

/** Supplies only what differs for CSV. */
public final class CsvImportJob extends ImportJob {
    @Override protected String name() { return "CSV"; }

    @Override
    protected List<String> readRows(String source) {
        return Arrays.stream(source.split("\n")).skip(1).toList();   // skip the header line
    }

    @Override
    protected String parseRow(String row) { return row.split(",")[0].trim(); }
}
```

```java
// File: code/lld/ch11/templatemethod/JsonImportJob.java
package lld.ch11.templatemethod;

import java.util.List;
import java.util.regex.Matcher;
import java.util.regex.Pattern;

/** Supplies what differs for JSON, and overrides two hooks. (Toy parsing: no JSON library.) */
public final class JsonImportJob extends ImportJob {
    private static final Pattern OBJECT = Pattern.compile("\\{[^}]*}");
    private static final Pattern ID = Pattern.compile("\"id\"\\s*:\\s*\"([^\"]*)\"");

    @Override protected String name() { return "JSON"; }

    @Override
    protected List<String> readRows(String source) {
        return OBJECT.matcher(source).results().map(m -> m.group()).toList();
    }

    @Override
    protected String parseRow(String row) {
        Matcher m = ID.matcher(row);
        return m.find() ? m.group(1) : "";
    }

    @Override protected boolean shouldValidate() { return false; }

    @Override
    protected void afterSave(int count) { System.out.println("  [hook] notified upstream: " + count + " ids
consumed"); }
}
```

```java
// File: code/lld/ch11/templatemethod/CaffeineBeverage.java
package lld.ch11.templatemethod;

/** The classic beverage example: same recipe skeleton, two steps and one hook vary. */
public abstract class CaffeineBeverage {
    public final void prepareRecipe() {          // template method
        boilWater();
        brew();
        pourInCup();
        if (customerWantsCondiments()) addCondiments();
    }

    protected abstract void brew();
    protected abstract void addCondiments();

    /** Hook: "Don't call us, we'll call you" - the base class decides WHEN this runs. */
    protected boolean customerWantsCondiments() { return true; }

    private void boilWater() { System.out.println("  boiling water"); }
    private void pourInCup() { System.out.println("  pouring into cup"); }
}
```

```java
// File: code/lld/ch11/templatemethod/Tea.java
package lld.ch11.templatemethod;

public final class Tea extends CaffeineBeverage {
    @Override protected void brew() { System.out.println("  steeping the tea"); }
    @Override protected void addCondiments() { System.out.println("  adding lemon"); }
}
```

```java
// File: code/lld/ch11/templatemethod/Coffee.java
package lld.ch11.templatemethod;

public final class Coffee extends CaffeineBeverage {
    private final boolean black;

    public Coffee(boolean black) { this.black = black; }

    @Override protected void brew() { System.out.println("  dripping coffee through filter"); }
    @Override protected void addCondiments() { System.out.println("  adding sugar and milk"); }
    @Override protected boolean customerWantsCondiments() { return !black; }
}
```

```java
// File: code/lld/ch11/templatemethod/Main.java
package lld.ch11.templatemethod;

public class Main {
    public static void main(String[] args) {
        System.out.println("=== 1. Import jobs ===");
        new CsvImportJob().run("id,name\nu1, Asha\nu2, Ben\nu3, Chen");
        new JsonImportJob().run("[{\"id\":\"p9\",\"qty\":1},{\"id\":\"p7\",\"qty\":4}]");

        System.out.println("\n=== 2. Beverages (hook controls an optional step) ===");
        System.out.println("tea:");
        new Tea().prepareRecipe();
        System.out.println("black coffee:");
        new Coffee(true).prepareRecipe();
    }
}
```

Output:

```
=== 1. Import jobs ===
Running the CSV import:
  parsed 3 records: [u1, u2, u3]
  validated 3 records, 0 blank
  saved 3 records (+ audit entry)
  done
Running the JSON import:
  parsed 2 records: [p9, p7]
  skipping validation, source is validated upstream
  saved 2 records (+ audit entry)
  [hook] notified upstream: 2 ids consumed
  done

=== 2. Beverages (hook controls an optional step) ===
tea:
  boiling water
  steeping the tea
  pouring into cup
  adding lemon
black coffee:
  boiling water
  dripping coffee through filter
  pouring into cup
```

Template Method vs Strategy

	Template Method	Strategy
What varies	**One step**; the surrounding algorithm is fixed	**The entire** algorithm
Mechanism	**Inheritance** — subclass supplies the step	**Composition** — caller passes an object in
When chosen	When the object is created (by which subclass you instantiate); fixed after that	Run time, can change per call
How many axes can vary	One (a class has one parent)	Several (hold several strategies)
What one file shows	Just the varying pieces	The complete algorithm

Strategy is usually the more flexible choice. Template Method pays off when **most of the flow is common**, only small pieces differ, and you want the compiler to **enforce the sequence**. They combine well: the base class fixes the sequence, but each step is a **strategy object** (or lambda) handed in rather than inherited — so the order is still enforced, yet you are not limited to one parent. Spring's `JdbcTemplate` (a helper around **JDBC**, Java's standard API for talking to SQL databases) works like this: it owns the fixed flow (get connection, create statement, execute, handle exceptions, close resources) and takes your varying part as a **callback** (a function or object you hand over so the other code can call you back — here `RowMapper`, `PreparedStatementSetter`) rather than a subclass.

Trade-offs

Pros	Cons
The shared flow is written once (DRY: Don't Repeat Yourself).	No single file tells the whole story: the parent holds the order, the child holds the pieces.
The order is guaranteed (`final`).	One parent only: two independent variations can't combine.
New variants are small.	Parent and children are bound tightly; altering one step's signature forces every subclass to change.
Abstract steps make the compiler report anything a subclass has not supplied.	Base classes tend to swell until they demand many abstract methods and nobody wants to extend them.

When not to use it

- **The flow is two lines** — nothing to protect.
- **Variants must combine** (an encrypted CSV import would need both an "encrypted" and a "CSV" parent) — use composition.
- **Behaviour must change after creation** — use Strategy.
- **Subclasses override every step** — the flow was never really shared.

Common mistakes

1. **Too many required steps.** A subclass should only have to write two or three methods; give the rest a default and make them hooks.
2. **Calling an overridable step from the base constructor.** The base constructor runs **before** the subclass's fields are initialised, so in Java the step sees `null`/`0`/`false`. (In C++ it is different but still wrong: during the base constructor a virtual call is dispatched to the base version, never the subclass override.) Call steps from the template method, never the constructor.
3. **Leaving out `final` on the template method** — then a subclass can reorder or skip steps; nothing is enforced any more and the pattern becomes a mere agreement. (C++: make it non-virtual. Python and JavaScript cannot enforce it at all, so it must be documented and checked in review.)
4. **Making steps `public`** — callers could run step 3 without steps 1 and 2. Keep them `protected` (or move reusable steps into a separate object).
5. **Violating Liskov** (the Liskov Substitution Principle: a subclass must work anywhere its parent is expected) in overrides (a hook that throws, or a step that changes the contract).

Template Method in other languages

- **Java:** `final` template method, `protected abstract` required steps, `protected` hooks with a body. An interface `default` method can also act as a template method, but an interface has no instance state and a default method cannot be `final`, so any implementer may override it.
- **Python:** `abc.ABC` with `@abstractmethod`. There is no `final` enforced at run time, so a comment (or `typing.final` for type checkers) is the only guard; a leading underscore marks internal steps.
- **TypeScript:** `abstract` classes give the compile-time check; plain JavaScript uses base methods that throw.
- **C++:** a non-virtual public template method calling `protected virtual` steps — the **non-virtual interface (NVI)** idiom.
- **Go and Rust** have no inheritance: a function taking an interface/trait with the varying steps — i.e. the Strategy shape.

Real-world examples

- **`java.io.InputStream`**: `read(byte[], int, int)` is implemented in terms of the abstract `read()`; subclasses supply the single-byte read (and override the bulk method for speed).
- **`java.util.AbstractList`**: implement `get(int)` and `size()`, and you inherit `iterator()`, `indexOf`, `contains`, `equals`, `hashCode`...
- **`HttpServlet.service()`** (Jakarta/Java Servlet) dispatches to `doGet`/`doPost`/`doPut`... by HTTP method; you override the ones you support, and the ones you do not override reject the request (405 Method Not Allowed on HTTP/1.1).
- **`AbstractQueuedSynchronizer`** (AQS — the JDK's internal building block for locks; behind `ReentrantLock`, `Semaphore`, `CountDownLatch`): `acquire()` is the template; subclasses implement `tryAcquire`/`tryRelease`.
- **Test frameworks**: JUnit (`@BeforeEach`/`@AfterEach`) and pytest (fixtures, `setup_method`/`teardown_method`) own the set-up → test → tear-down flow; your hooks never call each other. **Mobile lifecycles**: Android `Activity` (`onCreate`, `onStart`, `onResume`...) and iOS `UIViewController` (`viewDidLoad`, `viewWillAppear`...). **Maven/Gradle** (Java build tools) build lifecycles (fixed phases, you plug in goals/tasks).
- **Sorting with a comparison**: `Arrays.sort` owns the algorithm and needs just one step from you, the comparison. Old designs had the elements supply it (`Comparable.compareTo`); modern APIs pass it in as a `Comparator` — the Strategy form of the same idea.
- **Spring `JdbcTemplate`, `RestTemplate`, `TransactionTemplate`** — "template + callback" variants of the same idea.

In the interview

> **30-second answer:** "Template Method puts an algorithm's outline in a single final method of a base class, and subclasses supply only the steps that differ. Steps a subclass must write are abstract; steps it may change are hooks with a default body; steps nobody should change are private. It's the Hollywood principle — the base class calls the subclass, not the other way round — which is how frameworks like servlets, JUnit and Android lifecycles work. It varies one step via inheritance; if I need run-time choice or several axes I prefer Strategy, or pass the steps in as callbacks like JdbcTemplate does."

Follow-ups:

- *What is a hook?* A step with a default implementation that subclasses may override (e.g. `shouldValidate()`), giving optional control points.
- *What is the Hollywood Principle?* "Don't call us, we'll call you": high-level components call low-level ones at the right time; low-level components plug in but don't call up. It prevents "dependency rot" (dependencies tangled in every direction, so nothing can change safely).
- *Why `final`?* It is the guarantee: without it a subclass could reorder or drop steps, and the pattern would be only a gentleman's agreement.
- *Template Method vs Factory Method?* A factory method is often one step of a template method — the step whose job is to create an object (GoF notes that template methods frequently call factory methods). The course frames it more strongly — a factory method is a special template-method step whose subclass-supplied job is creation, while most template steps create nothing. Take that as "a factory method usually lives inside a template method", not as a strict rule: a factory method can also be called directly by clients.
- *Template Method vs Decorator?* A decorator wraps an existing object at run time, and several can be layered; a template-method subclass is decided when the object is built and cannot be layered.

- *Template Method vs Builder?* Both impose an order, but a Builder director invokes the steps on a **different** object (the builder it holds), while a template method invokes them on **its own** instance via inheritance.
- *Constructor trap?* Never call overridable methods from a constructor; the subclass isn't initialised yet.

Self-check

1. **Q:** Which method is `final`? **A:** The template method (`run`, `prepareRecipe`).
2. **Q:** Difference between an abstract step and a hook? **A:** Abstract steps must be implemented; hooks have defaults and are optional.
3. **Q:** Name two JDK template methods. **A:** `InputStream.read(byte[],int,int)`, `AbstractList`'s methods built on `get`/`size`, AQS `acquire`.
4. **Q:** Why is `JdbcTemplate` more flexible than a classic template method? **A:** It takes the varying step as a callback object (composition), not a subclass.
5. **Q:** What goes wrong if the base constructor calls an abstract step? **A:** The subclass fields aren't initialised yet.

TL;DR

Fixed order in a `final` base method; subclasses fill steps; hooks are optional steps. Hollywood principle. Inheritance-based and compile-time — prefer Strategy/callbacks when you need flexibility.

11.5 Visitor

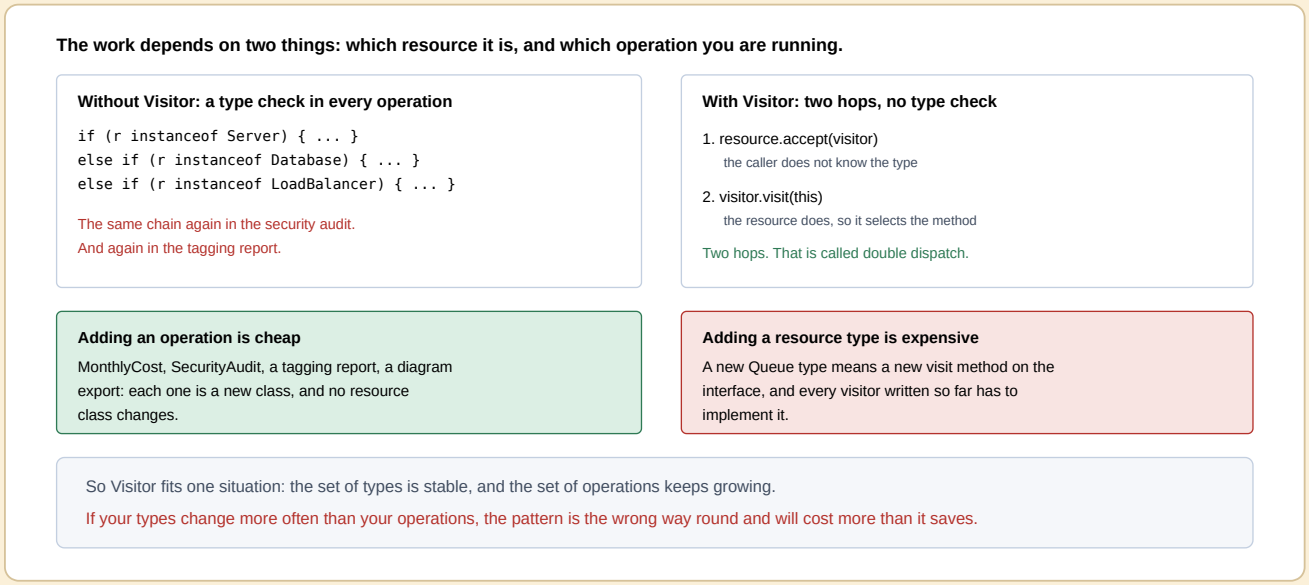


Figure — Without Visitor, every operation repeats an instanceof chain; with Visitor, two calls (accept, then visit) select the right code with no type check (course diagram)

What it is

Visitor lets you **introduce new operations** over a group of classes **while leaving those classes untouched**. Every operation lives in its own **visitor** class, which has a separate method for each kind of element; each element keeps one tiny method, `accept(visitor)`, whose body is `visitor.visit(this)`.

GoF intent (paraphrased): represent an operation to be performed on the elements of an object structure as a separate object, so you can define a new operation without changing the classes of the elements it works on.

GoF participants (and who plays them in our code):

Participant	Role	In `lld.ch11.visitor`
Visitor	Declares one `visit` operation per ConcreteElement class	`PlanVisitor`
ConcreteVisitor	Implements every `visit`; one class per operation, often accumulating a result	`MonthlyCost`, `SecurityAudit`
Element	Declares `accept(visitor)`	`Resource`
ConcreteElement	Implements `accept` as `visitor.visit(this)`	`Server`, `Database`, `LoadBalancer`, `ResourceGroup`
ObjectStructure	Holds the elements and lets a visitor reach each of them (a list or a Composite)	the `ResourceGroup` tree built in `Main`

Everyday analogy: a tax inspector visiting different businesses. The businesses don't each contain tax rules; the inspector brings them and applies the right rule for "restaurant", "shop" or "factory". Next year, a fire-safety inspector visits the same businesses with different rules — the businesses don't change.

The problem it solves

Picture an infrastructure plan made of just three resource kinds — server, database, load balancer. That **list of kinds is stable**. The **operations never stop arriving**: a monthly bill, a security review, a tag report, a diagram export, and so on.

- Put each operation **inside** the resource classes → `Server` holds pricing, security, tagging and drawing code; unrelated teams edit the same file.
- Put it **outside** with type checks → an `instanceof` chain in every operation. Add a resource kind, and you must find every chain; the compiler won't tell you which one you missed.

Visitor gives each operation its own class, and uses **double dispatch** to pick the right method without any type check.

How it works — double dispatch

Java chooses **which override** (a subclass's replacement of an inherited method) of a method runs based on the **run-time type of the receiver** — the object before the dot (single dispatch) — but chooses **which overload** (one of several same-named methods with different parameter types: `visit(Server)` vs `visit(Database)`) at **compile time**, from the **static type** (the type the compiler sees in the declaration) of the argument. If you hold a `Resource r`, `visitor.visit(r)` cannot compile to the right overload — the compiler only knows "Resource".

Visitor makes **two calls**:

1. `resource.accept(visitor)` — dispatch #1 on the **resource's** run-time type: `Server.accept` runs.
2. Inside `Server.accept`, `visitor.visit(this)` — here `this` has static type `Server`, so the compiler picks `visit(Server)`; dispatch #2 then happens on the **visitor's** run-time type (`MonthlyCost` or `SecurityAudit`).

The method that finally runs depends on **two** types — element and visitor. That is **double dispatch**.

Structure (UML)

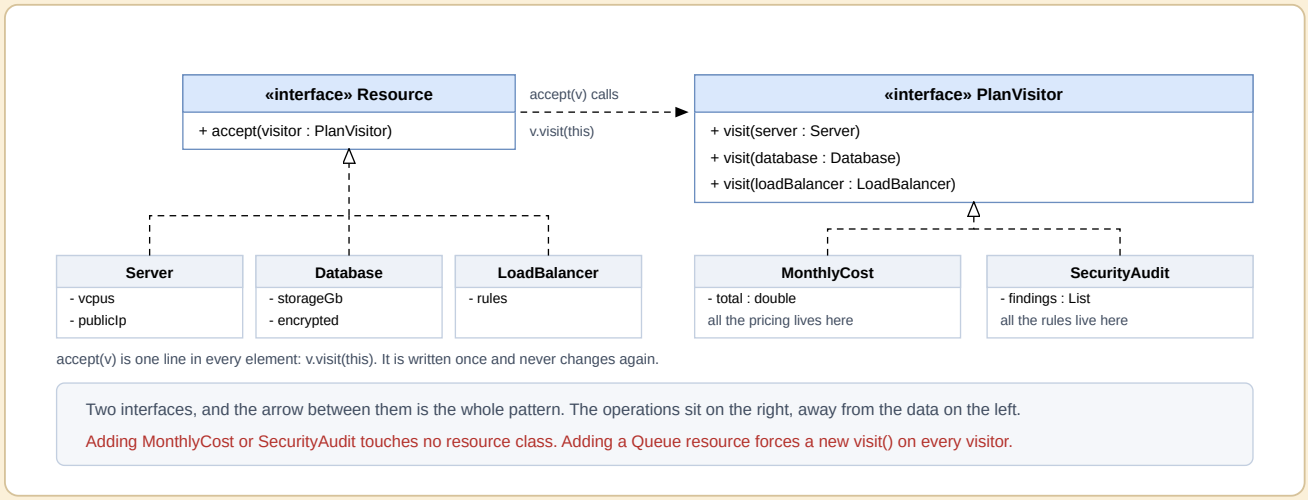

Figure — Class diagram: Resource with accept; Server, Database, LoadBalancer implement it; PlanVisitor has one visit per resource type; MonthlyCost and SecurityAudit implement it (course diagram; it shows `total : double`, our Java code uses `BigDecimal` for money)

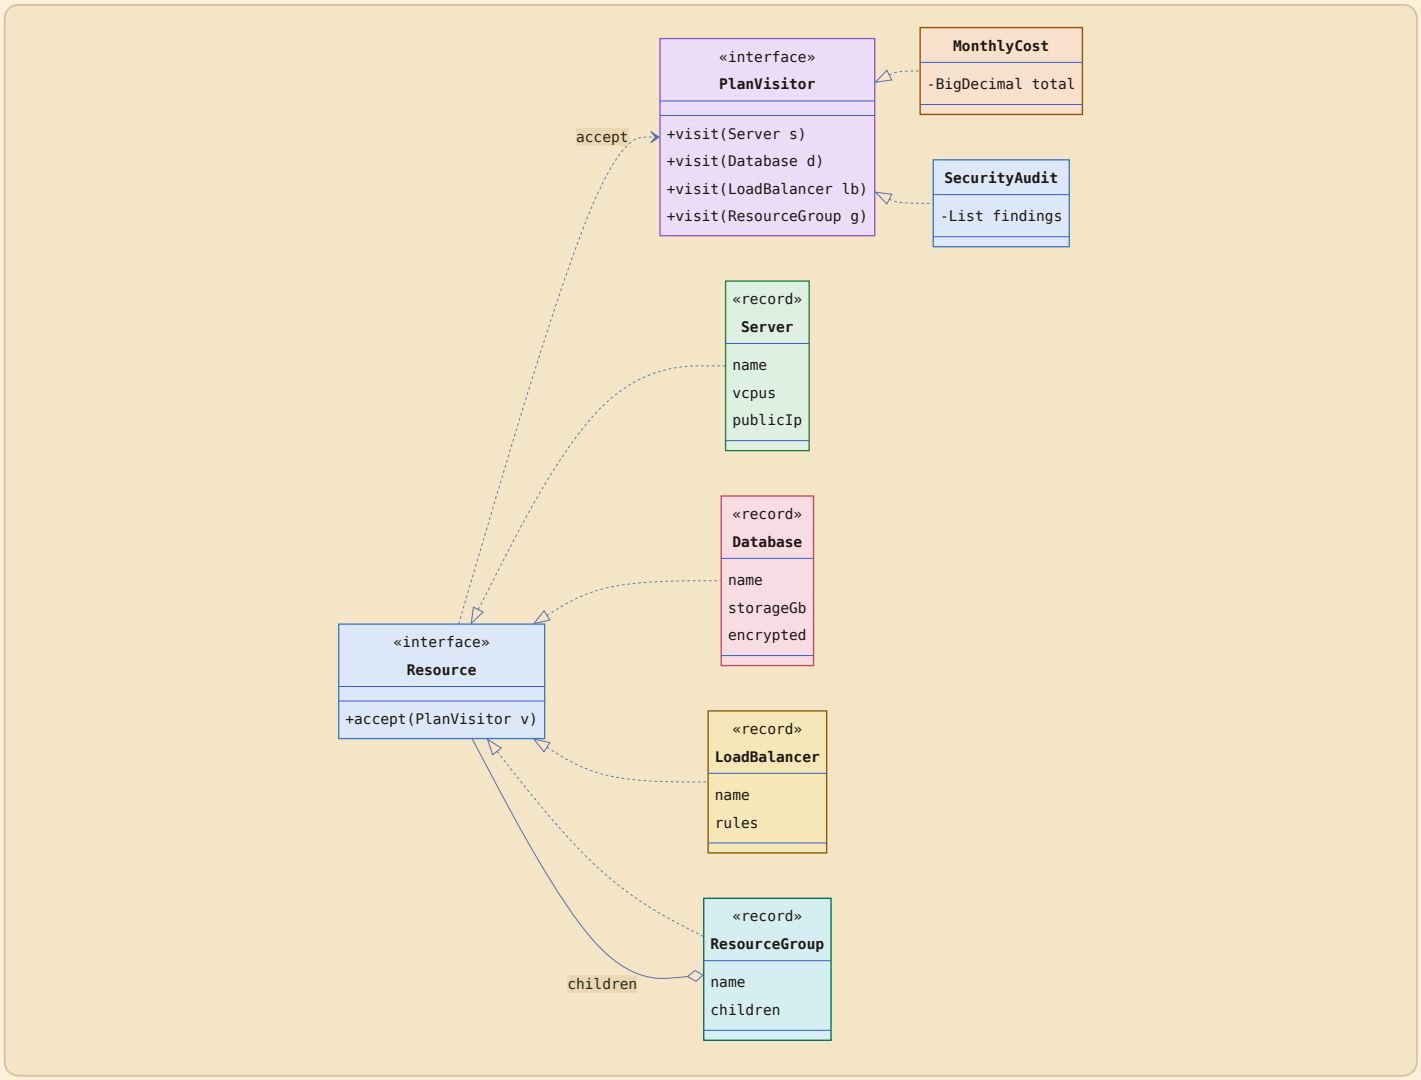
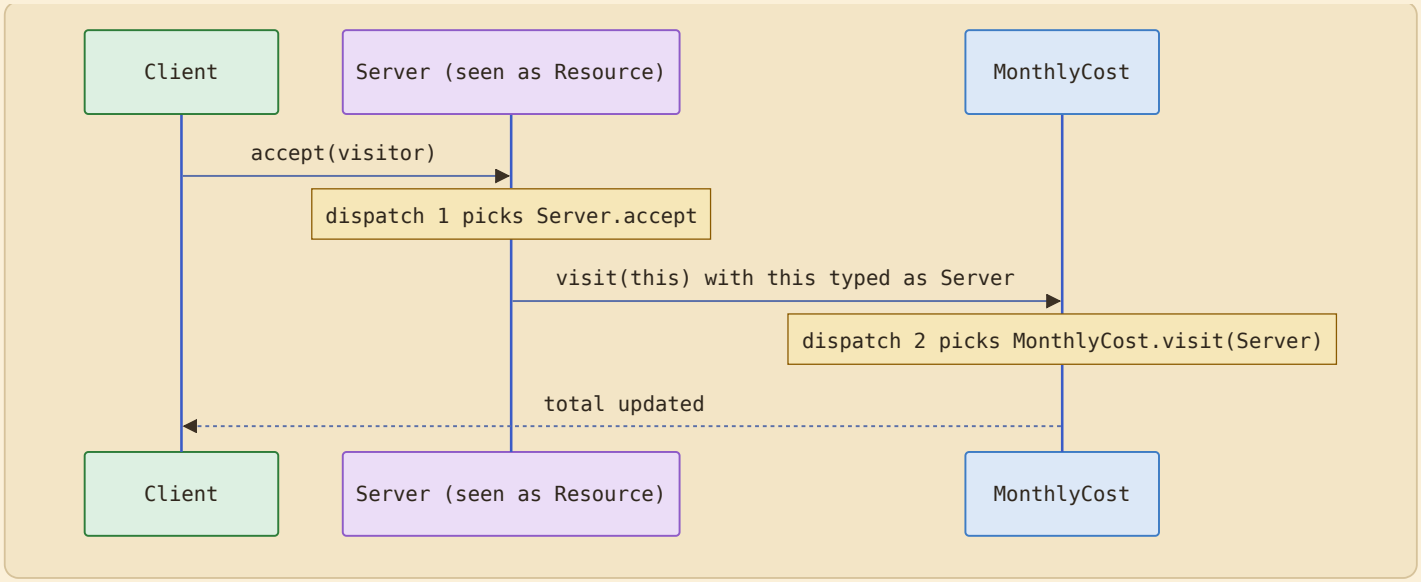
In the diagram above the two sets of arrows point in opposite directions: each element depends on the visitor interface (its `accept` has a visitor parameter), while each visitor depends on every element type (it has a `visit` for each). That second arrow is why **adding an element type is expensive**.

Our Java design (with a Composite group element):





Java example

`lld.ch11.visitor` has **both** styles over the same domain:

1. **Classic Visitor.** Elements are **records** (so visitors read data through accessors, not public fields). `ResourceGroup` is a **Composite** (the pattern in which a group and a single item share one interface, so a tree can be handled uniformly): its `accept` visits itself and then its children. (A tree is optional: Visitor only requires a stable set of element types, and it works just as well over a flat list. Composite is simply the most common route into Visitor.) Prices are `BigDecimal`, never `double`. `MonthlyCost` and `SecurityAudit` each keep all their rules in one file; neither touches a resource class. A new visitor instance is used per run because they accumulate results.
2. **Java 21 alternative — sealed interface + pattern matching** (`ModernPlan`). `Infra` is `sealed ... permits Vm, Sql, Lb`. `monthlyCost` is a `switch` with **no** **`default`** — the compiler checks it is **exhaustive** (covers every possible case), so adding a new permitted record breaks every switch that forgot it (the same safety net Visitor gave you). `audit` uses **record patterns** (deconstruction, `case Sql(String n, int gb, boolean enc)`) and **guards** (`when !enc`). A guarded case never counts toward exhaustiveness (the compiler cannot know the guard is sometimes true), which is why `audit` also needs the three unguarded `case Vm vm` / `Sql db` / `Lb lb` lines.

```java
// File: code/lld/ch11/visitor/Resource.java
package lld.ch11.visitor;

/** ELEMENT interface: the only thing every resource must provide is accept. */
public interface Resource {
    void accept(PlanVisitor visitor);
}
```

```java
// File: code/lld/ch11/visitor/PlanVisitor.java
package lld.ch11.visitor;

/** VISITOR interface: one visit per element type. This list is what makes new types expensive. */
public interface PlanVisitor {
    void visit(Server server);
    void visit(Database database);
    void visit(LoadBalancer loadBalancer);
    void visit(ResourceGroup group);
}
```

```java
// File: code/lld/ch11/visitor/Server.java
package lld.ch11.visitor;

/** Records expose data through accessors, so visitors need no public fields. */
public record Server(String name, int vcpus, boolean publicIp) implements Resource {
    public void accept(PlanVisitor v) { v.visit(this); }   // 2nd dispatch: overload picked by static type Server
}
```

```java
// File: code/lld/ch11/visitor/Database.java
package lld.ch11.visitor;

public record Database(String name, int storageGb, boolean encrypted) implements Resource {
    public void accept(PlanVisitor v) { v.visit(this); }
}
```

```java
// File: code/lld/ch11/visitor/LoadBalancer.java
package lld.ch11.visitor;

public record LoadBalancer(String name, int rules) implements Resource {
    public void accept(PlanVisitor v) { v.visit(this); }
}
```

```java
// File: code/lld/ch11/visitor/ResourceGroup.java
package lld.ch11.visitor;

import java.util.List;

/** COMPOSITE element: visits itself, then passes the visitor to every child. */
public record ResourceGroup(String name, List<Resource> children) implements Resource {
    public void accept(PlanVisitor v) {
        v.visit(this);
        for (Resource child : children) child.accept(v);
    }
}
```

```java
// File: code/lld/ch11/visitor/MonthlyCost.java
package lld.ch11.visitor;

import java.math.BigDecimal;

/**
 * Operation 1: ALL pricing rules in one file. New instance per run (it accumulates).
 * Money is BigDecimal: exact decimal arithmetic, no binary rounding surprises.
 */
public final class MonthlyCost implements PlanVisitor {
    static final BigDecimal PER_VCPU = new BigDecimal("24.00");
    static final BigDecimal DB_BASE = new BigDecimal("40.00");
    static final BigDecimal PER_GB = new BigDecimal("0.25");
    static final BigDecimal LB_BASE = new BigDecimal("18.00");
    static final BigDecimal PER_RULE = new BigDecimal("1.50");

    private BigDecimal total = BigDecimal.ZERO;

    public BigDecimal total() { return total; }

    public void visit(Server s)        { total = total.add(PER_VCPU.multiply(BigDecimal.valueOf(s.vcpus()))); }
    public void visit(Database d)      { total =
total.add(DB_BASE.add(PER_GB.multiply(BigDecimal.valueOf(d.storageGb())))); }
    public void visit(LoadBalancer lb) { total =
total.add(LB_BASE.add(PER_RULE.multiply(BigDecimal.valueOf(lb.rules())))); }
    public void visit(ResourceGroup g) { /* groups are free */ }
}
```

```java
// File: code/lld/ch11/visitor/SecurityAudit.java
package lld.ch11.visitor;

import java.util.ArrayList;
import java.util.List;

/** Operation 2: added later without touching a single resource class. */
public final class SecurityAudit implements PlanVisitor {
    private final List<String> findings = new ArrayList<>();

    public List<String> findings() { return findings; }

    public void visit(Server s) {
        if (s.publicIp()) findings.add(s.name() + ": server has a public IP");
    }
    public void visit(Database d) {
        if (!d.encrypted()) findings.add(d.name() + ": storage not encrypted");
    }
    public void visit(LoadBalancer lb) {
        if (lb.rules() == 0) findings.add(lb.name() + ": load balancer has no rules");
    }
    public void visit(ResourceGroup g) {
        if (g.children().isEmpty()) findings.add(g.name() + ": empty group");
    }
}
```

```java
// File: code/lld/ch11/visitor/ModernPlan.java
package lld.ch11.visitor;

import java.math.BigDecimal;
import java.util.Optional;

/**
 * The Java 21 alternative: a SEALED hierarchy + pattern-matching switch.
 * No accept(), no visitor interface. The compiler still checks exhaustiveness:
 * add a new record to 'permits' and every switch without it stops compiling.
 */
public final class ModernPlan {
    private ModernPlan() {}

    public sealed interface Infra permits Vm, Sql, Lb {}
    public record Vm(String name, int vcpus, boolean publicIp) implements Infra {}
    public record Sql(String name, int storageGb, boolean encrypted) implements Infra {}
    public record Lb(String name, int rules) implements Infra {}

    /** Operation 1 as a plain function. No 'default' branch, on purpose. Same prices as MonthlyCost. */
    public static BigDecimal monthlyCost(Infra r) {
        return switch (r) {
            case Vm vm -> MonthlyCost.PER_VCPU.multiply(BigDecimal.valueOf(vm.vcpus()));
            case Sql db ->
MonthlyCost.DB_BASE.add(MonthlyCost.PER_GB.multiply(BigDecimal.valueOf(db.storageGb())));
            case Lb lb -> MonthlyCost.LB_BASE.add(MonthlyCost.PER_RULE.multiply(BigDecimal.valueOf(lb.rules())));
        };
    }

    /** Operation 2 with record deconstruction patterns and guards. */
    public static Optional<String> audit(Infra r) {
        return switch (r) {
            case Vm(String n, int cpus, boolean pub) when pub -> Optional.of(n + ": server has a public IP");
            case Sql(String n, int gb, boolean enc) when !enc -> Optional.of(n + ": storage not encrypted");
            case Lb(String n, int rules) when rules == 0 -> Optional.of(n + ": load balancer has no rules");
            case Vm vm -> Optional.empty();     // no finding
            case Sql db -> Optional.empty();
            case Lb lb -> Optional.empty();
        };
    }
}
```

```java
// File: code/lld/ch11/visitor/Main.java
package lld.ch11.visitor;

import java.math.BigDecimal;
import java.util.List;
import java.util.Optional;

public class Main {
    public static void main(String[] args) {
        System.out.println("=== 1. Classic Visitor (double dispatch) over a composite plan ===");
        Resource plan = new ResourceGroup("prod", List.of(
            new Server("web-1", 4, true),
            new Server("worker-1", 2, false),
            new Database("orders-db", 200, false),
            new LoadBalancer("edge-lb", 4),
            new ResourceGroup("staging", List.of())));

        MonthlyCost cost = new MonthlyCost();
        plan.accept(cost);
        System.out.println("  monthly cost: " + cost.total());

        SecurityAudit audit = new SecurityAudit();
        plan.accept(audit);
        audit.findings().forEach(f -> System.out.println("  finding: " + f));

        System.out.println("\n=== 2. Java 21: sealed interface + pattern matching switch ===");
        List<ModernPlan.Infra> infra = List.of(
            new ModernPlan.Vm("web-1", 4, true), new ModernPlan.Vm("worker-1", 2, false),
            new ModernPlan.Sql("orders-db", 200, false), new ModernPlan.Lb("edge-lb", 4));
        BigDecimal total = infra.stream().map(ModernPlan::monthlyCost).reduce(BigDecimal.ZERO, BigDecimal::add);
        System.out.println("  monthly cost: " + total);
        infra.stream().map(ModernPlan::audit).flatMap(Optional::stream)
             .forEach(f -> System.out.println("  finding: " + f));
    }
}
```

Output:

```
=== 1. Classic Visitor (double dispatch) over a composite plan ===
  monthly cost: 258.00
  finding: web-1: server has a public IP
  finding: orders-db: storage not encrypted
  finding: staging: empty group

=== 2. Java 21: sealed interface + pattern matching switch ===
  monthly cost: 258.00
  finding: web-1: server has a public IP
  finding: orders-db: storage not encrypted
```

Both styles give the same answer (cost 96.00 + 48.00 + 90.00 + 24.00 = 258.00; the empty `staging` group is free). The modern one needs no `accept`, no visitor interface, and each operation is just a function.

The one question that decides it: the expression problem

	Add a new operation	**Add a new type**
Methods on the classes (plain OO)	Edit every class	One new class
Visitor (or sealed + switch)	One new visitor/function	Edit the visitor interface **and every visitor** (compiler finds them)

So ask: **which changes more often here — the types or the operations?** Settled types + growing operations → Visitor (or sealed types with pattern matching). Growing types → put the operations on the classes. No ordinary OO design makes both cheap; this trade-off is called the **expression problem**.

Open/Closed trade-off: Visitor makes the element hierarchy **closed for modification but open for new operations** — at the price of being **closed to new element types** (each one forces edits to all visitors).

Sealed interfaces + pattern matching (Java 17/21) as the modern alternative: sealed classes arrived in Java 17 (JEP 409 — a JEP, JDK Enhancement Proposal, is the numbered design document for a Java feature); pattern matching for `switch` and record patterns were finalised in Java 21 (JEPs 441 and 440). Together they give the exhaustiveness check that was Visitor's main advantage, with far less code. The exact rules:

- A `switch` **expression** must always be exhaustive. A `switch` **statement** must be exhaustive too as soon as it uses patterns or `case null` (old-style statements over constants need not be).
- Over a `sealed` type, covering every permitted subtype with an **unguarded** pattern makes the switch exhaustive with no `default`. Guarded cases (`when ...`) do not count.
- Over a type that is **not** sealed, the compiler cannot know all subtypes, so you need a `default` (or a total pattern such as `case Infra i`) — and then the check is gone.
- If a new subtype appears at run time without recompiling the switch (separate compilation), the compiler-generated fallback throws `MatchException`.
- **Dominance:** cases are tried top to bottom, and a case that can never match because an earlier one already covers it is a compile error. That is why the guarded `case Vm(...) when pub` must come **before** the unguarded `case Vm vm`, never after.
- **`null`:** a pattern `switch` without a `case null` throws `NullPointerException` when the selector is `null`; `default` alone does not match `null`.

Write a classic Visitor when the element hierarchy **is not and cannot be sealed** — typically because the element classes **belong to another team or library** and you cannot edit them — but already exposes `accept` (typical of libraries such as ASM — a library for reading and rewriting Java **bytecode**, the compiled instructions the JVM (Java Virtual Machine) runs — or javac's tree API, which ship their own visitor interfaces), when you need a **walk with per-node callbacks** over a big tree, or when each operation should be a separately testable, injectable class.

Visitor outside Java. Kotlin: a sealed class with an exhaustive `when`. Python: `match` with class patterns, or `functools.singledispatch` (dispatch on the argument type with no `accept`). C++: `std::variant` + `std::visit` — the pattern as a library feature. Rust and Swift: enums with associated values plus `match`/`switch`, where a missing case is a build error. Languages without overloading (Python, JavaScript) name the methods `visitServer`, `visitDatabase`, ... instead of overloading `visit`.

Trade-offs

Pros	Cons
Adding an operation = writing one class; elements stay as they are.	Adding an element type forces a change in every existing visitor.
Related logic stays together (all pricing in one file).	Double dispatch is indirect; `accept` tells you nothing about what runs.
The compiler reports any element type a visitor has not handled.	Elements often must expose their data (weaker encapsulation).
Elements stay small: data + one-line `accept`.	Ceremony for small sets of types.

When not to use it

- **New types arrive often** — every one edits every visitor.
- **A tiny model** (say three element types and a single operation) — a type check or a plain method is simpler.
- **The operation concerns one type only** — it's a method.
- **Your language checks switch exhaustiveness** (Java 21 sealed types, Kotlin `when`, Rust `match`) — use that.

Common mistakes

1. Reaching for Visitor with two element types.
2. Making element fields **public** for visitors (use accessors/records).
3. **Reusing a stateful visitor** (like `MonthlyCost`) across runs without resetting — create a new one per run.
4. Adding a `default` branch to a sealed-type switch — it **turns off** the exhaustiveness check you wanted.

5. Forgetting that the composite's `accept` must forward to children (or deciding where traversal lives: element, visitor, or an Iterator).
6. **Writing a visitor where a sealed-type `switch` would do.** If your language checks exhaustiveness (Java 21, Kotlin, Rust, Swift), that gives the same safety with a fraction of the code.

Real-world examples

- **Compilers and linters** (tools that flag suspicious code): an **AST** (abstract syntax tree — the tree a compiler builds from source code) has a fixed set of node kinds and endless passes (type check, optimise, format, lint rules). The JDK's `com.sun.source.tree.TreeVisitor` (javac tree API) and `javax.lang.model.element.ElementVisitor` (annotation processing) are visitors; ANTLR (a parser generator) generates visitor classes for your grammar.
- **Bytecode libraries**: ASM's `ClassVisitor` / `MethodVisitor`.
- **`java.nio.file.FileVisitor`** with `Files.walkFileTree` — named after the pattern and often cited, but strictly it is a **tree-walk callback** interface (`preVisitDirectory`, `visitFile`, `visitFileFailed`, `postVisitDirectory`): there is no `accept` and no double dispatch over element classes. The *spirit* (operation kept outside the file-system objects) is Visitor's; the mechanism is closer to a Template Method walk calling your hooks.
- **Document models**: a **DOM** (Document Object Model — the tree of elements that makes up a web page or XML document) has a fixed set of node kinds and ever more operations — serialise to HTML/PDF, pull out the plain text, collect all links; **infrastructure tools** computing cost, policy and diagrams over resource plans (this lesson's example); **query planners** (the database component that decides how to run a SQL query: cost estimation, rewriting, EXPLAIN).

In the interview

> **30-second answer:** "Visitor pulls an operation out of the element classes and into a separate class that has a method for each element type. Each element has a one-line `accept` that calls `visitor.visit(this)`, which gives double dispatch: the method chosen depends on both the element type and the visitor type, so no `instanceof` chains. It makes adding operations cheap and adding types expensive — the expression problem — so it fits stable type sets like ASTs. In Java 21 I'd usually use a sealed interface with an exhaustive pattern-matching switch instead, which gives the same compiler check with much less code."

Follow-ups:

- *Explain double dispatch.* Java picks overloads at compile time from static types; `accept` runs on the element's run-time type, and inside it `this` has the concrete static type, so the right `visit` overload is chosen; then the visitor's run-time type picks the implementation.
- *Why not just overload `visit` and call `visitor.visit(resource)`?* With a `Resource` static type, the compiler can't choose `visit(Server)`; it needs `visit(Resource)`, which doesn't exist.
- *Visitor vs Iterator?* Iterator decides the route through the structure; Visitor decides the work done at each stop. Real code often combines them.
- *Visitor vs Strategy?* A strategy is a single algorithm that ignores element types; a visitor is a set of methods, one for each element type, and exists precisely to dispatch on type.
- *Visitor vs Composite?* Composite lets a client treat a whole tree and a single node alike; Visitor adds new operations over a stable set of types, whether or not they form a tree. The two frequently appear together.
- *Visitor vs Interpreter?* Interpreter keeps evaluation **in** each node class; Visitor moves it **out**. Many interpreters begin in the first style and switch to the second once another pass (type checking, pretty-printing) is needed.
- *How do you add a new element type?* Add it to the interface's `visit` list (or the `permits` clause) and fix every visitor/switch the compiler flags.

Self-check

1. **Q:** What is the body of every `accept` method? **A:** `visitor.visit(this)`.
2. **Q:** What change is cheap with Visitor, and what is expensive? **A:** New operations are cheap; new element types are expensive.
3. **Q:** What Java 21 features replace most visitors? **A:** Sealed interfaces + pattern-matching `switch` (with record patterns), checked for exhaustiveness.
4. **Q:** Why no `default` in `monthlyCost`'s switch? **A:** A `default` would hide missing cases; without it the compiler forces every permitted type to be handled.

5. **Q:** Where does the traversal live for a composite? **A:** Here, in the composite's `accept` (it visits itself, then its children).

> **TL;DR**

Operations become visitor classes; elements just `accept`; double dispatch picks the method. Cheap new operations, expensive new types (expression problem). In Java 21, prefer **sealed interfaces + exhaustive pattern matching**.

11.6 GoF behavioral patterns: quick-reference summary

A single table with the key features, when to apply each pattern, an example, and pros and cons (compiled from the course summary plus this book's material).

Pattern	Distinctive feature	Apply when	Example	Pros	Cons
Chain of Responsibility	Passes a request along a chain of handlers	Several objects may handle a request and the handler isn't known in advance	Help systems, HTTP middleware (code run before/after each web request)	Decouples sender and receiver	A request may go unhandled; long chains can be inefficient and slow to debug
Command	Wraps a request as an object	Actions must be queued, logged, retried or undone	GUI actions, job queues	Decouples invoker from receiver; undo/redo	Many small command classes
Interpreter	One class per grammar rule	Evaluating sentences of a small language	Regex, rule DSLs (small domain-specific languages)	Easy to extend the grammar	Unmanageable for large grammars
Iterator	Sequential access without exposing representation	You need a standard way to traverse any collection	Browsing a playlist	Simple client code; hides the structure	Hidden costs; state handling in lazy iterators
Mediator	Centralises communication between peers	Many objects interact in tangled ways	Chat application, air traffic control	Fewer dependencies; reusable components	The mediator can become a god object (one class that knows and does too much)
Memento	Captures and externalises state without breaking encapsulation	Undo, checkpoints, rollback	Editor undo, save games	Preserves encapsulation; atomic restore	Memory-heavy for big/frequent snapshots
Observer	Notifies dependents of state changes	A change in one object must reach others	Live stock/data feeds	Subject and observers are loosely coupled	Leaks, unexpected performance costs, no ordering
State	Behaviour changes with internal state	An object's behaviour depends on a state that changes at run time	Game modes, order lifecycles	Localises state-specific behaviour	More classes; graph spread across files
Strategy	Algorithm chosen at run time	Several ways to do one task, chosen dynamically	Compression algorithms, retry policies	Swap algorithms; isolate each	More classes; someone must choose
Template Method	Algorithm skeleton in a base class, steps in subclasses	The structure is fixed but some steps vary	Frameworks' lifecycles	Code reuse; enforced order	Inheritance rigidity; harder to follow
Visitor	Separates operations from the objects they work on	Many operations over a stable set of types	Processing document elements, compiler passes	Easy to add operations; related code together	Adding element types is hard; bloated visitor interface

11.7 Beyond GoF: patterns every LLD interview expects

The GoF book (1994) is not the whole story. The patterns below come from later sources — *Patterns of Enterprise Application Architecture* (Fowler, 2002), *Domain-Driven Design* (Evans, 2003 — DDD, an approach that shapes code around the business domain and its vocabulary), *Head First Design Patterns*, and decades of framework practice. You will use them in almost every case study in this book.

11.7.1 Null Object

What it is

A **Null Object** is a real object that implements an interface with **neutral, do-nothing behaviour**, used instead of `null` to mean "no object here". Callers can call it safely without `if (x != null)` checks.

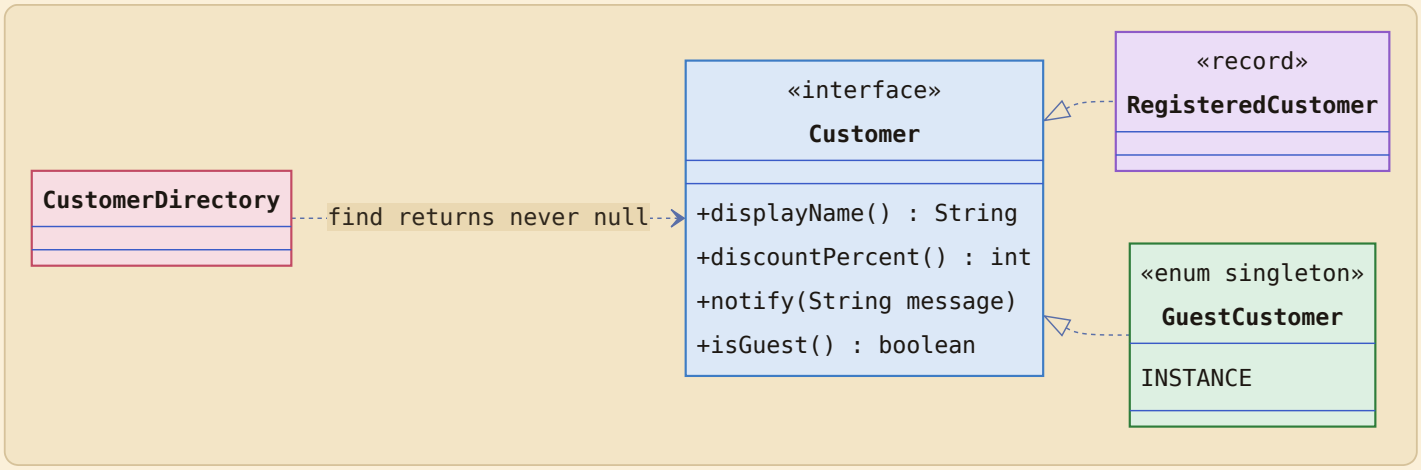
Analogy: a "guest" badge at an office. Guests can walk through the lobby like anyone else; the badge simply opens no special doors.

The problem it solves

Returning `null` for "not found" forces **every caller** to remember a null check. One forgotten check → `NullPointerException` (NPE — the error Java throws when you call a method on `null`) in production. The checks also clutter the business logic.

How it works

1. Define an interface (`Customer`).
2. Implement the real class (`RegisteredCustomer`) and a **null class** (`GuestCustomer`) whose methods return neutral values (0% discount) or do nothing (`notify` is empty).
3. Where you would return `null`, return the null object instead. Stateless null objects can be a **singleton** (a class with exactly one shared instance — here an `enum` constant).
4. If some caller really must know, offer an `isGuest()`/`isNull()` query — sparingly.



Java example

```java
// File: code/lld/ch11/nullobject/Customer.java
package lld.ch11.nullobject;

/** The abstraction both the real object and the Null Object implement. */
public interface Customer {
    String displayName();
    int discountPercent();
    void notify(String message);
    default boolean isGuest() { return false; }
}
```

```java
// File: code/lld/ch11/nullobject/RegisteredCustomer.java
package lld.ch11.nullobject;

public record RegisteredCustomer(String name, int discountPercent, String email) implements Customer {
    public String displayName() { return name; }
    public void notify(String message) { System.out.println("    email to " + email + ": " + message); }
}
```

```java
// File: code/lld/ch11/nullobject/GuestCustomer.java
package lld.ch11.nullobject;

/**
 * NULL OBJECT: a real, do-nothing implementation with neutral values.
 * Stateless, so one shared instance is enough (an enum singleton).
 */
public enum GuestCustomer implements Customer {
    INSTANCE;

    public String displayName() { return "guest"; }
    public int discountPercent() { return 0; }            // neutral value
    public void notify(String message) { }                // does nothing, on purpose
    @Override public boolean isGuest() { return true; }   // for the rare caller that must know
}
```

```java
// File: code/lld/ch11/nullobject/CustomerDirectory.java
package lld.ch11.nullobject;

import java.util.Map;
import java.util.Optional;

public final class CustomerDirectory {
    private final Map<String, Customer> byId = Map.of(
        "c1", new RegisteredCustomer("Asha", 10, "asha@example.com"));

    /** Style 1: never return null; return the Null Object instead. */
    public Customer find(String id) { return byId.getOrDefault(id, GuestCustomer.INSTANCE); }

    /** Style 2: make absence explicit in the type; the caller chooses the fallback. */
    public Optional<Customer> lookup(String id) { return Optional.ofNullable(byId.get(id)); }
}
```

```java
// File: code/lld/ch11/nullobject/Main.java
package lld.ch11.nullobject;

import java.math.BigDecimal;
import java.math.RoundingMode;

public class Main {
    private static final BigDecimal HUNDRED = BigDecimal.valueOf(100);

    static void checkout(Customer c, BigDecimal price) {
        // No "if (customer != null)" anywhere: the Null Object answers every call safely.
        BigDecimal payable = price.multiply(BigDecimal.valueOf(100 - c.discountPercent()))
                                  .divide(HUNDRED, 2, RoundingMode.HALF_EVEN);
        System.out.printf("  %-6s pays %s%n", c.displayName(), payable);
        c.notify("thanks for your order");
    }

    public static void main(String[] args) {
        CustomerDirectory dir = new CustomerDirectory();
        System.out.println("=== Null Object ===");
        checkout(dir.find("c1"), new BigDecimal("100.00"));
        checkout(dir.find("unknown-id"), new BigDecimal("100.00"));

        System.out.println("=== Optional (absence visible in the signature) ===");
        Customer c = dir.lookup("unknown-id").orElse(GuestCustomer.INSTANCE);
        System.out.println("  lookup(unknown-id) present? " + dir.lookup("unknown-id").isPresent() + " -> using " +
c.displayName());
    }
}
```

Output:

```
=== Null Object ===
  Asha   pays 90.00
    email to asha@example.com: thanks for your order
  guest  pays 100.00
=== Optional (absence visible in the signature) ===
  lookup(unknown-id) present? false -> using guest
```

`checkout` has no null checks, and the guest's `notify` silently does nothing. (Prices are `BigDecimal` with an explicit rounding mode, never `double`.)

Trade-offs, when not to use it, mistakes

Pros	Cons
Removes repetitive null checks; fewer NPEs.	Can **hide real errors** — a missing object that *should* exist fails silently.
Polymorphism instead of conditionals.	One more class per interface.
Easy to test; a natural default.	Callers may not realise they got a "nothing" object.

- **Don't use it** when absence is an **error** (throw an exception) or when the caller must decide what absence means (return `Optional<T>` — a JDK container that either holds a value or is empty).
- **Null Object vs `Optional`:** Null Object hides absence behind neutral behaviour; `Optional` makes absence **visible in the type** and lets each caller choose (`orElse`, `orElseThrow`). Use `Optional` for return values of lookups; use Null Object for **collaborators** that are legitimately optional (a logger, a listener, a discount policy).
- **Common mistakes:** a null object with **side effects** or non-neutral values; a mutable null-object singleton; overusing `isNull()` checks (which brings the conditionals back).

Real-world examples

`Collections.emptyList()` / `emptyMap()` (empty, not null); `InputStream.nullInputStream()`, `OutputStream.nullOutputStream()`, `Reader.nullReader()`, `Writer.nullWriter()` (Java 11); SLF4J's (a common Java logging API) `NOPLogger`; a "no-op" (does nothing) `MeterRegistry`/tracer in **observability** libraries (metrics, logs and traces that show what a running system is doing).

In the interview

> **30-second answer:** "Null Object replaces `null` with an implementation that does nothing or returns neutral values, so callers never need null checks — like returning an empty list instead of null. I use it for optional collaborators like loggers or discount policies, and `Optional` for lookups where the caller should decide. I avoid it when absence is actually an error, because it would hide the bug."

Follow-up — is it a GoF pattern? No; it was described by Bobby Woolf (in *Pattern Languages of Program Design 3*) and appears in Fowler's *Refactoring* as "Introduce Special Case" (earlier "Introduce Null Object").

Self-check. Q: What does `Collections.emptyList()` have to do with this? A: It's a null object for lists — safe to iterate, never null. Q: When should you throw instead? A: When the object must exist and its absence is a bug.

> **TL;DR:** Return a harmless "nothing" object instead of `null`; use `Optional` when the caller must choose; throw when absence is a bug.

11.7.2 Dependency Injection (DI)

What it is

Dependency Injection means a class **receives** the objects it depends on (its *dependencies*) from outside, instead of **creating** them itself with `new` or looking them up. It is the most common way to implement **Inversion of Control (IoC)** — the framework or a "composition root" builds and wires objects, not the objects themselves. The name was settled by Martin Fowler in his 2004 article on IoC containers.

Analogy: a restaurant kitchen doesn't grow its own vegetables; suppliers deliver them. Change the supplier, and the chef's recipes don't change.

The problem it solves

```
class OrderService {
    private final EmailSender sender = new EmailSender();   // hard-wired
}
```

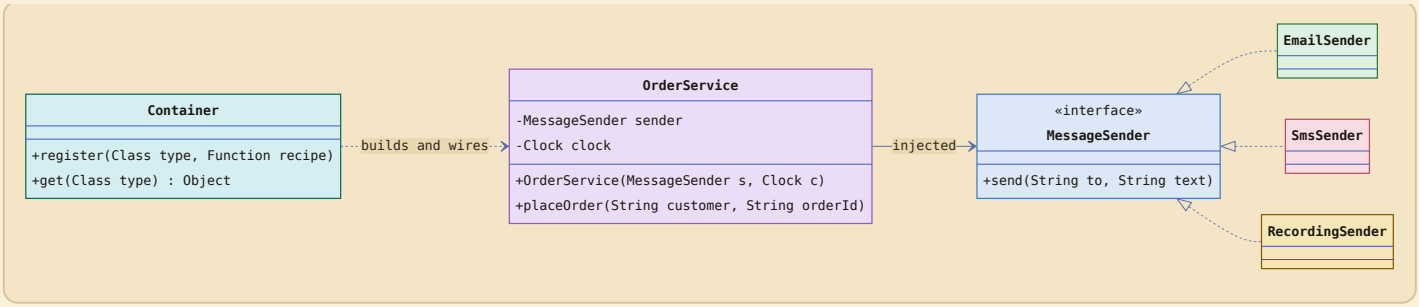
This class can never send SMS, can't be unit-tested without really sending email, and hides its dependencies. DI fixes all three: depend on an **interface** (`MessageSender`), receive it through the **constructor**, and let someone else decide which implementation.

How it works

1. The class declares dependencies as **constructor parameters** typed by **interfaces** (Dependency Inversion Principle, Chapter 4).
2. A **composition root** (usually `main`, or a DI container at start-up) creates the concrete objects and passes them in.
3. Tests pass **fakes** (simple stand-in implementations used only in tests) instead.

Three injection styles:

Style	How	Use for
Constructor injection	Dependencies are constructor parameters, stored in `final` fields	Required dependencies — the default choice
Setter injection	`setX(...)` after construction	Optional dependencies or ones that can change
Field injection	Framework writes directly into fields (`@Autowired` annotation on a field)	Avoid: hides dependencies and makes testing harder



Java example

`OrderService` receives both a `MessageSender` and a `java.time.Clock` — injecting the clock makes time **testable** (`Clock.fixed`). `Container` is a toy IoC container: you register a *recipe* per type; `get` builds objects on demand (recipes can ask the container for their own dependencies) and caches them as singletons.

```java
// File: code/lld/ch11/di/MessageSender.java
package lld.ch11.di;

/** The abstraction the service depends on (Dependency Inversion). */
public interface MessageSender {
    void send(String to, String text);
}
```

```java
// File: code/lld/ch11/di/EmailSender.java
package lld.ch11.di;

public final class EmailSender implements MessageSender {
    public void send(String to, String text) { System.out.println("  [smtp] to " + to + ": " + text); }
}
```

```java
// File: code/lld/ch11/di/SmsSender.java
package lld.ch11.di;

public final class SmsSender implements MessageSender {
    public void send(String to, String text) { System.out.println("  [sms] to " + to + ": " + text); }
}
```

```java
// File: code/lld/ch11/di/RecordingSender.java
package lld.ch11.di;

import java.util.ArrayList;
import java.util.List;

/** Test double: records instead of sending. Only possible because the dependency is injected. */
public final class RecordingSender implements MessageSender {
    public final List<String> sent = new ArrayList<>();
    public void send(String to, String text) { sent.add(to + "|" + text); }
}
```

```java
// File: code/lld/ch11/di/OrderService.java
package lld.ch11.di;

import java.time.Clock;
import java.time.LocalTime;

/**
 * CONSTRUCTOR INJECTION: the service declares what it needs and never calls 'new'
 * on its collaborators. Even the clock is injected, so time is testable.
 */
public final class OrderService {
    private final MessageSender sender;
    private final Clock clock;

    public OrderService(MessageSender sender, Clock clock) {
        this.sender = sender;
        this.clock = clock;
    }

    public void placeOrder(String customer, String orderId) {
        LocalTime now = LocalTime.now(clock);
        sender.send(customer, "order " + orderId + " placed at " + now);
    }
}
```

```java
// File: code/lld/ch11/di/Container.java
package lld.ch11.di;

import java.util.HashMap;
import java.util.Map;
import java.util.function.Function;

/**
 * A toy IoC container: register how to build each type once; ask for the type later.
 * Real containers (Spring, Guice, Dagger) add scanning, scopes, proxies and lifecycles.
 */
public final class Container {
    private final Map<Class<?>, Function<Container, ?>> recipes = new HashMap<>();
    private final Map<Class<?>, Object> singletons = new HashMap<>();

    public <T> void register(Class<T> type, Function<Container, ? extends T> recipe) {
        recipes.put(type, recipe);
    }

    public <T> T get(Class<T> type) {
        Object existing = singletons.get(type);
        if (existing != null) return type.cast(existing);
        Function<Container, ?> recipe = recipes.get(type);
        if (recipe == null) throw new IllegalStateException("no binding for " + type.getSimpleName());
        T created = type.cast(recipe.apply(this));   // the recipe may ask the container for its own deps
        singletons.put(type, created);
        return created;
    }
}
```

```java
// File: code/lld/ch11/di/Main.java
package lld.ch11.di;

import java.time.Clock;
import java.time.Instant;
import java.time.ZoneOffset;

public class Main {
    public static void main(String[] args) {
        Clock fixed = Clock.fixed(Instant.parse("2026-01-15T09:30:00Z"), ZoneOffset.UTC);

        System.out.println("=== 1. Manual DI: the composition root wires everything ===");
        new OrderService(new EmailSender(), fixed).placeOrder("asha@example.com", "A-1");
        new OrderService(new SmsSender(), fixed).placeOrder("+91-90000-00000", "A-2");

        System.out.println("\n=== 2. In a unit test: inject a fake ===");
        RecordingSender fake = new RecordingSender();
        new OrderService(fake, fixed).placeOrder("ben", "T-9");
        System.out.println("  fake recorded: " + fake.sent);

        System.out.println("\n=== 3. A toy IoC container ===");
        Container c = new Container();
        c.register(Clock.class, k -> fixed);
        c.register(MessageSender.class, k -> new EmailSender());
        c.register(OrderService.class, k -> new OrderService(k.get(MessageSender.class), k.get(Clock.class)));
        c.get(OrderService.class).placeOrder("chen@example.com", "A-3");
        System.out.println("  same instance each time: " + (c.get(OrderService.class) ==
c.get(OrderService.class)));
    }
}
```

Output:

```
=== 1. Manual DI: the composition root wires everything ===
  [smtp] to asha@example.com: order A-1 placed at 09:30
  [sms] to +91-90000-00000: order A-2 placed at 09:30

=== 2. In a unit test: inject a fake ===
  fake recorded: [ben|order T-9 placed at 09:30]

=== 3. A toy IoC container ===
  [smtp] to chen@example.com: order A-3 placed at 09:30
  same instance each time: true
```

Trade-offs, when not to use it, mistakes

Pros	Cons
Swap implementations without editing the class (OCP, DIP).	More indirection: "where does this come from?"
Easy unit tests with fakes.	Containers add "magic" (reflection — code inspecting classes at run time; proxies — generated wrapper objects) and start-up cost.
Dependencies are explicit in the constructor.	Misconfiguration may only show at start-up (or run time).

- **Don't** inject value objects or simple data (`new Money(...)` is fine), or add interfaces with only one implementation "just for DI" when no test or variation needs them.
- **Common mistakes:** the **Service Locator** anti-pattern (classes call `container.get(...)` themselves — dependencies hidden again); field injection; **constructor with 8+ dependencies** (a sign the class does too much — split it); **circular dependencies** (A needs B while B needs A).

Real-world examples

Spring (`@Component` + constructor injection, `ApplicationContext` as the container), **Google Guice**, **Dagger/Hilt** (compile-time DI on Android), **Jakarta CDI**, **Micronaut/Quarkus** (compile-time DI for fast start-up). Spring can even inject a `Map<String, PaymentStrategy>` of all strategy beans — DI + Strategy together.

In the interview

> **30-second answer:** "Dependency injection means a class receives its collaborators through its constructor, typed by interfaces, instead of creating them. It's how we apply Dependency Inversion and Inversion of Control: a composition root or a container like Spring wires the graph. The benefits are swappable implementations and easy testing with fakes — I even inject the Clock. I prefer constructor injection, avoid field injection and service locators, and treat a huge constructor as a **design smell** (a surface sign that something deeper is wrong)."

Follow-ups: **DI vs IoC?** IoC is the general idea (the framework calls you / controls object creation); DI is one way to achieve it. **DI vs Service Locator?** With a locator the class asks for dependencies (hidden); with DI they're handed in (visible). **DI vs Factory?** A factory creates objects on request; DI supplies ready-made dependencies — containers use factories internally.

Self-check. Q: Why inject `Clock`? A: To make time-dependent code deterministic in tests. Q: Which injection style is preferred? A: Constructor injection.

> **TL;DR:** Don't `new` your collaborators — **receive them** (constructor, interfaces). Wire at the composition root or with a container.

11.7.3 Repository

What it is

A **Repository** is a **collection-like interface for loading and saving domain objects**, written in the language of the domain (`findByEmail`, `findActive`), that **hides how and where data is stored** (SQL — relational databases queried with the SQL language; NoSQL — non-relational stores such as key-value or document databases; files; memory). Described by Fowler (*PoEAA*) and central to Evans's *Domain-Driven Design*.

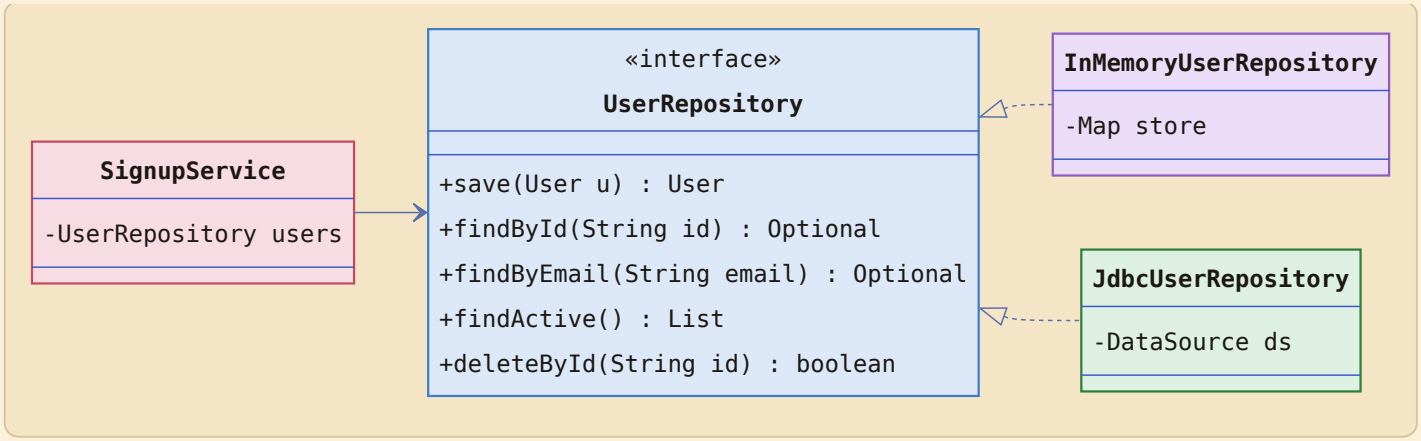
Analogy: a library's front desk. You ask for "books by this author"; you don't need to know which shelf, basement or branch they come from.

The problem it solves

When SQL, connection handling and mapping code are scattered through business classes, the business rules become hard to read, impossible to unit-test without a database, and tied to one storage technology.

How it works

1. Define the interface in the **domain layer** (the code that holds business rules) (`UserRepository`: `save`, `findById`, `findByEmail`, ...). Return `Optional` for "maybe not found".
2. Implement it in the **infrastructure layer** (code that talks to databases, networks and files): `InMemoryUserRepository` for tests, a JDBC/JPA one (JPA, the Java Persistence API, maps objects to tables) for production.
3. Services depend on the **interface** (injected — see DI).



(`JdbcUserRepository` is shown to illustrate a production implementation; the demo code includes the in-memory one.)

Java example

```java
// File: code/lld/ch11/repository/User.java
package lld.ch11.repository;

/** A domain object. It knows nothing about storage. */
public record User(String id, String email, boolean active) {}
```

```java
// File: code/lld/ch11/repository/UserRepository.java
package lld.ch11.repository;

import java.util.List;
import java.util.Optional;

/**
 * REPOSITORY: a collection-like interface for aggregates, in DOMAIN language.
 * The domain depends on this; the storage details live in implementations.
 */
public interface UserRepository {
    User save(User user);
    Optional<User> findById(String id);
    Optional<User> findByEmail(String email);
    List<User> findActive();
    boolean deleteById(String id);
}
```

```java
// File: code/lld/ch11/repository/InMemoryUserRepository.java
package lld.ch11.repository;

import java.util.Comparator;
import java.util.List;
import java.util.Map;
import java.util.Optional;
import java.util.concurrent.ConcurrentHashMap;

/** One implementation: in memory (tests, prototypes). A JDBC/JPA one would implement the same interface. */
public final class InMemoryUserRepository implements UserRepository {
    private final Map<String, User> store = new ConcurrentHashMap<>();

    public User save(User user) { store.put(user.id(), user); return user; }
    public Optional<User> findById(String id) { return Optional.ofNullable(store.get(id)); }

    public Optional<User> findByEmail(String email) {
        return store.values().stream().filter(u -> u.email().equalsIgnoreCase(email)).findFirst();
    }

    public List<User> findActive() {
        return store.values().stream().filter(User::active)
                    .sorted(Comparator.comparing(User::id)).toList();
    }

    public boolean deleteById(String id) { return store.remove(id) != null; }
}
```

```java
// File: code/lld/ch11/repository/SignupService.java
package lld.ch11.repository;

/** Business logic talks to the repository interface only: no SQL, no maps, no files. */
public final class SignupService {
    private final UserRepository users;

    public SignupService(UserRepository users) { this.users = users; }

    public String signUp(String id, String email) {
        if (users.findByEmail(email).isPresent()) return "rejected: " + email + " already registered";
        users.save(new User(id, email, true));
        return "created " + id;
    }

    public void deactivate(String id) {
        users.findById(id).ifPresent(u -> users.save(new User(u.id(), u.email(), false)));
    }
}
```

```java
// File: code/lld/ch11/repository/Main.java
package lld.ch11.repository;

public class Main {
    public static void main(String[] args) {
        UserRepository repo = new InMemoryUserRepository();   // swap for a JDBC version in production
        SignupService service = new SignupService(repo);
        System.out.println("  " + service.signUp("u1", "asha@example.com"));
        System.out.println("  " + service.signUp("u2", "ben@example.com"));
        System.out.println("  " + service.signUp("u3", "ASHA@example.com"));
        service.deactivate("u2");
        System.out.println("  active users: " + repo.findActive());
        System.out.println("  findById(u9): " + repo.findById("u9"));
        System.out.println("  deleteById(u2): " + repo.deleteById("u2"));
    }
}
```

Output:

```
created u1
created u2
rejected: ASHA@example.com already registered
active users: [User[id=u1, email=asha@example.com, active=true]]
findById(u9): Optional.empty
deleteById(u2): true
```

Trade-offs, when not to use it, mistakes

Pros	Cons
Business logic is storage-agnostic and testable in memory.	Another layer; trivial CRUD (create, read, update, delete) apps may not need it.
One place for queries per aggregate.	Can leak storage concerns (lazy loading — fetching data only when first touched; transactions — changes that succeed or fail together) anyway.
Swap storage (SQL → NoSQL) behind the interface.	"Generic repository for everything" becomes a thin, useless wrapper.

- **Don't** create a repository per table; create one per **aggregate root** (DDD: the entry point object of a cluster, e.g. `Order` with its `OrderLine`s).
- **Repository vs DAO:** a DAO (Data Access Object) is table/record-oriented and closer to the database; a repository is domain-oriented and behaves like a collection of aggregates. In small apps they often look the same.
- **Common mistakes:** returning `null` instead of `Optional`; exposing SQL types (`ResultSet`) in the interface; putting business rules in the repository; dozens of `findByXAndYOrZ` methods — use **Specification** (next).
- **Thread-safety note:** `InMemoryUserRepository` uses a `ConcurrentHashMap` (the JDK's thread-safe hash map), so each single call is safe, but `SignupService.signUp` is **check-then-act** (a race where the answer to the check can be stale by the time you act on it) (`findByEmail`, then `save`): two concurrent sign-ups with the same email can both pass the check. A real system enforces uniqueness with a database **unique constraint** (a rule that makes the database reject a duplicate value in a column) (or an atomic `putIfAbsent` keyed by email in memory).

Real-world examples

Spring Data `CrudRepository` / `JpaRepository` (derived query methods like `findByEmail` are generated from method names), Micronaut Data, Hibernate/JPA behind them; Android Room DAOs wrapped in repositories (Android architecture guidance).

In the interview

30-second answer: "A repository is a collection-like interface for aggregates in domain language — save, findById, findByEmail — that hides storage. Services depend on the interface, so business logic is testable with an in-memory implementation and storage can change. In machine-coding rounds I always put an in-memory repository behind an interface, so the design is ready for a database later."

Self-check. Q: What does a repository return when nothing is found? A: `Optional.empty()` (or an empty list). Q: One repository per table? A: No, per aggregate root.

TL;DR: A **domain-language collection interface** over storage; services use the interface; start in-memory, swap later.

11.7.4 Specification

What it is

A **Specification** is a **business rule packaged as an object** with one question — `isSatisfiedBy(candidate)` — that can be **combined** with `and`, `or` and `not`. Introduced by Eric Evans and Martin Fowler.

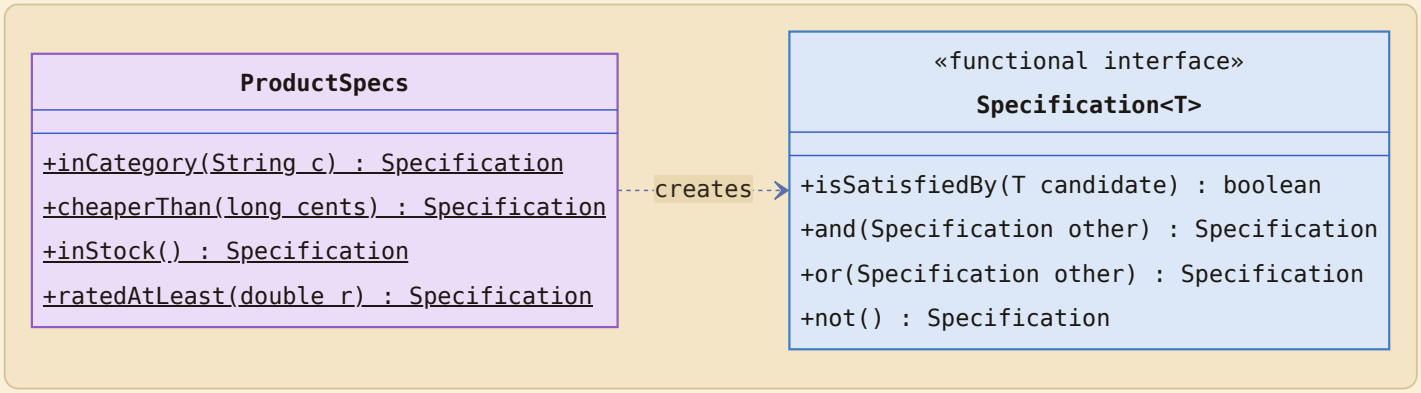
Analogy: the filter panel on a shopping site. "Electronics" ✓, "under ₹5,000" ✓, "in stock" ✓ — each is a separate rule, and the site combines the ones you tick.

The problem it solves

Rules like "bargain electronics = category electronics AND price < 50.00 AND in stock" end up duplicated in queries, validations and UI filters, or as an explosion of repository methods (`findByCategoryAndPriceLessThanAndStockGreaterThan...`). Specification gives each rule a **name**, makes it **reusable** in several places (selection, validation, building to order), and **composable**.

How it works

1. `Specification<T>` with `isSatisfiedBy(T)`; default methods `and`, `or`, `not` return new composite specifications (this is the **Composite** pattern + **Interpreter**-like evaluation).
2. Write small named factories (`inStock()`, `cheaperThan(...)`).
3. Combine them where needed; pass them to a repository or a stream filter.



Java example

```java
// File: code/lld/ch11/specification/Specification.java
package lld.ch11.specification;

/**
 * SPECIFICATION: a business rule as a small, named, combinable object.
 * isSatisfiedBy answers "does this candidate meet the rule?"
 */
@FunctionalInterface
public interface Specification<T> {
    boolean isSatisfiedBy(T candidate);

    default Specification<T> and(Specification<T> other) { return c -> isSatisfiedBy(c) && other.isSatisfiedBy(c);
}
    default Specification<T> or(Specification<T> other)  { return c -> isSatisfiedBy(c) || other.isSatisfiedBy(c);
}
    default Specification<T> not()                       { return c -> !isSatisfiedBy(c); }
}
```

```java
// File: code/lld/ch11/specification/Product.java
package lld.ch11.specification;

public record Product(String name, String category, long priceCents, int stock, double rating) {}
```

```java
// File: code/lld/ch11/specification/ProductSpecs.java
package lld.ch11.specification;

/** Named rules, in the language of the business. Each is tiny and testable alone. */
public final class ProductSpecs {
    private ProductSpecs() {}

    public static Specification<Product> inCategory(String c) { return p -> p.category().equals(c); }
    public static Specification<Product> cheaperThan(long cents) { return p -> p.priceCents() < cents; }
    public static Specification<Product> inStock() { return p -> p.stock() > 0; }
    public static Specification<Product> ratedAtLeast(double r) { return p -> p.rating() >= r; }
}
```

```java
// File: code/lld/ch11/specification/Main.java
package lld.ch11.specification;

import static lld.ch11.specification.ProductSpecs.*;

import java.util.List;

public class Main {
    static List<String> select(List<Product> catalog, Specification<Product> spec) {
        return catalog.stream().filter(spec::isSatisfiedBy).map(Product::name).toList();
    }

    public static void main(String[] args) {
        List<Product> catalog = List.of(
            new Product("usb-cable", "electronics", 499, 120, 4.1),
            new Product("headphones", "electronics", 7_999, 0, 4.6),
            new Product("keyboard", "electronics", 4_999, 8, 4.7),
            new Product("novel", "books", 1_299, 30, 4.8),
            new Product("cookbook", "books", 2_499, 0, 3.9));

        // The same rule objects are reused for querying AND for validation.
        Specification<Product> bargainElectronics =
inCategory("electronics").and(cheaperThan(5_000)).and(inStock());
        Specification<Product> recommendable = ratedAtLeast(4.5).and(inStock());
        Specification<Product> needsRestock = inStock().not();

        System.out.println("  bargain electronics: " + select(catalog, bargainElectronics));
        System.out.println("  recommendable:       " + select(catalog, recommendable));
        System.out.println("  needs restock:       " + select(catalog, needsRestock));
        System.out.println("  books or top-rated:  " + select(catalog, inCategory("books").or(ratedAtLeast(4.7))));
        System.out.println("  is 'novel' recommendable? " + recommendable.isSatisfiedBy(catalog.get(3)));
    }
}
```

Output:

```
  bargain electronics: [usb-cable, keyboard]
  recommendable:       [keyboard, novel]
  needs restock:       [headphones, cookbook]
  books or top-rated:  [keyboard, novel, cookbook]
  is 'novel' recommendable? true
```

Trade-offs, when not to use it, mistakes

Pros	Cons
Rules are named, reusable and testable one by one.	In-memory specs don't translate to SQL automatically — you need a query-building version (e.g. JPA Criteria) for large data.
Combining rules replaces a method explosion.	Overkill for one or two fixed filters.
The same rule serves querying and validation.	Deeply nested combinations can be hard to debug.

- Java's own `Predicate<T>` (the JDK interface for a yes/no test on a value, with `and`, `or`, `negate`) is already a specification; a named `Specification` type adds domain meaning and a place for SQL translation.
- **Common mistake:** filtering millions of rows in memory — push specifications down to the database.

Real-world examples

Spring Data JPA `Specification<T>` (`where(...).and(...)`, `JpaSpecificationExecutor.findAll(spec)`), e-commerce search filters, eligibility rules (loan, coupon, delivery-slot eligibility), access-control policies.

In the interview

> **30-second answer:** "A specification is a named business rule object with `isSatisfiedBy`, combinable with and/or/not. It removes duplicated conditions and the explosion of repository finder methods, and the same rule can filter a query and validate an object. In Java, `Predicate` is the building block; Spring Data JPA has a `Specification` that translates to SQL."

Self-check. Q: What three combinators does a specification usually have? A: `and`, `or`, `not`. Q: Which pattern does combining specifications resemble? A: Composite (and Interpreter for evaluation).

> **TL;DR: Rules as small combinable objects**; reuse them for querying and validation.

11.7.5 MVC — Model–View–Controller (the Head First "compound pattern")

What it is

MVC splits an interactive application into three roles:

- **Model** — the data and business rules. Knows nothing about screens.
- **View** — displays the model and receives user input.
- **Controller** — interprets user input and tells the model what to change.

It was created by Trygve Reenskaug for Smalltalk at Xerox PARC in the late 1970s. *Head First Design Patterns* calls MVC a **compound pattern** — several patterns working together:

Pattern inside MVC	Where
Observer	The model notifies views (and sometimes controllers) when its state changes; views re-render.
Strategy	The view delegates "what should this input do?" to a controller object; swap the controller to change behaviour (e.g. read-only mode).
Composite	The view is a tree of nested components (panels containing labels, lists, buttons) rendered uniformly.

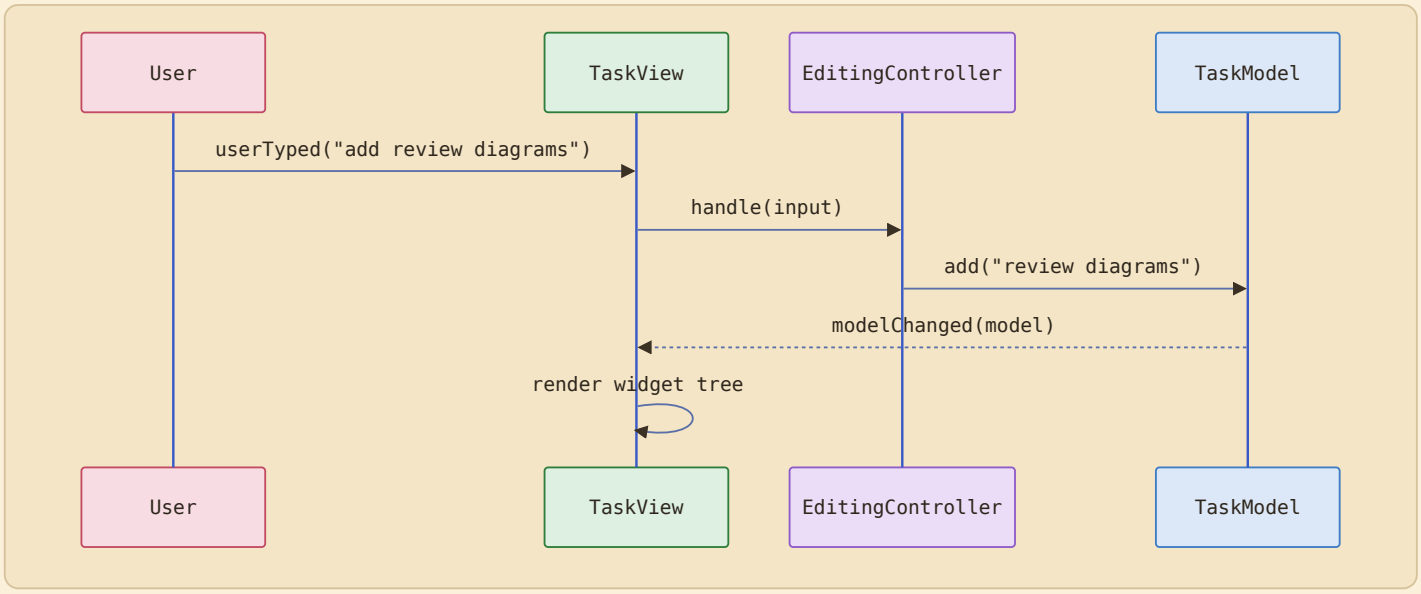
Analogy: a restaurant. The kitchen and pantry are the **model**; the dining-room menu and plates are the **view**; the waiter who takes your order and passes it to the kitchen is the **controller**.

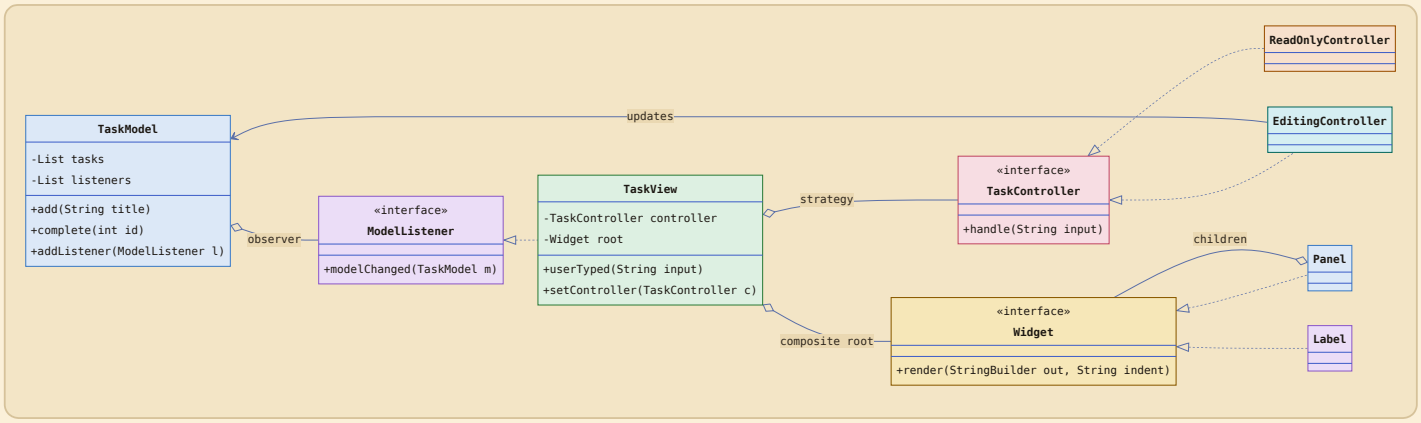
The problem it solves

When UI code, input handling and business rules are mixed, you cannot change the screen without risking the rules, cannot show the same data in two ways, and cannot test the rules without a UI.

How it works

1. The user acts on the **view** (`userTyped("add ...")`).
2. The view hands the input to its **controller** (strategy).
3. The controller calls the **model** (`model.add(title)`); it does **not** redraw anything.
4. The model changes and **notifies its listeners** (observer).
5. The view re-renders its **composite** widget tree from the model.





Java example

A console to-do app. `TaskModel` knows only `ModelListener`s. `TaskView` implements `ModelListener`, renders a **composite** of `Widget.Panel` / `Widget.Label`, and forwards input to a swappable `TaskController`. Switching to `ReadOnlyController` changes behaviour without touching the view or model.

```java
// File: code/lld/ch11/mvc/Task.java
package lld.ch11.mvc;

public record Task(int id, String title, boolean done) {}
```

```java
// File: code/lld/ch11/mvc/TaskModel.java
package lld.ch11.mvc;

import java.util.ArrayList;
import java.util.List;

/** MODEL: state + business rules. Knows NOTHING about views or controllers, only listeners. */
public final class TaskModel {
    private final List<Task> tasks = new ArrayList<>();
    private final List<ModelListener> listeners = new ArrayList<>();
    private int nextId = 1;

    public void addListener(ModelListener l) { listeners.add(l); }

    public List<Task> tasks() { return List.copyOf(tasks); }

    public void add(String title) {
        if (title.isBlank()) throw new IllegalArgumentException("title must not be blank");
        tasks.add(new Task(nextId++, title, false));
        fireChanged();
    }

    public void complete(int id) {
        for (int i = 0; i < tasks.size(); i++) {
            Task t = tasks.get(i);
            if (t.id() == id) {
                tasks.set(i, new Task(t.id(), t.title(), true));
                fireChanged();
                return;
            }
        }
        throw new IllegalArgumentException("no task " + id);
    }

    private void fireChanged() { listeners.forEach(l -> l.modelChanged(this)); }
}
```

```java
// File: code/lld/ch11/mvc/ModelListener.java
package lld.ch11.mvc;

/** OBSERVER interface between model and views. */
public interface ModelListener {
    void modelChanged(TaskModel model);
}
```

```java
// File: code/lld/ch11/mvc/Widget.java
package lld.ch11.mvc;

import java.util.List;
import java.util.function.Supplier;

/** COMPOSITE: the view is a tree of widgets rendered the same way. */
public interface Widget {
    void render(StringBuilder out, String indent);

    record Label(Supplier<String> text) implements Widget {
        public void render(StringBuilder out, String indent) { out.append(indent).append(text.get()).append('\n');
}
    }

    record Panel(String title, List<Widget> children) implements Widget {
        public void render(StringBuilder out, String indent) {
            out.append(indent).append("+ ").append(title).append('\n');
            children.forEach(c -> c.render(out, indent + "  "));
        }
    }
}
```

```java
// File: code/lld/ch11/mvc/TaskController.java
package lld.ch11.mvc;

/** CONTROLLER as a STRATEGY: the view delegates "what does this input mean?" to it. */
public interface TaskController {
    void handle(String input);
}
```

```java
// File: code/lld/ch11/mvc/EditingController.java
package lld.ch11.mvc;

/** Interprets user input and updates the MODEL. It does not redraw anything itself. */
public final class EditingController implements TaskController {
    private final TaskModel model;
    private final TaskView view;

    public EditingController(TaskModel model, TaskView view) {
        this.model = model;
        this.view = view;
    }

    public void handle(String input) {
        try {
            if (input.startsWith("add ")) model.add(input.substring(4));
            else if (input.startsWith("done ")) model.complete(Integer.parseInt(input.substring(5).trim()));
            else view.showMessage("unknown command: " + input);
        } catch (IllegalArgumentException e) {        // NumberFormatException is a subclass
            view.showMessage("error: " + e.getMessage());
        }
    }
}
```

```java
// File: code/lld/ch11/mvc/ReadOnlyController.java
package lld.ch11.mvc;

/** Alternative strategy: same view, different behaviour (e.g. a viewer role). */
public final class ReadOnlyController implements TaskController {
    private final TaskView view;

    public ReadOnlyController(TaskView view) { this.view = view; }

    public void handle(String input) { view.showMessage("read-only mode, ignored: " + input); }
}
```

```java
// File: code/lld/ch11/mvc/TaskView.java
package lld.ch11.mvc;

import java.util.List;
import java.util.stream.Collectors;

/** VIEW: observes the model, renders it (composite), forwards user input to its controller (strategy). */
public final class TaskView implements ModelListener {
    private TaskController controller;
    private final Widget root;
    private TaskModel lastSeen;

    public TaskView() {
        root = new Widget.Panel("My Tasks", List.of(
            new Widget.Label(() -> lastSeen == null ? "(empty)" : lastSeen.tasks().stream()
                .map(t -> (t.done() ? "[x] " : "[ ] ") + t.id() + ". " + t.title())
                .collect(Collectors.joining("\n    "))),
            new Widget.Panel("Summary", List.of(
                new Widget.Label(() -> lastSeen == null ? "0 open" :
                    lastSeen.tasks().stream().filter(t -> !t.done()).count() + " open")))));
    }

    public void setController(TaskController controller) { this.controller = controller; }

    /** A user action arrives at the view... and is handed straight to the controller. */
    public void userTyped(String input) {
        System.out.println("> " + input);
        controller.handle(input);
    }

    public void showMessage(String msg) { System.out.println("  (" + msg + ")"); }

    @Override
    public void modelChanged(TaskModel model) {     // Observer callback: re-render from the model
        lastSeen = model;
        StringBuilder out = new StringBuilder();
        root.render(out, "  ");
        System.out.print(out);
    }
}
```

```java
// File: code/lld/ch11/mvc/Main.java
package lld.ch11.mvc;

public class Main {
    public static void main(String[] args) {
        TaskModel model = new TaskModel();
        TaskView view = new TaskView();
        model.addListener(view);                                    // Observer: model -> view
        view.setController(new EditingController(model, view));  // Strategy: view -> controller

        view.userTyped("add write chapter 11");
        view.userTyped("add review diagrams");
        view.userTyped("done 1");
        view.userTyped("done 42");

        System.out.println("-- switching the view to a read-only controller --");
        view.setController(new ReadOnlyController(view));
        view.userTyped("add sneaky task");
    }
}
```

Output:

```
> add write chapter 11
  + My Tasks
    [ ] 1. write chapter 11
    + Summary
      1 open
> add review diagrams
  + My Tasks
    [ ] 1. write chapter 11
    [ ] 2. review diagrams
    + Summary
      2 open
> done 1
  + My Tasks
    [x] 1. write chapter 11
    [ ] 2. review diagrams
    + Summary
      1 open
> done 42
  (error: no task 42)
-- switching the view to a read-only controller --
> add sneaky task
  (read-only mode, ignored: add sneaky task)
```

Trade-offs, variants and mistakes

Pros	Cons
Separation of concerns; business rules testable without UI.	More classes and indirection for tiny apps.
Several views on one model (list, chart, widget).	Update flows via observers can be hard to trace.
Swap controllers/views independently.	Controllers tend to get "fat" if business logic leaks into them.

- **Web MVC is different.** In **Spring MVC** (a "Model 2" design), a **front controller** (`DispatcherServlet` — a *servlet* is a Java class that handles HTTP requests inside a web server) routes each HTTP request to a `@Controller` method, which fills a model and returns a view name; the view renders once per request. The view does **not** observe the model — there is no long-lived observer link over HTTP.
- **Relatives: MVP** (Model–View–Presenter: a passive view, the presenter updates it) and **MVVM** (Model–View–ViewModel: the view binds to observable properties of a view-model — Android Jetpack `ViewModel` + `LiveData`/`StateFlow`, WPF). MVVM's view-model also plays a **mediator** role.

- **Common mistakes:** business logic in controllers ("fat controller"); views changing the model directly; models that import UI classes.

Real-world examples

Spring MVC, Ruby on Rails, Django (which calls it MTV), ASP.NET MVC, Swing (each component has a model, e.g. `JTable` + `TableModel` with `TableModelListener`), iOS UIKit (`UIViewController`), Android (MVVM).

In the interview

> **30-second answer:** "MVC separates the model — data and rules — from the view that shows it and the controller that interprets input. Head First calls it a compound pattern: the model is an Observer subject for the views, the controller is a Strategy the view delegates to, and the view is a Composite of widgets. On the web, like Spring MVC, it becomes request-driven with a front controller, and the view doesn't observe the model."

Self-check. Q: Which three patterns make up MVC? A: Observer, Strategy, Composite. Q: Does the controller redraw the view? A: No — it updates the model, and the model's notification makes the view redraw.

> **TL;DR:** **Model** (state + rules, observable) → **View** (composite, observes) → **Controller** (strategy that interprets input).

11.7.6 Event Sourcing (lite)

What it is

Event Sourcing stores **every change as an immutable event** ("ItemAdded", "ItemRemoved", "CheckedOut") in an **append-only log** (a log you can only add to at the end, never edit), and derives the current state by **replaying** those events — instead of storing only the latest state and overwriting it. It is included here because it **borrows ideas from Command, Memento and Observer at system level** (events look like recorded commands, snapshots are mementos, projections observe the log), and it shows up in design interviews about carts, wallets, orders and audit trails.

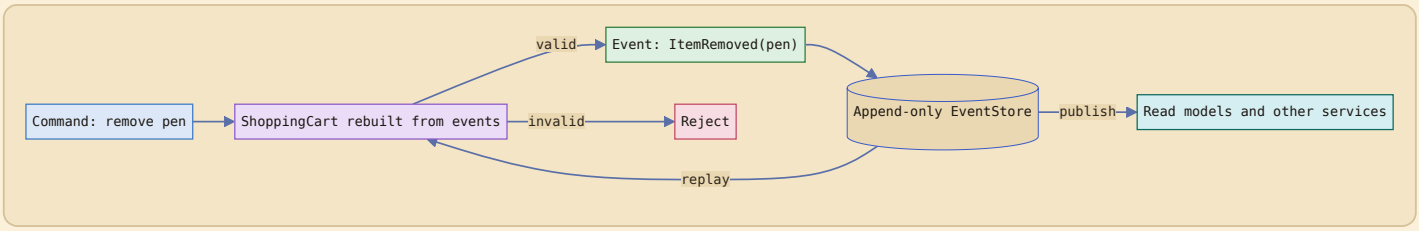
Analogy: a bank passbook. The balance is not the source of truth; the list of transactions is. The balance can always be recomputed from it.

The problem it solves

With "update in place", history is lost: you can't answer "what did the cart look like before checkout?", audit who changed what, or rebuild a **read model** (a copy of the data shaped for fast queries) after a bug. With events, the full history is kept, and you can **time-travel**, **audit**, and **build new views** later by replaying.

How it works

1. **Command side:** load the aggregate by replaying its events; **validate** the command against current state; if valid, **emit an event** (a fact, past tense).
2. **Append** the event to the store — never update or delete events.
3. **Apply**: a **pure function** (its output depends only on its inputs, and it changes nothing else) updates state from an event (no validation, no side effects — events are facts).
4. **Read side:** replay (all or the first *n* events) to get state at any point; publish events to **observers** that build read models (this split is **CQRS** — Command Query Responsibility Segregation).
5. For long streams, save periodic **snapshots** (Memento!) and replay only newer events.



Java example

A **sealed** `CartEvent` hierarchy; `ShoppingCart.apply` is an exhaustive pattern-matching `switch` over it (a `switch` *statement* with patterns must be exhaustive in Java 21, so a new event type that `apply` forgets is a compile error); `EventStore` is an append-only in-memory log whose methods are `synchronized`, so appends and reads from several threads are safe. Prices are `BigDecimal`.

```java
// File: code/lld/ch11/eventsourcing/CartEvent.java
package lld.ch11.eventsourcing;

import java.math.BigDecimal;

/** Facts that HAPPENED (past tense). Immutable; never updated or deleted. */
public sealed interface CartEvent permits CartEvent.ItemAdded, CartEvent.ItemRemoved, CartEvent.CheckedOut {
    record ItemAdded(String sku, int qty, BigDecimal unitPrice) implements CartEvent {}
    record ItemRemoved(String sku) implements CartEvent {}
    record CheckedOut() implements CartEvent {}
}
```

```java
// File: code/lld/ch11/eventsourcing/EventStore.java
package lld.ch11.eventsourcing;

import java.util.ArrayList;
import java.util.List;
import java.util.Map;
import java.util.concurrent.ConcurrentHashMap;

/** Append-only log per stream (cart id). The log IS the source of truth. */
public final class EventStore {
    private final Map<String, List<CartEvent>> streams = new ConcurrentHashMap<>();

    public synchronized void append(String streamId, CartEvent e) {
        streams.computeIfAbsent(streamId, k -> new ArrayList<>()).add(e);
    }

    public synchronized List<CartEvent> read(String streamId) {
        return List.copyOf(streams.getOrDefault(streamId, List.of()));
    }
}
```

```java
// File: code/lld/ch11/eventsourcing/ShoppingCart.java
package lld.ch11.eventsourcing;

import java.math.BigDecimal;
import java.util.LinkedHashMap;
import java.util.List;
import java.util.Map;

/** Aggregate whose current state is DERIVED by replaying events. */
public final class ShoppingCart {
    private final Map<String, BigDecimal> lineTotals = new LinkedHashMap<>();
    private boolean checkedOut;

    /** Rebuild state from history (optionally only the first n events: "time travel"). */
    public static ShoppingCart replay(List<CartEvent> history, int n) {
        ShoppingCart cart = new ShoppingCart();
        history.stream().limit(n).forEach(cart::apply);
        return cart;
    }

    /** Pure state transition: no validation, no side effects. Events are facts. */
    private void apply(CartEvent e) {
        switch (e) {
            case CartEvent.ItemAdded a -> lineTotals.merge(a.sku(),
a.unitPrice().multiply(BigDecimal.valueOf(a.qty())), BigDecimal::add);
            case CartEvent.ItemRemoved r -> lineTotals.remove(r.sku());
            case CartEvent.CheckedOut c -> checkedOut = true;
        }
    }

    /** Command side: validate against current state, THEN emit an event. */
    public CartEvent decideRemove(String sku) {
        if (checkedOut) throw new IllegalStateException("cart already checked out");
        if (!lineTotals.containsKey(sku)) throw new IllegalArgumentException(sku + " not in cart");
        return new CartEvent.ItemRemoved(sku);
    }

    @Override
    public String toString() {
        BigDecimal total = lineTotals.values().stream().reduce(new BigDecimal("0.00"), BigDecimal::add);
        return lineTotals.keySet() + " total=" + total + (checkedOut ? " CHECKED-OUT" : "");
    }
}
```

```java
// File: code/lld/ch11/eventsourcing/Main.java
package lld.ch11.eventsourcing;

import java.math.BigDecimal;
import java.util.List;

public class Main {
    public static void main(String[] args) {
        EventStore store = new EventStore();
        String cartId = "cart-7";
        store.append(cartId, new CartEvent.ItemAdded("book", 2, new BigDecimal("12.99")));
        store.append(cartId, new CartEvent.ItemAdded("pen", 5, new BigDecimal("0.99")));

        ShoppingCart current = ShoppingCart.replay(store.read(cartId), Integer.MAX_VALUE);
        store.append(cartId, current.decideRemove("pen"));      // validated, then recorded
        store.append(cartId, new CartEvent.CheckedOut());

        List<CartEvent> history = store.read(cartId);
        System.out.println("event log:");
        history.forEach(e -> System.out.println("  " + e));

        System.out.println("state after each event (replay = time travel):");
        for (int n = 0; n <= history.size(); n++) {
            System.out.println("  after " + n + ": " + ShoppingCart.replay(history, n));
        }

        try {
            ShoppingCart.replay(history, history.size()).decideRemove("book");
        } catch (IllegalStateException e) {
            System.out.println("command rejected: " + e.getMessage());
        }
    }
}
```

Output:

```
event log:
  ItemAdded[sku=book, qty=2, unitPrice=12.99]
  ItemAdded[sku=pen, qty=5, unitPrice=0.99]
  ItemRemoved[sku=pen]
  CheckedOut[]
state after each event (replay = time travel):
  after 0: [] total=0.00
  after 1: [book] total=25.98
  after 2: [book, pen] total=30.93
  after 3: [book] total=25.98
  after 4: [book] total=25.98 CHECKED-OUT
command rejected: cart already checked out
```

Trade-offs, when not to use it, mistakes

Pros	Cons
Complete audit trail and time travel.	More complex than CRUD; a learning curve for the team.
Rebuild or add read models at any time.	**Event schema evolution** (versioning old events) is hard.
Natural fit with event-driven architectures.	Reads need projections (read models built from events); eventual consistency (the read side catches up after a short delay) between write and read sides.

- **Don't use it** for simple CRUD without audit or history needs.
- **Common mistakes:** putting validation in `apply` (replay of old facts may then fail); events named as commands (`RemoveItem` instead of `ItemRemoved`); mutable events; storing derived data inside events; no snapshots for very long streams; **appending without an expected-version check** — two commands decided on the same old state

can both append. Real event stores take an `expectedVersion` on append and reject the second writer (optimistic concurrency). The toy `EventStore` here omits it.

Real-world examples

Bank ledgers and payment systems (balances derived from ledger entries); Git (the version-control system — its history of commits); **Axon Framework** and **EventStoreDB**; Kafka used as an event log with long or unlimited **retention** (how long stored messages are kept) (not *compacted* topics — compaction keeps only the latest record per key, which throws away the history event sourcing needs); shopping carts and order histories where "what happened when" matters.

In the interview

30-second answer: "Event sourcing stores every change as an immutable, past-tense event in an append-only log and derives state by replaying. Commands are validated against the replayed state and then produce events; `apply` just folds events into state. You get audit and time travel, and can build new read models by replaying; the costs are complexity, schema evolution and eventual consistency. Snapshots keep replay fast — that's Memento plus a command log."

Self-check. Q: Where does validation happen? A: On the command side, before emitting the event — never in `apply`. Q: How do you keep replay fast? A: Periodic snapshots.

TL;DR: Store facts, not state; rebuild by replay; validate commands, never events; snapshot long streams.

11.8 Choose the right behavioral pattern

Start from the **symptom** in the code or requirement, not from the pattern name.

If you see / need...	Use	Not to be confused with
A request must pass several independent checks; any may reject it; different routes need different checks	**Chain of Responsibility**	Decorator (every layer always runs)
Undo/redo, queue, schedule, retry, or log *requested actions*	**Command**	Strategy (how, not what)
Evaluate user-written rules/expressions in a small language	**Interpreter** (+ Specification)	Visitor (for many operations over the AST)
Walk a collection/tree/paged API without exposing structure	**Iterator** (`Iterable`)	Visitor (what to do at each node)
Many objects depend on each other's changes and the *order* of reactions matters	**Mediator**	Observer (no coordination)
Roll back to an earlier state without exposing internals	**Memento**	Command undo (store actions instead)
One change must notify an open-ended set of independent listeners	**Observer** (or a message broker for durability)	Mediator
Three or more methods repeat one `switch` over a status; which actions are legal depends on that status	**State**	Strategy (chosen from outside)
Several interchangeable algorithms for one job, chosen by config/user/run time	**Strategy** (often a lambda)	State, Template Method
Several classes share a long fixed flow and differ in a few steps	**Template Method** (or template + callbacks)	Strategy
Many new operations over a stable set of types	**Visitor**, or **sealed types + pattern matching** in Java 21	Iterator, Strategy
`null` checks everywhere for an optional collaborator	**Null Object** (or `Optional` for lookups)	—
Classes create their own collaborators; hard to test	**Dependency Injection**	Service Locator (anti-pattern)
Business logic mixed with storage code	**Repository**	DAO (table-oriented)
The same business rule duplicated in queries and validation; finder-method explosion	**Specification**	—
UI, input handling and business rules tangled together	**MVC / MVVM**	—
Need full history, audit, time travel of changes	**Event Sourcing** (+ snapshots)	Plain audit log

Three questions that settle the famous look-alikes:

1. **Do the alternatives reference each other?** Yes → **State**. No → **Strategy** (or Bridge if chosen once at wiring).
2. **Can one participant stop the flow?** Yes → **Chain of Responsibility**. Every participant always runs → **Decorator** / pipeline. Everyone is told, nobody stops anyone → **Observer**.
3. **Does a central object decide what happens next?** Yes → **Mediator**. Each listener decides for itself → **Observer**.

In the interview (chapter-level)

"Which patterns have you used in production?" Pick concrete ones and name the *trade-off*: "Strategy for payment methods, chosen by a map injected by Spring; Observer via Spring events for sending emails after an order, moved to Kafka when we needed retries; State for the order lifecycle, with the DB update guarded by `WHERE status = ?` to avoid races."

"When would you avoid patterns?" When only two branches exist and a third is not expected; when a lambda or an enum does the job; when the indirection costs more readability than it buys flexibility. Patterns are a vocabulary for trade-offs, not a checklist.

Self-check (whole chapter)

1. **Q:** An order moves placed → accepted → preparing → delivered and "cancel" is only legal in early stages. Pattern? **A:** State (enum or class per state).

2. **Q:** Checkout must support card, UPI, wallet, and new methods next quarter. Pattern? **A:** Strategy, selected by a factory/DI map.
3. **Q:** After an order is placed, send email, update analytics and notify the restaurant; more reactions will come. Pattern? **A:** Observer in-process, or pub/sub via a broker for reliability.
4. **Q:** A compiler needs type-checking, optimisation and pretty-printing passes over a fixed AST. Pattern? **A:** Visitor, or sealed interfaces + pattern matching in Java 21.
5. **Q:** Three report generators share "load → filter → format → export" but differ in format. Pattern? **A:** Template Method (or a fixed pipeline taking a formatting strategy).
6. **Q:** What three GoF patterns make up MVC? **A:** Observer, Strategy, Composite.

TL;DR

- **Observer** broadcasts; **Mediator** coordinates; **CoR** lets someone stop the flow.
- **State** vs **Strategy**: same diagram — states know each other and advance themselves; strategies are chosen from outside.
- **Template Method** = inheritance, one step varies; **Strategy** = composition, whole algorithm varies.
- **Visitor** = cheap new operations, expensive new types; Java 21 **sealed + switch** usually replaces it.
- Beyond GoF: **Null Object**, **DI**, **Repository**, **Specification**, **MVC**, **Event Sourcing** — the everyday glue of real systems and machine-coding answers.

Chapter 12 — Concurrency & Multithreading for LLD (Java)

> **Why this chapter exists.** In a low-level design (LLD) interview you will often hear: *"Now two users click **Book** on the same seat at the same moment. What happens?"* If your design has no answer, it is incomplete. This chapter teaches you, from zero, the ideas and Java tools you need to answer that question well. Chapter 13 then applies them to the classic concurrency interview problems, and chapters 14–21 use them inside full case studies.

How to read this chapter. Every concept follows the same path: *What it is → The problem it solves → How it works → Java example → Trade-offs → When not to use it → Common mistakes → Real-world examples → In the interview → Self-check → TL;DR.* All code is Java 21, standard library only, and lives in `code/lld/ch12/<topic>/Main.java`. Every `Main` compiles and runs; the real output is shown under each listing.

Run any example from `chapters/12-concurrency-concepts/code`:

```
javac --release 21 -d /tmp/lld_12 $(find . -name '*.java')
java -cp /tmp/lld_12 lld.ch12.threads.Main
```

Map of the chapter

Part	Sections	Code package
A. Foundations	12.1 Concurrency vs parallelism · 12.2 Processes vs threads · 12.3 Thread lifecycle · 12.4 Creating threads	`threads`
B. What goes wrong	12.5 Race conditions & critical sections · 12.6 Java Memory Model (visibility, happens-before, `volatile`)	`race`
C. Locks	12.7 Mutex / `synchronized` · 12.8 `ReentrantLock` · 12.9 Try-lock & timed locking · 12.10 Read-write locks & `StampedLock` · 12.11 Coarse vs fine-grained locking	`locks`
D. Coordination	12.12 Semaphores · 12.13 Condition variables · 12.14 `CountDownLatch` & `CyclicBarrier`	`coordination`
E. Lock-free	12.15 Compare-and-swap & atomics · 12.16 Concurrent collections	`atomics`, `collections`
F. Liveness failures	12.17 Deadlock · 12.18 Livelock · 12.19 Starvation	`deadlock`
G. Patterns	12.20 Signaling · 12.21 Thread pool · 12.22 Producer-consumer · 12.23 Reader-writer · 12.24 Immutability & thread confinement	`patterns`
H. Interviews	12.25 Concurrency in LLD interviews (parking spots, seat booking, inventory)	`lldcases`
	12.26 Choosing the right tool · 12.27 Chapter self-check · 12.28 Chapter TL;DR	

Words you will see everywhere (defined once here):

Term	Meaning in one line
Thread	One independent sequence of instructions running inside a program.
Shared state	Data (fields, objects) that more than one thread can read or write.
Thread-safe	A class that behaves correctly no matter how threads interleave, with no extra locking by callers.
Atomic	Happens as one indivisible step: other threads see either "before" or "after", never "halfway".
Lock / mutex	A token only one thread can hold at a time. Code that needs the token waits for it.
Critical section	A piece of code that touches shared state and must not run in two threads at once.
Contention	Many threads wanting the same lock at the same time, so they queue up.
Blocking	A thread stops and waits (for a lock, I/O, a signal) instead of using the CPU.
Liveness	"Something good eventually happens" — the program keeps making progress (no deadlock, livelock, starvation).
Safety	"Nothing bad ever happens" — no corrupted data, no double booking.

Part A — Foundations

12.1 Concurrency vs parallelism

What it is

- **Concurrency** is about *dealing with* many things at once: the program is structured as several tasks whose lifetimes overlap. They may take turns on one **CPU core** (one independent processing unit inside the processor; a modern CPU has several).
- **Parallelism** is about *doing* many things at once: tasks literally execute at the same instant on different CPU cores.

> **Analogy.** One chef cooking three dishes, switching between them while each simmers, is *concurrent*. Three chefs each cooking one dish at the same time is *parallel*. A restaurant with three chefs who also switch between dishes is both.

The problem it solves

Programs wait a lot — for disks, networks, databases, users. Concurrency lets the program do useful work while one task waits (better *responsiveness* and *throughput* — how much work gets finished per second; see System Design Fundamentals). Parallelism lets CPU-heavy work (sorting, image processing) finish sooner by using all cores (better *speed-up*).

How it works

1. The operating system (OS) *scheduler* (the part of the OS that decides which thread runs next) gives each runnable thread a short time slice on a core.
2. When the slice ends, or the thread blocks (for **I/O** — input/output such as disk or network reads — a lock, `sleep`), the scheduler performs a **context switch**: it saves that thread's **registers** (the CPU's few, fastest storage slots) and loads another's.
3. On one core, switching fast creates the *illusion* of simultaneity → concurrency.
4. On many cores, several threads really run at the same instant → parallelism.

	Concurrency	Parallelism
Core idea	Structure: many tasks in progress	Execution: many tasks running at the same instant
Needs multiple cores?	No	Yes
Main benefit	Responsiveness, overlapping waiting (I/O-bound work: mostly waiting on disk/network)	Speed on CPU-bound work (mostly computing)
Java tools	Threads, executors, virtual threads, `CompletableFuture`	Fork/Join, parallel streams, `Arrays.parallelSort`
Typical example	A web server handling 10,000 connections	Sorting 100 million numbers

Java example

Section 12.4's `Main` shows both: 10,000 tasks that each *sleep* 50 ms finish in well under a second on virtual threads (concurrency hides waiting). Chapter 13's multi-threaded merge sort uses **Fork/Join** (the JDK framework that splits a task into subtasks and runs them on all cores) to split CPU work over cores (parallelism).

Trade-offs

Concurrency adds complexity (races, deadlocks) and some overhead (context switches). Parallelism has a limit: **Amdahl's law** says that if a fraction *s* of the work is inherently sequential, the speed-up with *N* cores can never exceed 1 / (s + (1 − s)/N). With 10% sequential work, even infinite cores give at most 10× speed-up.

When not to use it

Small, fast, CPU-light tasks: splitting them over threads costs more than it saves. A single-threaded design is also a valid choice when it removes all locking (Redis — an in-memory key-value database — executes commands on one main thread for this reason; Node.js, a server-side JavaScript runtime, runs JavaScript on one **event-loop** thread: a single loop that handles ready events one at a time and never blocks).

Common mistakes

- Saying "concurrent" when you mean "parallel" (and vice versa) in an interview.
- Expecting more threads to always mean more speed. Past the core count, CPU-bound work gets *slower* from switching.

Real-world examples

- **Concurrency:** Tomcat and Jetty (Java web servers) serve many HTTP requests with a **pool** of threads (a fixed set of reusable worker threads); Netty (a Java networking library) and Node.js serve thousands of connections with a few event-loop threads.
- **Parallelism:** `Arrays.parallelSort`, parallel streams, and Spark/Hadoop (distributed data-processing frameworks) jobs splitting data across cores and machines.

In the interview

> **30-second answer:** "Concurrency is about structure — several tasks in progress, possibly interleaved on one core. Parallelism is about execution — tasks running at the same instant on several cores. Concurrency helps I/O-bound work; parallelism helps CPU-bound work."

Follow-ups:

- *Can you have concurrency without parallelism?* Yes — a single-core machine running several threads by time-slicing.
- *Can you have parallelism without concurrency?* Yes, in a narrow sense: SIMD (one instruction on many data items) runs in parallel inside a single task.
- *How many threads for a CPU-bound pool?* About the number of cores (`Runtime.getRuntime().availableProcessors()`). For I/O-bound work, more — roughly cores × (1 + wait time / compute time).

Self-check

- **Q:** A chat server with 50,000 idle connections — concurrency or parallelism problem? **A:** Concurrency: most connections are waiting, not computing.
- **Q:** What limits the speed-up of parallel code? **A:** The sequential part (Amdahl's law), plus coordination overhead.

TL;DR

Concurrency = dealing with many things (structure). Parallelism = doing many things at once (execution). I/O-bound → concurrency; CPU-bound → parallelism.

12.2 Processes vs threads

What it is

- A **process** is a running program with its *own* memory space (**heap** — the memory area where objects live — code, open files). Two processes cannot see each other's memory.
- A **thread** is a unit of execution *inside* a process. All threads of a process share the process's heap memory, but each thread has its own **stack** (local variables, call frames) and **program counter** (the address of the next instruction to run).

> **Analogy.** A process is a house; threads are people living in it. People in the same house share the kitchen (heap) — fast to share, but they can bump into each other. People in different houses (processes) must phone each other (inter-process communication) — slower, but no bumping.

The problem it solves

Threads let one program do several things at once while sharing data cheaply. Processes give strong isolation: one crashing does not corrupt the others.

How it works

1. The OS creates a process with a private **virtual address space** (the process's own view of memory, which the OS maps onto real RAM).
2. The process starts with one thread (`main` in Java).
3. The program can create more threads; they share heap objects, and each gets its own stack.
4. Communication: threads just read/write shared objects (with synchronization); processes use **pipes** (one-way byte channels between processes), **sockets** (network-style connection endpoints), shared-memory segments or message queues.

	Process	Thread
Memory	Private address space	Shares the process's heap; own stack
Creation cost	High (new address space)	Lower (platform thread ≈ an OS thread with ~1 MB stack reserved by default on 64-bit JVMs — Java Virtual Machines, the programs that run Java bytecode); virtual threads are much cheaper still
Communication	IPC: sockets, pipes, files	Shared objects — fast, but needs synchronization
Failure isolation	Strong: one crash does not kill others	Weak: an unhandled error can bring down the whole process (e.g. `OutOfMemoryError`)
Context switch	Heavier (address-space switch)	Lighter
Java	`ProcessBuilder`, `Runtime.exec`	`Thread`, executors

Java example

```java
// A new PROCESS (separate memory):
Process p = new ProcessBuilder("ls", "-l").inheritIO().start();
p.waitFor();

// A new THREAD (shares this JVM's heap):
Thread t = new Thread(() -> System.out.println("same heap, different stack"));
t.start();
t.join();
```

Trade-offs

Threads: fast sharing, but every shared mutable field is a potential bug. Processes: safe isolation, but communication is slower and needs **serialization** (turning objects into bytes so they can be sent).

When not to use it

Do not reach for threads when isolation matters more than speed (running untrusted plugins, running a crash-prone **native library** — machine code, e.g. written in C, called from Java); use separate processes or **containers** (lightweight isolated environments such as Docker).

Common mistakes

- Thinking local variables are shared between threads. They are not: each thread has its own stack. Only objects reachable from shared references are shared.
- Creating one platform thread per request without limit — each has a large stack and an OS thread behind it. Use a pool, or virtual threads.

Real-world examples

- **Google Chrome** runs tabs in separate *processes* so one crashing page does not take down the browser.
- **PostgreSQL** (a popular SQL database) uses one process per connection; **MySQL** uses one thread per connection.
- A **JVM** is one process; your application's threads, **garbage-collector** threads (the GC frees memory that nothing uses any more) and **JIT-compiler** threads (Just-In-Time compiler: turns frequently run bytecode into fast machine code while the program runs) all live inside it.

In the interview

30-second answer: "A process is an isolated program with its own memory; a thread is a path of execution inside a process that shares its heap but has its own stack. Threads are cheaper and share data easily but need synchronization; processes are isolated and safer but communicate through IPC."

Follow-ups:

- *What does a thread own privately?* Its stack (locals, call frames), program counter, and `ThreadLocal` values (variables that hold a separate copy per thread).
- *Why are threads cheaper to switch?* They share the address space, so the CPU's memory mappings stay the same.

Self-check

- **Q:** Two threads each declare `int x = 0;` inside a method and increment it. Race? **A:** No — locals live on each thread's own stack.
- **Q:** Two threads increment the same object's field. Race? **A:** Yes, unless synchronized.

TL;DR

Process = isolated house with private memory. Thread = a worker inside it sharing the heap, owning only its stack. Share cheaply, synchronize carefully.

12.3 Thread lifecycle & states

What it is

A Java thread moves through well-defined states. `Thread.getState()` returns one of the six values of the enum `java.lang.Thread.State`:

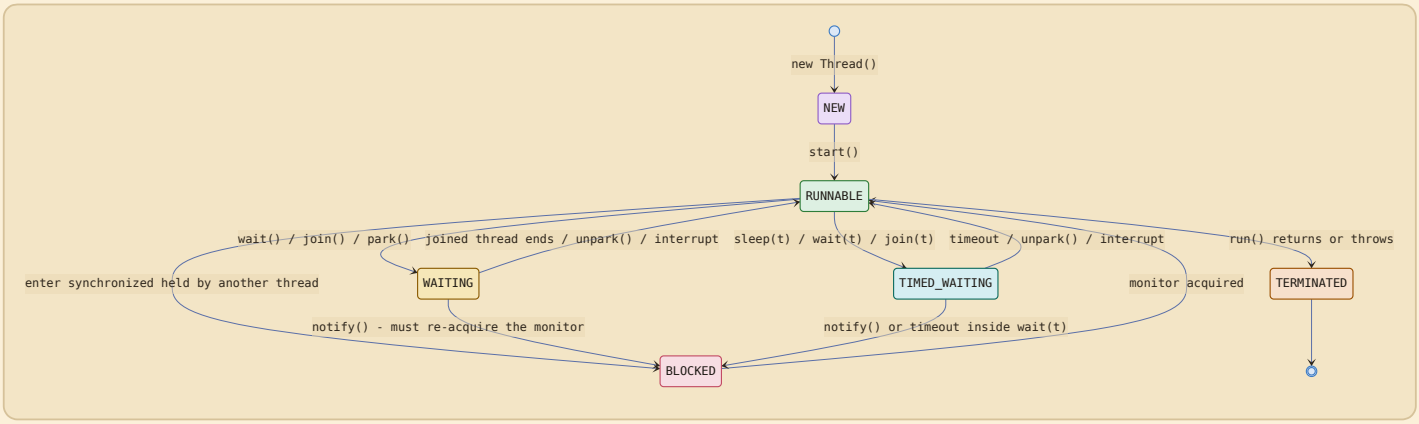
State	Meaning
`NEW`	Created with `new Thread(...)` but `start()` not called yet.
`RUNNABLE`	Started and either running on a CPU or ready to run (waiting only for the scheduler). Java does not distinguish "running" from "ready". A thread blocked in most I/O calls also shows as `RUNNABLE`.
`BLOCKED`	Waiting to *enter* a `synchronized` block/method whose monitor (the object's built-in lock, §12.7) another thread holds.
`WAITING`	Waiting with no time limit for another thread to act: `Object.wait()`, `Thread.join()`, `LockSupport.park()` (the low-level JDK call that suspends a thread; `ReentrantLock`, `Condition`, `CountDownLatch` use it).
`TIMED_WAITING`	Same, but with a timeout: `Thread.sleep(ms)`, `wait(ms)`, `join(ms)`, `parkNanos`, `tryLock(timeout)`.
`TERMINATED`	`run()` has returned or thrown. A thread cannot be restarted.

Analogy. A customer at a bank: `NEW` = has a ticket but hasn't entered; `RUNNABLE` = at the counter or next in line; `BLOCKED` = the only pen is being used, waiting to grab it; `WAITING` = told "wait until we call you"; `TIMED_WAITING` = "come back in 10 minutes"; `TERMINATED` = left the bank.

The problem it solves

Knowing the states lets you read **thread dumps** (a snapshot of every thread's state and call stack, taken with `jstack` or `jcmd <pid> Thread.print`, where pid is the process ID) and diagnose hangs: many threads `BLOCKED` on the same monitor → lock contention or **deadlock** (threads waiting on each other forever, §12.17); many `WAITING` on a queue → idle pool.

How it works



1. `new Thread(task)` → `NEW`.
2. `start()` → `RUNNABLE` (calling `start()` twice throws `IllegalThreadStateException`).
3. Trying to enter a busy `synchronized` block → `BLOCKED` until the monitor is free.
4. Calling `wait()`, `join()` or parking → `WAITING`; the timed versions → `TIMED_WAITING`.
5. A thread that wakes from `wait()` must first re-acquire the monitor, so it may pass through `BLOCKED` before returning to `RUNNABLE`.
6. When `run()` ends → `TERMINATED`.

Interruption. `t.interrupt()` sets a flag on `t`. If `t` is in `sleep`, `wait`, `join` (or other interruptible blocking calls), it wakes up with `InterruptedException` and the flag is cleared. Interruption is *cooperative*: the thread decides how to react. `Thread.stop()` is unsafe and no longer works on modern JDKs — never rely on it.

Java example

See `threadStates()` in the next section's `Main.java`: it drives one thread into each state and prints `getState()` (output lines under "Thread.State tour").

Trade-offs

Not applicable (it's a model, not a choice) — but note the `RUNNABLE` state hides whether the thread is *actually* on a CPU or stuck in native I/O.

When not to use it

Never use `getState()` for program logic (e.g. "if thread is WAITING then…"); states change between the check and your action. Use it only for monitoring and debugging.

Common mistakes

- Calling `run()` instead of `start()`: the code runs on the *current* thread; no new thread is created.
- Swallowing `InterruptedException` silently. Either rethrow it or restore the flag with `Thread.currentThread().interrupt()`.
- Thinking `BLOCKED` and `WAITING` are the same. `BLOCKED` = waiting for a *monitor*; `WAITING` = waiting for a *signal*.

Real-world examples

Production incident triage: a `jstack` dump showing 200 Tomcat worker threads `BLOCKED` on one `synchronized` logger or connection-pool method is a classic sign of a coarse lock bottleneck.

In the interview

> **30-second answer:** "Java threads have six states: NEW, RUNNABLE, BLOCKED, WAITING, TIMED_WAITING, TERMINATED. BLOCKED means waiting for a monitor lock; WAITING/TIMED_WAITING mean waiting for another thread's action, optionally with a timeout."

Follow-ups:

- *Is there a RUNNING state?* Not in Java's enum — running and ready are both `RUNNABLE`.
- *What state is a thread in during `ReentrantLock.lock()` when the lock is taken?* `WAITING` (it parks via `LockSupport`), not `BLOCKED` — `BLOCKED` is only for intrinsic monitors.
- *Can you restart a terminated thread?* No; create a new one (or submit the task to a pool).

Self-check

- **Q:** State of a thread inside `Thread.sleep(1000)`? **A:** `TIMED_WAITING`.
- **Q:** State of a thread inside `latch.await()`? **A:** `WAITING`.

TL;DR

NEW → RUNNABLE ↔ (BLOCKED | WAITING | TIMED_WAITING) → TERMINATED. BLOCKED = waiting for a monitor; WAITING = waiting for a signal. Use `start()`, never `run()`, and respect interrupts.

12.4 Creating threads: `Thread`, `Runnable`, `Callable`, `ExecutorService`, virtual threads

What it is

Five ways to run code concurrently in Java:

Way	What you write	Returns a value?	Use when
Extend `Thread`	`class T extends Thread { run() }`	No	Almost never — mixes the task with the worker
`Runnable`	`() -> { ... }` passed to `new Thread(r)` or a pool	No	A fire-and-forget task
`Callable<V>`	`() -> value` (may throw checked exceptions — ones the compiler forces you to catch or declare)	Yes, via `Future<V>`	You need a result or an exception back
`ExecutorService`	`pool.submit(task)`	`Future<V>`	Default choice: reuse threads, limit concurrency
Virtual threads (Java 21)	`Thread.ofVirtual().start(r)` / `Executors.newVirtualThreadPerTaskExecutor()`	via `Future`	Very many *blocking* (I/O-bound) tasks

> **Analogy.** A `Runnable` is a job description. A `Thread` is a worker. An `ExecutorService` is a staffing agency that keeps a team of workers and hands them job descriptions. A `Future` is the receipt you use to collect the finished job. Virtual threads are like freelancers who cost almost nothing to hire, so you hire one per job.

The problem it solves

Creating an OS thread per task is expensive and unbounded. Executors separate **what** to run (task) from **how** it runs (pooling, queueing, scheduling). Virtual threads remove the cost problem for blocking code, so you can go back to a simple "one thread per request" style.

How it works

1. Write the task as a `Runnable` (no result) or `Callable<V>` (result/exception).
2. Submit it to an `ExecutorService` (e.g. `Executors.newFixedThreadPool(n)`); you get a `Future<V>`.
3. `future.get()` blocks until the result is ready (or rethrows the task's exception wrapped in `ExecutionException`).
4. When done, `shutdown()` the pool (stop accepting tasks) and `awaitTermination(...)`; or, since Java 19, use **try-with-resources** (a `try (...)` block that closes its resource automatically at the end) — `ExecutorService.close()` waits for tasks to finish.
5. **Virtual threads** (final in Java 21, JEP 444 — a JEP, JDK Enhancement Proposal, is the numbered design document for a Java feature) are lightweight threads managed by the JVM. Many virtual threads run on a small pool of OS "carrier" threads (a `ForkJoinPool` sized to the number of cores by default). When a virtual thread blocks on I/O, `sleep`, or a `java.util.concurrent` lock, the JVM *unmounts* it and the carrier runs another virtual thread. The exception is **pinning**: a virtual thread that cannot unmount keeps its carrier busy while it blocks. On Java 21–23 this happens when it blocks inside a `synchronized` block/method (including `Object.wait()`) or inside a native method; JDK 24 (JEP 491) removed the `synchronized` case, leaving mainly native/foreign-function calls (and blocking inside a class initializer) as pinning causes.

Java example

```java
// File: code/lld/ch12/threads/Main.java
package lld.ch12.threads;

import java.util.ArrayList;
import java.util.List;
import java.util.concurrent.Callable;
import java.util.concurrent.CountDownLatch;
import java.util.concurrent.ExecutorService;
import java.util.concurrent.Executors;
import java.util.concurrent.Future;
import java.util.concurrent.TimeUnit;
import java.util.stream.IntStream;

/** Five ways to run code on another thread, plus a tour of every Thread.State. */
public class Main {

    // Way 1: subclass Thread (works, but couples "the task" with "the worker").
    static class GreeterThread extends Thread {
        GreeterThread() { super("greeter-thread"); }
        @Override public void run() {
            System.out.println("1) extends Thread   -> hello from " + getName());
        }
    }

    public static void main(String[] args) throws Exception {
        creatingThreads();
        virtualThreads();
        threadStates();
    }

    static void creatingThreads() throws Exception {
        System.out.println("=== Creating threads ===");
        Thread t1 = new GreeterThread();
        t1.start();          // start() creates a new call stack; run() would run on *this* thread
        t1.join();           // wait for it to finish so output order is predictable

        // Way 2: Runnable = a task with no result. Preferred over subclassing Thread.
        Runnable task = () -> System.out.println("2) Runnable         -> hello from " +
Thread.currentThread().getName());
        Thread t2 = new Thread(task, "runnable-thread");
        t2.start();
        t2.join();

        // Way 3 + 4: Callable (returns a value / throws) submitted to an ExecutorService (a thread pool).
        ExecutorService pool = Executors.newFixedThreadPool(2);
        try {
            Callable<Integer> sumTask = () -> IntStream.rangeClosed(1, 100).sum();
            Future<Integer> future = pool.submit(sumTask);   // returns immediately
            System.out.println("3) Callable+Future  -> sum 1..100 = " + future.get()); // get() blocks until done

            List<Callable<String>> jobs = List.of(() -> "A", () -> "B", () -> "C");
            List<String> results = new ArrayList<>();
            for (Future<String> f : pool.invokeAll(jobs)) results.add(f.get());   // invokeAll keeps input order
            System.out.println("4) ExecutorService  -> invokeAll results " + results);
        } finally {
            pool.shutdown();                                  // stop accepting work
            pool.awaitTermination(5, TimeUnit.SECONDS);       // wait for running tasks
        }
    }

    static void virtualThreads() throws Exception {
        System.out.println("=== Virtual threads (Java 21) ===");
        Thread vt = Thread.ofVirtual().name("virtual-1").start(
                () -> System.out.println("5) virtual thread   -> isVirtual=" +
Thread.currentThread().isVirtual()));
        vt.join();
```

```
        // 10,000 blocking tasks: cheap with virtual threads (each sleep parks the virtual thread,
        // freeing its carrier OS thread for other work).
        long start = System.nanoTime();
        int completed;
        try (ExecutorService vexec = Executors.newVirtualThreadPerTaskExecutor()) {
            List<Future<Integer>> fs = new ArrayList<>();
            for (int i = 0; i < 10_000; i++) {
                fs.add(vexec.submit(() -> { Thread.sleep(50); return 1; }));
            }
            int sum = 0;
            for (Future<Integer> f : fs) sum += f.get();
            completed = sum;
        } // close() waits for all tasks
        long ms = (System.nanoTime() - start) / 1_000_000;
        System.out.println("10,000 tasks that each sleep 50 ms completed: " + completed
                + " (well under 10,000 x 50 ms = 500 s: " + (ms < 60_000) + ")");
    }

    static void threadStates() throws Exception {
        System.out.println("=== Thread.State tour ===");
        Object monitor = new Object();

        Thread sleeper = new Thread(() -> {
            try { Thread.sleep(10_000); } catch (InterruptedException e) { /* woken early: fine */ }
        }, "sleeper");
        System.out.println("after new Thread()            : " + sleeper.getState());      // NEW
        sleeper.start();
        awaitState(sleeper, Thread.State.TIMED_WAITING);
        System.out.println("inside Thread.sleep(10s)      : " + sleeper.getState());      // TIMED_WAITING
        sleeper.interrupt();
        sleeper.join();
        System.out.println("after run() returns           : " + sleeper.getState());      // TERMINATED

        CountDownLatch gate = new CountDownLatch(1);
        Thread waiter = new Thread(() -> {
            try { gate.await(); } catch (InterruptedException ignored) { }
        }, "waiter");
        waiter.start();
        awaitState(waiter, Thread.State.WAITING);
        System.out.println("inside latch.await()          : " + waiter.getState());       // WAITING
        gate.countDown();
        waiter.join();

        Thread blocked;
        synchronized (monitor) {             // main holds the monitor...
            blocked = new Thread(() -> { synchronized (monitor) { /* got it */ } }, "blocked");
            blocked.start();
            awaitState(blocked, Thread.State.BLOCKED);
            System.out.println("waiting to enter synchronized : " + blocked.getState()); // BLOCKED
        }                                    // ...released here, so 'blocked' can proceed
        blocked.join();

        java.util.concurrent.atomic.AtomicBoolean stop = new java.util.concurrent.atomic.AtomicBoolean();
        Thread spinner = new Thread(() -> { while (!stop.get()) Thread.onSpinWait(); }, "spinner");
        spinner.start();
        System.out.println("busy running on a CPU         : " + spinner.getState());      // RUNNABLE
        stop.set(true);
        spinner.join();
    }

    /** Poll until the thread reaches the wanted state (max ~5 s). */
    static void awaitState(Thread t, Thread.State wanted) throws InterruptedException {
        long deadline = System.nanoTime() + TimeUnit.SECONDS.toNanos(5);
        while (t.getState() != wanted && System.nanoTime() < deadline) Thread.sleep(1);
    }
}
```

Explaining each part:

- `GreeterThread` subclasses `Thread` — shown only for completeness. Prefer passing a `Runnable`.
- `t1.start()` creates the new call stack; `t1.join()` waits for it to finish, which also guarantees that everything `t1` wrote is visible to `main` afterwards (a *happens-before* edge, section 12.6).
- `pool.submit(sumTask)` returns a `Future` immediately; `future.get()` blocks.
- `invokeAll` runs a list of `Callable`s and returns futures **in the same order** as the input list.
- `shutdown()` + `awaitTermination()` is the classic clean shutdown. `newVirtualThreadPerTaskExecutor()` in try-with-resources uses `close()`, which waits for all tasks.
- 10,000 sleeping tasks finish quickly: each `sleep` parks its virtual thread instead of holding an OS thread.
- `threadStates()` drives threads into each state (NEW, TIMED_WAITING, TERMINATED, WAITING, BLOCKED, RUNNABLE). `awaitState` polls, because a state change is not instant after `start()`.

Output:

```
=== Creating threads ===
1) extends Thread   -> hello from greeter-thread
2) Runnable         -> hello from runnable-thread
3) Callable+Future  -> sum 1..100 = 5050
4) ExecutorService  -> invokeAll results [A, B, C]
=== Virtual threads (Java 21) ===
5) virtual thread   -> isVirtual=true
10,000 tasks that each sleep 50 ms completed: 10000 (well under 10,000 x 50 ms = 500 s: true)
=== Thread.State tour ===
after new Thread()            : NEW
inside Thread.sleep(10s)      : TIMED_WAITING
after run() returns           : TERMINATED
inside latch.await()          : WAITING
waiting to enter synchronized : BLOCKED
busy running on a CPU         : RUNNABLE
```

Trade-offs

	Platform thread pool	**Virtual threads**
Cost per thread	High (OS thread + large stack)	Very low (heap-allocated stack that grows as needed)
How many	Hundreds to a few thousand	Millions
Best for	CPU-bound work (size ≈ cores)	Blocking I/O-bound work
Limits concurrency?	Yes, by pool size	No — add a `Semaphore` if a downstream resource needs a limit
Pooling	Yes	No — never pool virtual threads; create one per task

When not to use it

- Do not use virtual threads for CPU-heavy computation — they give no extra cores; use a fixed pool or Fork/Join.
- On Java 21–23, a virtual thread that blocks *inside a* `synchronized` *block* stays **pinned** to its carrier thread, reducing scalability; prefer `ReentrantLock` around blocking calls on those versions. (JDK 24's JEP 491 removed most of this pinning.)
- Do not use `Executors.newCachedThreadPool()` for unbounded incoming traffic — it can create unlimited platform threads.

Common mistakes

- Forgetting `shutdown()`: non-daemon pool threads keep the JVM alive after `main` ends (a **daemon** thread is a background thread that does not keep the JVM running; ordinary threads do).
- Ignoring the `Future` of a submitted `Runnable`: exceptions thrown inside are captured in the `Future` and silently lost if you never call `get()`.
- Using `Executors.newFixedThreadPool` for untrusted load: its queue is **unbounded** (`LinkedBlockingQueue`), so a burst can exhaust memory. Build a `ThreadPoolExecutor` with a bounded queue (section 12.21).

Real-world examples

- `Executors` factory methods are the textbook **Factory** pattern in the JDK.
- **Spring** (the most widely used Java application framework): its `@Async` runs methods on a `TaskExecutor` (commonly a `ThreadPoolTaskExecutor`).
- Spring Boot 3.2+ can run request handling on virtual threads with `spring.threads.virtual.enabled=true`; Tomcat and Jetty can be configured to use virtual threads too.

In the interview

> **30-second answer:** "I never manage raw threads in business code. I describe work as `Runnable` / `Callable` and submit it to an `ExecutorService` sized for the workload: about cores for CPU-bound work, bounded queue with a rejection policy for incoming traffic. For many blocking I/O tasks on Java 21, I use virtual threads — one per task — and protect scarce resources with a semaphore." (A **semaphore** is a counter of permits that caps how many threads may proceed at once — §12.12.)

Follow-ups:

- *`Runnable` vs `Callable`?* `Callable` returns a value and may throw checked exceptions; `Runnable` does neither.
- *`submit` vs `execute`?* `execute(Runnable)` returns nothing and uncaught exceptions go to the thread's handler; `submit` returns a `Future` that captures the exception.
- *What does `CompletableFuture` add?* Non-blocking composition: `thenApply`, `thenCombine`, `allOf`, error handling with `exceptionally`, without calling `get()` at each step.

Self-check

- **Q:** What happens if you call `thread.run()`? **A:** The code runs synchronously on the current thread.
- **Q:** Why not pool virtual threads? **A:** They are cheap to create; pooling adds nothing and hides the one-thread-per-task model. Limit concurrency with a semaphore instead.

TL;DR

Tasks = `Runnable` / `Callable`. Run them with an `ExecutorService`, get results via `Future`. Java 21 virtual threads make one-thread-per-blocking-task cheap. Always shut pools down.

Part B — What goes wrong

12.5 Race conditions & critical sections

What it is

- A **race condition** is a bug where the result depends on the unlucky timing (interleaving) of threads.
- A **critical section** is the code that touches shared mutable state and must therefore run in only one thread at a time.
- A **data race** (the precise Java Memory Model term) is when two threads access the same variable, at least one writes, and there is no happens-before ordering between them (section 12.6).

> **Analogy.** Two people share a bank account with ₹100. Both check the balance at the same moment, both see ₹100, both withdraw ₹80. The bank gave out ₹160 from ₹100. The "check the balance, then withdraw" steps were the critical section.

The problem it solves

Understanding races tells you *which* code needs protection and *why* it goes wrong. The two classic shapes:

Shape	Example	Why it breaks
Read-modify-write	`count++`	It is really `tmp = count; tmp = tmp + 1; count = tmp`. Two threads read the same old value; one update is lost.
Check-then-act	`if (!map.containsKey(k)) map.put(k, v);` or `if (seat.isFree()) seat.book(me);`	The condition can become false between the check and the act.

How it works

1. Find all **shared mutable state** (fields reachable by more than one thread and changed after construction).
2. Find every **invariant** (a rule about the data that must always hold true) involving it (e.g. "a seat has at most one owner", "balance ≥ 0").
3. Mark the code that reads and then updates that state as a **critical section**.
4. Make each critical section **atomic** — with a lock (`synchronized`, `ReentrantLock`), with a single atomic operation (`AtomicInteger.incrementAndGet`, `ConcurrentHashMap.putIfAbsent`), or by removing the sharing (immutability — objects that never change; confinement — data only one thread touches; see §12.24).

Java example

```java
// File: code/lld/ch12/race/Main.java
package lld.ch12.race;

import java.util.ArrayList;
import java.util.List;
import java.util.concurrent.atomic.AtomicInteger;

/** Race conditions, three fixes, and the visibility problem solved with volatile. */
public class Main {

    interface Counter { void increment(); int get(); }

    /** BROKEN: count++ is read-modify-write (3 steps), so concurrent increments get lost. */
    static class UnsafeCounter implements Counter {
        private int count;
        public void increment() { count++; }
        public int get() { return count; }
    }

    /** Fix 1: a mutex (the object's intrinsic lock) makes the critical section atomic. */
    static class SynchronizedCounter implements Counter {
        private int count;
        public synchronized void increment() { count++; }
        public synchronized int get() { return count; }   // reads need the lock too (visibility)
    }

    /** Fix 2: a lock-free atomic built on compare-and-swap. */
    static class AtomicCounter implements Counter {
        private final AtomicInteger count = new AtomicInteger();
        public void increment() { count.incrementAndGet(); }
        public int get() { return count.get(); }
    }

    static final int THREADS = 4, PER_THREAD = 250_000;

    static int hammer(Counter c) throws InterruptedException {
        List<Thread> ts = new ArrayList<>();
        for (int i = 0; i < THREADS; i++) {
            Thread t = new Thread(() -> { for (int j = 0; j < PER_THREAD; j++) c.increment(); });
            ts.add(t);
            t.start();
        }
        for (Thread t : ts) t.join();   // join() also creates a happens-before edge: we see their writes
        return c.get();
    }

    // ---------- Visibility ----------
    static class Worker implements Runnable {
        private volatile boolean running = true;   // without volatile the loop may never see 'false'
        private long iterations;
        public void run() { while (running) iterations++; }
        void stop() { running = false; }
    }

    public static void main(String[] args) throws Exception {
        int expected = THREADS * PER_THREAD;
        System.out.println("expected                : " + expected);
        int unsafe = hammer(new UnsafeCounter());
        System.out.println("unsafe counter          : " + (unsafe == expected ? "correct this run (luck!)" : "LOST
" + (expected - unsafe) + " updates"));
        System.out.println("synchronized counter    : " + hammer(new SynchronizedCounter()));
        System.out.println("atomic counter          : " + hammer(new AtomicCounter()));

        // Check-then-act race, shown safely: two threads both "see" an empty seat.
        // Here we fix it with a single atomic operation instead of check + act.
        AtomicInteger seatOwner = new AtomicInteger(0);          // 0 = free
```

```
        Thread a = new Thread(() -> seatOwner.compareAndSet(0, 1));
        Thread b = new Thread(() -> seatOwner.compareAndSet(0, 2));
        a.start(); b.start(); a.join(); b.join();
        System.out.println("seat has exactly one owner: " + (seatOwner.get() == 1 || seatOwner.get() == 2));

        Worker w = new Worker();
        Thread t = new Thread(w);
        t.start();
        Thread.sleep(50);
        w.stop();                       // volatile write ...
        t.join(2_000);                  // ... is guaranteed to become visible to the worker
        System.out.println("volatile flag stopped worker: " + !t.isAlive());
    }
}
```

Explaining each part:

- `UnsafeCounter.increment()` does `count++` with no protection → updates get lost.
- `SynchronizedCounter` wraps the critical section in the object's intrinsic lock. Note that `get()` is synchronized too — that is for *visibility* (next section).
- `AtomicCounter` uses `incrementAndGet()`, a single hardware-backed atomic step (compare-and-swap, section 12.15).
- The seat example fixes a check-then-act race with one atomic call: `compareAndSet(0, id)` only succeeds if the seat is still free.
- `Worker` uses a `volatile` flag so the stop request is guaranteed to be seen (section 12.6).

Output (the number of lost updates changes every run — that unpredictability *is* the race):

```
expected                : 1000000
unsafe counter          : LOST 680044 updates
synchronized counter    : 1000000
atomic counter          : 1000000
seat has exactly one owner: true
volatile flag stopped worker: true
```

Trade-offs

Fix	Pros	Cons
Lock (`synchronized` / `ReentrantLock`)	Protects any multi-step, multi-variable invariant	Threads wait; risk of deadlock if nested
Atomic variable / atomic collection method	Fast, no blocking, no deadlock	Only covers one variable or one map entry
Immutability / confinement	No synchronization at all	Must redesign so state isn't shared or changed

When not to use it

Don't lock data that is never shared (method locals, objects confined to one thread) or never changed after safe construction (immutable objects).

Common mistakes

- Protecting writes but not reads ("reads are harmless") — a reader can see stale or half-updated state.
- Using two *separate* thread-safe calls and assuming the combination is atomic: `if (!map.containsKey(k))` `map.put(k,v)` on a `ConcurrentHashMap` is still a race. Use `putIfAbsent` / `computeIfAbsent`.
- Locking on different objects in different methods — each lock protects nothing against the other.
- Believing a race is fixed because tests pass. Races show up rarely and under load.

Real-world examples

- Double-booking in ticketing systems, overselling limited-stock items in **flash sales** (short, heavily promoted sales of limited stock), duplicate payment processing when a user double-clicks "Pay" — all check-then-act races, solved with atomic operations, locks, or database constraints (unique indexes that reject duplicate

values, `SELECT ... FOR UPDATE` — a SQL read that locks the rows it returns — and optimistic version columns: a version number checked on every update, so a write based on stale data fails).

In the interview

> **30-second answer:** "A race condition is when correctness depends on thread timing. The two common shapes are read-modify-write, like `count++`, and check-then-act, like 'if seat is free then book it'. I find the shared mutable state and its invariants, and make each critical section atomic — with a lock, an atomic operation like `putIfAbsent` or `compareAndSet`, or by removing sharing."

Follow-ups:

- *Is `volatile int count; count++` safe?* No. `volatile` gives visibility, not atomicity; the three steps can still interleave.
- *Is `ConcurrentHashMap` enough to make my class thread-safe?* Only if every invariant lives in single map operations. Multi-key invariants still need a lock or careful design.

Self-check

- **Q:** Why does `count++` lose updates? **A:** It is read, add, write — two threads can read the same value before either writes.
- **Q:** Name the race in `if (cache.get(k) == null) cache.put(k, load(k));`. **A:** Check-then-act; two threads may both load and put. Use `computeIfAbsent`.

TL;DR

Race = result depends on timing. Watch for read-modify-write and check-then-act. Make every critical section atomic, including reads.

12.6 Java Memory Model basics: visibility, happens-before, `volatile`

What it is

The **Java Memory Model (JMM)** (Java Language Specification, chapter 17) defines *when a write by one thread is guaranteed to be seen by a read in another thread*. Without the right synchronization, a thread may see a stale value — or never see the update at all.

- **Visibility**: will thread B *see* what thread A wrote?
- **Reordering**: compilers, the JIT, and CPUs may reorder instructions for speed as long as a *single* thread can't tell the difference. Other threads can.
- **Happens-before (HB)**: a guarantee that if action X *happens-before* action Y, then X's effects are visible to Y and X appears ordered before Y.
- `volatile`: a field modifier that makes reads/writes of that field visible to all threads and orders them (no caching in registers, no harmful reordering around it).

> **Analogy.** Each thread works from its own notepad (**CPU caches** — small, fast memories next to each core — and registers) and only sometimes copies to the shared whiteboard (main memory). Happens-before rules are the moments when the notepad is guaranteed to be synced with the whiteboard.

The problem it solves

The `Worker` loop `while (running) iterations++;` with a *non-volatile* `running` may never stop: the JIT is allowed to read `running` once and turn the loop into `while (true)`. Visibility bugs like this are invisible in code review unless you know the JMM.

How it works

The key **happens-before rules** (you can quote these in an interview):

Rule	Meaning
Program order	Within one thread, each action HB the next one.
Monitor lock	An **unlock** of a monitor HB every later **lock** of the *same* monitor.
Volatile	A **write** to a volatile field HB every later **read** of that field.
Thread start	`t.start()` HB every action in thread `t`.
Thread join	Every action in `t` HB another thread's successful return from `t.join()`.
Transitivity	If A HB B and B HB C, then A HB C.
Final fields	Strictly a separate guarantee (JLS §17.5), not a happens-before edge: once a constructor finishes without leaking `this`, any thread that obtains a reference to the object sees the correct values of its `final` fields (and of objects reachable through them, as of the end of the constructor) — even if the reference was shared without synchronization.
`java.util.concurrent`	E.g. putting into a `BlockingQueue` HB taking it out; `countDown()` HB a return from `await()`; `Future` completion HB `get()` returning.

Steps to apply them:

1. For each shared variable, ask: "Is every write-then-read pair connected by a happens-before edge?"
2. If they are protected by the same lock → yes (monitor rule).
3. If the variable is a single independent flag or reference → `volatile` is enough.
4. If it is a compound update (`x++`, check-then-act) → `volatile` is **not** enough; use a lock or atomic.

Safe publication. An object is *safely published* when the reference to it is made visible through an HB edge: stored in a `volatile` field (or an `AtomicReference`), stored in a `final` field of a properly constructed object, created by a static initializer, put into a concurrent collection, or written under a lock that the reader also takes. Otherwise a reader might see the reference but not the fully constructed object.

Double-checked locking (lazy Singleton — a class with exactly one shared instance, created only on first use) is only correct if the instance field is `volatile`:

```
class Config {
    private static volatile Config instance;          // volatile is essential
    static Config get() {
        Config c = instance;
        if (c == null) {
            synchronized (Config.class) {
                c = instance;
                if (c == null) instance = c = new Config();
            }
        }
        return c;
    }
}
```

(Simpler and just as lazy: the *holder idiom* — `private static class Holder { static final Config I = new Config(); }` — class initialization is thread-safe by the JLS.)

Java example

`Worker` in the race example above: `private volatile boolean running`. The write `running = false` in `main` HB the worker's next read of `running`, so the loop exits. The output line `volatile flag stopped worker: true` confirms it.

Trade-offs

Tool	Visibility	Atomic compound ops	Blocking	Cost
`volatile`	Yes	No	No	Low
`synchronized` / `Lock`	Yes (for code under the same lock)	Yes	Yes	Medium
`Atomic*`	Yes	Yes, for one variable	No	Low–medium
`final` (immutable)	Yes, after construction	N/A — never changes	No	Free

When not to use it

Don't use `volatile` for anything that combines several steps or several variables — use a lock or an atomic class.

Common mistakes

- "It works on my laptop" — x86 CPUs (Intel/AMD) reorder less than ARM ones (e.g. Apple Silicon, AWS Graviton). Code without proper HB edges may fail only on other hardware or after **JIT warm-up** (once the JIT has compiled and optimised the hot code).
- Leaking `this` from a constructor (registering a listener, starting a thread in the constructor) — other threads may see a half-built object, and final-field guarantees are lost.
- Thinking `synchronized` on the writer alone is enough. The reader must use the *same* lock.

Real-world examples

- `volatile boolean running` shutdown flags in server loops and schedulers.
- `ConcurrentHashMap`, `AtomicInteger`, `CopyOnWriteArrayList` internally use volatile reads/writes and CAS (compare-and-swap, §12.15) to give HB guarantees without locks for readers.
- The JDK's `String` is immutable with `final` fields, so strings can be shared across threads freely.

In the interview

> **30-second answer:** "The Java Memory Model says a thread is only guaranteed to see another thread's write if there's a happens-before edge — unlock-then-lock of the same monitor, a volatile write-then-read, thread start/join, or a concurrent-collection handoff. `volatile` gives visibility and ordering for a single variable but not atomicity; for compound actions I use locks or atomics."

Follow-ups:

- *Why must the double-checked-locking field be volatile?* Without it, the write of the reference can be reordered before the constructor's writes, so another thread might see a non-null but half-initialized object.
- *Does `volatile` make `long`/`double` writes atomic?* Yes — non-volatile 64-bit `long`/`double` writes may be split into two 32-bit halves by the JLS (rare on modern 64-bit JVMs, but allowed); volatile ones cannot.

Self-check

- **Q:** Thread A sets a non-volatile `ready = true` after preparing data; thread B spins on `ready`. Two possible bugs? **A:** B may never see `ready` become true, or may see `ready` true but stale data (reordering).
- **Q:** Which JDK classes give HB for you? **A:** Locks, `Atomic*`, concurrent collections, `BlockingQueue`, `CountDownLatch`, `Future`, `ExecutorService.submit`.

TL;DR

Writes are only guaranteed visible across threads through happens-before edges. `volatile` = visibility + ordering for one variable, not atomicity. Locks = visibility + atomicity. Publish objects safely.

Part C — Locks

12.7 Mutex (mutual exclusion) and `synchronized`

What it is

A **mutex** (mutual-exclusion lock) is a lock that at most one thread can hold. In Java every object has a built-in mutex called its **intrinsic lock** or **monitor**. The `synchronized` keyword acquires it:

```
public synchronized void deposit(int amt) { balance += amt; }   // locks 'this'
public static synchronized void log() { ... }                    // locks the Class object
void transfer() { synchronized (lock) { ... } }                  // locks 'lock'
```

Analogy. A single-occupancy restroom with one key on a hook. Take the key to enter; others wait; hang it back when you leave.

The problem it solves

Makes a critical section **atomic** (no interleaving) and **visible** (the next thread to take the lock sees everything done before the unlock).

How it works

1. Thread reaches `synchronized (obj)`. If nobody holds `obj`'s monitor, it takes it and continues.
2. If another thread holds it, this thread goes to `BLOCKED` until the monitor is free.
3. On leaving the block — normally *or by exception* — the monitor is released automatically.
4. Intrinsic locks are **reentrant**: the holder can enter other `synchronized` code on the same object again without blocking itself.

Java example

`SynchronizedCounter` in section 12.5, and `Mailbox` / `FooBarMonitor` style classes later. A tip: lock on a **private final** object, not on `this`, when you don't want outside code to be able to take your lock:

```
private final Object lock = new Object();
void add(Item i) { synchronized (lock) { items.add(i); } }
```

Trade-offs

Pros	Cons
Simplest syntax; auto-release even on exceptions	No timeout, no `tryLock`, not interruptible while waiting
JVM-optimised (uncontended locking is cheap)	One wait-set (the threads parked in `wait()`) per object (only one "condition")
Reentrant	No fairness option (fair = longest-waiting thread goes first); on Java 21–23 pins virtual threads when blocking inside

When not to use it

When you need a timeout, interruptible waiting, fairness, several condition queues, or read/write separation — use `ReentrantLock` / `ReentrantReadWriteLock`.

Common mistakes

- Synchronizing on a *changing* reference (`synchronized (list)` after `list = new ArrayList<>()`) — different threads lock different objects.
- Synchronizing on **boxed values** (objects such as `Integer` that wrap a primitive) or string literals (`synchronized ("LOCK")`, `synchronized (Integer.valueOf(1))`) — these may be shared JVM-wide, causing mysterious contention or deadlocks.
- Doing slow I/O while holding the lock.

Real-world examples

`Vector`, `Hashtable`, `StringBuffer` and `Collections.synchronizedList(...)` wrap every method in `synchronized` — thread-safe per call but slow under contention, which is why `ArrayList`/`HashMap`/`StringBuilder` plus concurrent collections replaced them.

In the interview

> **30-second answer:** "A mutex lets one thread at a time into a critical section. In Java, `synchronized` uses the object's monitor: it's reentrant, released automatically, and gives visibility. I lock on a private final object and keep the section short."

Follow-ups:

- *What does a static synchronized method lock?* The `Class` object, e.g. `Counter.class` — a different lock from instance methods.
- *Is `synchronized` slow?* Uncontended, it's cheap. Under heavy contention, any lock is slow — reduce sharing or use finer locks.

Self-check

- **Q:** Two synchronized instance methods on *different* objects — do they block each other? **A:** No, different monitors.
- **Q:** Does an exception inside `synchronized` release the lock? **A:** Yes.

TL;DR

Mutex = one holder at a time. `synchronized` is Java's built-in, reentrant, auto-releasing mutex. Lock a private final object; keep the section short.

12.8 `ReentrantLock` and reentrancy

What it is

`java.util.concurrent.locks.ReentrantLock` is an explicit mutex with the same basic meaning as `synchronized` plus extra features. **Reentrant** means the thread holding the lock can acquire it again (a hold count goes up) and must release it the same number of times.

> **Analogy.** A room key that remembers who has it: if you already hold it, walking into an inner door of the same room doesn't make you wait for yourself.

The problem it solves

- Without reentrancy, a locked method calling another locked method of the same object would **deadlock with itself**.
- Compared with `synchronized`, `ReentrantLock` adds: `tryLock()` / `tryLock(timeout)`, `lockInterruptibly()`, optional **fairness** (`new ReentrantLock(true)`), multiple `Condition`s per lock, and queries like `isLocked()`, `getHoldCount()`.

How it works

1. `lock.lock()` — acquire (hold count 0 → 1), or wait if another thread holds it.
2. Same thread calls `lock.lock()` again → hold count 2; no waiting.
3. Each `unlock()` decrements; at 0 the lock is released and a waiting thread may proceed.
4. **Always** release in `finally`:

```
lock.lock();
try {
    // critical section
} finally {
    lock.unlock();
}
```

Java example

```java
// File: code/lld/ch12/locks/Main.java
package lld.ch12.locks;

import java.util.HashMap;
import java.util.Map;
import java.util.concurrent.BrokenBarrierException;
import java.util.concurrent.CountDownLatch;
import java.util.concurrent.CyclicBarrier;
import java.util.concurrent.TimeUnit;
import java.util.concurrent.TimeoutException;
import java.util.concurrent.locks.Lock;
import java.util.concurrent.locks.ReadWriteLock;
import java.util.concurrent.locks.ReentrantLock;
import java.util.concurrent.locks.ReentrantReadWriteLock;
import java.util.concurrent.locks.StampedLock;

/** synchronized vs ReentrantLock, reentrancy, tryLock, ReadWriteLock, StampedLock. */
public class Main {

    // ---------- Reentrancy ----------
    static class Account {
        private final ReentrantLock lock = new ReentrantLock();
        private int balance = 100;

        void withdraw(int amount) {
            lock.lock();
            try {
                if (canWithdraw(amount)) balance -= amount;   // calls another locked method
            } finally {
                lock.unlock();                                // ALWAYS unlock in finally
            }
        }
        boolean canWithdraw(int amount) {
            lock.lock();                                      // same thread re-acquires: no self-deadlock
            try {
                System.out.println("hold count inside nested call = " + lock.getHoldCount());
                return balance >= amount;
            } finally {
                lock.unlock();
            }
        }
        int balance() { lock.lock(); try { return balance; } finally { lock.unlock(); } }
    }

    // ---------- Read-write lock: many readers OR one writer ----------
    static class ConfigStore {
        private final Map<String, String> map = new HashMap<>();
        private final ReadWriteLock rw = new ReentrantReadWriteLock();
        private final Lock r = rw.readLock(), w = rw.writeLock();

        String get(String k) { r.lock(); try { return map.get(k); } finally { r.unlock(); } }
        void put(String k, String v) { w.lock(); try { map.put(k, v); } finally { w.unlock(); } }

        /** Used by the demo: prove several readers are inside the read lock at once. */
        <T> T readWhile(java.util.concurrent.Callable<T> action) throws Exception {
            r.lock(); try { return action.call(); } finally { r.unlock(); }
        }
    }

    // ---------- StampedLock optimistic read ----------
    static class Point {
        private final StampedLock sl = new StampedLock();
        private double x, y;

        void move(double dx, double dy) {
            long stamp = sl.writeLock();
```

```
            try { x += dx; y += dy; } finally { sl.unlockWrite(stamp); }
        }
        double distanceFromOrigin() {
            long stamp = sl.tryOptimisticRead();   // no locking at all, just a version number
            double cx = x, cy = y;                 // copy fields to locals
            if (!sl.validate(stamp)) {             // a writer slipped in: fall back to a real read lock
                stamp = sl.readLock();
                try { cx = x; cy = y; } finally { sl.unlockRead(stamp); }
            }
            return Math.hypot(cx, cy);
        }
    }

    public static void main(String[] args) throws Exception {
        System.out.println("=== Reentrancy ===");
        Account acc = new Account();
        acc.withdraw(30);
        System.out.println("balance = " + acc.balance());

        System.out.println("=== tryLock with timeout ===");
        ReentrantLock printer = new ReentrantLock();
        CountDownLatch mainHolds = new CountDownLatch(1);
        printer.lock();                            // main grabs the printer and keeps it
        try {
            Thread impatient = new Thread(() -> {
                try {
                    mainHolds.await();
                    if (printer.tryLock(100, TimeUnit.MILLISECONDS)) {
                        try { System.out.println("worker: got the printer"); } finally { printer.unlock(); }
                    } else {
                        System.out.println("worker: printer busy for 100 ms, doing something else instead");
                    }
                } catch (InterruptedException e) { Thread.currentThread().interrupt(); }
            });
            impatient.start();
            mainHolds.countDown();
            impatient.join();
        } finally {
            printer.unlock();
        }
        System.out.println("tryLock() now (free)  = " + printer.tryLock());
        printer.unlock();

        System.out.println("=== ReadWriteLock: readers share ===");
        ConfigStore store = new ConfigStore();
        store.put("mode", "fast");
        int readers = 3;
        CyclicBarrier allReadersInside = new CyclicBarrier(readers);
        Thread[] rs = new Thread[readers];
        boolean[] ok = new boolean[readers];
        for (int i = 0; i < readers; i++) {
            final int id = i;
            rs[i] = new Thread(() -> {
                try {
                    ok[id] = store.readWhile(() -> {
                        // If the read lock were exclusive, the barrier would time out.
                        allReadersInside.await(2, TimeUnit.SECONDS);
                        return "fast".equals(store.get("mode"));   // read lock is reentrant too
                    });
                } catch (TimeoutException | BrokenBarrierException e) {
                    ok[id] = false;
                } catch (Exception e) { throw new RuntimeException(e); }
            });
            rs[i].start();
        }
        for (Thread t : rs) t.join();
        System.out.println(readers + " readers held the read lock at the same time: " + (ok[0] && ok[1] && ok[2]));

        System.out.println("=== StampedLock optimistic read ===");
```

```
        Point p = new Point();
        p.move(3, 4);
        System.out.println("distance = " + p.distanceFromOrigin());
    }
}
```

Explaining each part:

- `Account.withdraw` locks, then calls `canWithdraw`, which locks again: `getHoldCount()` prints 2 — reentrancy in action.
- "tryLock with timeout": `main` holds `printer`; the worker waits at most 100 ms, then does something else (section 12.9).
- `ConfigStore` uses a `ReentrantReadWriteLock`. Three readers all wait at a `CyclicBarrier` *while holding the read lock*; if the read lock were exclusive, the barrier would time out. It prints `true` (section 12.10).
- `Point` uses `StampedLock.tryOptimisticRead()`: read without locking, then `validate(stamp)`; fall back to a real read lock if a writer interfered (section 12.10).

Output:

```
=== Reentrancy ===
hold count inside nested call = 2
balance = 70
=== tryLock with timeout ===
worker: printer busy for 100 ms, doing something else instead
tryLock() now (free)  = true
=== ReadWriteLock: readers share ===
3 readers held the read lock at the same time: true
=== StampedLock optimistic read ===
distance = 5.0
```

Trade-offs

Feature	`synchronized`	`ReentrantLock`
Release	Automatic	Manual (`finally`) — easy to forget
Try / timeout	No	`tryLock()`, `tryLock(t, unit)`
Interruptible wait	No	`lockInterruptibly()`
Fairness	No	Optional (`true` = longest waiter first; lower throughput)
Conditions	One wait set	Many `Condition` objects
Reentrant	Yes	Yes

When not to use it

If you need none of the extra features, `synchronized` is shorter and can't be left locked by mistake.

Common mistakes

- `lock()` *inside* the `try` — if `lock()` threw, `finally` would `unlock()` a lock you don't hold (`IllegalMonitorStateException`). Call `lock()` just before `try`.
- Forgetting `unlock()` on an early `return` or exception path — the lock stays held forever.
- Turning on fairness "to be safe" — fair locks are noticeably slower; use them only when starvation is a real problem.

Real-world examples

`ArrayBlockingQueue`, `LinkedBlockingQueue` and `ThreadPoolExecutor` use `ReentrantLock` internally (`CopyOnWriteArrayList` did up to Java 8; since Java 9 it uses `synchronized` on an internal lock object). `ReentrantLock`, `ReentrantReadWriteLock`, `Semaphore` and `CountDownLatch` are all built on `AbstractQueuedSynchronizer` (AQS — the JDK's shared framework for building locks and synchronizers); `CyclicBarrier` is built on a `ReentrantLock` + `Condition`.

In the interview

> **30-second answer:** "`ReentrantLock` is an explicit mutex with the same semantics as `synchronized` plus try-lock with timeout, interruptible acquisition, optional fairness, and multiple conditions. Reentrant means the owner can re-acquire it; the hold count must drop to zero to release. I always unlock in `finally`."

Follow-ups:

- *Why would a non-reentrant lock deadlock?* A method holding it that calls another method needing the same lock would wait for itself forever.
- *Is `StampedLock` reentrant?* No — e.g. a thread that holds its write lock and calls `writeLock()` or `readLock()` again blocks forever on itself. It also has no owner and no `Condition`s.

Self-check

- **Q:** A thread calls `lock()` 3 times and `unlock()` 2 times. Is the lock free? **A:** No; hold count is 1.
- **Q:** What does `new ReentrantLock(true)` change? **A:** Waiting threads get the lock in roughly FIFO (first in, first out) order (fair), at a throughput cost.

TL;DR

`ReentrantLock` = `synchronized` + tryLock/timeout/interruptible/fairness/conditions. Owner can re-enter. `lock(); try { … } finally { unlock(); }` always.

12.9 Try-lock & timed locking

What it is

- `tryLock()` — take the lock **only if it is free right now**; return `true`/`false` immediately.
- `tryLock(timeout, unit)` — wait up to the timeout; return `false` if still unavailable. Interruptible.

> **Analogy.** Knocking on a meeting room: if it's busy you don't stand there forever — you wait five minutes, then book another room.

The problem it solves

Plain `lock()` waits forever. That causes hung requests and makes deadlocks permanent. Try-lock lets a thread **give up and do something else** — fail fast, retry later, return "busy" to a user — and it breaks the *hold and wait* condition of deadlock (section 12.17).

How it works

1. Call `tryLock(timeout)`.
2. If it returns `true`: `try { work } finally { unlock(); }`.
3. If it returns `false`: take the fallback path (return an error, retry with **back-off** — waiting a short while before trying again — or release other locks you hold).
4. When acquiring several locks: if any `tryLock` fails, **release everything you already hold**, back off for a random short time, and retry.

Java example

In `locks/Main.java` above: the worker calls `printer.tryLock(100, TimeUnit.MILLISECONDS)` while `main` holds it, gets `false`, and prints the fallback message. In `deadlock/Main.java` (section 12.17), `transferTryLock` uses try-lock plus random back-off to avoid deadlock.

Trade-offs

Pros	Cons
No infinite waits; can report "busy"	Caller must handle failure paths
Breaks deadlock (hold-and-wait)	Retry loops without random back-off can **livelock**
Timeouts give predictable **latency** (time one operation takes)	Choosing the timeout is a judgement call

When not to use it

When failing is not acceptable and waiting is fine (e.g. a background **batch job** — one that processes data in bulk, with no user waiting — updating a counter) — plain `lock()` is simpler.

Common mistakes

- Calling `unlock()` when `tryLock` returned `false` → `IllegalMonitorStateException`.
- Retrying immediately in a tight loop — burns CPU and can livelock with another thread doing the same.
- Expecting untimed `tryLock()` to respect fairness — it *barges* (takes a free lock even if others are queued); `tryLock(0, unit)` respects fairness.

Real-world examples

- **Distributed locks** (locks shared by many servers, kept in an external store: Redis `SET key value NX PX 30000` — set only if absent, expire after 30,000 ms — Redisson's (a Java Redis client) `tryLock(wait, lease, unit)`, ZooKeeper (a coordination service for clusters) recipes) follow the same idea: try for a bounded time, give up, or let the lock expire.
- Seat-hold features on ticketing sites: if the seat is locked by someone else's checkout, you're told immediately rather than made to wait.

In the interview

> **30-second answer:** "`tryLock` with a timeout lets a thread give up instead of waiting forever. I use it when latency matters or when I need several locks: if I can't get all of them, I release what I hold, back off randomly and retry — which prevents deadlock."

Follow-ups:

- *Why random back-off?* Two threads retrying on the same schedule can keep colliding forever (livelock); randomness breaks the symmetry.

Self-check

- **Q:** What does `tryLock(0, SECONDS)` do? **A:** Tries once without waiting but, unlike `tryLock()`, respects a fair lock's queue.

TL;DR

Try-lock = acquire only if available (optionally within a timeout). Handle `false`, release everything on failure, back off randomly.

12.10 Read-write locks: `ReadWriteLock` and `StampedLock`

What it is

A **read-write lock** is a pair of locks: a shared **read lock** (many readers at once) and an exclusive **write lock** (one writer, no readers). Java provides `ReentrantReadWriteLock` and, since Java 8, `StampedLock` (adds cheap *optimistic reads*).

> **Analogy.** A museum exhibit: any number of visitors can look at it together, but when a curator needs to rearrange it, the room is cleared and only the curator is inside.

The problem it solves

With a plain mutex, readers block each other even though reading doesn't change anything. For **read-heavy** data (configuration, **caches** — fast copies of data kept for quick reads — price catalogues) a read-write lock lets reads proceed in parallel.

How it works

1. Reader: `readLock().lock()` — succeeds if no writer holds the write lock. Many readers can hold it at once.
2. Writer: `writeLock().lock()` — waits until there are **no readers and no writer**, then holds exclusively.
3. `ReentrantReadWriteLock` rules: a writer may **downgrade** (acquire the read lock while holding the write lock, then release the write lock). A reader may **not upgrade** (asking for the write lock while holding the read lock deadlocks — it waits for all readers, including itself).
4. `StampedLock` optimistic read: `long s = tryOptimisticRead()` (no locking) → read fields into locals → `validate(s)`. If a writer acquired the lock in between, `validate` returns `false` and you retry with a real `readLock()`.

Java example

`ConfigStore` and `Point` in `locks/Main.java` above. The output line `3 readers held the read lock at the same time: true` proves readers share the lock.

Trade-offs

	synchronized / ReentrantLock	ReentrantReadWriteLock	StampedLock
Parallel readers	No	Yes	Yes (and optimistic reads take no lock at all)
Reentrant	Yes	Yes	**No**
Conditions	Yes	Write lock only	No
Overhead	Lowest	Higher bookkeeping	Low for optimistic reads; more complex code
Best when	Short sections or write-heavy	Reads ≫ writes and reads are not trivially short	Very read-heavy, tiny critical sections (e.g. coordinates)

When not to use it

- Write-heavy or very short critical sections — the extra bookkeeping of a RW lock can make it *slower* than a plain mutex.
- When a copy-on-write snapshot is simpler: keep an immutable map in a `volatile` field and replace it on write (readers never lock; see 12.23).

Common mistakes

- Trying to upgrade read → write in `ReentrantReadWriteLock` (self-deadlock).
- Modifying state while holding only the *read* lock.
- Using data read under an optimistic stamp before calling `validate`, or reading fields directly instead of copying them to locals first.
- Writer starvation in non-fair mode under a constant stream of readers (construct it with `new ReentrantReadWriteLock(true)` if it matters; `StampedLock` gives no fairness guarantee either).

Real-world examples

- In-memory caches and configuration holders; routing tables that are read on every request and updated rarely.
- `ConcurrentHashMap` goes further: reads take no lock at all.

In the interview

> **30-second answer:** "A read-write lock lets many readers in together but gives writers exclusive access. It helps when reads vastly outnumber writes. `ReentrantReadWriteLock` allows downgrade but not upgrade; `StampedLock` adds optimistic reads that take no lock and are validated afterwards, but it's not reentrant."

Follow-ups:

- *How would you design a thread-safe config service?* Either a RW lock around a `HashMap`, or an immutable `Map` in a `volatile` field replaced atomically on reload (readers never block).

Self-check

- **Q:** Two readers and one writer arrive; which can run together? **A:** The two readers; the writer runs alone.
- **Q:** Why copy fields to locals in an optimistic read? **A:** So that after `validate` succeeds you use a consistent snapshot, not fields that might change after the check.

TL;DR

Many readers OR one writer. Use for read-heavy shared data. No upgrade in `ReentrantReadWriteLock`; `StampedLock` = optimistic, non-reentrant.

12.11 Coarse-grained vs fine-grained locking

What it is

- **Coarse-grained locking**: one lock protects a large amount of state (e.g. the whole parking lot).
- **Fine-grained locking**: many locks, each protecting a small piece (e.g. one lock per floor, per spot, or per **hash bucket** — one slot of the internal array a hash map spreads its entries over).

> **Analogy.** One key for an entire office building (coarse) vs a key per room (fine). One key is simple but everyone queues at the front door; room keys let people work in parallel but you must manage many keys.

The problem it solves

Choosing the right granularity balances **simplicity and safety** against **throughput under contention**.

How it works

1. Start coarse: one lock around the whole object. Measure.
2. If contention is the bottleneck, split state into **independent** parts whose invariants don't cross — each gets its own lock (**lock splitting**).
3. For a big collection, use **lock striping**: N locks; item *i* uses lock `hash(i) % N` (Java 7's `ConcurrentHashMap` had 16 segments by default; chapter 13 builds a striped map).
4. When an operation needs several fine locks (e.g. booking seats A1 and A2), always acquire them in a **global order** to avoid deadlock.
5. Keep critical sections short: do slow work (I/O, computation) *outside* the lock.

	Coarse-grained	Fine-grained
Simplicity	High	Lower — more locks, ordering rules
Concurrency	Low: one thread at a time	High: threads on different parts run together
Deadlock risk	Low (one lock)	Higher (many locks) — needs lock ordering
Overhead	One lock	Memory and bookkeeping for many locks
Cross-part invariants	Easy	Hard — may need to take several locks

Java example

- Coarse: `SynchronizedCounter` (12.5).
- Fine: `Show` in `lldcases/Main.java` (12.25) has **one lock per seat**, taken in sorted order; `StripedHashMap` in chapter 13 has one lock per stripe.

Trade-offs

See table above. Rule of thumb: *correct first, then fine-grained only where **profiling** (measuring where a program really spends its time) shows contention*.

When not to use it

Don't split locks when an invariant spans the parts (e.g. "total seats booked ≤ capacity" across all rows) unless you also handle the cross-part check.

Common mistakes

- Premature fine-graining → complexity and deadlocks without real benefit.
- Locking fine-grained parts in inconsistent order.
- "Fine-grained" locks that still funnel through a shared counter everyone updates (the counter becomes the **bottleneck** — the one slow point that limits the whole system — use `LongAdder`, a counter that spreads updates over several cells, §12.15).

Real-world examples

- `ConcurrentHashMap` (Java 8+) locks only the head node of one bin for writes — extremely fine-grained.
- Databases use row-level locks (fine) vs table-level locks (coarse).
- Python's GIL (Global Interpreter Lock) is a famous coarse lock: simple, but one thread runs Python **bytecode** (the compiled instructions the interpreter executes) at a time.

In the interview

> **30-second answer:** "I start with one lock for correctness, then refine where contention matters: per-floor or per-spot locks for a parking lot, per-show or per-seat locks for booking, striping for maps. Finer locks raise throughput but need a consistent lock order to avoid deadlock."

Follow-ups:

- *Per-show or per-seat locking for BookMyShow (an Indian movie-ticketing site)?* Per-show is simple and usually enough (contention is per show). Per-seat allows more parallelism but multi-seat bookings must lock seats in sorted order.

Self-check

- **Q:** What is lock striping? **A:** Using a fixed array of N locks and mapping each item to one by hash, to get fine-grained locking with bounded lock count.

TL;DR

Coarse = simple, low throughput. Fine = parallel, complex, deadlock-prone. Start coarse, refine with measurements, and order your locks.

Part D — Coordination

12.12 Semaphores

What it is

A **semaphore** holds a number of **permits**. `acquire()` takes one (waiting if none are left); `release()` gives one back. `java.util.concurrent.Semaphore` implements it. A semaphore with 1 permit behaves like a mutex, *except* it has no owner — any thread may release it.

> **Analogy.** A car park with 3 spaces and a display showing free spaces. Cars enter only if the number is above zero; leaving increases it.

The problem it solves

- **Limiting concurrency**: at most N threads use a resource (DB connections, **API** calls — calls to another service's programming interface — GPU slots).
- **Signaling** between threads: a semaphore with 0 permits acts as "wait until someone signals" (used heavily in chapter 13).

How it works

1. `new Semaphore(n)` — n permits. The default is **non-fair**: a thread calling `acquire()` may *barge* ahead of threads already waiting. `new Semaphore(n, true)` is **fair**: permits go to waiting threads in first-in-first-out order (at some throughput cost). Even on a fair semaphore, the untimed `tryAcquire()` barges; `tryAcquire(0, TimeUnit.SECONDS)` respects fairness.
2. `acquire()` — if permits > 0, decrement and continue; else wait.
3. `release()` — increment and wake a waiter.
4. Also: `tryAcquire()`, `tryAcquire(timeout, unit)`, `acquire(k)` for several permits.
5. Always `release()` in `finally` after a successful `acquire()`.

Java example

```java
// File: code/lld/ch12/coordination/Main.java
package lld.ch12.coordination;

import java.util.ArrayList;
import java.util.List;
import java.util.concurrent.CountDownLatch;
import java.util.concurrent.CyclicBarrier;
import java.util.concurrent.ExecutorService;
import java.util.concurrent.Executors;
import java.util.concurrent.Semaphore;
import java.util.concurrent.TimeUnit;
import java.util.concurrent.atomic.AtomicInteger;
import java.util.concurrent.locks.Condition;
import java.util.concurrent.locks.ReentrantLock;

/** Semaphore, wait/notify, Condition, CountDownLatch, CyclicBarrier. */
public class Main {

    // ---------- Condition variable with the built-in monitor (wait / notifyAll) ----------
    /** A one-slot mailbox: put waits while full, take waits while empty. */
    static class Mailbox<T> {

                    for (int p = 0; p < 2; p++) {
                        Thread.sleep((long) (Math.random() * 20)); // uneven work
                        barrier.await();                           // reusable: works for every phase
                    }
                } catch (Exception e) { throw new RuntimeException(e); }
            });
            ws.add(t);
            t.start();
        }
        for (Thread t : ws) t.join();
    }
}
```

Explaining each part:

- `semaphoreDemo`: 10 tasks, 3 permits; `maxSeen` records the peak number of concurrent users and never exceeds 3.
- `Mailbox` is a condition variable built on `wait/notifyAll` (section 12.13).
- `TurnTable` is a condition variable built on `ReentrantLock` + `Condition` (section 12.13).
- `latchDemo` / `barrierDemo`: section 12.14.

Output:

```
=== Semaphore: at most 3 concurrent DB connections ===
10 queries done, never more than 3 at once: true
=== wait/notifyAll: one-slot mailbox ===
received in order: [m1, m2, m3]
=== Lock + Condition: strict turn-taking ===
PING PONG PING PONG PING PONG
=== CountDownLatch: wait for 3 services to start ===
all services ready: true (count now 0)
=== CyclicBarrier: 3 workers, 2 phases ===
phase 1 complete: all 3 workers arrived
phase 2 complete: all 3 workers arrived
```

Trade-offs

Pros	Cons
Simple way to cap concurrency	No owner: a bug can release more than acquired (permits grow)
Works as a signal (0 permits)	Doesn't protect data by itself — only counts

When not to use it

Don't use a semaphore as a mutex around shared data when a lock would do — locks have ownership checks and reentrancy.

Common mistakes

- Releasing in a path where `acquire` never succeeded (e.g. `acquire` interrupted) → permit leak upward.
- Forgetting to release on exceptions → permits slowly disappear, system stalls.

Real-world examples

- **Bulkhead pattern** (isolating resources per dependency, like watertight compartments in a ship, so one failure can't sink everything): Resilience4j's `SemaphoreBulkhead` (and Hystrix's — Netflix's older fault-tolerance library — semaphore isolation) cap concurrent calls to a dependency.
- **Connection pools** (sets of open database connections reused across requests) bound the number of connections handed out (HikariCP, a popular JDBC pool, enforces its maximum pool size).
- With virtual threads, a `Semaphore` is the recommended way to limit calls to a slow **downstream** service (one that your code calls).

In the interview

> **30-second answer:** "A semaphore is a permit counter: acquire takes a permit or waits, release returns one. I use it to cap concurrent access to a limited resource — a bulkhead — or with zero initial permits as a signal from one thread to another. Unlike a lock it has no owner."

Follow-ups:

- *Binary semaphore vs mutex?* Both allow one holder, but a mutex has an owner (only the holder may unlock, and it's usually reentrant); a binary semaphore can be released by any thread and isn't reentrant.

Self-check

- **Q:** `new Semaphore(0)`: what does `acquire()` do? **A:** Waits until some thread calls `release()` — a signal.

TL;DR

Semaphore = N permits. Cap concurrency or signal. No ownership, so release carefully in `finally`.

12.13 Condition variables: `wait/notify` and `Condition`

What it is

A **condition variable** lets a thread *sleep until some condition about shared state becomes true*, releasing the lock while it sleeps, and lets another thread *wake it* after changing that state.

- Built-in: `Object.wait()`, `notify()`, `notifyAll()` — used inside `synchronized` on the same object.
- Explicit: `Condition c = lock.newCondition(); c.await(); c.signal(); c.signalAll();` — used while holding that `ReentrantLock`.

> **Analogy.** A restaurant pager: you (the thread) hand back your table (release the lock) and wait. When the table is ready, staff buzz the pager (notify). You then come back and check that the table really is free (re-check the condition), because someone might have taken it.

The problem it solves

Waiting for a state change without **busy-waiting** (spinning in a loop wasting CPU) and without missing the moment it happens.

How it works

The canonical pattern — memorize it:

```
synchronized (lock) {                 // or: lock.lock(); try {
    while (!conditionHolds()) {       // ALWAYS a while loop, never if
        lock.wait();                  //   cond.await();  releases the lock while waiting
    }
    doAction();                       // condition is true AND we hold the lock
    lock.notifyAll();                 //   cond.signal()/signalAll() if we changed state others wait for
}                                     // } finally { lock.unlock(); }
```

1. Acquire the lock.
2. While the condition is false, call `wait()` / `await()` — this **atomically releases the lock** and sleeps.
3. When woken, the thread **re-acquires the lock** before returning, then re-checks the condition (loop).
4. After changing state, call `notifyAll()` / `signal()` so waiters re-check.

Why the `while` loop? (a) **Spurious wakeups** — the JLS and the `Condition` docs allow a thread to wake without being notified. (b) Another thread may have grabbed the state between the notify and your re-acquisition. (c) With `notifyAll`, several threads wake but only one can succeed.

`notify` vs `notifyAll`: `notify()` wakes one arbitrary waiter. If different kinds of threads (producers and consumers) wait on the same monitor, `notify()` can wake the wrong kind and everyone sleeps forever. Use `notifyAll()` with a single monitor, or use separate `Condition`s (`notFull`, `notEmpty`) and targeted `signal()`.

Java example

`Mailbox` (monitor version) and `TurnTable` (Lock + Condition) in `coordination/Main.java` above. Output: `received in order: [m1, m2, m3]` and `PING PONG PING PONG PING PONG`.

Trade-offs

	wait/notify	Lock + Condition
Conditions per lock	One wait set	Many (e.g. `notFull`, `notEmpty`)
Targeted wake-up	No — use `notifyAll`	Yes — `signal()` on the right condition
Timed wait	`wait(ms)`	`await(t, unit)`, `awaitNanos` (returns time left)
Verbosity	Less	More (manual unlock)

When not to use it

Most of the time you don't need raw condition variables: `BlockingQueue`, `Semaphore`, `CountDownLatch`, `CompletableFuture` already solve the common waiting problems. Write your own only for custom coordination (interview problems, custom synchronizers).

Common mistakes

- `if` instead of `while` around `wait()`.
- Calling `wait()`/`notify()` without holding that object's monitor → `IllegalMonitorStateException`.
- Changing state *without* notifying → waiters sleep forever (a "lost wakeup").
- Calling `wait()` on one object while synchronized on another.

Real-world examples

`ArrayBlockingQueue` uses one `ReentrantLock` with two `Condition`s, `notEmpty` and `notFull` — exactly the pattern built by hand in chapter 13.

In the interview

> **30-second answer:** "A condition variable lets a thread release a lock and sleep until another thread changes the state and signals it. I always wait in a while loop that re-checks the condition, because of spurious wakeups and competing threads. With one monitor I use notifyAll; with ReentrantLock I use separate Conditions and targeted signal."

Follow-ups:

- *Why must `wait()` be called while holding the lock?* So the check-then-sleep is atomic; otherwise a notify could happen between your check and your wait and be lost.

Self-check

- **Q:** What does `wait()` do with the monitor? **A:** Releases it while sleeping and re-acquires it before returning.

TL;DR

Condition variable = "release lock, sleep until signalled, re-acquire, re-check". Always `while`, prefer `notifyAll` or separate `Condition`s.

12.14 `CountDownLatch` and `CyclicBarrier`

What it is

- **`CountDownLatch(n)`**: a one-time gate. Threads call `await()` and wait until `countDown()` has been called *n* times. It cannot be reset.
- **`CyclicBarrier(n, action)`**: a reusable meeting point. Each of *n* threads calls `await()`; when the *n*th arrives, the optional barrier action runs once, all are released, and the barrier resets for the next round.

> **Analogy.** Latch = a race starter who waits for all 3 judges to say "ready" and then fires the pistol once. Barrier = hikers who agree to wait for each other at every checkpoint before continuing.

The problem it solves

Coordinating *phases*: "start only after all services are up" (latch), "all workers finish step 1 before anyone starts step 2" (barrier), and "release all test threads at the same instant" (latch with count 1 — used throughout this book to maximise contention in tests).

How it works

	CountDownLatch	CyclicBarrier
Who waits	Any thread(s) calling `await()`	The *n* participating threads themselves
Who counts	Anyone calling `countDown()` (need not wait)	Arrival at `await()`
Reusable	No	Yes (auto-reset after each trip)
Extra	Count reaching 0 is permanent: later `await()` calls return at once. One thread may call `countDown()` several times	Barrier action runs once per trip; if one party is interrupted/times out, the barrier **breaks** and others get `BrokenBarrierException` (`reset()` repairs it)
Happens-before	Actions before `countDown()` HB actions after the matching `await()` returns	Actions before `await()` HB the barrier action, which HB actions after the other parties return from `await()`

`Phaser` (Java 7) generalises both: parties can register/deregister dynamically across many phases.

Java example

`latchDemo` and `barrierDemo` in `coordination/Main.java` above. Output shows `all services ready: true (count now 0)` and `phase 1 complete…`, `phase 2 complete…`.

Trade-offs

Latch: dead simple, one-shot. Barrier: reusable but fragile — one failing party breaks it for all.

When not to use it

For "wait for these N tasks and collect results", `ExecutorService.invokeAll` or `CompletableFuture.allOf(...)` is usually clearer.

Common mistakes

- Waiting on a latch forever because a worker threw before `countDown()` — put `countDown()` in `finally`, and use `await(timeout)`.
- Using a barrier with fewer threads than parties → everyone waits forever.

Real-world examples

- Test harnesses start N threads and release them together with a `CountDownLatch(1)` to maximise races (JCStress — OpenJDK's harness for testing concurrency correctness — uses stronger tools, but the idea is the same).
- Application start-up: wait for caches, DB pools, and message consumers to be ready before accepting traffic.

In the interview

> **30-second answer:** "`CountDownLatch` is a one-shot gate that opens after N countDowns; `CyclicBarrier` is a reusable rendezvous where N threads wait for each other each phase, optionally running an action when all arrive."

Follow-ups:

- *Can a latch be reset?* No — create a new one or use `CyclicBarrier`/`Phaser`.

Self-check

- **Q:** Which one would you use so 3 worker threads sync at the end of every simulation step? **A:** `CyclicBarrier(3)`.

TL;DR

Latch = one-shot "wait for N events". Barrier = reusable "wait for N threads". Put `countDown` in `finally`; use timeouts.

Part E — Lock-free

12.15 Compare-and-swap (CAS) & atomics

What it is

Compare-and-swap is a single CPU instruction (e.g. `LOCK CMPXCHG` on x86; LL/SC — load-linked/store-conditional — or CAS instructions on ARM): "if the value at this address is still `expected`, replace it with `new` and report success; otherwise change nothing and report failure." Java exposes it through `java.util.concurrent.atomic` classes: `AtomicInteger`, `AtomicLong`, `AtomicBoolean`, `AtomicReference`, `AtomicIntegerArray`, `LongAdder`, and through `VarHandle`.

> **Analogy.** Editing a shared wiki page: you save only if the page version is still the one you started from. If someone saved first, your save is rejected; you reload and try again.

The problem it solves

Atomic updates **without locks** (**lock-free**: no thread ever blocks another, and some thread always makes progress): no blocking, no deadlock, and usually faster under low-to-moderate contention. It is how lock-free data structures and the JDK's own concurrency utilities are built.

How it works

The **CAS retry loop**:

1. Read the current value.
2. Compute the new value from it.
3. `compareAndSet(current, new)`. If it succeeds, done.
4. If it fails, another thread changed the value — go back to step 1.

Helpers do the loop for you: `incrementAndGet`, `addAndGet`, `updateAndGet(fn)`, `accumulateAndGet(x, fn)` (the function may run more than once, so it must be side-effect-free).

`LongAdder` spreads updates over several internal cells when contended and sums them on `sum()` — much faster than `AtomicLong` for hot counters (metrics), but `sum()` is not an atomic snapshot.

ABA problem. A value goes A → B → A. A thread that read A earlier sees A again and its CAS succeeds, although the state changed in between. This matters for pointer-based structures (e.g. reusing nodes in a lock-free stack). Fix: attach a version — `AtomicStampedReference` (value + int stamp) or `AtomicMarkableReference`. (In Java, garbage collection prevents the classic node-reuse ABA for freshly allocated nodes, which is why the Treiber stack below is safe.)

Java example

```java
// File: code/lld/ch12/atomics/Main.java
package lld.ch12.atomics;

import java.util.ArrayList;
import java.util.List;
import java.util.concurrent.atomic.AtomicInteger;
import java.util.concurrent.atomic.AtomicReference;
import java.util.concurrent.atomic.AtomicStampedReference;
import java.util.concurrent.atomic.LongAdder;

/** Compare-and-swap (CAS), a lock-free stack, LongAdder, and the ABA problem. */
public class Main {

    /** Increment written by hand as a CAS retry loop (this is what incrementAndGet does inside). */
    static int casIncrement(AtomicInteger a) {
        while (true) {
            int current = a.get();                    // 1. read
            int next = current + 1;                   // 2. compute
            if (a.compareAndSet(current, next)) {     // 3. write only if nobody changed it meanwhile
                return next;
            }                                         // 4. someone won the race: retry
        }
    }

    /** Treiber stack: a classic lock-free data structure built on one AtomicReference. */
    static class LockFreeStack<T> {
        private record Node<T>(T value, Node<T> next) { }
        private final AtomicReference<Node<T>> head = new AtomicReference<>();

        void push(T v) {
            Node<T> oldHead, newHead;
            do {
                oldHead = head.get();
                newHead = new Node<>(v, oldHead);
            } while (!head.compareAndSet(oldHead, newHead));
        }
        T pop() {
            Node<T> oldHead;
            do {
                oldHead = head.get();
                if (oldHead == null) return null;
            } while (!head.compareAndSet(oldHead, oldHead.next()));
            return oldHead.value();
        }
    }

    static void runThreads(int n, Runnable r) throws InterruptedException {
        List<Thread> ts = new ArrayList<>();
        for (int i = 0; i < n; i++) { Thread t = new Thread(r); ts.add(t); t.start(); }
        for (Thread t : ts) t.join();
    }

    public static void main(String[] args) throws Exception {
        AtomicInteger counter = new AtomicInteger();
        runThreads(4, () -> { for (int i = 0; i < 100_000; i++) casIncrement(counter); });
        System.out.println("hand-written CAS loop counter = " + counter.get());

        AtomicInteger highWater = new AtomicInteger();
        runThreads(4, () -> {
            for (int i = 0; i < 1_000; i++) highWater.accumulateAndGet(i, Math::max);  // atomic "max"
        });
        System.out.println("atomic max                    = " + highWater.get());

        LockFreeStack<Integer> stack = new LockFreeStack<>();
        runThreads(4, () -> { for (int i = 0; i < 10_000; i++) stack.push(i); });
        int popped = 0;
```

```
        while (stack.pop() != null) popped++;
        System.out.println("lock-free stack popped        = " + popped);

        LongAdder hits = new LongAdder();              // striped counter: fast under heavy contention
        runThreads(8, () -> { for (int i = 0; i < 100_000; i++) hits.increment(); });
        System.out.println("LongAdder sum                 = " + hits.sum());

        // ABA: value goes A -> B -> A; a plain CAS cannot tell anything happened.
        AtomicReference<String> ref = new AtomicReference<>("A");
        String seen = ref.get();
        ref.set("B"); ref.set("A");                     // another thread's changes
        System.out.println("plain CAS after A->B->A succeeds   : " + ref.compareAndSet(seen, "C"));

        AtomicStampedReference<String> sref = new AtomicStampedReference<>("A", 0);
        int[] stampHolder = new int[1];
        String seen2 = sref.get(stampHolder);
        int seenStamp = stampHolder[0];
        sref.set("B", seenStamp + 1); sref.set("A", seenStamp + 2);
        System.out.println("stamped CAS after A->B->A succeeds : " + sref.compareAndSet(seen2, "C", seenStamp,
seenStamp + 1));
    }
}
```

Explaining each part:

- `casIncrement` is the textbook retry loop — this is what `incrementAndGet` does conceptually.
- `accumulateAndGet(i, Math::max)` atomically tracks a maximum.
- `LockFreeStack` (the *Treiber stack*): push/pop swing the `head` reference with CAS; a failed CAS means another thread pushed/popped first — retry.
- `LongAdder` counts 800,000 increments from 8 threads with little contention.
- The ABA lines show a plain CAS succeeding after A→B→A, while the stamped CAS fails because the stamp moved from 0 to 2.

Output:

```
hand-written CAS loop counter = 400000
atomic max                    = 999
lock-free stack popped        = 40000
LongAdder sum                 = 800000
plain CAS after A->B->A succeeds   : true
stamped CAS after A->B->A succeeds : false
```

Trade-offs

	Locks	CAS / atomics
Blocking	Yes	No (threads retry)
Deadlock	Possible	Impossible (no locks)
Scope	Any number of variables	One variable/reference per CAS
Under heavy contention	Threads sleep (saves CPU)	Many failed retries (wastes CPU) — use `LongAdder` or striping
Difficulty	Moderate	Hard for anything beyond counters/flags/one reference

When not to use it

Invariants spanning several variables (move money between two accounts) — a single CAS can't cover them; use a lock, or put all fields into one immutable object and CAS the reference (as the lock-free token bucket in chapter 13 does).

Common mistakes

- Separate `get()` then `set()` on an atomic → still a race. Use `compareAndSet`/`updateAndGet`.
- Side effects inside `updateAndGet` lambdas (they may run several times).
- Using `AtomicLong` for a very hot metrics counter where `LongAdder` would scale better.

Real-world examples

- `ConcurrentHashMap` inserts into empty bins with CAS; `ConcurrentLinkedQueue` is a lock-free (Michael–Scott) queue; `AbstractQueuedSynchronizer` (behind `ReentrantLock`) uses CAS on its state.
- Optimistic locking in databases and ORMs (Object-Relational Mappers — libraries that map objects to database tables; JPA `@Version`, `UPDATE ... WHERE version = ?`) is CAS at the database level.
- LMAX Disruptor (a high-performance inter-thread messaging library) uses CAS-based sequences for its lock-free **ring buffer** (a fixed-size array used as a circular queue).

In the interview

> **30-second answer:** "CAS atomically updates a value only if it still equals what I read; otherwise I retry. Java's atomic classes wrap it, so counters, flags and single references can be updated without locks and without deadlock. It covers one variable at a time, can suffer ABA — fixed with a stamped reference — and under heavy contention I prefer `LongAdder`."

Follow-ups:

- *Is lock-free always faster?* No. Under heavy contention retries waste CPU; a lock that parks threads can be better.
- *How would you do a lock-free update of two fields?* Put them in an immutable object and CAS an `AtomicReference` to it.

Self-check

- **Q:** What does a failed `compareAndSet` mean? **A:** Another thread changed the value after you read it; re-read and retry.
- **Q:** What fixes ABA? **A:** A version stamp: `AtomicStampedReference`.

TL;DR

CAS = "update only if unchanged", retried in a loop. Atomics give lock-free, deadlock-free updates to one variable. Watch ABA; use `LongAdder` for hot counters.

12.16 Concurrent collections

What it is

Thread-safe collections in `java.util.concurrent` designed for high concurrency (unlike the old fully-`synchronized` `Vector` / `Hashtable`):

Need	Use	Key behaviour
Map	`ConcurrentHashMap`	Lock-free reads; writes lock only one bin; atomic `putIfAbsent`, `computeIfAbsent`, `compute`, `merge`; **no null keys/values**; *weakly consistent* iterators (see below)
Sorted map/set	`ConcurrentSkipListMap` / `Set`	Lock-free, sorted, O(log n) (cost grows very slowly with size)
List read ≫ write	`CopyOnWriteArrayList` / `Set`	Each write copies the whole array; iteration uses a snapshot (never throws CME, `ConcurrentModificationException`)
Queue (non-blocking)	`ConcurrentLinkedQueue` / `Deque`	Lock-free; `poll()` returns null when empty
Queue (blocking)	`ArrayBlockingQueue` (bounded), `LinkedBlockingQueue` (optionally bounded), `PriorityBlockingQueue`, `DelayQueue`, `SynchronousQueue` (no capacity: hand-off), `LinkedTransferQueue`	`put` waits when full, `take` waits when empty; `offer` / `poll` with timeouts

Two `ConcurrentHashMap` guarantees worth quoting exactly:

- **`computeIfAbsent` / `compute` / `merge` are atomic.** The Javadoc says the whole call is performed atomically, and for `computeIfAbsent` the mapping function is invoked **exactly once if the key is absent, otherwise not at all** — so two racing threads can never both create a value for the same key. Some updates by other threads (at least those hitting the same bin) block while the function runs, so keep it short and never touch the same map inside it. (The default `ConcurrentMap.computeIfAbsent` used by some other maps, e.g. `ConcurrentSkipListMap`, may call the function more than once and discard results — only the final put is atomic.)
- **Iterators are weakly consistent.** They never throw `ConcurrentModificationException`, may proceed while other threads modify the map, return each element at most once, and reflect the map's state at some point at or after the iterator was created — they *may or may not* show later updates. `size()` / `isEmpty()` are likewise only estimates while updates are in flight.

> **Analogy.** A supermarket with many tills (ConcurrentHashMap's bins) instead of one till for the whole store (`Hashtable`).

The problem it solves

Wrapping a `HashMap` in one lock **serialises** every access (forces accesses to happen one at a time). Concurrent collections let many threads read and write different parts at the same time and offer **atomic compound operations** so you don't need external locks for common patterns.

How it works

1. Pick the collection by access pattern (table above).
2. Replace check-then-act sequences with a single atomic method:
   - `if (!m.containsKey(k)) m.put(k, v)` → `m.putIfAbsent(k, v)`
   - `m.put(k, m.get(k) + 1)` → `m.merge(k, 1, Integer::sum)`
   - lazy creation → `m.computeIfAbsent(k, key -> new ...)`
3. For hand-offs between threads, use a `BlockingQueue` (producer-consumer, 12.22).
4. Remember *compound operations across several calls are still not atomic*.

Java example

```java
// File: code/lld/ch12/collections/Main.java
package lld.ch12.collections;

import java.util.ArrayList;
import java.util.List;
import java.util.Map;
import java.util.TreeMap;
import java.util.concurrent.ArrayBlockingQueue;
import java.util.concurrent.BlockingQueue;
import java.util.concurrent.ConcurrentHashMap;
import java.util.concurrent.CopyOnWriteArrayList;
import java.util.concurrent.TimeUnit;

/** ConcurrentHashMap atomic compound ops, CopyOnWriteArrayList snapshots, BlockingQueue. */
public class Main {

    public static void main(String[] args) throws Exception {
        // ---------- ConcurrentHashMap ----------
        ConcurrentHashMap<String, Integer> wordCount = new ConcurrentHashMap<>();
        String[] words = {"apple", "banana", "apple", "cherry", "banana", "apple"};
        List<Thread> ts = new ArrayList<>();
        for (int t = 0; t < 4; t++) {
            Thread th = new Thread(() -> {
                for (int rep = 0; rep < 1_000; rep++)
                    for (String w : words) wordCount.merge(w, 1, Integer::sum);   // atomic per key
            });
            ts.add(th); th.start();
        }
        for (Thread th : ts) th.join();
        System.out.println("word counts (4 threads x 1000 reps): " + new TreeMap<>(wordCount));

        // computeIfAbsent: create-once per key, even under races (e.g. one lock/queue per user).
        ConcurrentHashMap<String, List<String>> ordersByUser = new ConcurrentHashMap<>();
        ordersByUser.computeIfAbsent("alice", k -> new CopyOnWriteArrayList<>()).add("order-1");
        ordersByUser.computeIfAbsent("alice", k -> new CopyOnWriteArrayList<>()).add("order-2");
        System.out.println("alice's orders: " + ordersByUser.get("alice"));

        // WRONG pattern (check-then-act across two calls) vs RIGHT (one atomic call):
        //   if (!map.containsKey(k)) map.put(k, v);   // two threads can both put
        //   map.putIfAbsent(k, v);                    // atomic
        Map<String, String> seats = new ConcurrentHashMap<>();
        System.out.println("first putIfAbsent returns : " + seats.putIfAbsent("A1", "bob"));
        System.out.println("second putIfAbsent returns: " + seats.putIfAbsent("A1", "eve") + "  (seat already
bob's)");

        // ---------- CopyOnWriteArrayList ----------
        CopyOnWriteArrayList<String> listeners = new CopyOnWriteArrayList<>(List.of("L1", "L2"));
        int seen = 0;
        for (String l : listeners) {          // iterates over a snapshot
            listeners.add(l + "-new");        // no ConcurrentModificationException
            seen++;
        }
        System.out.println("iterated " + seen + " items; list now " + listeners);

        // ---------- BlockingQueue ----------
        BlockingQueue<Integer> q = new ArrayBlockingQueue<>(2);   // bounded = back-pressure
        System.out.println("offer 1: " + q.offer(1) + ", offer 2: " + q.offer(2) + ", offer 3: " + q.offer(3) + "
(full)");
        System.out.println("take -> " + q.take() + ", poll -> " + q.poll() + ", poll(50ms) on empty -> "
                + q.poll(50, TimeUnit.MILLISECONDS));
    }
}
```

Explaining each part:

- `merge(w, 1, Integer::sum)` is an atomic per-key increment; totals are exact.

- `computeIfAbsent` creates each per-user list once, even under races.
- `putIfAbsent` returns `null` for the winner and the existing value for losers — perfect for "claim this seat".
- Iterating a `CopyOnWriteArrayList` while adding to it sees the old snapshot (2 items) and throws no exception.
- `ArrayBlockingQueue(2)`: `offer` returns `false` when full; `poll(50ms)` returns `null` when empty.

Output:

```
word counts (4 threads x 1000 reps): {apple=12000, banana=8000, cherry=4000}
alice's orders: [order-1, order-2]
first putIfAbsent returns : null
second putIfAbsent returns: bob  (seat already bob's)
iterated 2 items; list now [L1, L2, L1-new, L2-new]
offer 1: true, offer 2: true, offer 3: false (full)
take -> 1, poll -> 2, poll(50ms) on empty -> null
```

Trade-offs

Collection	Great for	Bad for
`ConcurrentHashMap`	General shared maps, caches, counters	Multi-key atomic operations; `size()` is only an estimate under concurrent updates
`CopyOnWriteArrayList`	Listener lists, rarely-changed config	Frequent writes (O(n) copy each)
`Collections.synchronizedMap`	Legacy code, low contention	High contention; iteration still needs manual `synchronized(map)`
`ArrayBlockingQueue`	Bounded hand-off with back-pressure	Very high throughput (single lock for put/take)
`LinkedBlockingQueue`	Higher throughput (separate put/take locks)	Default constructor is **unbounded** (capacity `Integer.MAX_VALUE`)

When not to use it

If an object is confined to one thread, a plain `HashMap`/`ArrayList` is faster. If you need a transaction across several keys, a single lock (or a database) is clearer.

Common mistakes

- Doing slow work or calling back into the same map inside `computeIfAbsent`/`compute` — the function runs while the bin is locked; recursive updates can throw `IllegalStateException` or deadlock.
- Putting `null` in a `ConcurrentHashMap` → `NullPointerException`.
- Unbounded queues that silently grow until `OutOfMemoryError`.

Real-world examples

- Caffeine's (a Java caching library) cache is built on `ConcurrentHashMap`; Guava's (Google's core Java library) `LocalCache` uses its own segmented design derived from Java 7's `ConcurrentHashMap`.
- Guava's `EventBus` keeps each event type's subscribers in a `CopyOnWriteArraySet`; listener lists in general are the textbook copy-on-write use case.
- Log4j2's async **appenders** (the components that write log events to a file or other destination) and many logging frameworks hand events from app threads to a writer thread through queues.

In the interview

30-second answer: "I use `ConcurrentHashMap` for shared maps and its atomic methods — `putIfAbsent`, `computeIfAbsent`, `merge` — instead of check-then-act. `CopyOnWriteArrayList` for read-mostly lists like listeners. `BlockingQueue`, preferably bounded, to hand work between threads."

Follow-ups:

- *How does Java 8+ `ConcurrentHashMap` achieve concurrency?* Reads are lock-free (volatile reads). Writes CAS into empty bins, otherwise `synchronized` on the bin's first node; long bins become **red-black trees** (self-balancing

sorted binary trees); resizing is done cooperatively by several threads. (Java 7 used 16 lock-striped segments by default.)

- *Why no nulls?* `get(k) == null` must unambiguously mean "absent"; with concurrency you can't follow up with `containsKey` atomically.

Self-check

- **Q:** Atomic way to count words in a shared map? **A:** `map.merge(word, 1, Integer::sum)`.
- **Q:** Why doesn't iterating a `CopyOnWriteArrayList` throw CME? **A:** It iterates an immutable snapshot of the array.

TL;DR

`ConcurrentHashMap` + atomic methods for maps, COW lists for read-mostly lists, bounded `BlockingQueue` for hand-offs. Single calls are atomic; sequences of calls are not.

Part F — Liveness failures

12.17 Deadlock

What it is

A **deadlock** is when two or more threads each wait forever for a resource another one holds. Nobody can proceed.

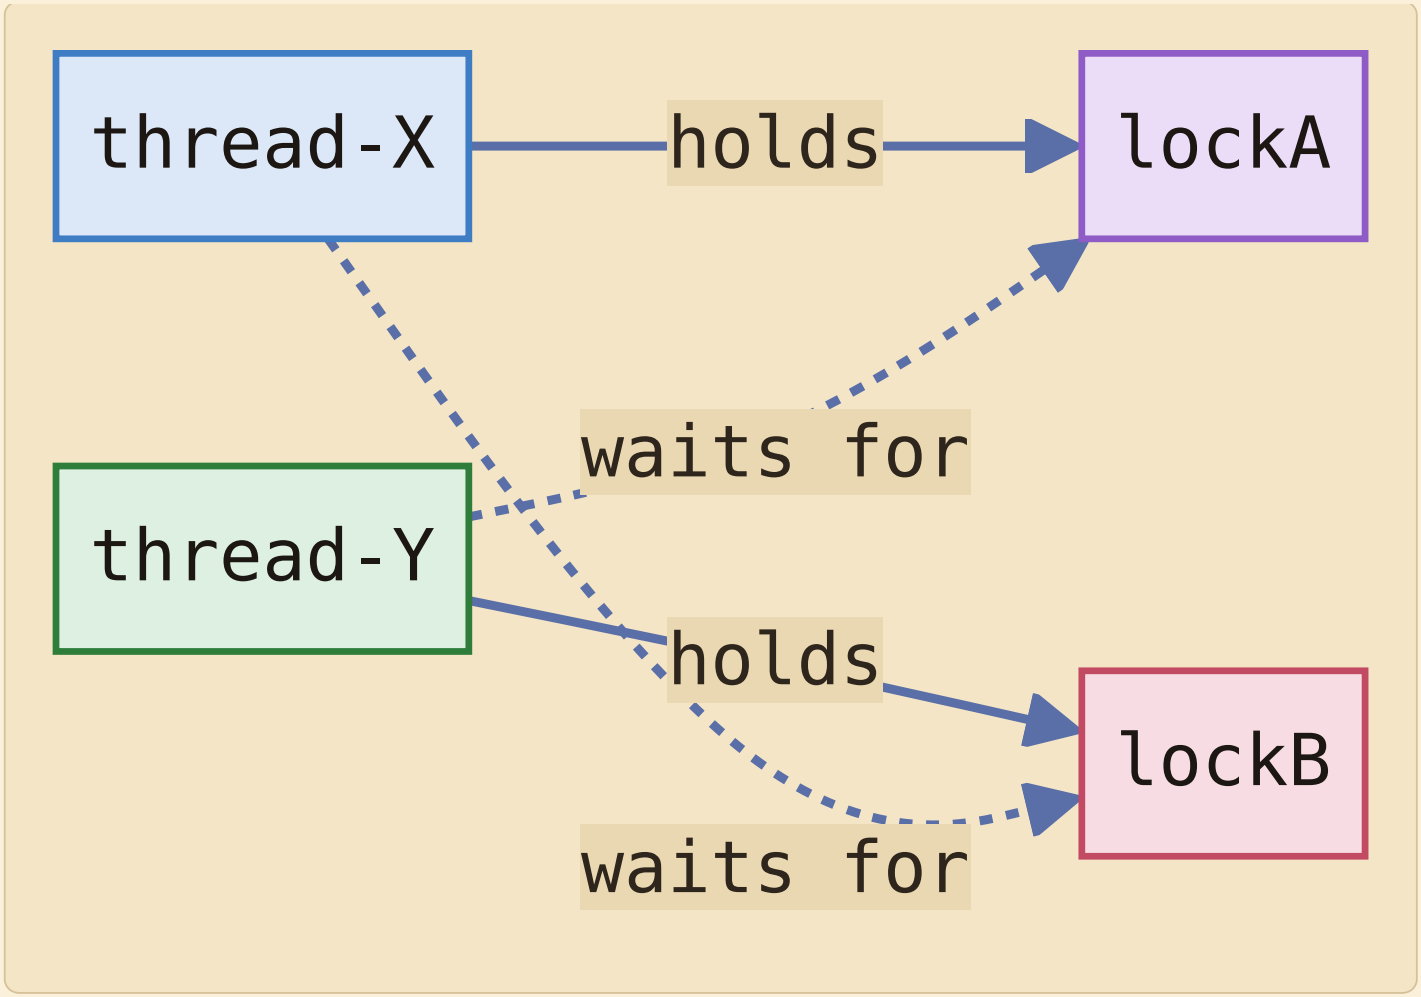
> **Analogy.** Two cars meet on a one-lane bridge from opposite ends. Each waits for the other to back up. Neither does.

The problem it solves

(Understanding deadlock lets you *design it out*.) A deadlock requires all four **Coffman conditions** (Coffman et al., 1971) at once:

#	Condition	Meaning	How to break it
1	**Mutual exclusion**	A resource can be held by only one thread	Use lock-free/immutable data, or shareable resources (read locks)
2	**Hold and wait**	A thread holds one resource while waiting for another	Acquire all resources at once, or use `tryLock` and release everything on failure
3	**No preemption**	Resources can't be taken away; only the holder releases	Timeouts (`tryLock(timeout)`), lock **leases** (locks that expire automatically after a set time)
4	**Circular wait**	A cycle: T1 waits for T2's lock, T2 waits for T1's	**Global lock ordering** (always lock lower id first)

Break **any one** condition and deadlock is impossible.



How it works

1. **Prevention by lock ordering (most common):** define a total order over locks (account id, seat id, `System.identityHashCode` with a tie-breaker lock) and always acquire in that order.
2. **Prevention by try-lock:** `tryLock(timeout)` each lock; if one fails, release all held locks, wait a random short time, retry.
3. **Avoid nested locks** where possible: call alien code (listeners, callbacks) *outside* your lock.
4. **Detection:** thread dumps (`jstack` / `jcmd`) print "Found one Java-level deadlock"; programmatically, `ThreadMXBean.findDeadlockedThreads()` (`ThreadMXBean` is the JDK's management interface for inspecting threads).
5. **Avoidance** (Banker's algorithm — grant a request only if the system can still finish every thread) exists in OS theory but is rarely used in application code.

Java example

```
// File: code/lld/ch12/deadlock/Main.java
package lld.ch12.deadlock;

import java.lang.management.ManagementFactory;
import java.lang.management.ThreadInfo;
import java.lang.management.ThreadMXBean;
import java.util.Arrays;
import java.util.concurrent.CyclicBarrier;
import java.util.concurrent.ThreadLocalRandom;
import java.util.concurrent.TimeUnit;
import java.util.concurrent.locks.ReentrantLock;

/** Create a real deadlock, detect it, then fix it two ways: lock ordering and tryLock + back-off. */
public class Main {

    static class Account {
        final int id;
        final ReentrantLock lock = new ReentrantLock();
        int balance;
        Account(int id, int balance) { this.id = id; this.balance = balance; }
    }

    // ---------- Fix 1: global lock ordering (always lock the smaller id first) ----------
    static void transferOrdered(Account from, Account to, int amount) {
        Account first = from.id < to.id ? from : to;
        Account second = from.id < to.id ? to : from;
        first.lock.lock();
        try {
            second.lock.lock();
            try {
                if (from.balance >= amount) { from.balance -= amount; to.balance += amount; }
            } finally { second.lock.unlock(); }
        } finally { first.lock.unlock(); }
    }

    // ---------- Fix 2: tryLock with timeout + random back-off (breaks "hold and wait") ----------
    static void transferTryLock(Account from, Account to, int amount) throws InterruptedException {
        while (true) {
            if (from.lock.tryLock(1, TimeUnit.MILLISECONDS)) {
                try {
                    if (to.lock.tryLock(1, TimeUnit.MILLISECONDS)) {
                        try {
                            if (from.balance >= amount) { from.balance -= amount; to.balance += amount; }
                            return;
                        } finally { to.lock.unlock(); }
                    }
                } finally { from.lock.unlock(); }         // give up what we hold
            }
            // Random back-off: without it, both threads could retry in lock-step forever (LIVELOCK).
            Thread.sleep(0, ThreadLocalRandom.current().nextInt(1, 100_000));
        }
    }

    public static void main(String[] args) throws Exception {
        demonstrateDeadlock();

        Account a = new Account(1, 1_000), b = new Account(2, 1_000);
        Thread t1 = new Thread(() -> { for (int i = 0; i < 50_000; i++) transferOrdered(a, b, 1); });
        Thread t2 = new Thread(() -> { for (int i = 0; i < 50_000; i++) transferOrdered(b, a, 1); });
        t1.start(); t2.start(); t1.join(); t2.join();
        System.out.println("lock ordering: finished, total money = " + (a.balance + b.balance));

        Account c = new Account(3, 1_000), d = new Account(4, 1_000);
        Thread t3 = new Thread(() -> { try { for (int i = 0; i < 5_000; i++) transferTryLock(c, d, 1); } catch
(InterruptedException ignored) { } });
        Thread t4 = new Thread(() -> { try { for (int i = 0; i < 5_000; i++) transferTryLock(d, c, 1); } catch
```

```
(InterruptedException ignored) { } });
        t3.start(); t4.start(); t3.join(); t4.join();
        System.out.println("tryLock + back-off: finished, total money = " + (c.balance + d.balance));
    }

    /** Two threads lock in opposite order. A barrier forces the bad interleaving every time. */
    static void demonstrateDeadlock() throws Exception {
        Object lockA = new Object(), lockB = new Object();
        CyclicBarrier bothHoldOne = new CyclicBarrier(2);
        Thread x = new Thread(() -> {
            synchronized (lockA) { await(bothHoldOne); synchronized (lockB) { System.out.println("never printed");
} }
        }, "thread-X");
        Thread y = new Thread(() -> {
            synchronized (lockB) { await(bothHoldOne); synchronized (lockA) { System.out.println("never printed");
} }
        }, "thread-Y");
        x.setDaemon(true); y.setDaemon(true);   // daemon threads do not keep the JVM alive
        x.start(); y.start();

        ThreadMXBean mx = ManagementFactory.getThreadMXBean();
        long[] ids = null;
        for (int i = 0; i < 200 && ids == null; i++) { Thread.sleep(10); ids = mx.findDeadlockedThreads(); }
        String[] names = ids == null ? new String[0]
                :
Arrays.stream(mx.getThreadInfo(ids)).map(ThreadInfo::getThreadName).sorted().toArray(String[]::new);
        System.out.println("deadlock detected between: " + Arrays.toString(names)
                + "  (states " + x.getState() + ", " + y.getState() + ")");
    }

    static void await(CyclicBarrier b) {
        try { b.await(); } catch (Exception e) { throw new RuntimeException(e); }
    }
}
```

Explaining each part:

- `demonstrateDeadlock` forces the deadly interleaving: each thread takes one lock, then both meet at a barrier, then each asks for the other's lock. `ThreadMXBean` finds the cycle; both threads show `BLOCKED`. They are daemon threads, so the JVM can still exit.
- `transferOrdered` always locks the account with the smaller id first → circular wait is impossible. 100,000 opposite-direction transfers finish and money is conserved.
- `transferTryLock` uses `tryLock(1 ms)` and releases on failure, with a random back-off (to avoid livelock, next section).

Output:

```
deadlock detected between: [thread-X, thread-Y]  (states BLOCKED, BLOCKED)
lock ordering: finished, total money = 2000
tryLock + back-off: finished, total money = 2000
```

Trade-offs

Strategy	Pros	Cons
Lock ordering	Simple, zero runtime cost	Needs a stable global order; hard across modules
Try-lock + back-off	Works without an order; bounded waits	Retry logic; possible livelock without randomness
Single coarse lock	No deadlock among your locks	Lower throughput
Lock-free / immutable	No locks at all	Harder to design

When not to use it

N/A — you always want to prevent deadlock. But don't add complicated detection/recovery in application code when simple lock ordering would prevent it.

Common mistakes

- Calling a listener or another object's synchronized method while holding your own lock (hidden nested locking).
- Ordering by `hashCode()` without handling equal hashes.
- Also *resource* deadlocks: a pool of 10 threads where each task submits a sub-task to the **same** pool and waits for it — when all 10 wait, nothing runs (thread-starvation deadlock).

Real-world examples

- Databases (MySQL InnoDB, PostgreSQL) detect deadlocks between **transactions** (groups of database operations that succeed or fail as one unit) and abort one as a victim — the "detect and recover" strategy.
- Bank transfer systems lock accounts in id order — the lock-ordering strategy.

In the interview

> **30-second answer:** "Deadlock needs four conditions: mutual exclusion, hold-and-wait, no preemption, and circular wait. I break circular wait with a global lock order — e.g. lock seats or accounts in ascending id — or break hold-and-wait with tryLock with timeout and release-and-retry. I avoid calling external code while holding a lock, and I'd detect it in production with thread dumps."

Follow-ups:

- *Two accounts with the same id order?* Same account → just one lock (transfer to self is a no-op or rejected).
- *How would you find a deadlock in production?* `jstack <pid>` or `jcmd <pid> Thread.print` shows it; monitoring can call `ThreadMXBean.findDeadlockedThreads()`.

Self-check

- **Q:** Which Coffman condition does lock ordering break? **A:** Circular wait.
- **Q:** Which does `tryLock` + release break? **A:** Hold and wait (and effectively no-preemption, by giving up).

TL;DR

Deadlock = cycle of waiting. Needs all 4 Coffman conditions. Break one: lock ordering (circular wait) or tryLock + release (hold and wait). Don't call alien code under a lock.

12.18 Livelock

What it is

A **livelock** is when threads are not blocked — they keep running and reacting to each other — but make **no progress**.

> **Analogy.** Two people in a corridor both step aside to let the other pass, in the same direction, again and again.

The problem it solves

(Recognising it.) Livelocks often appear *as a side effect of deadlock avoidance*: two threads that both `tryLock`, fail, release, and retry at the same rhythm can collide forever.

How it works (and how to fix it)

1. Thread 1 takes lock A, tries B, fails, releases A.
2. Thread 2 takes lock B, tries A, fails, releases B.
3. Both retry immediately → same collision, forever.
4. **Fixes:** random back-off (different waits break the symmetry), exponential back-off, a consistent lock order (then no retries are needed), or a priority/tie-breaker (e.g. the older transaction wins).

Java example

`transferTryLock` in `deadlock/Main.java` sleeps a **random** number of nanoseconds (`ThreadLocalRandom`) after a failed attempt. Remove that line and the two threads could, in principle, keep failing in lock-step.

Trade-offs

Random back-off makes progress very likely but adds latency; exponential back-off adapts to contention.

When not to use it

Don't design retry loops that react only to each other with no randomness or tie-breaker.

Common mistakes

- Fixed retry delays (`sleep(10)` for everyone).
- Retrying forever without a limit or alert.

Real-world examples

- **Ethernet (CSMA/CD)** (the classic wired-network rule: listen before sending, detect collisions) uses *binary exponential back-off* (doubling the maximum random wait after each collision) after collisions for exactly this reason.
- Retry policies in AWS SDKs (Amazon Web Services' client libraries) and Resilience4j (a Java fault-tolerance library) use exponential back-off **with jitter** (a small random amount added to each wait) to stop synchronized **retry storms** (crowds of clients all retrying at the same moment).

In the interview

> **30-second answer:** "Livelock is when threads keep reacting to each other without progress — like two people side-stepping in a corridor. It often comes from symmetric retry logic; I fix it with randomized or exponential back-off, or remove retries by using a lock order."

Self-check

- **Q:** Deadlock vs livelock — thread states? **A:** Deadlocked threads are blocked/waiting; livelocked threads are running (`RUNNABLE`) but achieving nothing.

TL;DR

Livelock = busy but no progress. Break symmetry with jittered back-off or a tie-breaker.

12.19 Starvation (and fairness)

What it is

Starvation is when a thread waits indefinitely because others keep getting the resource first, even though the system as a whole makes progress.

> **Analogy.** At a busy bar, a quiet customer never gets served because louder customers keep catching the bartender's eye.

The problem it solves

(Recognising it.) Causes: unfair (barging) locks under heavy contention, a writer waiting behind a constant stream of readers in a read-write lock, low thread priority, or a long-running task hogging a single-thread executor.

How it works (fixes)

1. Use **fair** locks/semaphores where it matters: `new ReentrantLock(true)`, `new Semaphore(n, true)`, `new ReentrantReadWriteLock(true)`. Fair = longest waiter goes next.
2. Keep critical sections short so the lock is free more often.

3. Separate pools for slow and fast work (bulkheads) so slow tasks can't starve fast ones.
4. Don't rely on `Thread.setPriority` — its effect is OS-dependent.

Java example

`Waiter` in chapter 13's Dining Philosophers uses `new Semaphore(n - 1, true)` so no philosopher waits forever for a seat.

Trade-offs

Fairness prevents starvation but reduces throughput (more context switches, no barging).

When not to use it

Don't make every lock fair "just in case"; use fairness when you've seen or can argue starvation risk.

Common mistakes

Confusing starvation with deadlock: in starvation *someone* progresses; in deadlock *nobody* does.

Real-world examples

OS schedulers use *aging* (raising the priority of long-waiting processes); Linux's schedulers (CFS, and its successor EEVDF since **kernel** — the core of the operating system — 6.6) aim to give every runnable task a fair share of CPU time.

In the interview

> **30-second answer:** "Starvation is when a thread never gets a resource because others always win — e.g. writers behind endless readers. Fair locks, short critical sections and separate pools fix it, at some throughput cost."

Self-check

- **Q:** One fix for writer starvation in `ReentrantReadWriteLock`? **A:** Construct it in fair mode (`new ReentrantReadWriteLock(true)`).

TL;DR

Starvation = some thread never gets a turn. Fairness, short sections, separate pools.

Part G — Concurrency patterns

The next five patterns share one runnable file.

```java
// File: code/lld/ch12/patterns/Main.java
package lld.ch12.patterns;

import java.util.ArrayList;
import java.util.List;
import java.util.concurrent.ArrayBlockingQueue;
import java.util.concurrent.BlockingQueue;
import java.util.concurrent.CompletableFuture;
import java.util.concurrent.LinkedBlockingQueue;
import java.util.concurrent.RejectedExecutionException;
import java.util.concurrent.Semaphore;
import java.util.concurrent.ThreadPoolExecutor;
import java.util.concurrent.TimeUnit;
import java.util.concurrent.atomic.AtomicInteger;
import java.util.concurrent.atomic.AtomicLong;

/** Signaling, thread pool, producer-consumer, immutability, thread confinement. */
public class Main {

    // ---------- 1. Signaling ----------
    static void signaling() throws InterruptedException {
        System.out.println("=== Signaling: B must run after A ===");
        Semaphore aDone = new Semaphore(0);                 // 0 permits = "not signalled yet"
        List<String> log = java.util.Collections.synchronizedList(new ArrayList<>());
        Thread b = new Thread(() -> {
            try { aDone.acquire(); log.add("B: send email (after payment)"); }
            catch (InterruptedException e) { Thread.currentThread().interrupt(); }
        });
        Thread a = new Thread(() -> { log.add("A: charge payment"); aDone.release(); });
        b.start(); a.start();                               // B starts first but must wait
        a.join(); b.join();
        log.forEach(System.out::println);
    }

    // ---------- 2. Thread pool (hand-made, to see the moving parts) ----------
    static class SimpleThreadPool {
        private static final Runnable POISON = () -> { };
        private final BlockingQueue<Runnable> tasks = new LinkedBlockingQueue<>();
        private final List<Thread> workers = new ArrayList<>();
        private boolean shutdown;                           // guarded by 'this'

        SimpleThreadPool(int size) {
            for (int i = 0; i < size; i++) {
                Thread w = new Thread(() -> {
                    try {
                        while (true) {
                            Runnable r = tasks.take();          // idle workers block here
                            if (r == POISON) return;
                            try { r.run(); } catch (RuntimeException e) { System.err.println("task failed: " + e);
}
                        }
                    } catch (InterruptedException e) { Thread.currentThread().interrupt(); }
                }, "pool-worker-" + i);
                workers.add(w);
                w.start();
            }
        }
        // submit and the pill-adding part of shutdown share one lock, so "check the flag, then
        // enqueue" is atomic: no task can slip into the queue AFTER the poison pills and be lost.
        synchronized void submit(Runnable r) {
            if (shutdown) throw new RejectedExecutionException("pool is shut down");
            tasks.add(r);                                   // unbounded queue: add() never blocks
        }
        void shutdownAndWait() throws InterruptedException {
            synchronized (this) {
                if (shutdown) return;
                shutdown = true;
                for (int i = 0; i < workers.size(); i++) tasks.add(POISON);   // one pill per worker
```

```
            }
            for (Thread w : workers) w.join();          // wait OUTSIDE the lock
        }
    }

    static void threadPool() throws InterruptedException {
        System.out.println("=== Thread pool ===");
        SimpleThreadPool pool = new SimpleThreadPool(3);
        AtomicInteger done = new AtomicInteger();
        for (int i = 0; i < 20; i++) pool.submit(done::incrementAndGet);
        pool.shutdownAndWait();
        System.out.println("hand-made pool ran " + done.get() + " tasks on 3 threads");

        // Production version: bounded queue + explicit rejection policy.
        ThreadPoolExecutor exec = new ThreadPoolExecutor(
                2, 4,                                   // core and max threads
                30, TimeUnit.SECONDS,                   // idle time before extra threads die
                new ArrayBlockingQueue<>(100),          // bounded: never an OOM from a huge backlog
                new ThreadPoolExecutor.CallerRunsPolicy()); // when full, the submitter runs it (back-pressure)
        CompletableFuture<Integer> price = CompletableFuture.supplyAsync(() -> 100, exec);
        CompletableFuture<Integer> tax = CompletableFuture.supplyAsync(() -> 18, exec);
        System.out.println("ThreadPoolExecutor + CompletableFuture: total = " + price.thenCombine(tax,
Integer::sum).join());
        exec.shutdown();
        exec.awaitTermination(5, TimeUnit.SECONDS);
    }

    // ---------- 3. Producer-consumer ----------
    static void producerConsumer() throws InterruptedException {
        System.out.println("=== Producer-consumer ===");
        BlockingQueue<Integer> queue = new ArrayBlockingQueue<>(10);   // producers block when full
        final int POISON = -1, CONSUMERS = 2;
        AtomicLong total = new AtomicLong();
        List<Thread> consumers = new ArrayList<>();
        for (int c = 0; c < CONSUMERS; c++) {
            Thread t = new Thread(() -> {
                try {
                    for (int x = queue.take(); x != POISON; x = queue.take()) total.addAndGet(x);
                } catch (InterruptedException e) { Thread.currentThread().interrupt(); }
            });
            consumers.add(t); t.start();
        }
        Thread producer = new Thread(() -> {
            try {
                for (int i = 1; i <= 1_000; i++) queue.put(i);
                for (int c = 0; c < CONSUMERS; c++) queue.put(POISON);   // tell each consumer to stop
            } catch (InterruptedException e) { Thread.currentThread().interrupt(); }
        });
        producer.start();
        producer.join();
        for (Thread t : consumers) t.join();
        System.out.println("consumed sum of 1..1000 = " + total.get() + " (expected 500500)");
    }

    // ---------- 4. Immutability ----------
    /** Immutable value object: final fields, no setters, defensive copy. Safe to share freely. */
    record Order(String id, List<String> items) {
        Order { items = List.copyOf(items); }                 // caller's list can't change ours
        Order withItem(String item) {                          // "modify" = return a new object
            List<String> copy = new ArrayList<>(items); copy.add(item);
            return new Order(id, copy);
        }
    }

    // ---------- 5. Thread confinement ----------
    private static final ThreadLocal<StringBuilder> BUFFER = ThreadLocal.withInitial(StringBuilder::new);

    static String render(String name) {
        StringBuilder sb = BUFFER.get();       // each thread has its own builder: no sharing, no locks
```

```
        sb.setLength(0);
        return sb.append("Hello, ").append(name).toString();
    }

    public static void main(String[] args) throws Exception {
        signaling();
        threadPool();
        producerConsumer();

        System.out.println("=== Immutability ===");
        List<String> mutable = new ArrayList<>(List.of("pen"));
        Order o1 = new Order("o1", mutable);
        mutable.add("hacked");
        Order o2 = o1.withItem("book");
        System.out.println("o1 = " + o1.items() + ", o2 = " + o2.items());

        System.out.println("=== Thread confinement (ThreadLocal) ===");
        Thread t1 = new Thread(() -> System.out.println(render("T1")));
        t1.start(); t1.join();
        Thread t2 = new Thread(() -> System.out.println(render("T2")));
        t2.start(); t2.join();
    }
}
```

Output:

```
=== Signaling: B must run after A ===
A: charge payment
B: send email (after payment)
=== Thread pool ===
hand-made pool ran 20 tasks on 3 threads
ThreadPoolExecutor + CompletableFuture: total = 118
=== Producer-consumer ===
consumed sum of 1..1000 = 500500 (expected 500500)
=== Immutability ===
o1 = [pen], o2 = [pen, book]
=== Thread confinement (ThreadLocal) ===
Hello, T1
Hello, T2
```

12.20 Signaling pattern

What it is

One thread **notifies** another that an event happened, so the second can proceed. "B must run after A."

> **Analogy.** A relay race baton: the next runner can't start until the baton is handed over.

The problem it solves

Enforcing ordering between threads without busy-waiting (spinning on a flag).

How it works

1. Create a signal object in the "not yet" state: `new Semaphore(0)`, `new CountDownLatch(1)`, a `CompletableFuture`, or a flag + condition variable.
2. The waiting thread calls `acquire()` / `await()` / `join()`.
3. The signalling thread calls `release()` / `countDown()` / `complete(value)`.
4. The waiter wakes and continues. The signal also provides happens-before, so the waiter sees everything A did.

Tool	Reusable	Carries a value	Good for
`Semaphore(0)`	Yes (each release = one signal)	No	Ping-pong between threads (FooBar, chapter 13)
`CountDownLatch(1)`	No	No	One-time "ready/go"
`CompletableFuture`	No	Yes	"Here is the result"
Condition variable	Yes	Via shared state	Complex conditions

Java example

`signaling()` above: B starts first but waits on `aDone.acquire()`; A logs and calls `release()`. Output shows A's line before B's every time.

Trade-offs

Semaphores are compact but easy to mis-count; latches can't be reset; futures are clean but single-use.

When not to use it

If the "signal" is really "here's a work item", use a `BlockingQueue` (producer-consumer).

Common mistakes

- Signalling before the waiter starts waiting with a tool that *forgets* signals (plain `notify()` without a state flag = lost wakeup). Semaphores and latches remember.

Real-world examples

`CompletableFuture` chains in Spring WebFlux (Spring's non-blocking web framework)/Netty **callbacks** (functions handed to a library so it can call you back later); start-up gates; "order paid → send confirmation" flows inside one service.

In the interview

"Signaling means one thread waits for an event raised by another. I use a zero-permit semaphore for repeated hand-offs, a latch for one-time events, or a `CompletableFuture` when a result travels with the signal."

Self-check

Q: Why is a bare `notify()` risky for signaling? **A:** If it happens before the other thread waits, the signal is lost; always pair it with a state variable checked in a loop.

TL;DR

Signal = "you may go now". Semaphore(0), latch, or future. Make sure signals can't be lost.

12.21 Thread pool pattern

What it is

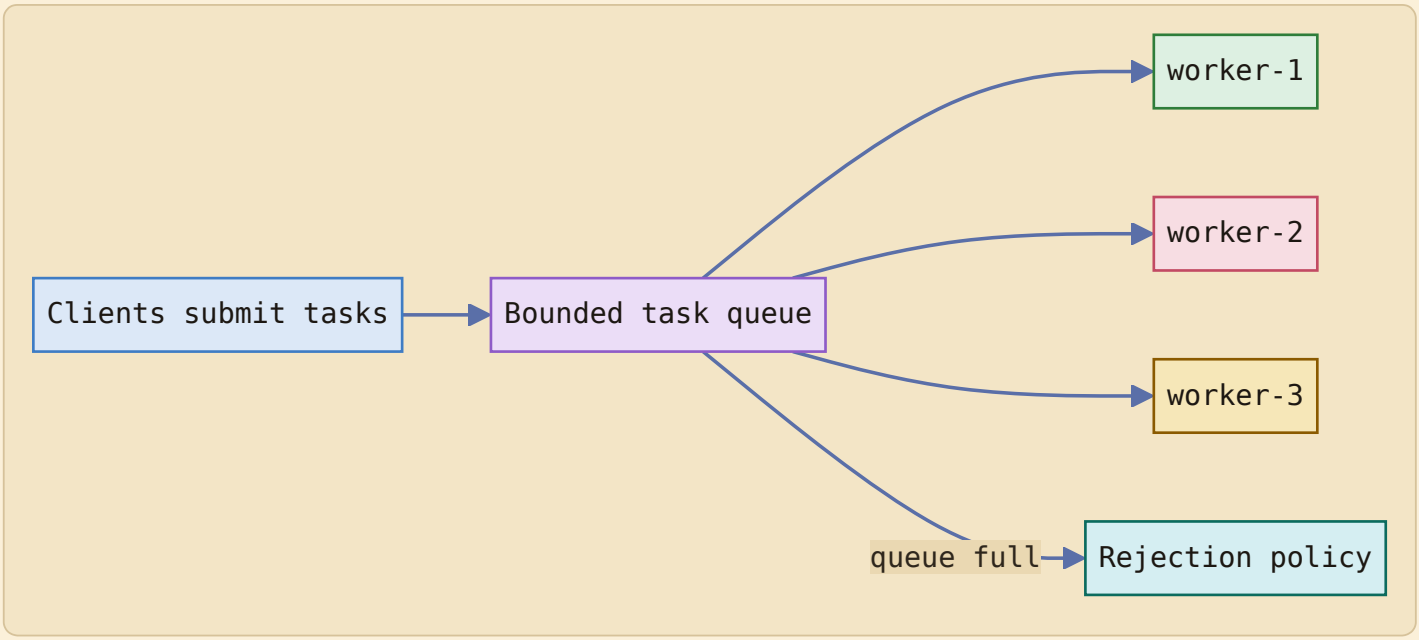
A fixed set of **worker threads** takes tasks from a shared **queue** and runs them, reusing threads instead of creating one per task.

> **Analogy.** A taxi rank: a few taxis serve a queue of passengers; taxis are reused, and if the queue gets too long, the rank manager turns people away.

The problem it solves

Creating/destroying threads per task is expensive and unbounded concurrency can overwhelm CPU, memory and downstream systems. A pool bounds concurrency and **amortises** thread creation (spreads its one-time cost over many tasks).

How it works



1. Workers loop: `task = queue.take(); task.run();`.
2. `submit` puts the task in the queue.
3. `ThreadPoolExecutor` rules: while fewer than **core** threads run, a new thread is created per task; then tasks go into the **queue**; if the queue is full, extra threads are created up to **max**; if still full, the **rejection policy** runs (`AbortPolicy` throws — default; `CallerRunsPolicy` runs it on the submitting thread, slowing producers; `DiscardPolicy`; `DiscardOldestPolicy`).
4. Shutdown: stop accepting, let workers drain the queue, then exit (the hand-made pool uses one "**poison pill**" — a special marker task meaning "stop now" — per worker). The "is it shut down? then enqueue" check in `submit` is a check-then-act, so `submit` and the pill-adding step of shutdown hold the same lock — otherwise a task could be enqueued *behind* the pills and silently never run.

Sizing: CPU-bound ≈ number of cores; I/O-bound ≈ cores × (1 + wait/compute) — or virtual threads.

Java example

`SimpleThreadPool` above (hand-made, to see the mechanics) and a production `ThreadPoolExecutor` with a bounded `ArrayBlockingQueue(100)` and `CallerRunsPolicy`, combined with `CompletableFuture.thenCombine`.

Trade-offs

Choice	Effect
Bounded queue	Protects memory; needs a rejection policy
Unbounded queue (`newFixedThreadPool`)	Never rejects, may run out of memory, and max-pool-size is never used
`CallerRunsPolicy`	Natural back-pressure: submitter slows down
Many pools (bulkheads)	Isolation between workloads; more threads overall

When not to use it

For huge numbers of blocking tasks on Java 21, virtual-thread-per-task is simpler. For fork/join-style recursive CPU work, use `ForkJoinPool` (**work stealing**: an idle thread takes queued tasks from a busy thread's queue).

Common mistakes

- Tasks that wait for other tasks in the same bounded pool (thread-starvation deadlock).
- Swallowed exceptions in `submit`ted tasks.
- Forgetting `shutdown()`.
- Using `ThreadLocal`s in pooled threads without clearing them (values leak between tasks).

Real-world examples

Tomcat's connector thread pool (`maxThreads`, default 200), Spring's `ThreadPoolTaskExecutor`, database connection pools (same idea for connections), `ForkJoinPool.commonPool()` behind parallel streams and `CompletableFuture.supplyAsync` without an executor.

In the interview

"A thread pool reuses a bounded set of workers fed by a queue. I size it by workload type, use a bounded queue with an explicit rejection policy for back-pressure, and give slow dependencies their own pool as a bulkhead."

Self-check

Q: In `ThreadPoolExecutor`, when are threads beyond `corePoolSize` created? **A:** Only when the queue is full (and fewer than max threads exist).

TL;DR

Workers + queue + rejection policy. Bound everything. Size by CPU vs I/O.

12.22 Producer-consumer pattern

What it is

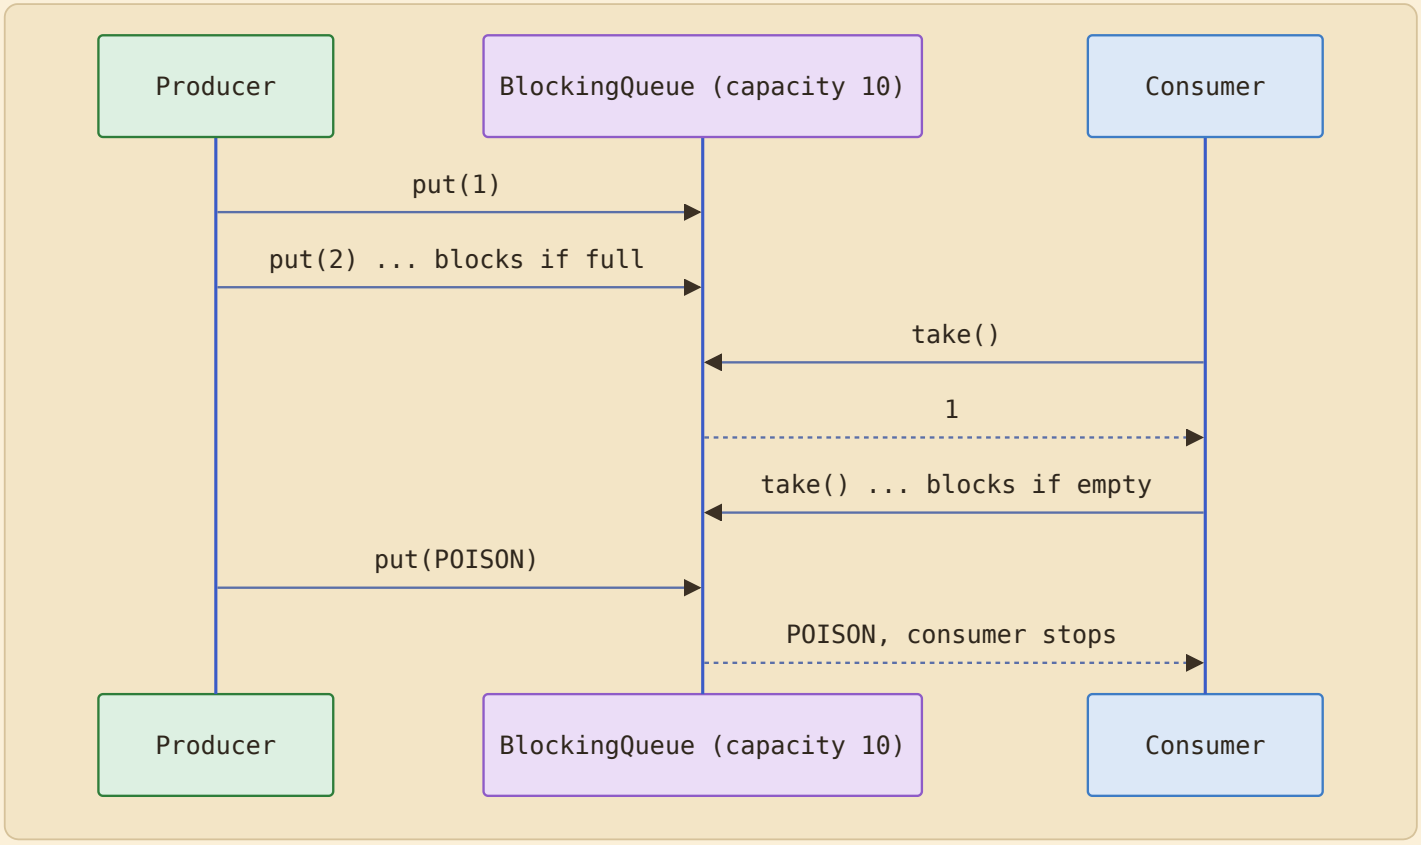
Producers create work items and put them into a shared **buffer**; **consumers** take items out and process them. The buffer decouples their speeds.

> **Analogy.** A restaurant kitchen's order rail: waiters (producers) clip tickets on the rail, cooks (consumers) take them off. If the rail is full, waiters wait; if empty, cooks wait.

The problem it solves

Producers and consumers run at different rates. A bounded buffer smooths bursts and applies **back-pressure** (producers slow down when consumers fall behind), without either side knowing about the other.

How it works



1. Share a bounded `BlockingQueue`.
2. Producers `put` (waits when full); consumers `take` (waits when empty).
3. Shutdown: each consumer must learn when to stop — a **poison pill** per consumer, or interrupting consumers, or a "done" flag plus `poll(timeout)`.

Java example

`producerConsumer()` above: 1 producer, 2 consumers, queue capacity 10, two poison pills. Sum is exactly 500500. Chapter 13 builds the blocking queue itself two ways.

Trade-offs

Pros	Cons
Decouples rates, enables back-pressure	Adds latency (queueing)
Easy to scale consumers	Ordering across multiple consumers isn't preserved
Clear separation of concerns	Need a shutdown protocol

When not to use it

When the caller needs the result immediately and synchronously, a direct call is simpler.

Common mistakes

- Unbounded buffer → no back-pressure → memory blow-up.
- One poison pill for N consumers → N−1 consumers hang forever.
- Busy-polling with `poll()` in a loop instead of blocking `take()`.

Real-world examples

Apache **Kafka** (a distributed, durable message log) is producer-consumer across machines (topics are the buffer; **consumer groups** — sets of consumers that split a topic's messages between them — scale consumers). Inside the Kafka Java producer, application threads append records to an in-memory accumulator and a background sender thread ships batches. Logging frameworks' async appenders, and `ThreadPoolExecutor` itself (submitters produce, workers consume).

In the interview

"Producer-consumer decouples producers from consumers with a bounded blocking queue: put waits when full, take waits when empty, giving natural back-pressure. I stop consumers with one poison pill each, and scale consumers independently."

Self-check

Q: Why bounded? **A:** So a slow consumer pushes back on producers instead of letting the queue grow until memory runs out.

TL;DR

Bounded `BlockingQueue` between producers and consumers. Back-pressure for free. One poison pill per consumer.

12.23 Reader-writer pattern

What it is

A design where **many readers may access shared data at the same time, but a writer needs exclusive access**.

> **Analogy.** A shared noticeboard: many people read it at once; when someone replaces a notice, readers step back for a moment.

The problem it solves

Read-mostly data (config, catalogues, routing tables) shouldn't be serialised through one mutex.

How it works

Two classic implementations:

1. **Read-write lock** (12.10): `readLock` for readers, `writeLock` for writers. Choose fair mode if writers could starve.
2. **Copy-on-write snapshot**: keep an immutable object in a `volatile` field. Readers just read the field (no lock). A writer builds a *new* immutable copy and swaps the reference (use a lock or `AtomicReference.updateAndGet` if several writers may race).

```
private volatile Map<String, String> config = Map.of();       // immutable snapshot
String get(String k) { return config.get(k); }                  // readers: no lock
synchronized void put(String k, String v) {                      // writers: serialized
    Map<String, String> copy = new HashMap<>(config);
    copy.put(k, v);
    config = Map.copyOf(copy);                                    // publish new snapshot
}
```

	RW lock	Copy-on-write snapshot
Reader cost	Acquire shared lock	One volatile read
Writer cost	Exclusive lock, in-place update	Copy whole structure
Readers see	Latest data	A consistent snapshot (maybe slightly old)
Best for	Frequent-ish writes, big data	Rare writes, small-to-medium data

Java example

`ConfigStore` (RW lock) in `locks/Main.java`; the snapshot code just above; `CopyOnWriteArrayList` in `collections/Main.java`.

Trade-offs

See table. Also: RW lock readers must not upgrade to write.

When not to use it

Write-heavy data — plain mutex or `ConcurrentHashMap` is better.

Common mistakes

Mutating the shared snapshot in place (breaks all readers' assumptions); upgrading read → write locks.

Real-world examples

Feature-flag and configuration clients that reload periodically and swap an immutable snapshot; Linux kernel RCU (read-copy-update) is the same idea at OS level.

In the interview

"For read-heavy data I use either a read-write lock or, if writes are rare, an immutable snapshot in a volatile field that writers replace — readers never block."

Self-check

Q: What guarantees readers see a fully built new snapshot? **A:** The `volatile` write of the reference happens-before later volatile reads, and the snapshot is immutable.

TL;DR

Many readers, one writer. RW lock, or immutable snapshot + volatile swap.

12.24 Immutability & thread confinement

What it is

Two ways to be thread-safe **without any synchronization**:

- **Immutability**: an object whose state can't change after construction (all fields `final`, no setters, no leaking mutable internals). Examples: `String`, `Integer`, `LocalDate`, `BigDecimal`, records with immutable components, `List.of(...)`.
- **Thread confinement**: data that only one thread ever touches. Local variables (stack confinement), `ThreadLocal<T>` (one copy per thread), or a design where one thread owns a structure (event loop, **actor** — an object with private state that processes messages from its mailbox one at a time).

> **Analogy.** Immutability: a printed book — everyone can read it at once, nobody can change it. Confinement: a personal notebook — you write freely because nobody else reads it.

The problem it solves

Races need *shared mutable* state. Remove "mutable" (immutability) or remove "shared" (confinement) and races are impossible.

How it works

Immutable class checklist:

1. Make the class `final` (or a `record`) so subclasses can't add mutability.
2. Make all fields `private final`.
3. No setters; "modifiers" return new objects (`withItem(...)`).
4. **Defensive-copy** (copy, so the caller's later changes can't reach you) mutable inputs in the constructor (`List.copyOf`) and don't expose mutable internals.
5. Don't let `this` escape during construction.

Confinement options:

1. Keep data in local variables.
2. `ThreadLocal.withInitial(...)` for per-thread helpers (formatters, buffers). Call `remove()` when used in pooled threads.
3. Single-writer design: one thread owns the state; others send it messages through a queue.

Java example

`Order` record above: the compact constructor does `List.copyOf(items)`, so the caller's later `mutable.add("hacked")` doesn't affect `o1`; `withItem` returns a new `Order`. `BUFFER` is a `ThreadLocal<StringBuilder>` — each thread gets its own builder.

Trade-offs

	Immutability	Confinement
Cost	New object per change (GC pressure — more garbage for the collector to clean)	Per-thread copies; ThreadLocal leaks if not cleaned
Sharing	Share freely	Not shareable by definition
Reasoning	Easiest possible	Easy, if confinement is really enforced

When not to use it

Very large objects changed at high frequency (copying costs too much) — use a concurrent structure instead.

Common mistakes

- `final List<String> items` is not immutable if the list itself is mutable and exposed.
- `ThreadLocal` in thread pools without `remove()` — values leak into the next task; with many virtual threads, heavy `ThreadLocal`s waste memory (*scoped values* are the alternative: a **preview** — an experimental feature you must opt into — in Java 21, final in Java 25 via JEP 506).

- Sharing `SimpleDateFormat` (mutable, not thread-safe) instead of using immutable `DateTimeFormatter`.

Real-world examples

- `java.time` types and `DateTimeFormatter` are immutable and thread-safe; `SimpleDateFormat` is not.
- **Netty** and **Vert.x** confine each connection to one event-loop thread, so handler code needs no locks.
- Redis executes commands on a single main thread (confinement at system level).
- Spring's `@Transactional` (marks a method to run inside a database transaction) stores the current transaction in `ThreadLocal`s (via `TransactionSynchronizationManager`).

In the interview

"The easiest thread-safety is none needed: make value objects immutable — final fields, defensive copies, 'with' methods — and confine mutable state to one thread with locals, ThreadLocal, or a single owner thread fed by a queue."

Self-check

Q: Is a class with `private final Date created` immutable? **A:** Not unless it copies the `Date` in and out — `Date` is mutable. Prefer `Instant`.

TL;DR

No shared mutable state → no races. Immutable objects share freely; confined objects aren't shared.

Part H — Concurrency in LLD interviews

12.25 How concurrency shows up in LLD interviews (parking, seat booking, inventory)

What it is

Most LLD case studies have a **contended resource**: a parking spot, a movie seat, a hotel room, a limited stock item, an elevator request, a wallet balance. The interviewer checks whether your design prevents double allocation and still performs.

The problem it solves

Showing you can turn a single-threaded class diagram into a **thread-safe design** with the smallest correct synchronization.

How it works — a 6-step recipe

1. **Name the shared mutable state** (free spots, seat → owner map, stock counts).
2. **State the invariant** ("a spot has at most one car", "stock ≥ 0", "a seat has at most one booking").
3. **Find the critical operation** (usually a check-then-act: *find free → assign*).
4. **Pick the smallest tool that makes it atomic:**
   - one item claimed → atomic op: `queue.poll()`, `map.putIfAbsent`, `AtomicBoolean.compareAndSet`, `AtomicInteger` CAS loop;
   - several items all-or-nothing → per-item locks acquired **in sorted order** (or one per-show/per-floor lock);
   - across processes/servers → database constraints/transactions, optimistic versioning, or a distributed lock.
5. **Choose granularity:** per floor/show/SKU (stock-keeping unit — one distinct product) locks rather than one global lock.
6. **Handle time:** temporary holds with expiry (seat held 10 minutes during payment), timeouts, and **idempotent** retries (safe to repeat, because doing the operation twice has the same effect as doing it once; see System Design Fundamentals).

        inv.addStock("iphone", 50);
        AtomicInteger sold = new AtomicInteger();
        raceAll(200, o -> { if (inv.reserve("iphone", 1)) sold.incrementAndGet(); });
        System.out.println("inventory: 200 buyers, 50 in stock -> sold " + sold.get() + ", left " +
inv.available("iphone"));
    }
}
```

Explaining each part:

- **Parking**: free spots per type live in a `ConcurrentLinkedQueue`. `poll()` atomically removes one spot, so two gates can never receive the same spot — no explicit lock. `leave` uses `ConcurrentHashMap.remove(ticket)`, so a duplicated exit event can't return a spot twice.
- **Seat booking**: one `ReentrantLock` per seat. `book` locks the requested seats **in sorted order** (breaking circular wait), checks that *all* are free, then books them all — all-or-nothing. Alice asks for `{A3, A4}` and Bob for `{A4, A3}` at the same moment: exactly one wins, no deadlock, and both seats get the same owner.
- **Inventory**: an `AtomicInteger` per SKU and a CAS loop that decrements only if enough stock remains — 200 buyers, 50 items → exactly 50 sold, never negative.
- `raceAll` releases all tasks through a `CountDownLatch` at once to maximise contention.

Output:

```
parking: 100 cars raced for 10 spots -> parked 10, distinct spots 10, free left 0
booking: 50 users wanted seat A2 -> successful bookings 1
booking: alice {A3,A4} vs bob {A4,A3} (opposite order) -> winners 1, A3 and A4 same owner: true
inventory: 200 buyers, 50 in stock -> sold 50, left 0
```

Trade-offs

Resource	In-memory approach	Across many servers
Parking spot	Lock-free queue per type/floor, or per-floor lock	DB row update `WHERE status='FREE'` + check affected rows
Seat	Per-show or per-seat locks in sorted order; hold with TTL (time-to-live, an expiry)	Unique constraint on (show, seat); short-lived holds in Redis (`SET NX PX`)
Inventory	`AtomicInteger` CAS / `compute`	`UPDATE stock SET qty = qty - 1 WHERE sku = ? AND qty >= 1`; reservations with expiry

When not to use it

Don't bolt `synchronized` onto every method of every class — interviewers read that as "doesn't know where the contention is". Protect the few operations that touch contended state.

Common mistakes

- A global `synchronized` on `ParkingLot.park()` — correct but serialises every gate.
- Checking availability with one call and booking with another (check-then-act).
- Locking seats in the order the user clicked them (deadlock between two multi-seat bookings).
- Forgetting that in-memory locks don't work across multiple app servers.

Real-world examples

- **BookMyShow / Ticketmaster-style** checkout: selected seats are *held* for a few minutes while you pay; if payment doesn't complete, the hold expires and the seats return to the pool — a lock with a lease.
- **Flash sales** (e.g. limited-stock phone launches) decrement stock atomically, often in Redis (`DECR` / Lua scripts, which Redis runs atomically) or with conditional SQL updates, to avoid overselling.
- **Uber-style dispatch**: offering one driver to one rider at a time is the same "claim a resource atomically" problem.

In the interview

> **30-second answer:** "The critical section is 'find a free X and assign it'. Inside one JVM I make that a single atomic step — a lock-free queue poll for spots, per-seat locks taken in sorted order for multi-seat booking, a CAS decrement for stock. Across servers I'd push it into the database with a conditional update or unique constraint, and add holds with expiry for seats during payment."

Follow-ups (with answers):

- *Two users book the same seat at the same millisecond?* Only one `putIfAbsent`/locked check-and-book succeeds; the other gets "seat unavailable".
- *How do you release a seat if payment fails or the user leaves?* Store a hold with an expiry time; a scheduler or lazy check frees expired holds (see the TTL cache in chapter 13).
- *Why not one global lock?* Correct but no parallelism: bookings for different shows would wait for each other.
- *What if the service runs on 10 machines?* JVM locks don't cross processes: use DB transactions/constraints, optimistic locking with a version column, or a distributed lock with a lease.

Self-check

- **Q:** Which Coffman condition does sorting seat ids break? **A:** Circular wait.
- **Q:** Why is `queue.poll()` safe for allocating spots? **A:** It's a single atomic remove; each spot can be removed by only one thread.

TL;DR

Find the contended resource and its invariant, make "check + claim" one atomic step with the smallest tool, keep locks fine-grained and ordered, and move to DB/distributed mechanisms when there's more than one server.

12.26 Choosing the right tool (cheat sheet)

I need to…	Use
Increment a shared counter	`AtomicInteger`/`AtomicLong`; `LongAdder` if very hot
Stop a loop from another thread	`volatile boolean` flag or `interrupt()`
Make a multi-step update atomic	`synchronized` or `ReentrantLock`
Give up if the lock is busy	`tryLock(timeout)`
Many readers, few writers	`ReentrantReadWriteLock`, `StampedLock`, or immutable snapshot in `volatile`
Limit concurrent access to N	`Semaphore(N)`
Wait for a condition on shared state	`Lock` + `Condition` (or `wait/notifyAll`) in a `while` loop
Wait for N events once	`CountDownLatch`
N threads meet each phase	`CyclicBarrier` / `Phaser`
Hand work between threads	Bounded `BlockingQueue`
Shared map	`ConcurrentHashMap` with `putIfAbsent`/`compute`/`merge`
Read-mostly list	`CopyOnWriteArrayList`
Run tasks	`ExecutorService` (bounded); virtual threads for blocking I/O
Split CPU work	`ForkJoinPool` / parallel streams
Combine async results	`CompletableFuture`
Avoid synchronization entirely	Immutability, thread confinement

12.27 Chapter self-check

1. **Q:** Concurrency vs parallelism in one line each? **A:** Concurrency = many tasks in progress (structure); parallelism = many tasks executing at the same instant (hardware).
2. **Q:** Name the six `Thread.State` values. **A:** NEW, RUNNABLE, BLOCKED, WAITING, TIMED_WAITING, TERMINATED.
3. **Q:** Why is `volatile` not enough for `count++`? **A:** It gives visibility, not atomicity of read-modify-write.
4. **Q:** Three happens-before rules? **A:** Unlock → later lock of the same monitor; volatile write → later read; `start()` → thread's actions; thread's actions → `join()` return.
5. **Q:** Why always `while` around `wait()`? **A:** Spurious wakeups and competing threads; the condition must be re-checked.
6. **Q:** Four Coffman conditions? **A:** Mutual exclusion, hold and wait, no preemption, circular wait.
7. **Q:** Deadlock vs livelock vs starvation? **A:** Nobody progresses and all wait / everybody runs but nobody progresses / some progress while one never does.
8. **Q:** `CountDownLatch` vs `CyclicBarrier`? **A:** One-shot count of events vs reusable meeting of N threads.
9. **Q:** What is ABA and its fix? **A:** Value changes A→B→A so CAS can't notice; add a version (`AtomicStampedReference`).
10. **Q:** How to allocate a parking spot to exactly one of many gates without a lock? **A:** Keep free spots in a concurrent queue and `poll()` — an atomic remove.

12.28 Chapter TL;DR

- Races come from **shared mutable state**; fix by making critical sections atomic, or by removing sharing/mutability.
- Visibility needs **happens-before** edges: locks, `volatile`, start/join, concurrent utilities.
- Toolbox: `synchronized` → `ReentrantLock` (try/timed/fair/conditions) → RW locks → semaphores → latches/barriers → atomics/CAS → concurrent collections.
- Liveness: prevent deadlock with **lock ordering** or **tryLock + back-off**; add jitter against livelock; fairness against starvation.
- Patterns: signaling, thread pool, producer-consumer, reader-writer, immutability/confinement.
- In LLD interviews: identify the contended resource, keep "check + claim" atomic, lock fine-grained and in order, and say what changes when there are many servers.

Chapter 13 — Classic Concurrency Problems

> **Goal.** Chapter 12 gave you the toolbox. This chapter uses it on the concurrency problems that interviewers actually ask — from LeetCode's (a popular coding-practice website) "Concurrency" section (FooBar, Zero-Even-Odd, FizzBuzz, H2O, Dining Philosophers) to "design a thread-safe X" **machine-coding** rounds (interviews where you write working code for a small system in an hour or two): TTL cache, concurrent hash map, blocking queue, Bloom filter, parallel merge sort, **rate limiter** (a component that caps how many requests a client may make per second).

How each problem is laid out: *Problem → Approach → Java solution (+ real output) → Why it's correct → Pitfalls → Real-world examples → In the interview → Self-check → TL;DR.*

All code is Java 21, standard library only, in `code/lld/ch13/<problem>/Main.java`. Run from `chapters/13-concurrency-problems/code`:

```
javac --release 21 -d /tmp/lld_13 $(find . -name '*.java')
java -cp /tmp/lld_13 lld.ch13.foobar.Main
```

Where the real order of events can vary between runs, the demo *verifies* the result and prints `true/false`, so the output shown here is what you get every time.

Key terms (all built in Chapter 12 — a one-line reminder each):

- **Thread-safe** — behaves correctly however threads interleave. A **race** is a bug where the result depends on the timing of threads.
- **Lock / monitor** — a token only one thread can hold at a time. Every Java object has a built-in one (its *monitor*), taken by `synchronized`; `ReentrantLock` is the explicit version.
- **Semaphore** — a counter of permits: `acquire()` takes one (waiting if none are left), `release()` gives one back.
- **Condition variable** (`wait/notifyAll`, or `Condition` with a `ReentrantLock`) — lets a thread sleep, releasing its lock, until another thread changes the shared state and wakes it.
- **Barrier** (`CyclicBarrier`) — a meeting point where N threads wait until all N have arrived, then all continue.
- **Atomic / CAS** — an *atomic* step happens all at once or not at all; *compare-and-swap* updates a value only if it still equals what you read. CAS is the basis of **lock-free** code (no locks; a thread that loses simply retries).
- **Happens-before** — the Java Memory Model rule that guarantees one thread's writes are visible to another (e.g. through the same lock, a `volatile` field, or a semaphore release → acquire).
- **Deadlock / livelock / starvation** — threads wait on each other forever / keep retrying but nobody progresses / one thread never gets its turn.

Problem map — which tool solves what

#	Problem	Core idea	Main tools
13.1	Print FooBar Alternately	Pass a "baton" between 2 threads	`Semaphore` ×2 (or monitor + turn flag)
13.2	Print Zero Even Odd	A dispatcher thread decides who goes next	`Semaphore` ×3
13.3	Fizz Buzz Multithreaded	4 threads, one shared counter, each waits for "its" numbers	`synchronized` + `wait/notifyAll`
13.4	Building H2O	Group threads into sets of 2 H + 1 O	`Semaphore` (slots) + `CyclicBarrier` (group)
13.5	Dining Philosophers	Avoid deadlock over shared forks	Lock ordering, or a "waiter" semaphore
13.6	Thread-safe cache with TTL	Expiring entries, no stampede	`ConcurrentHashMap`, `compute`, scheduled sweeper
13.7	Concurrent HashMap (simplified)	Lock striping (N locks, each guarding a slice of the data)	`ReentrantLock[]`, all-stripe resize
13.8	Bounded Blocking Queue	Wait when full / empty	`wait/notifyAll` **and** `Lock` + 2 `Condition`s
13.9	Concurrent Bloom Filter	Lock-free bit set	`AtomicLongArray` + atomic OR
13.10	Multi-threaded Merge Sort	Divide and conquer on cores	`ForkJoinPool`, `RecursiveAction`
13.11	Rate limiter (token bucket)	Atomic refill-and-take	`synchronized`, or CAS on an immutable state

Reusable mental checklist for any concurrency problem

1. What is the **shared state**? (a turn flag, a counter, a map, a buffer)
